### Example of a mock file

Here is an example of a mock file.

```
{
  "id": "R1Module1",
  "config": {
    "imageAlignment": "left",
    "productTitle": "Retro Horn Rimmed Keyhole Nose Bridge Round Sunglasses",
    "productDetails": "High-quality and pioneered with the perfect blend of timeless classic and modern technology with hint of old school glamor.",
    "productImage": {
      "src": "https://bit.ly/33cMGxr",
      "altText": "Retro Horn Rimmed Keyhole Nose Bridge Round Sunglasses"
    },
    "buttonText": "Buy Now",
    "productIds": "68719498121"
  },
  "data": {
    "actionResponse": {
      "text": "Sample Action Response"
    }
  },
  "typeName": "product-feature"
}
```

Several configuration properties are used to set values for configuration fields that are set in the module definition file. When modules are run on a production server, this data comes from the Microsoft Dynamics content management system (CMS) database, as configured by the page authors, instead of a mock file.

## Render a module by using mock file data

To render a module by using data from a mock file, run the **yarn start** command, and then open the following URL in a web browser: `https://localhost:4000/modules?type=MODULE_NAME`.

## Add mock files

In addition to the default mock file, you can add multiple other mock files. In this way, you can view and test various scenarios.

To add a mock file, create a new JavaScript Object Notation (JSON) file in the mocks folder, and give it a unique name (for example, `\src\MODULE_NAME\MOCKS\MODULE_NAME_TEST.json`).

To render a module by using a different mock file, run the **yarn start** command, and then open the following URL in a web browser: `https://localhost:4000/modules?type=MODULE_NAME:MODULE_NAME_TEST`.

# Module test file

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic covers the module test file in Microsoft Dynamics 365 Commerce.

## Overview

The module test file is used for local unit testing. It contains the mock data that is required to run the tests.

## Example

The following example shows a default test file that is created for a new module.

```
import { buildMockModuleProps } from '@msdyn365-commerce/core';
/// <reference types="jest" />

// tslint:disable-next-line:no-unused-variable
import * as React from 'react';
import * as renderer from 'react-test-renderer';

import ProductFeature from '../productFeature';
import { IProductFeatureData } from '../productFeature.data';
import {
    IProductFeatureConfig,
    IProductFeatureProps
} from '../productFeature.props.autogenerated';

const mockData: IProductFeatureData = {
    actionResponse: {
        text: 'Sample Response Data'
    }
};

const mockConfig: IProductFeatureConfig = {
    showText: 'productFeature'
};

const mockActions = {};

describe('ProductFeature', () => {
    let moduleProps: IProductFeatureProps<IProductFeatureData>;
    beforeAll(() => {
        moduleProps = buildMockModuleProps(mockData, mockActions, mockConfig) as
IProductFeatureProps<IProductFeatureData>;
    });
    it('renders correctly', () => {
        const component: renderer.ReactTestRenderer = renderer.create(
            <ProductFeature {...moduleProps} />
        );
        const tree: renderer.ReactTestRendererJSON | null = component.toJSON();
        expect(tree).toMatchSnapshot();
    });
});
```

Note that the mock data fields are set inside this file.

# Module props.autogenerated.ts file

2/18/2021 • 2 minutes to read • [Edit Online](#)

## Overview

The props.autogenerated.ts file is a TypeScript file that is automatically generated for a module. It shouldn't be manually changed. If new configuration values are added to the module definition file and module data files, this file is automatically built so that it includes the appropriate interfaces.

## Example

The following example shows the props.autogenerated.ts file for a module.

```
/**
 * Copyright (c) 2018 Microsoft Corporation
 * IProductFeature contentModule Interface Properties
 * THIS FILE IS AUTO-GENERATED - MANUAL MODIFICATIONS WILL BE LOST
 */

import * as Msdyn365 from '@msdyn365-commerce/core';

export const enum imageAlignment {
    left = 'left',
    right = 'right'
}

export interface IProductFeatureConfig extends Msdyn365.IModuleConfig {
    imageAlignment?: imageAlignment;
    productTitle?: string;
    productDetails?: Msdyn365.RichText;
    productImage?: Msdyn365.IImageData;
    buttonText?: string;
    productIds?: string;
}

export interface IProductFeatureResources {
    resourceKey: string;
}

export interface IProductFeatureProps<T> extends Msdyn365.IModule<T> {
    resources: IProductFeatureResources;
    config: IProductFeatureConfig;
}
```

# Create a new module

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic describes how to create a new module in Dynamics 365 Commerce.

## Overview

To create a new module in Commerce, the online software development kit (SDK) provides the **add-module** command-line interface (CLI) command. When you run the command as in the following example, you replace **MODULE\_NAME** with the name that you want to give to the new module.

```
yarn msdyn365 add-module MODULE_NAME
```

## Example

The following example shows how to create a module that is named **product-feature**.

```
yarn msdyn365 add-module product-feature
```

It can take 20 to 30 seconds to create a module and generate all the template files for it. After the command has finished running, you can find the new module in the `\src\modules\` directory.

## Preview a module

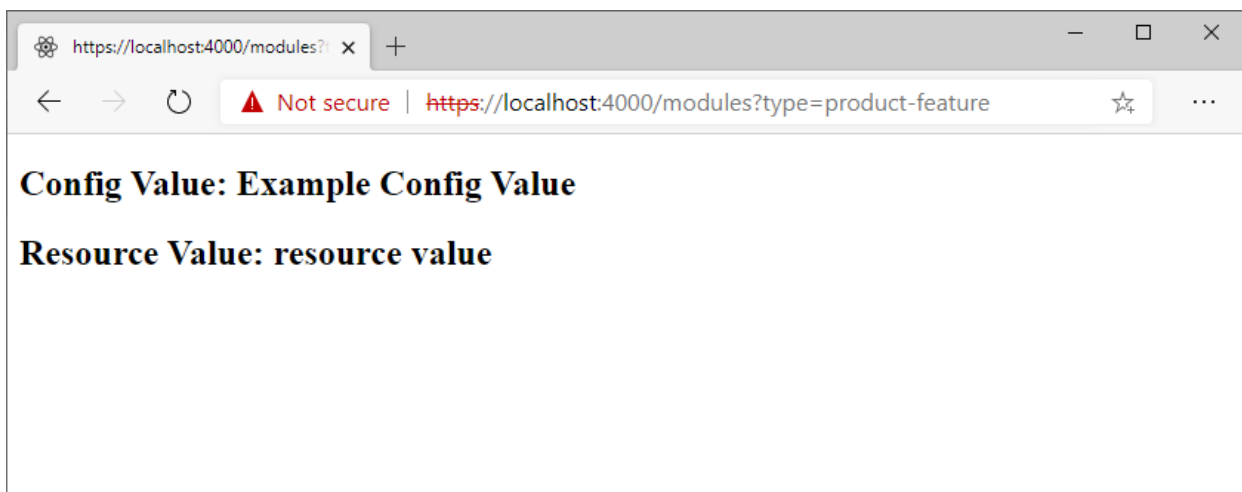

To preview the new module in a local web browser, follow these steps.

1. At a command prompt, go to your root SDK folder, and run the **yarn start** command. Here is an example.

```
c:\repos\Msdy365.Commerce.Online>yarn start
```

2. In a web browser, open the following URL to view the module:

`https://localhost:4000/modules?type=product-feature`. Notice the module name in the **type=MODULE\_NAME** query string parameter.

## Module naming conventions

Module names are case-insensitive. We recommend that you use whole words for module names whenever you can.

## Deferred module rendering

By default all modules are rendered server-side, but deferred loading of some modules may be needed to improve page load performance. For more information, see [Page load data actions](#).

Any references to window or document objects that are only available in the context of a browser should be handled appropriately during server-side rendering. This will avoid unexpected rendering behavior such as page flicker and Document Object Model (DOM) mismatch issues. The following SDK utility function can be used for this purpose.

```
import MsDyn365 from '@msdyn365-commerce/core';

if (MsDyn365.isBrowser) {
  return new URL(window.location.href);
}
```

## Module error handling

If a module encounters an error during server-side rendering, the failed module is then wrapped into an **ErrorModule** component to prevent any module-level render error from breaking the page. For example, a module using window or document objects during a server-side render would fail because these objects are non-existent on the server-side. In this case, the module would then be wrapped in an error component. The module would then attempt to render again on the client. In development mode, to determine if a module failed on server side use a `?debug=true` query string parameter.

# Clone a module library module

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic describes how to clone a module library module.

## Overview

The Microsoft Dynamics 365 Commerce online software development kit (SDK) includes a set of module library modules that can be used on an e-Commerce site. Although these modules can't be modified directly, they can be cloned into new modules and then updated.

You can also create module extension views. In this way, you can provide alternative layout views without having to clone a module. We recommend that you avoid cloning if you can, because clones will be copies of module library modules and won't receive any automatic service updates that the module library modules get. For more information, see [Theming overview](#).

## Clone and update a module

To clone a module and then update it, use the `clone` command-line interface (CLI) command. When you run the below command, you replace `SDK_MODULE_NAME` with the name of the module that you want to modify and `NEW_MODULE_NAME` with the name of the new module.

```
yarn msdyn365 clone SDK_MODULE_NAME NEW_MODULE_NAME
```

This command adds the source code for the module to the `/src/modules/` directory and pulls in any required dependencies for the module.

## Example

The following example shows how to clone the hero SDK module so that you can update it.

```
yarn msdyn365 clone content-block super-content-block
```

It can take up to a minute to clone a module. After the command has finished running, you can find the new module in the `\src\modules\` directory.

### NOTE

Module dependencies aren't automatically pulled down when you clone a module. Before you build the module, you must run Yarn and fix any missing dependencies. If any errors occur when you run the `yarn start` command, you might also have to fix some references inside the module source code.

## Preview a module

To preview the new module in a local web browser, follow these steps.

1. At a command prompt, go to your root SDK folder, and run the `yarn start` command. Here is an example.

```
c:\repos\Msdy365.Commerce.Online>yarn start
```

2. In a web browser, open the following URL to view the module:

`https://localhost:4000/modules?type=super-content-block`. Notice the module name in the `type=MODULE_NAME` query string parameter.

You can now update the module code as needed.

# Add module configuration fields

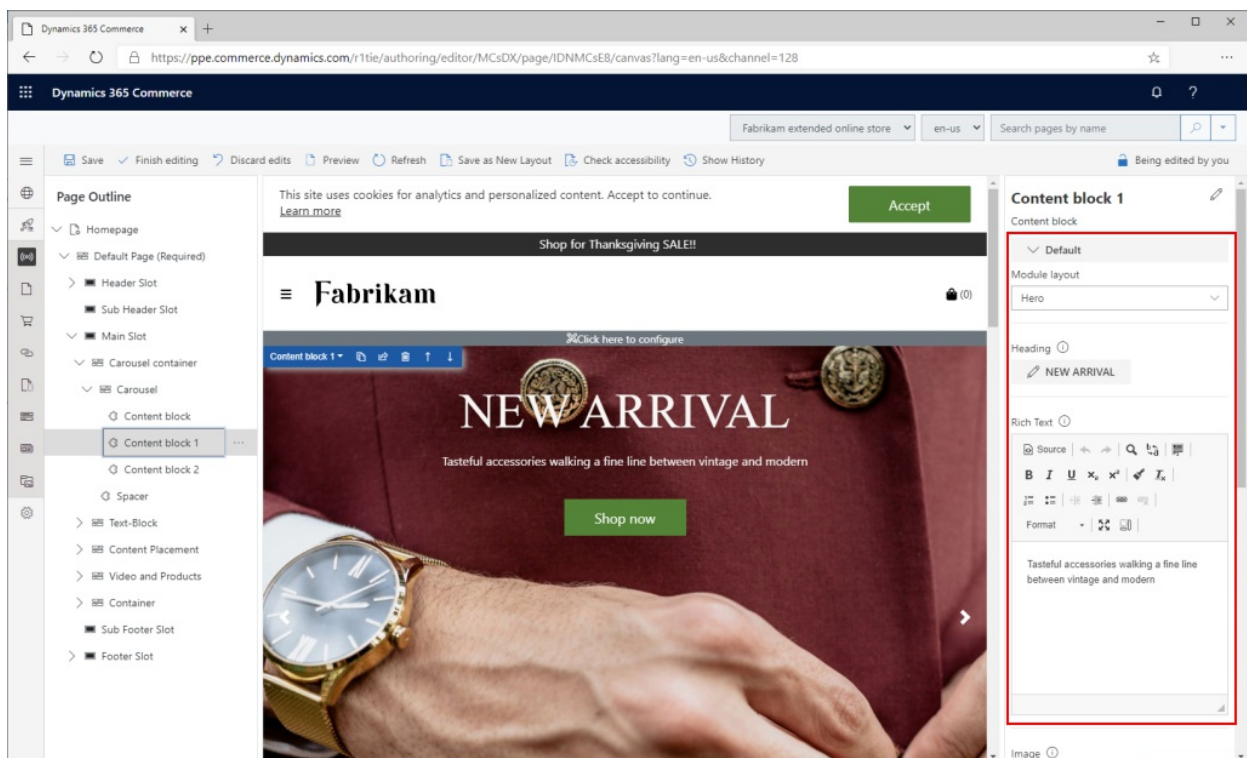

2/18/2021 • 7 minutes to read • [Edit Online](#)

This topic describes how to add module configuration fields in Microsoft Dynamics 365 Commerce.

## Overview

Configuration fields can be added to a module to expose them to page authors and give them control of various module features. Examples of these features include different views, alignment properties, Boolean switches to turn features on or off, module titles or headings, rich text descriptions, call-to-action links, image URLs, and Commerce product data.

The following illustration shows how these fields appear in the page authoring tools.

## Add new module configuration fields

To add configuration fields, you add an entry in the **config** section of the module definition file, **MODULE\_NAME.definition.json**.

### Example

In the following example of a module definition file, an **imageAlignment** configuration field has been added so that page authors can configure the alignment of an image inside a module. There are two enumeration (enum) options: **"Left"** (the default option) and **"Right"**.

```

{
  "$type": "contentModule",
  "friendlyName": "Product Feature",
  "name": "product-feature",
  "description": "Feature module used to highlight a product.",
  "categories": [
    "storytelling"
  ],
  "tags": [
    ""
  ],
  "dataActions": {
    "products": {
      "path": "@msdyn365-commerce-modules/retail-actions/dist/lib/get-simple-products",
      "runOn": "server"
    }
  },
  "config": {
    "imageAlignment": {
      "friendlyName": "Image Alignment",
      "description": "Sets the desired alignment of the image, either left or right on the text.",
      "type": "string",
      "enum": {
        "left": "Left",
        "right": "Right"
      },
      "default": "left",
      "scope": "module",
      "group": "Layout Properties"
    }
  }
}

```

## Module configuration schema

The `config` section of the module definition file contains a list of all the module's exposed configuration fields that will be used in the authoring tools.

- **configuration name** – The local name that is used to access the configuration values from your React source code. This name is case-insensitive.
- **"friendlyName"** – The friendly name that is shown as the configuration name in the authoring tools.
- **"description"** – The description that is shown as the configuration description in the authoring tools.
- **"type"** – The type of the configuration. The possible values are **"string"**, **"bool"**, **"number"**, **"integer"**, **"richText"**, **"image"**, **"imageSettings"**, **"css"**, **"video"**, and **"array"**.
- **"enum"** – For an enumerator type, the value must be set to **"string"**.
- **"default"** – The default value that is set if no value is set in the authoring tools.
- **"scope"** – This field is used to scope the configuration to either a specific module instance or all modules on the site. Possible values are **"module"** and **"site"**. If the value is set to **"site"**, the module configuration doesn't appear on a page and can't be configured there. It appears and can be configured only at the site level. In this way, the value can be set one time for the entire site. If you don't set this field, the default value is **"module"**.
- **"group"** – Groups are used to organize the configurations into organized groups in the authoring tools.
- **"required"** – A Boolean flag that specifies whether a property must be set on the module. If the value is set to **true**, the authoring tools will show an error if the required property isn't set, and an error will be shown when the module is rendered.
- **"resources"** – This field is used for localization resources.
- **"definitions"** – This field can contain complex config type definitions, which can be referenced in the config

sections as extended types.

The following example shows how the various supported data types are used.

```
{
  "$type": "contentModule",
  "friendlyName": "Sample Config",
  "name": "sample-config",
  "description": "Sample Config",
  "categories": ["sample-config"],
  "tags": ["samples"],
  "dataActions": {},
  "config": {
    "title": {
      "type": "string",
      "friendlyName": "Title",
      "description": "Example config value",
      "default": "",
      "scope": "module"
    },
    "subTitle": {
      "type": "richText",
      "friendlyName": "SubTitle",
      "description": "Sub title rich text field"
    },
    "bgImage": {
      "type": "image",
      "friendlyName": "Background image",
      "description": "Background image"
    },
    "images": {
      "type": "array",
      "friendlyName": "Images",
      "description": "Image array",
      "items": {
        "type": "image"
      }
    },
    "backgroundImageSettings": {
      "type": "imageSettings",
      "friendlyName": "Background image settings",
      "description": "Image settings for background image settings"
    },
    "ambientVideo": {
      "type": "video",
      "friendlyName": "Ambient video",
      "description": "Ambient video",
    },
    "headingArray": {
      "type": "array",
      "friendlyName": "Headings",
      "description": "Heading array",
      "items": {
        "$ref": "#/definitions/heading"
      }
    },
    "heading": {
      "$ref": "#/definitions/heading"
    },
    "heading2": {
      "type": "object",
      "friendlyName": "Heading2",
      "description": "Heading2 property with its own enum",
      "properties": {
        "style": {
          "type": "string",
          "enum": {
            "bold": "Bold"
          }
        }
      }
    }
  }
}
```

```
        "underline": "Underline",
        "italics": "Italics",
        "strong": "Strong",
        "emphasized": "Emphasized",
        "none": "None"
    },
    "friendlyName": "Style",
    "description": "Heading style"
}
}
},
"textPlacement":{
    "friendlyName": "Text placement",
    "description": "Placement of the text",
    "type": "object",
    "enum":{
        "left": "Left",
        "right": "Right",
        "center": "Center"
    },
    "default": "left"
}
},
"definitions": {
    "heading": {
        "type": "object",
        "friendlyName": "Heading",
        "description": "Heading property",
        "properties": {
            "text": {
                "type": "string",
                "friendlyName": "Text",
                "description": "Heading Text"
            },
            "style": {
                "type": "string",
                "enum": {
                    "bold": "Bold",
                    "underline": "Underline",
                    "none": "None"
                },
                "friendlyName": "Style",
                "description": "Heading style"
            },
            "showImage":{
                "type":"boolean",
                "friendlyName": "Show image?",
                "description": "Should Show Image"
            },
            "bgImage": {
                "type": "image",
                "friendlyName": "Background image",
                "description": "Background image"
            },
            "imageArray":{
                "type": "array",
                "friendlyName": "Images",
                "description": "Image Array",
                "items": {
                    "type": "image"
                }
            }
        }
    }
}
}
}
```

## css configuration type

The configuration type of module configuration properties can also be declared as **"type": "css"**. Module configuration properties declared as the **css** type must specify a set of string enums of the classes that can be applied to a module. Only one of the enum options can be selected for a given module configuration property. When an enum option is selected, the selected class is appended to the list of classes that is passed down to the module in the format *propertyName\_\_propertyValue* via the **this.props.config.className** property. Note that **css** configuration types can't be accessed directly from the **this.props.config** property, because they are merged into the **this.props.config.className** property.

## className property

Every content module includes a built-in configuration field that is named **className**. This configuration field can be accessed inside the module's view via the **this.props.config.className** property. This configuration field will appear in the site authoring tools. Therefore, page authors can add a string of space-separated Cascading Style Sheets (CSS) class names that should be appended to the module root class.

## \_\_cssClassName\_\_ property

**\_\_cssClassName\_\_** is another special property that is declared inside a module definition file. It provides a way for the module creator to specify a non-authorable, non-editable, read-only **className** property that will always be applied to the module. Therefore, its **editable** property must be set to **false**, and a default value must be specified.

In the following example, the module creator has given this field a default value of **hero**. Therefore, every instance of this module will always have the **hero** class as part of the **this.props.config.className** property.

```
...
  "__cssClassName__": {
    "default": "hero",
    "editable": false,
    "friendlyName": "Readonly CSS Class Name(s)",
    "description": "Provides a way to set constant, unchangeable default css class(es) to apply to your
module.",
    "type": "string"
  },
  ...
```

## Use mock data in configuration fields for local testing

The following example shows how to set a mock value for a new configuration field in the **mocks/MODULE\_NAME.json** file. Mock data is useful when a module is rendered in a local development environment.

```
{
  "id": "R1Module1",
  "config": {
    "imageAlignment": "left",
    "productTitle": "Retro Horn Rimmed Keyhole Nose Bridge Round Sunglasses",
    "productDetails": "High-quality and pioneered with the perfect blend of timeless classic and modern
technology with hint of old school glamor.",
    "productImage": {
      "src": "https://bit.ly/33cMGxr",
      "altText": "Retro Horn Rimmed Keyhole Nose Bridge Round Sunglasses"
    },
    "buttonText": "Buy Now",
    "productIds": "68719498121"
  },
  "data": {
    "actionResponse": {
      "text": "Sample Action Response"
    }
  },
  "typeName": "product-feature"
}
```

### Access configuration fields in the module React component

To access configuration fields in the React component, use the `props.config` application programming interface (API).

The following example creates a `props` property that has configuration values that will be sent to the module view file to render the appropriate HTML.

```

import * as React from 'react';

import { IProductFeatureData } from './product-feature.data';
import { imageAlignment, IProductFeatureProps } from './product-feature.props.autogenerated';

export interface IProductFeatureViewProps extends IProductFeatureProps<IProductFeatureData> {
  productName: string;
  productInfo: string;
  productImageUrl: string;
  productPrice: string;
  buttonInfo: string;
  alignment: imageAlignment;
}

/**
 *
 * ProductFeature component
 * @extends {React.PureComponent<IProductFeatureProps<IProductFeatureData>>}
 */
class ProductFeature extends React.PureComponent<IProductFeatureProps<IProductFeatureData>> {
  public render(): JSX.Element | null {
    const { config } = this.props;

    // set default product info values
    const ProductName = config.productTitle ? config.productTitle : 'No product name defined';
    const ProductInfo = config.productDetails ? config.productDetails.toString() : 'No product details
defined';
    const ProductImageUrl = config.productImage ? config.productImage.src : '';
    const ButtonInfo = config.buttonText ? config.buttonText : 'No button text defined';
    const ProductPrice = '129';

    const ProductFeatureViewProps = {
      ...this.props,
      productName: ProductName,
      productInfo: ProductInfo,
      productImageUrl: ProductImageUrl,
      productPrice: ProductPrice,
      buttonInfo: ButtonInfo,
      alignment: config.imageAlignment
    };

    return this.props.renderView(ProductFeatureViewProps);
  }
}

```

The following example shows the corresponding module view file that handles the HTML layout.

```

import * as React from 'react';
import { IProductFeatureViewProps } from './product-feature';
import { imageAlignment } from './product-feature.props.autogenerated';

const _renderImage=(productImageUrl: string, productName: string): JSX.Element => {
    return <img src={productImageUrl} alt={productName} className='img-fluid p-3' />;
};

const _renderInfo=(productName: string, productInfo: string, productPrice: string, buttonInfo: string):
JSX.Element => {
    return (
        <div className='container'>
            <h2>{productName}</h2>
            <p>{productInfo}</p>
            <p>{productPrice}</p>
            <button type='button' className='btn btn-primary'>{buttonInfo}</button>
        </div>
    );
};

export default (props: IProductFeatureViewProps) => {
    const { productName, productInfo, productImageUrl, productPrice, buttonInfo, alignment } = props;

    let left;
    let right;

    if (alignment === imageAlignment.left) {
        left = _renderImage(productImageUrl, productName);
        right = _renderInfo(productName, productInfo, productPrice, buttonInfo);
    } else {
        right = _renderImage(productImageUrl, productName);
        left = _renderInfo(productName, productInfo, productPrice, buttonInfo);
    }

    return (
        <div className='row align-items-center'>
            <div className='col-sm-6'>
                {left}
            </div>
            <div className='col-sm-6'>
                {right}
            </div>
        </div>
    );
};

```

# Preview and debug a module

2/18/2021 • 3 minutes to read • [Edit Online](#)

This topic describes how to test a module by previewing and debugging it in a web browser.

## Overview

During development of a module, you can preview and debug the module in your local web browser.

## Preview a module

To preview a module in a local web browser, follow these steps.

1. At a command prompt, go to your root SDK folder, and run the **yarn start** command. Here is an example.

```
c:\repos\Msdyn365.Commerce.Online>yarn start
```

2. In a web browser, open the following URL to view the module:

```
https://localhost:4000/modules?type=product-feature
```

Notice the module name in the **type=MODULE\_NAME** query string parameter. This parameter is shorthand for **type=:MODULE\_NAME:MOCK\_FILE\_NAME**, where the default mock file that matches the name of the module is loaded. Therefore, the preceding URL is equivalent to

```
https://localhost:4000/modules?type=product-feature:product-feature
```

By adding **&debug=true**, you can get more verbose debug information in the Yarn output window, and the browser will show the details of any error details that occur.

```
https://localhost:4000/modules?type=product-feature&debug=true
```

## Debug a module

A debugger can be attached to both the client and the server. Sometimes, you might have to use both methods.

### Debug the client (browser)

You can debug in the browser in two ways:

- Add a **debugger**; statement in your code, and then open the developer tools window in your browser. (In modern browsers, you can typically open the developer tools by pressing the **F12** key.) Your breakpoint should be hit, and you can then use the debugging capabilities of your web browser (for example, watch, locals, or expression evaluation).
- Open the developer tools window, and open the file where you want to set a breakpoint. Depending on your browser, you might be able to use the **Ctrl+P** keyboard shortcut to go to the file and show full source maps. After you set a breakpoint at the desired line number and refresh the page, execution should pause at that breakpoint.

### Debug the server (Node.js)

#### Open debugging tools

Node.js includes dedicated tools that let you attach a debugger to a running application.

To open debugging tools in Google Chrome, go to **chrome://inspect**.

From the view that is opened, you can attach a debugger to the running Node.js applications that expect a

debugger to connect. Keep this view open while you attach the debugger.

### Attach the debugger

To inform Node.js that you want to attach a debugger, start your application by using the following command.

```
yarn start --inspect-brk
```

As you can see, the **inspect-brk** argument is added to the regular **start** command. After the application is compiled, a message that resembles the following message should appear in your console: "Waiting for debugger..."

The previously opened window should gain focus. The application isn't actually run until you select **Play** in the debugging window. After you allow the application to continue, you can set breakpoints by using the methods that are described in the [Debug the client \(browser\)](#) section earlier in this topic.

### Additional reading

- [Documentation for debugging Node.js in Microsoft Visual Studio Code \(VS Code\)](#)

### Troubleshooting

- If the debugger doesn't stop at the breakpoint that you set, it's usually a good idea to restart the server. In this way, you help guarantee that you have a clean build, because the Hot Module Replacement (HMR) functionality doesn't always achieve the best results.
- Sometimes, the transpiled code (TypeScript to JavaScript) makes debugging more challenging, and you must review the raw JavaScript to understand the code that is running. In these cases, you should turn off JavaScript source maps and follow standard instructions for adding breakpoints in JavaScript code.
- If you're debugging a node, make sure that the debugging port is configured for auto-connection by using the dedicated DevTools for Node.js.

# Test modules with module mocks

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic describes how to test modules by using module mocks.

## Overview

Modules typically get their data from data actions and configuration fields, and the HTML that they present is then based on that data. Because modules might not have direct access to the data (such as the Commerce Scale Unit data) when they run in a local development environment, module mock data files can be used for testing. These files are used to set data that can be used to render a module when it runs locally through a web browser.

## Module mock files

Module mock data files are stored under the `/src/<MODULE_NAME>/mocks` directory. The default mock file uses the `<MODULE_NAME>.json` file, but you can add other mock files. To specify different module mock data files when you test in a web browser, append a colon (`:`) and a comma-separated list of mock file names (but without the `.json` file name extension) to the module name.

For example, for a module mock data file that is named `mockTest1.json` and added to the module `mocks` directory, use the URL `http://localhost:4000/modules?type=product-feature:mockTest1`. In this example, the mock name is `product-feature`, which is used in the URL.

## Mock configuration and data fields

To mock the configuration fields of a module, put the configuration names under the `config` section in the mock `.json` file. To mock the data fields of a module, put the data names under the `data` section in the mock `.json` file.

The following example shows a configured module mock `.json` file.

```
{
  "id": "R1Module1",
  "config": {
    "imageAlignment": "left",
  },
  "data": {
    "actionResponse": {
      "text": "Sample Action Response"
    }
  },
  "typeName": "product-feature"
}
```

## Example

The following example shows a module config file that includes various configuration definitions, and the corresponding mock file.

Sample module definition file:

```

{
  "$type": "contentModule",
  "friendlyName": "Product Feature",
  "name": "product-feature",
  "description": "Feature module used to highlight a product.",
  "categories": [
    "storytelling"
  ],
  "tags": [
    ""
  ],
  "dataActions": {
  },
  "config": {
    "imageAlignment": {
      "friendlyName": "Image Alignment",
      "description": "Sets the desired alignment of the image, either left or right on the text.",
      "type": "string",
      "enum": {
        "left": "Left",
        "right": "Right"
      },
      "default": "left",
      "scope": "module",
      "group": "Layout Properties"
    },
    "productTitle": {
      "type": "string",
      "friendlyName": "Product Title",
      "description": "Product placement title"
    },
    "productDetails": {
      "type": "richText",
      "friendlyName": "Product Details",
      "description": "Rich text representing the featured product details"
    },
    "productImage": {
      "type": "image",
      "friendlyName": "Product Image",
      "description": "Image representing the featured product"
    },
    "buttonText": {
      "type": "string",
      "friendlyName": "Button Text",
      "description": "Text to show on the call to action button"
    },
    "productIds": {
      "friendlyName": "Product ID",
      "description": "Provide a Product Id that the module will display",
      "type": "string",
      "scope": "module",
      "group": "Content Properties"
    }
  },
  "resources": {
    "resourceKey": {
      "comment": "resource description",
      "value": "resource value"
    }
  }
}

```

Sample mock file:

```
{
  "id": "R1Module1",
  "config": {
    "imageAlignment": "left",
    "productTitle": "Retro Horn Rimmed Keyhole Nose Bridge Round Sunglasses",
    "productDetails": "High-quality and pioneered with the perfect blend of timeless classic and modern
technology with hint of old school glamor.",
    "productImage": {
      "src": "https://bit.ly/33cMGxr",
      "altText": "Retro Horn Rimmed Keyhole Nose Bridge Round Sunglasses"
    },
    "buttonText": "Buy Now",
    "productIds": "68719498121"
  },
  "data": {
    "actionResponse": {
      "text": "Sample Action Response"
    }
  },
  "typeName": "product-feature"
}
```

# Test modules by using page mocks

2/18/2021 • 5 minutes to read • [Edit Online](#)

This topic describes how to test modules by using page mocks.

## Overview

Some modules are built to interact with other modules. You can use page mocks to test those modules together in a local development environment.

Page mock files are stored under the `/src/pageMocks` directory. They can be loaded by using the URL `https://localhost:4000/page?mock=PAGE MOCK`, where **PAGE MOCK** is the file name of the mock file, but without the `.json` file name extension.

## Create a new page mock

To create a new page mock, create a blank `.json` file under the `/src/pageMocks` directory, such as `/src/pageMocks/campaign-page.json`.

## Example

The following example shows a page mock that adds two instances of the same module to a page but uses different mock data for each instance.

```

{
  "exception": null,
  "pageRoot": {
    "id": "core-root_0",
    "typeName": "core-root",
    "modules": {
      "body": [
        {
          "id": "default-page_0",
          "typeName": "default-page",
          "modules": {
            "primary": [
              {
                "id": "ProductFeature_0",
                "typeName": "product-feature",
                "config": {
                  "imageAlignment": "left",
                  "buttonText": "Buy Now",
                  "productIds": "68719490621"
                }
              },
              {
                "id": "ProductFeature_1",
                "typeName": "product-feature",
                "config": {
                  "imageAlignment": "right",
                  "productIds": "68719498121",
                  "buttonText": "Buy Now"
                }
              }
            ]
          }
        }
      ]
    }
  },
  "renderingContext": {
    "gridSettings": {
      "xs": {
        "w": 767
      },
      "sm": {
        "w": 991
      },
      "md": {
        "w": 1199
      },
      "lg": {
        "w": 1599
      },
      "xl": {
        "w": 1600
      }
    },
    "staticContext": {
      "staticCdnUrl": "/_scnr/"
    },
    "locale": "en-us"
  },
  "statusCode": 200
}

```

Every page defines a root (**core-root** in the example above) that controls the page HTML structure with slots for "HTML Head", "Body Begin", "Body" and "Body End". The **body** then must have a page container module. In this example, the **default-page** page container is used.

The **modules** section lists the modules that are included inside the page arranged by named slots. The **default-page** page container has a slot that is named **primary**. This container is responsible for laying out the modules that are included inside it. In this example, the **productFeature** module is rendered two times in a row with the mock data defined in the **config** section for each.

The preceding example can be accessed by using the following URL:

```
https://localhost:4000/page?mock=campaign-page .
```

## Rendering context mocks

The **renderingContext** node provides additional mock data that modules can access via the **this.props.context.request** object. This mock data can include the bootstrap grid breakpoints, the locale, and the user context. For more information, see [Request properties object](#).

### Simulate the signed-in state

Some modules might have logic that must check the signed-in state of the user before they take the appropriate action. Typically, a module gets the state from the **this.props.context.request.user** object. Because business-to-consumer (B2C) sign-in isn't supported in a development environment, the user object can be mocked by using the **user** node, as shown in the following example.

```
{
  "exception": null,
  "pageRoot": {
    "id": "core-root_0",
    "typeName": "core-root",
    "modules": {
      "body": [
        {
          "id": "default-page_0",
          "typeName": "default-page",
          "modules": {
            "primary": [
              {
                "id": "ProductFeature__0",
                "typeName": "product-feature",
                "config": {
                  "imageAlignment": "left",
                  "buttonText": "Buy Now",
                  "productIds": "68719490621"
                }
              }
            ]
          }
        }
      ]
    }
  },
  "renderingContext": {
    "gridSettings": {
      "xs": {
        "w": 767
      },
      "sm": {
        "w": 991
      },
      "md": {
        "w": 1199
      },
      "lg": {
        "w": 1599
      },
      "xl": {
        "w": 1600
      }
    }
  }
}
```

```

    },
    "staticContext": {
      "staticCdnUrl": "/_scnr/"
    },
    "user": {
      "token": "<TOKEN>",
      "isAuthenticated": true,
      "signInUrl": "https://dev.fabrikam.com/fedev/_msdyn365/signin",
      "signOutUrl": "https://dev.fabrikam.com/fedev/_msdyn365/signout",
      "signUpUrl": "https://dev.fabrikam.com/fedev/_msdyn365/signup",
      "editProfileUrl": "https://dev.fabrikam.com/fedev/_msdyn365/editprofile",
      "signInName": "<User Name>",
      "firstName": "<User First Name>",
      "lastName": "<User Last Name>",
      "tenantId": "",
      "customerAccountNumber": "<User Account Number(HQ)>",
      "name": "<User Name>",
      "emailAddress": "<User Email Address>"
    },
    "locale": "en-us"
  },
  "statusCode": 200
}

```

If you must simulate real data or the token that is returned from Commerce Server after a user signs in, sign in to your production e-Commerce site, and use the F12 browser tools to copy the data. The user information is available in the `___initialData___requestContext.user` global JavaScript variable. While the F12 browser tools are open and a user is signed in, open a console window, and enter `___initialData___requestContext.user` to see the object. You can then update the `userContext` properties in the preceding example as required. Those properties include `token`, `signInName`, `firstName`, `lastName`, `customerAccountNumber`, `name`, and `emailAddress`.

## Create a dynamic page mock from a production e-Commerce page

You can create dynamic page mocks that mimic live e-Commerce site pages and can be used locally to test module interaction. For example, these page mocks can mock the signed-in state and other page contextual properties as required. Therefore, they can be helpful when you locally test pages such as account pages and wishlist pages, or interactions such as order checkout flow.

### Save a live e-Commerce page's raw JSON structure

The raw JavaScript Object Notation (JSON) structure of any live e-Commerce page can be captured and saved so that it can be used as a page mock. Open the e-Commerce site page that you want to capture, and sign in if the signed-in state is desired. Next, append the query string parameter `?item=nodeserviceproxy:true` to the page URL, and then reload the page to obtain the JSON of the raw page context.

#### NOTE

For this operation to work, you must have secure Azure Active Directory (Azure AD) access to your production site, and you might be prompted to sign in if you aren't already signed. Use the same Azure AD account that you use to sign in to Commerce site builder.

Next, in your development environment, create a new page mock JSON file under the `src/pageMocks` directory. Paste in the JSON file that you obtained from the capture and save operation.

The structure of the JSON file should have sections that resemble the sections in the following example. These sections should include the `pageRoot` section that defines the set of modules for the page and the `renderingContext` section that includes the `user` context for signed-in user information.

```
{
  "exception": null,
  "pageRoot": {
    "id": "core-root_0",
    "typeName": "core-root",
    "modules": {
    }
  },
  "renderingContext": {
    ...
    "user": {
      ...
    }
  },
  "statusCode": 200
  ...
}
```

To test the page mock locally, start your Node server by using **yarn start** command. Access the page mock by using the URL format `https://localhost:4000/page?mock=PAGE MOCK`, where **PAGE MOCK** is the file name of the mock file without the `.json` file name extension.

You can now modify the page mock as desired.

# Container modules

2/18/2021 • 2 minutes to read • [Edit Online](#)

Container modules help you control the layout when you build complex modules or pages out of small component modules. For example, a container module might be a header, footer, or buy box module that has nested modules inside it.

Container modules can define "slots" that are exposed to template authors. You can think of slots as regions inside the container module. Page authors can configure which modules go into each slot. The code of the container module is responsible for the HTML layout of the slots.

Configuration settings can also be exposed to page authors. In this way, page authors can do additional configuration of the layout of container modules. The container module is responsible for building a responsive design, to help guarantee that the module will look good at any size, regardless of whether it's viewed on a mobile device screen or in a full web browser.

Container modules are created just like regular modules. However, in the `MODULE_NAME.definition.json` file, you must change the `$type` value as shown in the following example.

```
"$type": "containerModule"
```

There are two types of container modules: layout container modules and page container modules.

## Layout container modules

Layout container modules are useful when you must make a complex module out of multiple simple modules, and you want to control the layout of those simple modules. For example, you can use a header layout container module that is made up of required or optional sub-modules, such as search, sign-in, and navigation modules. The purpose of the layout container is to provide an adaptive layout.

For more information, see [Create a layout container module](#).

## Page container modules

Page container modules contain the core structure for page authoring. For example, you can create a page container where slots are defined for the header area, main content area, and footer area. A page container is just a module that controls the layout of a set of named slots, and that can be embedded only at the root of a page. Each page must have only one page container. This page container is added to a template in the authoring tools.

Like layout container modules, page container modules can define named slots that are exposed to template authors. Page authors can configure which modules go into each slot, and the rendering code for the container controls the layout of those slots. Configuration settings can also be exposed to page authors, so that they can do additional configuration of the layout.

For more information, see [Create a page container module](#).

# Create a layout container module

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic describes how to create, test, and preview a layout container module.

## Overview

The Microsoft Dynamics 365 Commerce online software development kit (SDK) provides a `yarn msdyn365 add-module MODULE_NAME` command-line interface (CLI) command. To create a new layout container module, you run this command to create a standard module, replacing `MODULE_NAME` with the name that you want to give to your module. Then change the `$type` value to `containerModule`.

### Examples

The following example shows how to create a container module that is named `campaign-container`.

```
yarn msdyn365 add-module campaign-container
```

After the command has finished running, open the new module's definition file, `campaignContainer.definition.json`, and change the `$type` value to `containerModule`.

The following example shows the addition of a `slots` section that contains two slots for this container.

```
{
  "$type": "containerModule",
  "friendlyName": "Sample Container",
  "name": "campaign-container",
  "description": "Sample container module",
  "categories": ["container"],
  "tags": [],
  "config": {
  },
  "slots": {
    "slot1": {
      "friendlyName": "Content Slot 1",
      "description": "Content to be rendered in container. Max 2",
      "allowedTypes": ["*"],
      "max": 2,
      "min": 0
    },
    "slot2": {
      "friendlyName": "Content Slot 2",
      "description": "Content to be rendered in container. Max 2",
      "allowedTypes": ["*"],
      "max": 2,
      "min": 0
    }
  }
}
```

The following example shows the module's React view file, `campaignContainer.view.tsx`, which uses the slots for the container. Note that this example uses a single React/View file, and that the `campaignContainer.tsx` can be deleted.

```

import * as React from 'react';
import { ICampaignContainerData } from './campaignContainer.data';
import { ICampaignContainerProps } from './campaignContainer.props.autogenerated';

const CampaignContainerView: React.FC<ICampaignContainerViewProps> = props => {
  return (
    <div {...this.props.renderModuleAttributes(this.props)} id={this.props.id}>
      <div className='row'>
        {slots.slot1[0]}
        {slots.slot2[0]}
      </div>
    </div>
  );
};

export default CampaignContainer;

```

## Test a layout container module

To test a container module in a local development environment, you must use a page mock.

The following example shows a sample page mock, campaign-containerMock.json, that you can use for testing. The file is saved in the \src\pageMocks directory.

```

{
  "exception": null,
  "pageRoot": {
    "id": "core-root_0",
    "typeName": "core-root",
    "modules": {
      "body": [
        {
          "id": "default-page_0",
          "typeName": "default-page",
          "modules": {
            "primary": [
              {
                "id": "primaryArea__0",
                "typeName": "campaign-container",
                "modules": {
                  "slot1": [
                    {
                      "id": "ProductFeature__0",

## Preview the page

To preview the page in a local web browser, follow these steps.

1. At a command prompt, go to your root SDK folder, and run the **yarn start** command. Here is an example.

```
c:\repos\Msdyn365.Commerce.Online>yarn start
```

2. In a web browser, open the following URL to view the module:

`https://localhost:4000/page?mock=campaign-containerMock` . Notice the name of the page mock in the `mock=` query string parameter.

# Create a page container module

2/18/2021 • 3 minutes to read • [Edit Online](#)

This topic describes how to create a page container module in Microsoft Dynamics 365 Commerce.

## Overview

A page container is a module that controls the core structure of a page through specific layout regions that are known as *slots*. For example, a page container might have slots that are defined for the header area, main content area, and footer area. A page container can be embedded only at the root of a page, and each page must have only one page container.

Like layout container modules, page container modules can define *named slots* that are exposed in the template authoring tool. Page authors can configure which modules go into each slot, and the container rendering code then controls the layout of those slots. Configuration settings can also be exposed to page authors so that they can further configure the layout.

## Create a new page container module

The Microsoft Dynamics 365 Commerce online software development kit (SDK) provides a `yarn msdyn365 add-module MODULE_NAME` command-line interface (CLI) command. To create a page container module, you use this command to create a new module, and then change the `$type` value to `pageModule`.

For example, run the following command to create a module that is named `campaign-page-container`.

```
yarn msdyn365 add-module campaign-page-container
```

Then open the definition file for the new module, `campaign-page-container.definition.json`, and change the `$type` value to `pageModule`.

In the following example, notice that the `slots` section contains the various named slots that the page container supports. To restrict a slot so that only a specific set of modules can be put into it, use the `"allowedTypes"` array to define the list of allowed modules. Alternatively, use an asterisk (\*) to allow any module to be put into the slot.

```

{
  "$type": "pageModule",
  "friendlyName": "Campaign Page Container",
  "name": "campaign-page-container",
  "description": "This is a test page container.",
  "categories": ["page"],
  "tags": [],
  "config": {},
  "slots": {
    "header":
    {
      "friendlyName": "Header Slot",
      "description": "This is the header slot",
      "allowedTypes": ["header"],
      "max": 1,
      "min": 0
    },
    "primary":
    {
      "friendlyName": "Main Slot",
      "description": "This is the Primary slot",
      "allowedTypes": ["campaign-container", "carousel", "content-block", "product-collection"],
      "max": 5,
      "min": 0
    },
    "footer":
    {
      "friendlyName": "Footer Slot",
      "description": "This is the footer slot",
      "allowedTypes": ["footer"],
      "max": 1,
      "min": 0
    }
  }
}

```

In the `MODULE_NAME.tsx` view file, you can define the HTML structure for the slots on the page.

The following example shows an excerpt from a React view file (`campaign-page-container.view.tsx`) that takes advantage of the slots for the container.

```

...
return (
  <div {...this.props.renderModuleAttributes(this.props)} id={this.props.id}>
    <div className='row'>
      {slots.header[0]}
    </div>
    <div className='row'>
      {slots.primary[0]}
    </div>
    <div className='row'>
      {slots.footer[0]}
    </div>
  </div>
);
}
...

```

## Test a page container module

To test a page container module in a local development environment, you must use a page mock.

The following example shows a page mock that can be used for testing. It's saved in the `/src/pageMocks`

directory as campaignContainerMock.json.

```
{
  "exception": null,
  "pageRoot": {
    "id": "core-root_0",
    "typeName": "core-root",
    "modules": {
      "body": [
        {
          "id": "default-page_0",
          "typeName": "campaign-page-container",
          "modules": {
            "primary": [
              {
                "id": "primaryArea__0",
                "typeName": "myContainer"
                "modules": {
                  "slot1": [
                    {
                      "id": "ProductFeature__0",
                      "typeName": "productFeature",
                      "config": {
                        "imageAlignment": "left",
                        "productTitle": "Men's Grand Wingtip Shoe",
                        "productDetails": "Genuine leather crafted with
perfection.",
                        "buttonText": "Buy Now"
                      }
                    }
                  ],
                  "slot2": [
                    {
                      "id": "ProductFeature__1",
                      "typeName": "productFeature" ,
                      "config": {
                        "imageAlignment": "right",
                        "productTitle": "Men's Grand Wingtip Shoe",
                        "productDetails": "Genuine leather crafted with
perfection.",
                        "buttonText": "Buy Now"
                      }
                    }
                  ]
                }
              }
            ]
          }
        }
      ]
    }
  },
  "renderingContext": {
    "staticContext": {
      "staticCdnUrl": "/_scnr/"
    },
    "locale": "en-us"
  },
  "statusCode": 200
}
```

Notice that the preceding page mock defines only the **primary** slot in the page container. However, you can also include the **header** and **footer** slots as you require.

## Preview the page

To preview the page in a local web browser, follow these steps.

1. At a command prompt, go to your root SDK folder, and run the **yarn start** command. Here is an example.

```
c:\repos\Msdyn365.Commerce.Online>yarn start
```

2. In a web browser, open the following URL to view the module:

`https://localhost:4000/page?mock=campaign-containerMock` . Note the name of the page mock in the **mock=** query string parameter.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Localize a module

2/18/2021 • 6 minutes to read • [Edit Online](#)

This topic describes how to localize a module for rendering. It also describes how to localize general module information, such as the module name, description, and configuration fields.

## Localize module-rendered strings

For modules that render strings, the data might already be localized when it's received from the content management system (CMS). For example, a product title might come back from Dynamics 365 Commerce in a localized format. Therefore, it doesn't require localization. However, some strings that are defined in the module might require localization. For example, a module that renders a list page might have **Next** and **Previous** buttons that are used for page navigation. The labels for those buttons must be localized.

### Create a new resource string

Resources are stored in locale-specific JavaScript Object Notation (JSON) files under the `/src/resources/` directory. A `global.json` file is used as the base for all locales, and [n-part locales](#) are supported.

Here is an example of the file structure:

- `/src`
  - `/resources`
    - `/modules`
      - `global.json`
      - `en-us.json`
      - `de-de.json`
      - `fr-fr.json`
      - `fr.json`

Each resource file contains key/value pairs, and an optional **comment** property can provide additional context about the resource key. All modules share a single set of resource files. Therefore, modules can share the same resource keys.

The following example shows a resource schema.

```
{
  "<property_name>":
  {
    "value": "",
    "_value.comment": ""
  }
}
```

The following example shows a resource file.

```
{
  "noResultsForRefinersText": {
    "value": "No results found for refinement criteria",
    "_value.comment": "Message to display when no products are returned with applied refinement
criteria"
  },
  "resultNotFoundText": {
    "value": "Result not found text",
    "_value.comment": "Result not found text for a category"
  },
}
```

### Reference a resource key in a module

To use a resource string in a module, you must reference the resource string keys under the **resources** node in the module definition. Default values can also be provided. Here is an example.

```

{
  "$type": "contentModule",
  "friendlyName": "Product Feature",
  "name": "product-feature",
  "description": "Feature module used to highlight a product.",
  "categories": [
    "storytelling"
  ],
  "tags": [
    ""
  ],
  "dataActions": {},
  "config": {
    "imageAlignment": {
      "friendlyName": "Image Alignment",
      "description": "Sets the desired alignment of the image, either left or right on the text.",
      "type": "string",
      "enum": {
        "left": "Left",
        "right": "Right"
      },
      "default": "left",
      "scope": "module",
      "group": "Layout Properties"
    },
    "productTitle": {
      "type": "string",
      "friendlyName": "Product Title",
      "description": "Product placement title"
    },
    "productDetails": {
      "type": "richText",
      "friendlyName": "Product Details",
      "description": "Rich text representing the featured product details"
    },
    "productImage": {
      "type": "image",
      "friendlyName": "Product Image",
      "description": "Image representing the featured product"
    },
    "buttonText": {
      "type": "string",
      "friendlyName": "Button Text",
      "description": "Text to show on the call to action button"
    },
    "productIds": {
      "friendlyName": "Product ID",
      "description": "Provide a Product Id that the module will display",
      "type": "string",
      "scope": "module",
      "group": "Content Properties"
    }
  },
  "resources": {
    "nextButtonText": {
      "value": "next",
      "comment": "Text for the next button"
    },
    "previousButtonText": {
      "value": "previous",
      "comment": "Text for the previous button"
    }
  }
}

```

**Access resources in the module view file**

Resources can be accessed in the module React file and module view file by using the **this.props.resources** property, as shown in the following example.

```
<button className="nextButton">
  {this.props.resources.nextButtonText}
</button>
```

## Localize module fields for authoring tools

Modules should be built so that they support localization. This guideline applies to any authoring metadata in the module definition file, including the module name, description, and configuration fields.

Each resource file must contain modules and properties groups. All the module-related authoring strings should be grouped under the **modules** section. There should be a child section for each module, and each module section should, in turn, include the related authoring property pairs as children. Each property is an object that has a **"value"** property and an optional **"\_value.comment"** property inside the module section.

The following example shows a resource schema.

```

{
  "modules": {
    "<module_name>": {
      "friendlyName": {
        "value": "",
        "_value.comment": ""
      },
      "description": {
        "value": "",
        "_value.comment": ""
      },
    },
    "config": {
      "<property_name>": {
        "friendlyName": {
          "value": "",
          "_value.comment": ""
        },
        "description": {
          "value": "",
          "_value.comment": ""
        },
        "errorMessage": {
          "value": "",
          "_value.comment": ""
        },
        "properties": {
          ...
        }
      }
    },
    "slots": {
      "content": {
        "friendlyName": {
          "value": "",
          "comment": ""
        }
      }
    },
    "options": {
      "enumKey": {
        "value": "",
        "_value.comment": ""
      }
    },
  },
}

```

The following example shows a resource file.

```

{
  "modules": {
    "hero": {
      "friendlyName": {
        "value": "Hero Module",
        "_value.comment": ""
      },
      "description": {
        "value": "Hero with slides",
        "_value.comment": ""
      },
      "config": {
        "headerText": {
          "friendlyName": {
            "value": "Partner hero",
            "_value.comment": ""
          }
        },
        "alignment": {
          "friendlyName": {
            "value": "Hero Image Alignment",
            "_value.comment": ""
          },
          "options": {
            "left": {
              "value": "Left Image",
              "_value.comment": ""
            },
            "right": {
              "value": "Right Image",
              "_value.comment": ""
            }
          }
        }
      },
      "slots": {
        "content": {
          "friendlyName": {
            "value": "Content Slots",
            "_value.comment": ""
          },
          "description": {
            "value": "Content to be rendered in container. Max 2",
            "_value.comment": ""
          }
        }
      },
      "options": {
        "text": {
          "value": "text",
          "_value.comment": ""
        },
        "glyph": {
          "value": "glyph",
          "_value.comment": ""
        }
      }
    }
  }
}

```

### Generate a resource global.json file

You can generate global.json files for module resources and authoring resources by running the `yarn msdyn365 generate-resources src` command in the SDK root folder. This command picks up both the module and authoring strings that are defined in the \*.definition.json files, and it generates the

resources/modules/global.json and resources/authoring/global.json files.

### Example global.json file

```
{
  "nextButtonText": {
    "value": "next",
    "_value.comment": "Text for the next button"
  },
  "previousButtonText": {
    "value": "previous",
    "_value.comment": "Text for the previous button"
  }
}
```

### Example fr-fr.json localized file

```
{
  "nextButtonText": {
    "value": "prochain",
    "_value.comment": "Text for the next button"
  },
  "previousButtonText": {
    "value": "précédent",
    "_value.comment": "Text for the previous button"
  }
}
```

## Override a resource string for a theme

The built-in module library set of modules and themes may have localized resource strings that you want to override. To override resource strings for a theme, modify the global.json resource file located in the src/resources/modules directory using the pattern in the following example.

```
"{ThemeNamespace}.{ThemeName}.{ResourceString}": {
  "value" : "",
  "_value.comment": ""
}
```

### Override resource strings for preinstalled themes

To override resource strings for preinstalled themes (fabrikam or starter), use **@msdyn365-commerce-modules** as the theme namespace. The following example shows how to change the sign-in link text on the fabrikam theme.

```
"@msdyn365-commerce-modules.fabrikam.signInLinkText": {
  "value": "Sign in now",
  "_value.comment": "Sign-in Link Text"
}
```

### Override resource strings for custom or local themes

For custom or local themes, use **local** for the theme namespace. The following example shows how to change the sign-in link text for a custom theme called "adventureworks."

```
"__local__.adventureworks.signInLinkText": {
  "value": "Log in",
  "_value.comment": "Log in Link Text"
}
```

#### NOTE

For [shared themes](#), child themes inherit all of the resources string overrides tied to the parent theme.

## Test localized content

To test localized content, you must use a page mock and change the locale to the locale you're testing. For more information about page mocks, see [Test modules by using page mocks](#).

# Request properties object

2/18/2021 • 3 minutes to read • [Edit Online](#)

This topic covers the request properties object in Microsoft Dynamics 365 Commerce.

## Overview

The request properties object represents an HTTP request and includes various data properties, such as the requested URL, locale, device, user, cookies, and query string parameters. To get the request information, modules can access a read-only request context object that is named **this.props.context**, and they can change module behavior as required.

## Example

The following example shows how to access the request properties object from within the request context.

```
if (this.props.context.request.user.isAuthenticated) {
    userName = this.props.context.request.user.signInName ? this.props.context.request.user.signInName : '';
    firstName = this.props.context.request.user.firstName ? this.props.context.request.user.firstName : '';
    lastName = this.props.context.request.user.lastName ? this.props.context.request.user.lastName : '';
}
```

## General properties

- **url** – The requested URL.
- **locale** – The locale context (for example, "en-us").
- **textDirection** – The text direction (the possible values are "rtl" and "ltr").
- **sitePath** – The full path of the site.
- **device** – The device that the request came from.
  - **Type** – The device type (for example, "pc").
- **user** – Information about the user. The following properties are included:
  - **token**
  - **isAuthenticated**
  - **signInURL**
  - **signoutURL**
  - **signUpUrl**
  - **editProfileUrl**
  - **signInName**
  - **name**
  - **firstName**
  - **lastName**
  - **emailAddress**
  - **customerAccountNumber**
- **query** – A list of query string parameters.

- cookies – Cookie information.

## Interface

```
interface IParsedQSP<TValue> {
    hasValue: boolean;
    isTruthy: boolean;
    value: TValue | undefined;
}

interface IRequestContextUrl {
    serverUrl: string;
    serverPageUrl: string;
    requestUrl: URL;
    staticCdnUrl: string;
}

interface IRequestContextParams {
    mock?: string;

}

```

## Test a module that has an authenticated signed-in state

Some modules might require that the state be **signed-in**. To test these modules, you can create a test page mock that has user authentication information.

To get started, follow these steps.

1. Load the e-Commerce webpage that you're working on, and sign in or create a new account.
2. Open your web browser's debugging tools. For example, if you're using Google Chrome, you can open the developer tools by pressing the F12 key.
3. Enter `___initialData___requestContext.user` in the console to get the user information. (User information is available in the `___initialData___requestContext.user` global JavaScript variable.)
4. Add the module that must be tested to a page mock.
5. In the `renderingContext` section of the page mock, add the following `userContext` section.

```

"userContext": {
  "token": "<TOKEN>",
  "isAuthenticated": true,
  "signInUrl": "https://dev.fabrikam.com/fedev/_msdyn365/signin",
  "signOutUrl": "https://dev.fabrikam.com/fedev/_msdyn365/signout",
  "signUpUrl": "https://dev.fabrikam.com/fedev/_msdyn365/signup",
  "editProfileUrl": "https://dev.fabrikam.com/fedev/_msdyn365/editprofile",
  "signInName": "<User Name>",
  "firstName": "<User First Name>",
  "lastName": "<User Last Name>",
  "tenantId": "",
  "customerAccountNumber": "<User Account Number(HQ)>",
  "name": "<User Name>",
  "emailAddress": "<User Email Address>"
},

```

6. Update the user information from the web browser's debugging tools.

The user information can now be obtained in the React component from within the `this.props.context.request.user` object.

Here is an example of the page mock.

```

{
  "exception": null,
  "pageRoot": {
    "id": "core-root_0",
    "typeName": "core-root",
    "modules": {
      "body": [
        {
          "id": "default-page_0",
          "typeName": "default-page",
          "modules": {
            "primary": [
              {

```

```

        "id": "ProductFeature_0",
        "typeName": "product-feature",
        "config": {
            "imageAlignment": "left",
            "productTitle": "Retro Horn Rimmed Keyhole Nose Bridge Round
Sunglasses",
            "productDetails": "High-quality and pioneered with the perfect blend of
timeless classic and modern technology with hint of old school glamor.",
            "productImage": {
                "src" : "https://bit.ly/33cMGxr",
                "altText" : "Retro Horn Rimmed Keyhole Nose Bridge Round Sunglasses"
            },
            "buttonText": "Buy Now"
        }
    }
}
],
},
"renderingContext": {
    "gridSettings": {
        "xs": {
            "w":767
        },
        "sm": {
            "w":991
        },
        "md": {
            "w":1199
        },
        "lg": {
            "w":1599
        },
        "xl": {
            "w":1600
        }
    },
    "staticContext": {
        "staticCdnUrl": "/_scnr/"
    },
    "locale": "en-us",
    "userContext": {
        "token": "<TOKEN>",
        "isAuthenticated": true,
        "signInUrl": "https://dev.fabrikam.com/fedev/_msdyn365/signin",
        "signOutUrl": "https://dev.fabrikam.com/fedev/_msdyn365/signout",
        "signUpUrl": "https://dev.fabrikam.com/fedev/_msdyn365/signup",
        "editProfileUrl": "https://dev.fabrikam.com/fedev/_msdyn365/editprofile",
        "signInName": "<User Name>",
        "firstName": "<User First Name>",
        "lastName": "<User Last Name>",
        "tenantId": "",
        "customerAccountNumber": "<User Account Number(HQ)>",
        "name": "<User Name>",
        "emailAddress": "<User Email Address>"
    },
},
},
"statusCode": 200
}

```

# App settings

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic covers app settings in Microsoft Dynamics 365 Commerce.

## Overview

The `\src\settings\app.settings.json` file holds app settings for global configurations, routes, and themes. The following example shows a JavaScript Object Notation (JSON) file that includes a section for each type of setting.

```
{
  "config": {
    "logoUrl": {
      "type": "image",
      "friendlyName": "Logo Image",
      "description": "Logo Image"
    }
  },
  "routes": {
    "cart": {
      "friendlyName": "Cart Page Route",
      "description": "Cart Page Route",
      "default": "/cart2"
    },
    "checkout": {
      "friendlyName": "Checkout Page Route",
      "description": "Checkout Page Route",
      "default": "/checkout"
    }
  },
  "themes": {
    "default": {
      "friendlyName": "Default Theme"
    }
    "spring": {
      "friendlyName": "Spring Theme"
    }
  }
}
```

## Config section

The **config** section of the `app.settings.json` file supports global configuration fields. These fields can be set at the site level in the authoring tools, and they are shared across all modules by using the `this.props.context.app.config.*` application programming interface (API).

The global configuration fields are helpful when you have data that should be set only one time across the whole online site, but the data is required by multiple modules. For example, an API key for ratings and reviews has the same value across the online site, and that value is required by multiple modules. Modules themselves also support site-scoped configuration settings, but those settings can't be shared across different modules.

The schemas for these configurations follow the same schemas that are used for module configurations.

## Routes section

The **routes** section in the app.settings.json file is used to add URL routes in a module. For example, if a module must create a link to the cart page, a "cart" route is added to the JSON file. The route can then be retrieved from the module code by using the authoring tools.

Routes can be accessed in the module view file by using the **this.props.context.app.routes.\*** API.

## Themes section

The **themes** section in the app.settings.json file is used to expose themes to the authoring tools. The themes in this section should match the theme names in the \src\themes\ directory. They should provide localizable friendly names that the authoring tools can show when they are used to set a theme at the site level, or in the template, layout, or page editor.

### Localized app settings

Both the **friendlyName** property and the **description** property of each app setting should be localized for the site locale in the Dynamics 365 Commerce authoring tools. The src/resources/authoring/global.json file should be updated so that it includes a **settings** property, and all the settings that are related to resource strings should be listed under that property.

### Resource schema

```
{
  "settings": {
    "<setting_property>": {
      "friendlyName": {
        "value": "",
        "_value.comment": ""
      },
      "description": {
        "value": "",
        "_value.comment": ""
      },
    },
  },
},
}
```

Here is an example of a resource file.

```
{
  "settings": {
    "logoUrl": {
      "friendlyName": {
        "value": "Logo Image",
        "_value.comment": ""
      },
      "description": {
        "value": "Logo Image",
        "_value.comment": ""
      }
    },
    "cart": {
      "friendlyName": {
        "value": "Cart URL",
        "_value.comment": ""
      },
      "description": {
        "value": "Cart page route",
        "_value.comment": ""
      }
    }
  }
}
```

# Platform settings file

2/18/2021 • 2 minutes to read • [Edit Online](#)

## IMPORTANT

Some or all of the functionality noted in this topic is available as part of a preview release. The content and the functionality are subject to change. For more information about preview releases, see [One version service updates FAQ](#).

This topic covers the various properties that are configured in the platform settings file in Microsoft Dynamics 365 Commerce.

The `platform.settings.json` file under the `\src\settings\` directory holds various platform property settings that are used by the Commerce e-commerce runtime. This file might not exist by default. If it doesn't exist, you can add it under the `\src\settings\` directory. The following example of a `platform.settings.json` file shows various supported property settings.

```
{
  "dataActionTimeoutInMs": 4000,
  "minClientChunkSize": 30000,
  "excludeModules": [ ],
  "namespaceExtensions" : [ ]
}
```

## dataActionTimeoutInMs

The `dataActionTimeoutInMs` property defines the maximum amount of time, in milliseconds, that data actions will wait for a response before they time out. The time-out represents a lower bound for page response, because the action framework will wait as long as the defined time-out before it times out and returns the page. The default value is 4,000 milliseconds (4 seconds).

## minClientChunkSize

The `minClientChunkSize` property defines the minimum size, in bytes, of webpack JavaScript chunks that will be sent to the browser. JavaScript chunks that are smaller than the minimum size will be grouped together to form chunks that are larger than the minimum size. The smaller the minimum size is, the more chunks will be generated. In this case, more code splitting will occur, and less unused JavaScript code will be included. However, many smaller chunks must be downloaded. By contrast, the larger the minimum size is, the fewer overall chunks will be generated. In this case, fewer JavaScript files must be downloaded, but some unused JavaScript code might be included. The default value is 30,000 bytes (30 KB).

## excludedModules

The `excludedModules` property defines a set of modules that will be excluded from webpack JavaScript chunks. Commerce modules are bundled into JavaScript chunks and sent to the browser on the client side. However, if modules aren't required on a site, they can be excluded to help reduce the size of JavaScript chunks and help increase the speed of page loads.

## namespaceExtensions

The `namespaceExtensions` property defines the supported namespaces that are used for module registration. By default, the only supported namespace is `@msdyn365-commerce-modules`. This namespace contains all the module library modules and the core set of modules. The module package name is defined in the following format: `<namespace>/<module_name>`. If modules are published that use a new namespace, the namespace can be added to the settings.

# Extend a module definition file

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic describes how to extend a module definition file. For example, you can create an extended module of another module to add new configuration fields.

## Overview

When you extend a property that is an object, you must extend the whole object. For example, to add a configuration property to your extended module, you first copy the existing configuration properties from the parent module to the child module. You then add the desired property.

## Examples

The following example of a module definition file shows how a core module can be extended by using a **\$ref** command to the core script injector module.

```
{
  "$ref": "@d365-commerce-modules/core-components/dist/lib/modules/script-injector/script-
injector.definition.json",
  "friendlyName": "Analytics Service",
  "name": "AnalyticsService"
  ...
}
```

The **\$ref** command can also include a relative path to another module in your `/src/modules/` directory.

```
{
  "$ref": "../productFeature/productFeature.definition.json",
  "friendlyName": "Extended Product Feature Module",
  "name": "extendedProductFeature",
  "config": {
    "extendedProductData": {
      "friendlyName": "Extended Product Data",
      "description": "Additional product data.",
      "type": "string"
    }
  }
}
```

After deployment, both the base module and the extended module appear in Microsoft Dynamics 365 Commerce.

# Cookie API overview

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic provides an overview of the application programming interfaces (APIs) in the Microsoft Dynamics 365 Commerce e-Commerce software development kit (SDK) that are used to set and get cookie data.

## Cookie consent

Before cookies can be stored, the user must give consent. The Dynamics 365 Commerce online SDK provides utilities that help guarantee that the read/write operation of a cookie depends on user consent.

## Cookie APIs

The Dynamics 365 Commerce online SDK provides a set of APIs that access cookies from within the `props.context.request` API, as shown in the following example.

```
get<T>(cookieName: string, isEssential?: boolean): ICookieValue<T>;
set<T>(cookieName: string, cookieValue: T, options?: ICookieSetOptions): void;
remove(cookieName: string): void;
isConsentGiven(): boolean;
setConsentCookie(): void;
deleteConsentCookie(): void;
```

### Obtain user consent

The `setConsentCookie()` API is used to obtain user consent before cookies can be written.

### Determine whether user consent has been given

The `isConsentGiven()` API is used to determine whether user consent has been given.

### Set a cookie

The following example shows how to set a cookie.

```
this.props.context.request.cookies.set<string>('favoriteColor', 'blue');
```

If user consent isn't given before this API is called, the SDK maintains a queue of all `set` operations and sets a cookie only after the user gives consent.

### Get the value of a cookie

The following example shows how to get the value of a cookie.

```
const favColor = this.props.context.request.cookies.get<string>('favoriteColor');
```

# Interactive components overview

2/18/2021 • 6 minutes to read • [Edit Online](#)

This topic covers interactive components that let site authors edit fields for text, rich text, links, images, and videos directly in visual page builder, the what-you-see-is-what-you-get (WYSIWYG) preview canvas in Microsoft Dynamics 365 Commerce site builder.

## Overview

In Commerce site builder, page or fragment authors can use interactive components to edit fields for text, rich text, links, images, and videos directly in visual page builder. Interactive components are released with the Commerce online software development kit (SDK) and include **Msdyn365.Text** for text, **Msdyn365.RichTextComponent** for rich text, **Msdyn365.Links** for links, **Msdyn365.Image** for images, and **Msdyn365.Video** for videos. After the interactive components are implemented, site builder will allow for inline editing of text, and it will open a picker window for links, images, and videos.

For the best authoring experience, module developers should use interactive components when they render configuration fields, to allow for inline editing. Any custom implementations of these components can be made interactive by wrapping the component in the **EditableField** higher-order component (HOC). Follow the guidelines in this topic to support interactive components inside a custom module.

## How interactive components work

An interactive component hooks an event handler to the component that will do the work of setting the specific configuration field that is required.

The following example shows how a text configuration field uses an interactive component to allow for inline editing of the text. A **productTitle** configuration value is specified in the **config** section of the module definition file.

```
...
  "config": {
    "productTitle": {
      "type": "string",
      "friendlyName": "Product Title",
      "description": "Product placement title"
    },
  },
}
```

To support an interactive canvas experience, the module uses the **Msdyn365.Text** interactive component. This interactive component specifies a **handleTextChange** event handler that will set the configuration value.

```
public handleTextChange = (event: Msdyn365.ContentEditableEvent) => this.props.config.productTitle!.text =
  event.target.value;

<Msdyn365.Text
  className={'product-title'}
  tag={'h2'}
  text={this.props.config.productTitle}
  editProps={{ onEdit: this.handleTextChange, requestContext: this.props.context.request }}
/>
```

# Interactive component reference

## Text component

After it's implemented, the text component lets site authors edit text inline, directly in visual page builder.

### Text component syntax

```
<Msdyn365.Text />
```

### Text component example

```
<Msdyn365.Text
  text={heading.text || ''}
  tag={'h2'}
  className={'display-4'}
  editProps={{ onEdit: this.handleTextChange, requestContext: this.props.context.request }}
/>

public handleTextChange = (event: Msdyn365.ContentEditableEvent) => this.props.config.heading!.text =
  event.target.value;
```

### Available properties

PROPERTY	DESCRIPTION	TYPE
text	The text to show.	String
tag	The HTML tag (for example, <b>DIV</b> or <b>H2</b> ) to use to render the text.	String
className	The Cascading Style Sheets (CSS) class name.	String
editProps	Properties that are required to enable interaction in site builder.	ITextEditProps

### ITextEditProps properties

PROPERTY	DESCRIPTION	TYPE
onEdit	The function handler that handles the text change event.	Function
requestContext	The Request context object.	IRequestContext

## Rich text component

After it's implemented, the rich text component lets site authors edit rich text inline, directly in visual page builder.

### Rich text component syntax

```
<Msdyn365.RichTextComponent />
```

### Rich text component example

```

<Msdyn365.RichTextComponent
  text={`<p className='d-none d-lg-block'>${paragraph}</p>`}
  editProps={{ onEdit: this.handleParagraphChange, requestContext: this.props.context.request }}
/>

```

#### Available properties

PROPERTY	DESCRIPTION	TYPE
text	The HTML text to show.	String
editProps	The properties that are required to enable interaction in site builder.	ITextEditProps

#### ITextEditProps properties

PROPERTY	DESCRIPTION	TYPE
onEdit	The function handler that handles the text change event.	Function
requestContext	The Request context object.	IRequestContext

### Links component

After it's implemented, the links component lets site authors edit an array of links in visual page builder.

#### Links component syntax

```

<Msdyn365.Links />

```

#### Links component example

```

<Msdyn365.Links
  links={config.links}
  editProps={{ onTextChange: this.handleLinkTextChange, requestContext: this.props.context.request }}
/>

```

#### Available properties

PROPERTY	DESCRIPTION	TYPE
link	The array of link data to render.	ILinksData[]
editProps	The properties that are required to enable interaction in site builder.	ITLinkEditProps

#### ILinksData properties

PROPERTY	DESCRIPTION	TYPE
linkText	The text to show as a link.	String
linkUrl	The URL to open.	String
openInNewTab	A flag that indicates whether the link should be opened on a new tab.	Boolean

PROPERTY	DESCRIPTION	TYPE
ariaLabel	The Accessible Rich Internet Applications (ARIA) label for accessibility.	String
className	The CSS class name.	String
key	The React key.	String
role	The role of the anchor tag (for example, <b>button</b> ).	String
additionalProperties	A dictionary of additional properties to add to the element.	[x: string]: string
linkTag	The HTML tag to use to render the link.	String
innerClassName	The CSS class name for the inner component in the anchor tag.	String
onClick	The click handler that handles the link click event.	Function

#### ILinkEditProps properties

PROPERTY	DESCRIPTION	TYPE
onTextChange	The function handler that handles the link text change event.	Function
requestContext	The Request context object.	IRequestContext

### Link component

After it's implemented, the link component lets site authors edit single links in visual page builder.

#### Link component syntax

```
<Msdyn365.Link />
```

#### Link component example

```
<Msdyn365.Link
  link={config.links[1]}
  editProps={{ onTextChange: this.handleLinkTextChange(1), requestContext: this.props.context.request }}
/>
```

#### Available properties

PROPERTY	DESCRIPTION	TYPE
links	The link data to render.	ILinksData
editProps	Properties that are required to enable interaction in site builder.	ILinkItemEditProps

## ILinksData properties

PROPERTY	DESCRIPTION	TYPE
linkText	The text to show as a link.	String
linkUrl	The URL to open.	String
openInNewTab	A flag that indicates whether the link should be opened on a new tab.	Boolean
ariaLabel	The ARIA label for accessibility.	String
className	The CSS class name.	String
key	The React key.	String
role	The role of the anchor tag (for example, <b>button</b> ).	String
additionalProperties	A dictionary of additional properties to add to the element.	[x: string]: string
linkTag	The HTML tag to use to render the link.	String
innerClassName	The CSS class name for the inner component in the anchor tag.	String
onClick	The click handler that handles the link click event.	Function

## ILinkItemEditProps properties

PROPERTY	DESCRIPTION	TYPE
onTextChange	The function handler that handles the link text change event.	Function
requestContext	The Request context object.	IRequestContext

## Image component

After it's implemented, the image component lets site authors edit images directly in visual page builder.

### Image component syntax

```
<Msdyn365.Image />
```

### Image component example

```
<Msdyn365.Image
  editProps={{ key: this.props.config.image || {}, requestContext: this.props.context.request }}
  {...config.image}
  {...imageProps}
/>
```

### Available properties

PROPERTY	DESCRIPTION	TYPE
src	The URL of the image source.	String
fallBackSrc	The fallback URL if the image can't be loaded.	String
altText	The alt text for the image.	String
caption	The caption string for the image.	String
title	The title for the image.	String
width	The width of the image.	number
height	The height of the image.	number
imageSettings	Settings for the image.	ImageSettings
additionalProperties	A dictionary of additional properties to add to the element.	[x: string]: string
editProps	Properties that are required to enable interaction in site builder.	IEditProps

#### IEditProps properties

PROPERTY	DESCRIPTION	TYPE
key	The path of the image property in the <b>config</b> section of the module definition file.	Object
requestContext	The Request context object.	IRequestContext

### Video component

After it's implemented, the video component lets site authors edit videos directly in visual page builder.

#### Video component syntax

```
<MsDyn365.Video></MsDyn365.Video>
```

#### Video component example

```
<MsDyn365.Video>
  <Player playerData={videoPlayerData} />
</MsDyn365.Video>
```

#### Available properties

PROPERTY	DESCRIPTION	TYPE
className	The CSS class name.	String

PROPERTY	DESCRIPTION	TYPE
editProps	Properties that are required to enable interaction in site builder.	IEditProps

#### IEditProps properties

PROPERTY	DESCRIPTION	TYPE
key	The path of the property in the <b>config</b> section of the module definition file.	Object
requestContext	The Request context object.	IRequestContext

## Generic editable HOC

Generic editable field components wrap any custom components and enable interactions in the context of site builder.

#### Generic editable HOC syntax

```
<EditableField />
```

#### Generic editable HOC example

```
<EditableField
  onChange={this.props.editProps ? this.props.editProps.onEdit : this.onEdit} // handle innerHTML change
  requestContext={this.props.editProps?.requestContext}
  fieldProps={{
    text: this.props.text,
    tag: this.props.tag,
    className: this.props.className
  }}
  type={FieldType.Text}
/>
```

#### Available properties

PROPERTY	DESCRIPTION	TYPE
fieldProps	Field properties.	[x: string]: string
type	The type of the field ( <b>text</b> , <b>image</b> , <b>video</b> , or <b>link</b> ).	FieldType
requestContext	The Request context object.	IRequestContext
onChange	The event handler for the <b>onChange</b> event.	Function
onMouseOver	The event handler for the <b>onMouseover</b> event.	Function
onMouseOut	The event handler for the <b>onMouseout</b> event.	Function

PROPERTY	DESCRIPTION	TYPE
onFocus	The event handler for the <b>onFocus</b> event.	Function
onBlur	The event handler for the <b>onBlur</b> event.	Function
placeholderText	The text to show when text is cleared from the field.	String
disabled	A flag that enables or disables editing of the file in site builder.	String

# Mock the signed-in state during local development

2/18/2021 • 6 minutes to read • [Edit Online](#)

This topic describes how to mock a signed-in user in a Dynamics 365 Commerce online local development environment.

Over the course of developing your e-Commerce online site, it may become necessary to develop and test scenarios for signed-in users. Rather than publish these pages and test against live pages, you can instead mock the signed-in state when running in developer mode.

## Configure your Azure AD B2C tenant

To take advantage of this feature, you must perform a one-time setup in your Azure Active Directory (Azure AD) business-to-consumer (B2C) tenant to allow you to mock the signed-in user status. To proceed with the following steps, you will need to be signed in as a user with global administrator privileges.

### Create a new resource owner password credentials (ROPC) flow

The first step is to create a new resource owner password credentials (ROPC) flow in your Azure AD B2C tenant.

To create a new ROPC flow, follow these steps.

1. Sign in to the [Azure portal](#) as the global administrator of your Azure AD B2C tenant, and then select the **Azure AD B2C** service.
2. Select **User flows** and **New user flow**.
3. Select **Sign in using resource owner password credentials (ROPC)**, and then select **Create**.
4. Enter a name for the user flow, for example "ROPC\_Auth". Copy and save the full name, as it will be used later as the `ropcUserFlowName` value in your `credentials.json` file.
5. Under **Application claims**, select **Show more**.
6. Select the following application claims:
  - **Display Name**
  - **Email Addresses**
  - **Given Name**
  - **Identity provider**
  - **SurName**
  - **User's object ID**
7. Select **OK**, and then select **Create**.
8. Select the new user flow, and then select **Run user flow**.

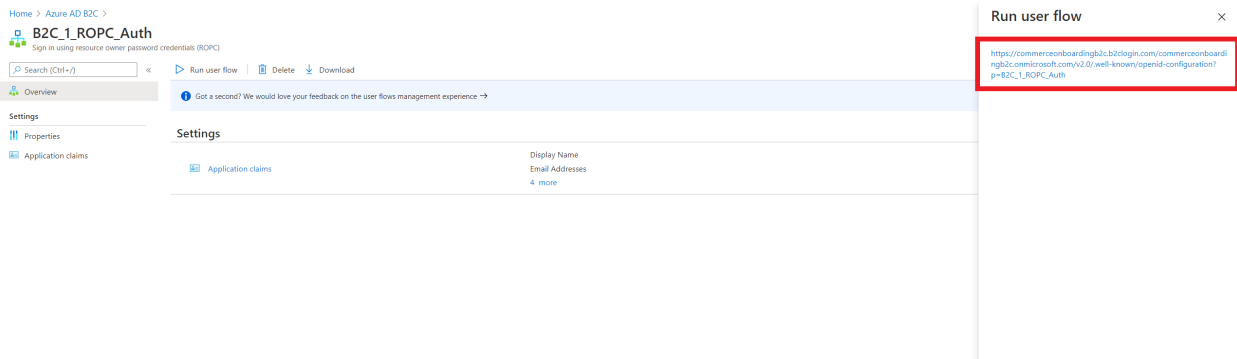

You have now created a new ROPC policy to enable local sign-in. Under **Run user flow** you should see an endpoint URL similar to

```
https://<LOGIN_DOMAIN>//<B2C_TENANT>.onmicrosoft.com/v2.0/.well-known/openid-configuration?p=B2C_1_ROPC_Auth
```

Take note of the `<LOGIN_DOMAIN>` and `<B2C_TENANT>` values from the URL, because this information will be used later in your `credentials.json` file.

In the following example image, the endpoint URL listed under **Run user flow** is

```
https://commerceonboardingb2c.b2clogin.com/commerceonboardingb2c.onmicrosoft.com/v2.0/.well-known/openid-configuration?p=B2C_1_ROPC_Auth
```

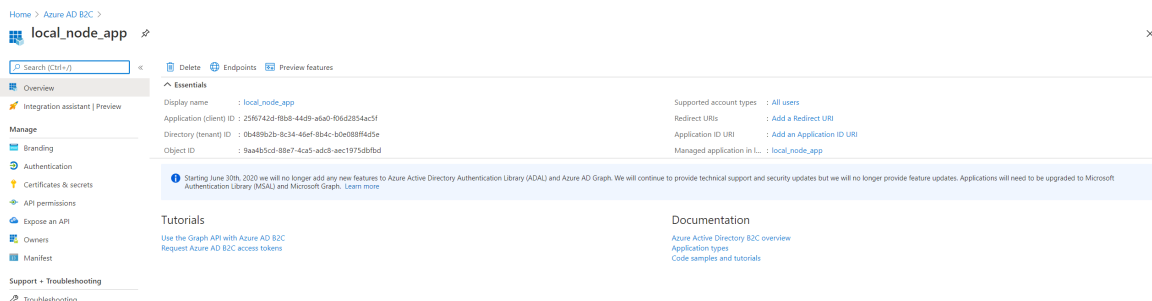

From the example above, you can obtain values for the `ropcUserFlowName`, `loginDomain`, and `b2cTenant` properties as follows:

PROPERTY NAME	EXAMPLE VALUE
<code>ropcFlowUserName</code>	B2C_1_ROPC_Auth
<code>loginDomain</code>	commerceonboardingb2c.b2clogin.com
<code>b2cTenant</code>	commerceonboardingb2c

### Create a native application

Next, you will create a native application meant to represent the Node application you will run during local development.

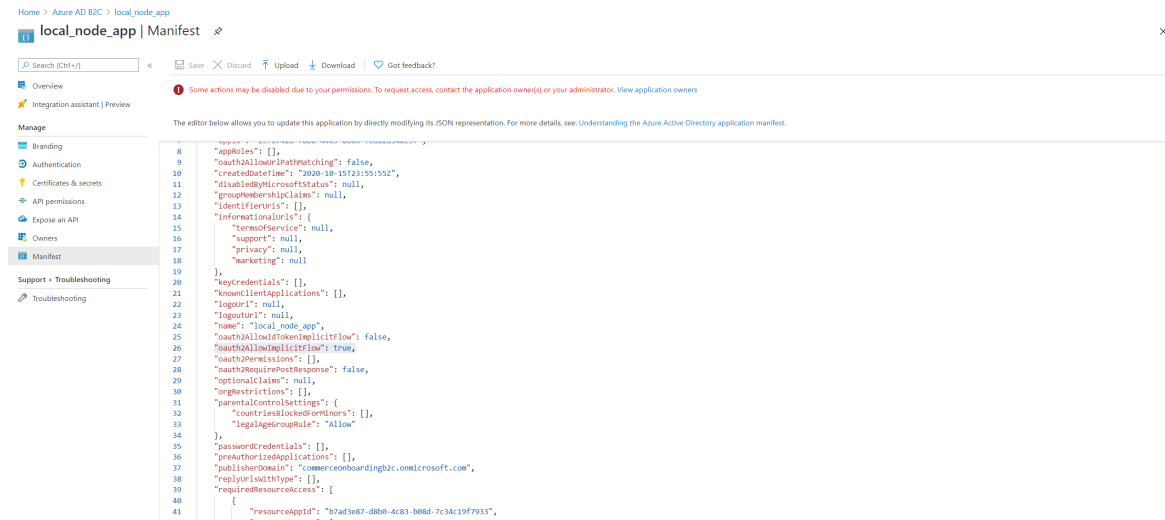

1. In the **Azure AD B2C** settings, select **App Registrations**, and then select **New registration**.
2. Enter a name for the application, for example "local\_node\_app".
3. For **Supported account types**, select **Accounts in any identity provider or organizational directory (for authenticating users with user flows)**.
4. For **Redirect URIs**, select **Public client/native (mobile & desktop)** from the drop-down list, and leave the URI as is.
5. Leave all other default values as is, and select **Register**.
6. Select the new application, and then copy and save the **Application (client) ID** value, as this ID will be used later as the `nativeApplicationId` property value in your `credentials.json` file.

7. In the left navigation pane under **Manage**, select **Authentication**.
8. Select **Try out the new experience** (if shown).
9. Under **Default client type**, select **Yes** for **Treat the application as a public client**. This setting is

required for the ROPC flow.

10. Select **Save**.
11. In the left navigation pane under **Manage**, select **Manifest** to open the manifest editor.
12. Set the `oauth2AllowImplicitFlow` attribute to `true`, and then select **Save**.

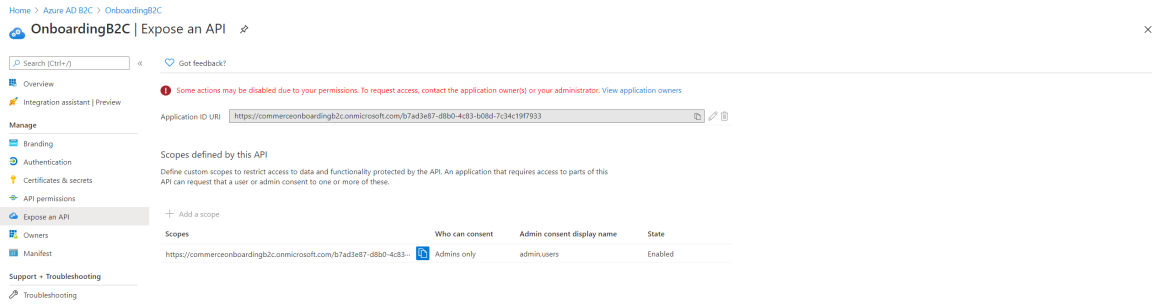

You have now created a new native application that will be used to represent your local Node application.

From the examples above, you have now obtained the following information:

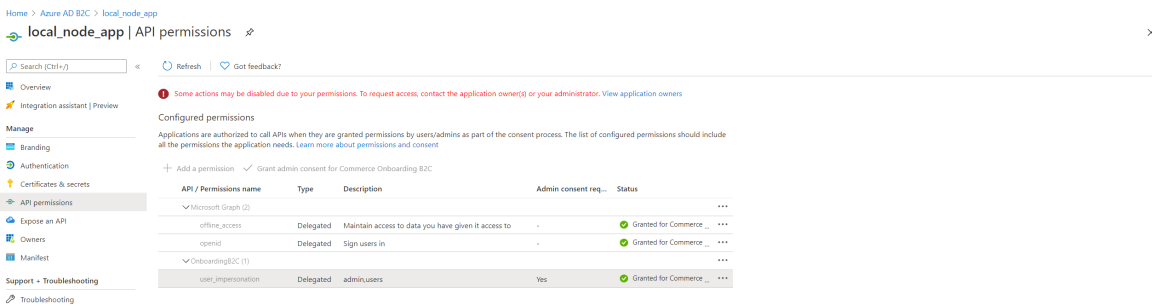

PROPERTY NAME	EXAMPLE VALUE
ropcFlowUserName	B2C_1_ROPC_Auth
loginDomain	commerceonboardingb2c.b2clogin.com
b2cTenant	commerceonboardingb2c
nativeApplicationId	25f6742d-f8b8-44d9-a6a0-f06d2854ac5f

### Configure scope and register the native application

1. In the Azure AD B2C settings, go to **App registrations**.
2. Open the application created above which is currently being used by the e-Commerce rendering application.
3. In the left navigation pane under **Manage**, select **Expose an API** and verify that a `user_impersonation` scope exists. If one does not exist, select **Add a scope** to create one. When prompted for an **Application ID URI**, leave the application ID URI as is and then add "user\_impersonation" for the **Scope name**. Then enter friendly values for **Admin consent display name** and **Admin consent description**.

4. Copy and save the full scope value, as this information will be used later as the `userImpersonationScopeURL` property value in your `credentials.json` file.
5. Return to the native application you just created, and in the left navigation pane under **Manage**, select **API permissions**.
6. Select **Add a permission**, and then select the **APIs my organization uses** tab.
7. Search for your e-Commerce rendering application that was created above, and then select it and add `user_impersonation` as a permission.

8. Select **Add permissions**.
9. Select **Grant admin consent for** (this name will contain your domain), and then select **Yes** to apply the consent. You should now see a green checkmark under **Status** for `user_impersonation`.

The Azure AD setup portion is now complete and you should now have your versions of all of the following example values.

PROPERTY NAME	EXAMPLE VALUE
ropcFlowUserName	B2C_1_ROPC_Auth
loginDomain	commerceonboardingb2c.b2clogin.com
b2cTenant	commerceonboardingb2c
nativeApplicationId	25f6742d-f8b8-44d9-a6a0-f06d2854ac5f
userImpersonationScopeURL	<code>https://commerceonboardingb2c.onmicrosoft.com/b7ad3e87-d8b0-4c83-b08d-7c34c19f7933/user_impersonation</code>

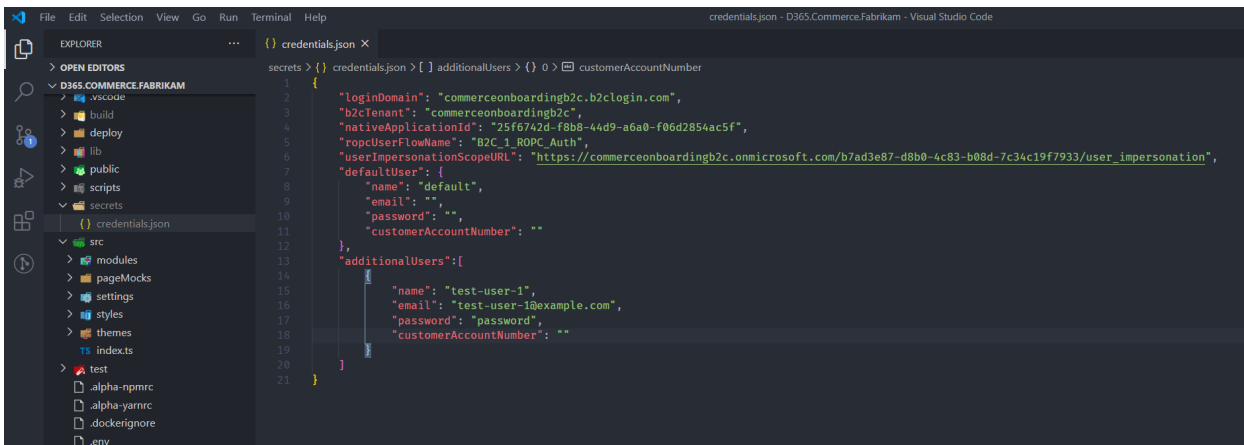

# Configure your Node application

After you have completed the steps to configure your Azure AD B2C tenant, you will need to create a credentials file in your online software development kit (SDK) Node application.

The credentials will live under the `secrets/` directory in your Node application. Create a `secrets/` directory in your application if you haven't already, and then create a new file named `credentials.json` that is similar to the following example that uses the data gathered above.

```
{
  "loginDomain": "commerceonboardingb2c.b2clogin.com",
  "b2cTenant": "commerceonboardingb2c",
  "nativeApplicationId": "25f6742d-f8b8-44d9-a6a0-f06d2854ac5f",
  "ropcUserFlowName": "B2C_1_ROPC_Auth",
  "userImpersonationScopeURL": "https://commerceonboardingb2c.onmicrosoft.com/b7ad3e87-d8b0-4c83-b08d-7c34c19f7933/user_impersonation",
  "defaultUser": {
    "name": "default",
    "email": "",
    "password": "",
    "customerAccountNumber": ""
  },
  "additionalUsers": [
    {
      "name": "test-user-1",
      "email": "test-user-1@example.com",
      "password": "password",
      "customerAccountNumber": ""
    }
  ]
}
```

A screenshot of the Visual Studio Code editor. The Explorer sidebar on the left shows a project structure with a 'secrets' directory containing 'credentials.json'. The main editor window displays the content of 'credentials.json', which matches the JSON code block shown above. The file path in the breadcrumb is 'secrets > {} credentials.json > {} additionalUsers > {} 0 > customerAccountNumber'. The code is syntax-highlighted and includes line numbers from 1 to 21.

## NOTE

Everything under the `secrets/` directory should be added to your `.gitignore` file to help prevent credentials from being leaked online.

After using the information collected in the Azure setup steps to populate your `credentials.json` file, you need to add test accounts that you want to use during local development. The accounts defined here should be valid accounts that have already been created in Dynamics 365 Commerce headquarters.

- **defaultUser:** The default user that will be used when the `mockUser` query parameter is set to `true`. The name value should be `default`.
- **additionalUsers:** An array of user objects that allows you to configure additional users to test with. Each entry in this array should be an object with a name, email address, password, and customer account number.

To sign in as one of these users, use the query parameter `mockUser= <name>`.

## Mock sign-in status

After all of the above configuration steps are complete, start your e-Commerce Node application in local dev mode using the `yarn start` command. Sign-in status is controlled using the `mockUser` query parameter and works to mock the signed-in state on mock pages as well as on published pages (for example,

`https://localhost:4000?mock=homepage&mockUser=true` OR `https://localhost:4000?mockUser=true`).

Use `mockUser= <true|false|name>` to control the signed-in behavior. The behavior of each of the query parameter values is described in the following table.

MOCKUSER VALUE	EXAMPLE	SIGN IN/SIGN OUT	DESCRIPTION
true	mockUser=true	Sign in	Signs in as the default user.
name	mockUser=test-user-1	Sign in	Signs in as the user specified in the query parameter.
false	mockUser=false	Sign out	Signs out the currently signed-in user.

You can use the `mockUser` query parameter to test pages as different users without signing out and signing back in again for each different user. For example, hitting `https://localhost:4000?mock=homepage&mockUser=true` and then `https://localhost:4000?mock=homepage&mockUser=test-user-1` would allow you to test the homepage mock as different signed-in users.

When you hit a page with `mockUser` turned on and successfully sign in, the signed-in state will persist across pages until you either sign in with a different user or sign out.

You can also make use of the sign-in and sign-out buttons on the webpage itself to mock signed-in user behavior. The sign-in button will sign you in as the default user while the sign-out button will sign out the currently signed-in user.

# Configure module properties to be shown based on context

2/18/2021 • 7 minutes to read • [Edit Online](#)

## IMPORTANT

Some or all of the functionality noted in this topic is available as part of a preview release. The content and the functionality are subject to change. For more information about preview releases, see [One version service updates FAQ](#).

This topic describes how to configure module properties so that they are shown or hidden based on the contextual values of other configuration properties.

Multiple module configuration properties can be defined in a module's definition file. However, there might be scenarios where the relevance of some property fields depends on the values that are set for other property fields of the module. Property fields that aren't relevant should be hidden to minimize the number of fields that are shown to a page editor who is configuring the module. This behavior helps reduce complexity and the possibility of confusion.

A module can use a conditional schema to define the rules that the module properties pane in Commerce site builder should follow to show or hide property fields based on the values of other property fields. For example, a module has a **layout** property that allows for two layouts, one of which has plain text, and the other of which has rich text and an image. In this case, the module designer might want to ensure that only property fields that are appropriate to the context (that is, the layout) are shown in site builder when a page editor configures the module.

The ability to show or hide property fields based on context is supported in module definition and module definition extension files that use the **dependentSchemas** property for conditional schemas. Two types of conditional schema are supported: *schema dependencies* and *property dependencies*.

## Schema dependencies

Schema dependencies can be used to declare that the schema should change when a specific value is selected for a configuration property. The **oneOf** property is used with the **dependentSchemas** property to declare the list of configuration properties that are applicable to a specific configuration value.

### Schema dependencies example

As the following example of a module definition file shows, when the **layout** property is set to **plainTextOnly**, the **featureText** property should be shown. Alternatively, when the **layout** property is set to **richTextWithImage**, the **featureRichText**, **featureImage**, and **imageAlignment** properties should be shown (but the **featureText** property should not be shown).

```
{
  "$type": "contentModule",
  "friendlyName": "Product Feature",
  "name": "product-feature",
  "description": "Feature module used to highlight a product.",
  "config": {
    "layout": {
      "friendlyName": "Text Layout",
      "description": "Sets the desired text output to be plain text or rich text with images.",
      "type": "string",
      "oneOf": [
        {
          "friendlyName": "Plain Text",
          "description": "Sets the text output to be plain text.",
          "type": "string",
          "value": "plainTextOnly",
          "dependentSchemas": {
            "featureText": true
          }
        },
        {
          "friendlyName": "Rich Text with Image",
          "description": "Sets the text output to be rich text with images.",
          "type": "string",
          "value": "richTextWithImage",
          "dependentSchemas": {
            "featureRichText": true,
            "featureImage": true,
            "imageAlignment": true,
            "featureText": false
          }
        }
      ]
    }
  }
}
```

```

        "enum": {
            "plainTextOnly": "Plain Text Only",
            "richTextWithImage": "Rich Text With Image"
        },
        "default": "plainTextOnly",
        "scope": "module",
        "group": "Layout Properties"
    }
},
"dependentSchemas": {
    "oneOf": [
        {
            "properties": {
                "layout": {
                    "enum": {
                        "plainTextOnly": "plainTextOnly"
                    }
                },
                "featureText": {
                    "type": "string",
                    "friendlyName": "Feature Text",
                    "description": "Main text title to show in module."
                }
            }
        },
        {
            "properties": {
                "layout": {
                    "enum": {
                        "richTextWithImage": "richTextWithImage"
                    }
                },
                "featureRichText": {
                    "type": "richText",
                    "friendlyName": "Feature Text",
                    "description": "Main rich text to show in module."
                },
                "featureImage": {
                    "type": "image",
                    "friendlyName": "Feature Title",
                    "description": "Image to show in module."
                },
                "imageAlignment": {
                    "friendlyName": "Image Alignment",
                    "description": "Sets the desired alignment of the image, either left or right on the
text.",
                    "type": "string",
                    "enum": {
                        "left": "Left",
                        "right": "Right"
                    },
                    "default": "left"
                }
            }
        }
    ]
}
}
}

```

## Property dependencies

Property dependencies can be used to declare that specific configuration properties must be present if the value of another configuration property is present.

### Property dependencies example

In the following example, the `dependentSchemas` property specifies that whenever the `productTitle` value is

entered, the **subTitle** configuration property should be shown in site builder.

```
{
  "$type": "contentModule",
  "friendlyName": "Product Feature",
  "name": "product-feature",
  "description": "Feature module used to highlight a product.",
  "config": {
    "productTitle": {
      "type": "string",
      "friendlyName": "Product Title",
      "description": "Product title."
    }
  },
  "dependentSchemas": {
    "productTitle": {
      "properties": {
        "subTitle" : {
          "type": "string",
          "friendlyName": "Product Sub Title",
          "description": "Product sub title."
        }
      },
      "required": ["productTitle"]
    }
  }
}
```

## Handling property override conflicts

Because the **dependentSchemas** property is supported in both module definition files and module definition extension files, there might be conflicts between the two types of files. By setting a Boolean **override** property to **true** in the module definition extension file, you can enable overrides of specific configuration properties.

The following examples show a module definition file and a module definition extension file that uses the **override** property.

### Module definition file example

```
{
  "$type": "contentModule",
  "friendlyName": "Product Feature",
  "name": "product-feature",
  "description": "Feature module used to highlight a product.",
  "config": {
    "layout": {
      "friendlyName": "Text Layout",
      "description": "Sets the desired text output to be plain text or rich text with images.",
      "type": "string",
      "enum": {
        "plainTextOnly": "Plain Text Only",
        "richTextWithImage": "Rich Text With Image"
      },
      "default": "plainTextOnly",
      "scope": "module",
      "group": "Layout Properties"
    }
  }
}
```

### Module definition extension file example

```
{
```

```

    "$type": "definitionExtension",
    "config": {
      "layout": {
        "friendlyName": "Text Layout",
        "description": "Sets the desired text output to be plain text or rich text with images.",
        "type": "string",
        "enum": {
          "plainTextOnly": "Plain Text Only",
          "richTextOnly": "Rich Text Only",
          "richTextWithImage": "Rich Text With Image"
        },
        "default": "plainTextOnly",
        "override": true
      }
    },
    "dependentSchemas": {
      "oneOf": [
        {
          "properties": {
            "layout": {
              "enum": {
                "plainTextOnly": "plainTextOnly"
              }
            },
            "featureText": {
              "type": "string",
              "friendlyName": "Feature Text",
              "description": "Main text title to show in module.",
            }
          }
        },
        {
          "properties": {
            "layout": {
              "enum": {
                "richTextOnly": "richTextOnly"
              }
            },
            "featureRichText": {
              "type": "richText",
              "friendlyName": "Feature Text",
              "description": "Main rich text to show in module.",
            }
          }
        },
        {
          "properties": {
            "layout": {
              "enum": {
                "richTextWithImage": "richTextWithImage"
              }
            },
            "featureRichText": {
              "type": "richText",
              "friendlyName": "Feature Text",
              "description": "Main rich text to show in module.",
            },
            "featureImage": {
              "type": "image",
              "friendlyName": "Feature Title",
              "description": "Image to show in module.",
            },
            "imageAlignment": {
              "friendlyName": "Image Alignment",
              "description": "Sets the desired alignment of the image, either left or right on the
text.",
              "type": "string",
              "enum": {
                "left": "left",

```

```
    "left": "Left",
    "right": "Right"
  },
  "default": "left"
}
}
}
]
}
```

## Conflict resolution scenarios

The following tables list possible scenarios and expected outcomes when schema dependencies are used with module definition and module definition extension files.

### Regular scenarios

SCENARIO	EXPECTED OUTCOME
A schema dependency is used only in the module definition file. No conflicts exist between properties in the schema dependency and the module definition extension file.	The schema dependency is applied.
A schema dependency is used only in the module definition extension file. No conflicts exist between properties in the schema dependency and the module definition extension file.	The schema dependency is applied.
A schema dependency is used only in the module definition file. A conflict exists between properties in the schema dependency and the module definition extension file. For example, property A is declared both in the schema dependency of the module definition file and in the module definition extension file, which doesn't have a schema dependency.	A build error occurs.
A schema dependency on the same property is used both in the module definition file and in the module definition extension file.	The module definition file takes precedence.
The same property is defined both in the module definition file and in the module definition extension file.	The module definition file takes precedence.

### Override scenarios

SCENARIO	EXPECTED OUTCOME
The same property is defined both in the module definition file and in the module definition extension file. Either no <b>override</b> property is set for the property in the module definition extension file, or the <b>override</b> property is set to <b>false</b> .	The module definition file takes precedence.
A schema dependency on the same property is used both in the module definition file and in the module definition extension file. The <b>override</b> property is set to <b>true</b> for the property in the module definition extension file.	The module definition extension file takes precedence.

SCENARIO	EXPECTED OUTCOME
A schema dependency on the same property is used both in the module definition file and in the module definition extension file. Either no <b>override</b> property is set for the property in the module definition extension file, or the <b>override</b> property is set to <b>false</b> .	The module definition file takes precedence.
The same property is defined both in the module definition file and in the schema dependency of the module definition extension file. The <b>override</b> property is set to <b>true</b> for the property in the module definition extension file.	The module definition extension file takes precedence.
The same property is defined both in the module definition file and in the schema dependency of the module definition extension file. Either no <b>override</b> property is set for the property in the module definition extension file, or the <b>override</b> property is set to <b>false</b> .	The module definition file takes precedence.

# Globalize modules by using the CultureInfoFormatter class

2/18/2021 • 10 minutes to read • [Edit Online](#)

This topic describes how to globalize modules by using the **CultureInfoFormatter** class.

## Overview

Globalization of an online site should include not only string localization, but also number, date, and currency formatting for the various languages and regions that your website serves.

The Microsoft Dynamics 365 Commerce Online Software Development Kit (SDK) provides a **CultureInfoFormatter** class that helps meet typical globalization requirements for the format of numbers, currencies as well as dates and times.

## Access the CultureInfoFormatter class in a module view file

An instance of the **CultureInfoFormatter** class is automatically created and can be accessed in the module view through the `this.props.context` object. The following examples shows how to use the **CultureInfoFormatter** methods to format currency.

```
public render(): JSX.Element | null {
  ...
  // this.props.context.cultureFormatter contains an initialized formatter
  // with locale of 'en-US' in this example
  const intlFormatter = this.props.context.cultureFormatter
  intlFormatter.formatCurrency(34.12);
  // expected output: $ 34.12
}
```

## Construct an instance of the CultureInfoFormatter class

The constructor of the **CultureInfoFormatter** class takes one argument, **lang-locale**.

The **lang-locale** argument must be a valid [BCP-47](#) language tag. A default value, 'en-US', is used if no language tag is specified. Language tags aren't case-sensitive. However, by convention, but the locale is usually capitalized.

### Example

```
import {CultureInfoFormatter} from '@msdyn365-commerce/core';

// Default constructor will use 'en-US' for locale
let intlFormatter = new CultureInfoFormatter();

// Constructs a new intl formatter using the French language as spoken in France
intlFormatter = new CultureInfoFormatter('fr-FR');

// Constructs a new intl formatter using the English language as spoken in Great Britain
intlFormatter = new CultureInfoFormatter('en-GB');
```

# CultureInfoFormatter class formatting functions

The `CultureInfoFormatter` class provides the following formatting functions:

- Currency formatting
- Date formatting
- Time formatting
- Number formatting

## Currency formatting

To format currency according to the conventions for a specific locale, use the `formatCurrency()` method as shown the following example.

```
/**
 * Returns a localized currency formatted version of a price.
 *
 * @param price Either a string or number representing the price that will be localized and formatted
 * @param currencyCode Optional argument. The three letter currency code that will be used for formatting
 the currency.
 * If the currency code is not provided the locale will be used to determine the best fit currency code.
 */
formatCurrency(price: string | number, currencyCode?: string): string;
```

The `currencyCode` argument is optional. If it's provided, it must be in [ISO 4217](#) format. If the `currencyCode` argument isn't provided, the formatter uses the locale to determine the best currency code to use.

## Currency formatting examples

```
import {CultureInfoFormatter} from '@msdyn365-commerce/core';

// Set locale to fr-FR
let cultureInfoFormatter = new CultureInfoFormatter('fr-FR');

// Using a string argument for the price
cultureInfoFormatter.formatCurrency('34.12', 'eur');
// expected output: "34,12 €"

// Using a number argument for the price and letting the formatter find
// the best currency code to use from the locale given
cultureInfoFormatter.formatCurrency(34.12);
// expected output: "34,12 €"

cultureInfoFormatter = new CultureInfoFormatter('en-IN');
cultureInfoFormatter.formatCurrency(34.12, 'inr');
// expected output: ₹ 34.12
```

## Date formatting

To format a date according to the conventions for a specific locale, use the `formatDate()` method as shown the following examples.

### SDK version 1.27.7 and greater

```
/**
 * Returns a localized formatted version of a date
 *
 * @param date Date object or valid date string representing the date that will be localized and formatted
 * @param options An optional argument that controls the formatting.
 */
public formatDate = (date: Date | string, options?: IDateFormatOptions): string
```

### SDK versions earlier than 1.27.7

```
/**
 * Returns a localized formatted version of a date
 *
 * @param date Date object representing the date that will be localized and formatted
 * @param options An optional argument that controls the formatting.
 */
formatDate(date: Date, options?: IDateFormatOptions): string;
```

The **options** argument is optional. It lets you control the localization and formatting. For more information about date formatting properties, see [IDateFormatOptions](#).

### Date formatting examples

```
import {CultureInfoFormatter} from '@msdyn365-commerce/core';
const testDate = new Date(2012, 11, 20, 3, 0, 0); // 12/20/2012 (in US format-mm/dd/yyyy)
let cultureInfoFormatter = new CultureInfoFormatter('en-US');

// Basic format with no options
cultureInfoFormatter.formatDate(testDate);
// expected output: "12/20/2012"

// Set lang-locale to English as spoken in Great Britain
cultureInfoFormatter = new CultureInfoFormatter('en-GB');
cultureInfoFormatter.formatDate(testDate);
// expected output: "20/12/2012"

// Set lang-locale to German as spoken in Germany
cultureInfoFormatter = new CultureInfoFormatter('de-DE');

let options: IDateFormatOptions = <IDateFormatOptions>{};
options = { weekday: 'long', year: 'numeric', month: 'long', day: 'numeric' };

cultureInfoFormatter.formatDate(testDate);
// expected output: "Donnerstag, 20. Dezember 2012"
```

### Time formatting

To format a time according to the conventions for a specific locale, use the **formatTime()** method as shown the following examples.

### SDK version 1.27.7 and greater

```
/**
 * Returns a localized formatted version of a time
 *
 * @param time Date object or valid date string representing the time that will be localized and formatted
 * @param options An optional argument that controls the formatting
 */
public formatTime = (time: Date | string, options?: ITimeFormatOptions): string;
```

### SDK versions earlier than 1.27.7

```
/**
 * Returns a localized formatted version of a time
 *
 * @param time Date object representing the time that will be localized and formatted
 * @param options An optional argument that controls the formatting
 */
formatTime(time: Date, options?: ITimeFormatOptions): string;
```

The **options** argument is optional. It lets you control the localization and formatting. For more information

about time formatting properties, see [ITimeFormatOptions](#).

### Time formatting examples

```
import {CultureInfoFormatter} from '@msdyn365-commerce/core';
const testDate = new Date(2012, 11, 20, 13, 34, 23); // 1:34:23 PM in en-US Format
let cultureInfoFormatter = new CultureInfoFormatter('en-US');
let options: ITimeFormatOptions = <ITimeFormatOptions>{};
options.hour12 = false;
// Format time with 24 hour time
cultureInfoFormatter.formatTime(testDate, options);

cultureInfoFormatter = new CultureInfoFormatter('fr-FR');
options = <ITimeFormatOptions>{};
options.second = 'numeric';
cultureInfoFormatter.formatTime(testDate, options);
// expected output: "13:34:23"
```

### Number formatting

To format a number according to the conventions for a specific locale, use the `formatNumber()` method as shown in the following example.

```
/**
 * Returns a localized formatted version of a number
 *
 * @param value The number that will be localized and formatted
 * @param options An optional argument that controls the formatting.
 */
formatNumber(value: number, options?: INumberFormatOptions): string;
```

The `options` argument is optional. It lets you control the localization and formatting. For more information about number formatting properties, see [INumberFormatOptions](#).

### Number formatting examples

```
import {CultureInfoFormatter} from '@msdyn365-commerce/core';

let cultureInfoFormatter = new CultureInfoFormatter('en-US');
cultureInfoFormatter.formatNumber(123456789);
// expected output: "123,456,789"
cultureInfoFormatter.formatNumber(1234567.89);
// expected output: "1,234,567.89"

// German language uses comma as decimal separator and period for thousands
cultureInfoFormatter = new CultureInfoFormatter('de-DE');
cultureInfoFormatter.formatNumber(1234567.89);
// expected output: "1.234.567,89"

const options: INumberFormatOptions = <INumberFormatOptions>{};
options.style = 'percent';
(cultureInfoFormatter.formatNumber(0.7842, options));
// expected output: "78,42 %"

// Setting the language to Arabic formats numbers using Arabic numerals
cultureInfoFormatter = new CultureInfoFormatter('ar-EG');
cultureInfoFormatter.formatNumber(1234567.89);
// expected output: "١,٢٣٤,٥٦٧,٨٩"
```

## Formatting options

This section covers the formatting options and property details for `ITimeFormatOptions`,

`IDateFormatOptions`, and `INumberFormatOptions` interfaces.

## `ITimeFormatOptions`

```
interface ITimeFormatOptions {
  localeMatcher?: 'best fit' | 'lookup';
  formatMatcher?: 'basic' | 'best fit';
  hourCycle?: 'h11' | 'h12' | 'h23' | 'h24';
  timeZone?: string;
  hour12?: boolean;
  hour?: 'numeric' | '2-digit';
  minute?: 'numeric' | '2-digit';
  second?: 'numeric' | '2-digit';
  timeZoneName?: 'short' | 'long';
}
```

### Property details

NAME	TYPE	ALLOWED VALUES	DESCRIPTION
<code>localeMatcher</code>	enum	'best fit' or 'lookup'	Specify the algorithm that is used to match and find the locale. The <b>'lookup'</b> matcher follows the lookup algorithm that is specified in <a href="#">BCP-47</a> . The <b>'best fit'</b> matcher lets the runtime provide a locale that is at least as well-suited to the request as the result of the lookup algorithm, although it might be better suited than that result.
<code>formatMatcher</code>	enum	'basic' or 'best-fit'	Specify the format matching algorithm that is used, and when it's used. The default value is <b>'best fit'</b> .
<code>hourCycle</code>	enum	'h11', 'h12', 'h23', or 'h24'	Specify the hour cycle that is used.
<code>timeZone</code>	string	Time zone names, as defined by the <a href="#">IANA time zone database</a>	Specify the time zone that is used. The default value is the runtime's default time zone. If the environment lacks native internationalization support and internationalization is polyfilled, this option won't be supported (because internationalization polyfill doesn't support time zones).

NAME	TYPE	ALLOWED VALUES	DESCRIPTION
hour12	boolean	'true' or 'false'	Specify whether 12-hour time is used instead of 24-hour time. This option overrides the <b>hourCycle</b> property, and its default value depends on the locale.
hour	enum	'numeric' or '2-digit'	Specify the representation of the hour. The <b>'2-digit'</b> value forces hours to be shown as two digits.
minute	enum	'numeric' or '2-digit'	Specify the representation of the minute. The <b>'2-digit'</b> value forces minutes to be shown as two digits.
second	enum	'numeric' or '2-digit'	Specify the representation of the second. The <b>'2-digit'</b> value forces seconds to be shown as two digits.
timeZoneName	enum	'short' or 'long'	Specify the representation of the time zone name. The <b>'short'</b> value shows the three-character abbreviation for the time zone. The <b>'long'</b> value shows the full name.

## IDateFormatOptions

```
interface IDateFormatOptions extends ITimeFormatOptions {
    weekday?: 'narrow' | 'short' | 'long';
    year: 'numeric' | '2-digit';
    month?: 'numeric' | '2-digit' | 'narrow' | 'short' | 'long';
    day?: 'numeric' | '2-digit';
}
```

### NOTE

All properties provided in `ITimeFormatOptions` interface can be used in `IDateFormatOptions` interface since the time object is a subcomponent of the date object.

### Property details

NAME	TYPE	ALLOWED VALUES	DESCRIPTION
------	------	----------------	-------------

NAME	TYPE	ALLOWED VALUES	DESCRIPTION
weekday	enum	'narrow', 'short', or 'long'	Specify the representation of the day. The <b>'narrow'</b> value shows the one-character or two-character representation of the day. The <b>'short'</b> value shows the three-character representation. The <b>'long'</b> value shows the full name.
year	enum	'numeric' or '2-digit'	Specify the representation of the year. The <b>'2-digit'</b> value shows the two most significant digits of the year (for example, the year 2018 is shown as <b>18</b> ). The <b>'numeric'</b> value shows the whole year.
month	enum	'numeric', '2-digit', 'narrow', 'short', or 'long'	Specify the representation of the month. The <b>'numeric'</b> value shows the numeric representation of the month (for example, April is shown as <b>4</b> ). The <b>'2-digit'</b> value shows the two-digit numeric representation (for example, April is shown as <b>04</b> ). The <b>'narrow'</b> value shows the two-character representation (for example, April is shown as <b>AP</b> ). The <b>'short'</b> value shows the three-character representation (for example, April is shown as <b>Apr</b> ). The <b>'long'</b> value shows the full name.
day	enum	'numeric' or '2-digit'	Specify the representation of the day. The <b>'2-digit'</b> value forces days to be shown as two digits.

No default value is defined for each date/time component property. However, if all component properties are undefined, the **'numeric'** value is assumed for the **year**, **month**, and **day** property.

### **INumberFormatOptions**

```

export interface INumberFormatOptions {
  localeMatcher?: 'best fit' | 'lookup';
  style?: 'decimal' | 'percent' | 'currency';
  currency?: string;
  minimumIntegerDigits?: number;
  minimumFractionDigits?: number;
  maximumFractionDigits?: number;
  minimumSignificantDigits?: number;
  maximumSignificantDigits?: number;
}

```

### Property details

NAME	TYPE	ALLOWED VALUES	DESCRIPTION
localeMatcher	enum	'best fit' or 'lookup'	Specify the algorithm that is used to match and find the locale. The <b>'lookup'</b> matcher follows the lookup algorithm that is specified in <a href="#">BCP-47</a> . The <b>'best fit'</b> matcher lets the runtime provide a locale that is at least as well-suited to the request as the result of the lookup algorithm, although it might better suited than that result.
style	enum	'decimal', 'percent', or 'currency'	Specify the formatting style that is used. Use the <b>'decimal'</b> value for plain number formatting, the <b>'currency'</b> value for currency formatting, and the <b>'percent'</b> value for percentage formatting. The default value is <b>'decimal'</b> .
currency	string	Three-character <a href="#">ISO 4217</a> currency codes	Specify the currency that is used in currency formatting. There is no default value. If the <b>style</b> property is set to <b>'currency'</b> , the <b>currency</b> property must be provided.
minimumIntegerDigits	number	Any integer value between 1 and 21	Specify the minimum number of integer digits that is used. The default value is 1.
minimumFractionDigits	number	Any integer value between 0 and 20	Specify the minimum number of fraction digits that is used. The default value for number and percentage formatting is 0 (zero). The default value for currency formatting is provided by the <a href="#">ISO 4217</a> standard.

NAME	TYPE	ALLOWED VALUES	DESCRIPTION
maximumFractionDigits	number	Any integer value between 0 and 20	Specify the maximum number of fraction digits that is used.
minimumSignificantDigits	number	Any integer value between 1 and 21	Specify the minimum number of significant digits that is used. The default value is 1.
maximumSignificantDigits	number	Any integer value between 1 and 21	Specify the maximum number of significant digits that is used. The default value is 21.

# Set up Azure Key Vault for secure key management

2/18/2021 • 8 minutes to read • [Edit Online](#)

This topic describes how to set up Azure Key Vault to provide secure key management in Dynamics 365 Commerce.

## Overview

Some Dynamics 365 Commerce e-Commerce development scenarios require business-sensitive data such as credentials or access tokens that must be stored securely. [Azure Key Vault](#) provides the capability to import, store, and manage cryptographic keys and certificates that can be securely accessed as needed.

This topic shows how to do the following:

- Create a Key Vault to securely store sensitive information.
- Configure your e-Commerce site to securely communicate with Retail Server.
- Set up Retail Server to securely communicate with your Key Vault.
- Access secret values from within your e-Commerce components.

## Create a Key Vault to store application secrets

The first step is to create a new Key Vault to store application secrets. You will need an Azure account to access Azure Key Vault.

To create a new Key Vault, follow these steps.

1. Navigate to your [Azure Portal homepage](#).
2. Select **Create a resource**.
3. Search for **Key Vault**, and then select **Create**.
4. Select the subscription and resource group you would like this Key Vault to be a part of.
5. Enter a name, region, and pricing tier for your Key Vault.
6. Select **Next**, and then create access policies and assign permissions to users. Leave all other settings as is.
7. Select **Review + create**.
8. After you have reviewed the configuration, select **Create** and then wait for the deployment to complete.
9. After the Key Vault has successfully been deployed, you can add any secrets under **Secrets**.

## Configure server-to-server authentication between the e-Commerce Node application and Retail Server

Next, the e-Commerce Node application needs to be configured to securely communicate with Retail Server.

For the following steps, you will need to have the tenant ID of the Azure App Service hosting your Node application, as well as the client ID of the managed identity tied to your Azure App Service. If you do not have access to Azure App Service, work with your service integrator or support team to obtain the required information.

### Find and copy your tenant ID

To find your tenant ID, follow these steps.

1. Navigate to your [Azure Portal homepage](#).

2. Go to the directory containing the Azure App Service hosting your Node application.
3. Go to **Azure Active Directory**.
4. In the left navigation pane, select **Properties**.
5. Find and copy the **Tenant ID**.

### Find and copy the client ID of the managed identity for your Node application

To find the client ID of the managed identity for your Node application, follow these steps.

1. Navigate to your [Azure Portal homepage](#).
2. Go to the directory containing the Azure App Service hosting your Node application.
3. In the left navigation pane, select **Identity**.
4. Select the **User assigned** tab.
5. Select the managed identity resource for your Node application.
6. In the left navigation pane, select **Overview**, and then copy the **Client ID** value.

The following example image highlights the **Client ID** value on the Azure Portal **Overview** page.

### Add your Node application details into Retail Server's authentication allow list

To add your Node application details into Retail Server's authentication allow list, follow these steps.

1. In Commerce headquarters, go to **Commerce Shared Parameters**.
2. Select the **Identity Providers** tab.
3. In the first section named **IDENTITY PROVIDERS**, select **Add**.
4. For **Issuer Value**, enter `https://sts.windows.net/<TENANT_ID>/`, where **<TENANT\_ID>** is your tenant ID.
5. For **Name**, enter "Azure AD".
6. For **Type**, enter "Active Directory".
7. In the second section named **RELYING PARTIES**, add an entry with the client ID of your managed identity.
8. For **Type**, select **Confidential**.
9. For **UserType**, select **Application**.
10. Provide a name for your Node application.
11. In the third section named **SERVER RESOURCE IDS**, add an entry with the server resource ID of `https://commerce.dynamics.com`, and then select **Save**.

You should now have a configuration similar to the one in the following example.

## Set up Identity Providers to be used by Retail Server

Identity Provider	Provider Type	Provider Name
https://localhost:44336/core	Commerce Identity Provider	Open ID Connect
https://sts.windows.net/[redacted]	Azure AD	Azure Active Directory

**RELYING PARTIES**

[Add](#) [Remove](#)

ClientId	Type	UserType
93b1ebe5-969a-4cb5-9d48-7b928ff2655e	Confidential	Application
d5527362-3bc8-4e63-b5b3-606dc14747e9	Public	Worker
d6b5a0bd-bf3f-4a8c-b370-619fb3d0e1cc	Public	Worker

**SERVER RESOURCE IDS**

[Add](#) [Remove](#)

Server Resource Id

https://commerce.dynamics.com

To synchronize the changes into the channel database, in Commerce headquarters go to **Distribution schedule** and execute job 1110 (Global configuration), as shown in the following image.

Finance and Operations | Distribution schedule

1110 Global configuration

Name	Description	Current batch job	Current batch status
1110	Global configuration		N/A

**General**

Direction of data flow: Download  Active  Yes

**Channel database groups**

+ Add - Remove

✓ Channel database group

Default

Your Node application will now be able to securely communicate and request Key Vault secrets from Retail Server.

## Add Key Vault details to Retail Server

Next, you will configure Retail Server to securely communicate with your Key Vault.

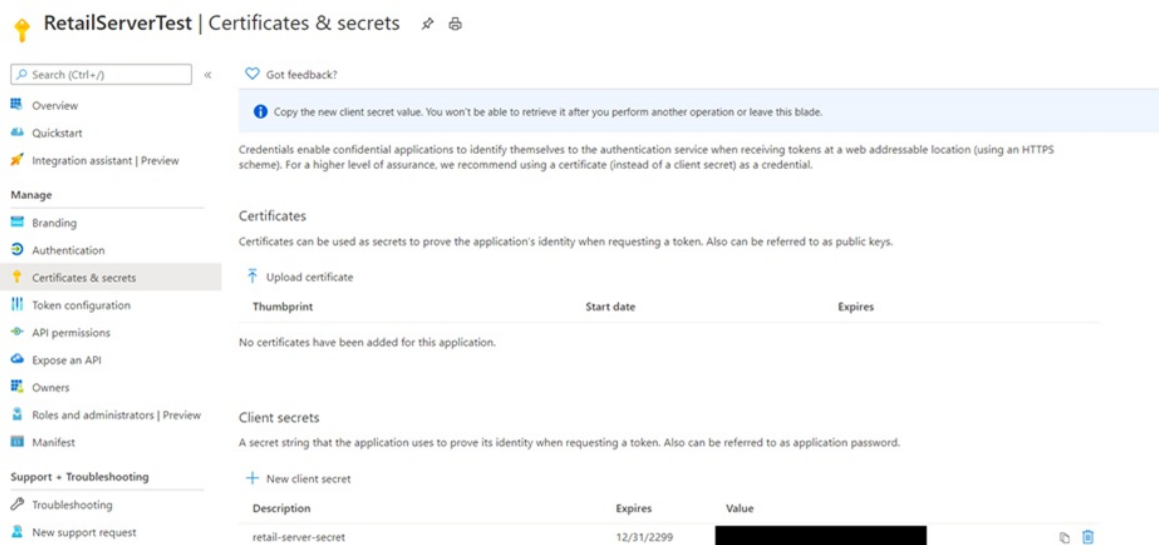

### Create a new app registration and add a client secret

You will first need to create a new app registration under Azure AD to represent your Retail Server so that you can register your Key Vault with Retail Server.

To create a new app registration, follow these steps.

1. Navigate to your [Azure Portal homepage](#).
2. Go to the directory containing the Azure App Service hosting your Node application.
3. Go to **Azure Active Directory**.

- In the left navigation pane, select **App registrations**.
- Select **New registration**, and then enter a name (for example, "RetailServer").
- In the overview panel, copy and save the **Application (client) ID** value for later use.
- Select **Certificates & secrets**, and then under **Client secrets** select **New client secret**.
- In the **Add a client secret** dialog box, enter a description under **Description** (for example, "retail-server-secret").
- Under **Expires**, select **Never**, and then select **OK**.
- On the **Certificates & secrets** page, copy the secret value In the **Value** box of your new client secret and store it in a safe place. This secret value is what will enable communication between Retail Server and your Key Vault.

#### NOTE

You will only have one opportunity to copy the secret value so it's important to do so now.

### Add an access policy in your Key Vault

Next, to add an access policy in your Key Vault, follow these steps.

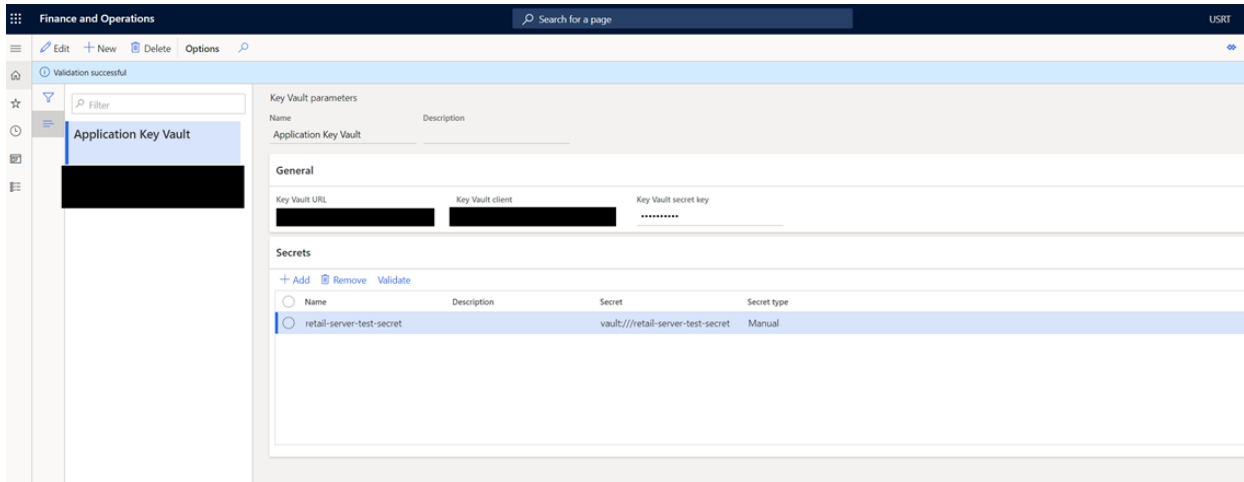

- Go to your Key Vault.
- Select **Access policies**, and then select **Add Access Policy**.
- For the first option, select **Key, Secret, and Certificate Management**.
- For **Select principal**, search for and select the app you registered earlier (for example, "RetailServer").
- Leave **Authorized application** blank.
- Select **Save**.

### Add the Key Vault details in Retail Server

Next, to add the Key Vault details in Retail Server, follow these steps.

- In Commerce headquarters, go to **Key Vault parameters**.
- From the store selector on the top right, select **USRT**.
- Select **New**, and then enter a name to represent your Key Vault.

4. Enter the **Key Vault URL**. This is the **Vault URI** value listed on your Key Vault's **Overview** page.
5. Enter the **Key Vault client**. This is the application ID of the registered app.
6. Enter the **Key Vault secret key**. This is the secret value saved from the app registration process.
7. Add the secrets you want to access from Retail Server. For example, if the secret name is "retail-server-test-secret", add "retail-server-test-secret" as the **Name**, and "vault:///retail-server-test-secret" as the **Secret**. The **Secret type** should be set to **Manual**.
8. Select **Validate** to test your configuration. If everything was configured correctly, you will see a message that says, "Validation successful."

### IMPORTANT

The Key Vault must be configured in the USRT store.

## Access secret values within your e-Commerce Node application

After the configuration steps above are complete, you will be able to access the secret values from within your e-Commerce Node application using the `SecretManager` class. This class is initialized on the global `msdyn365Commerce` object and implements the interface shown in the following example. Along with the `secretKey`, the `baseURL` for your Retail Server needs to be passed in as a second argument. This base URL can be found in the `RequestContext` API under the `requestContext.apiSettings.baseUr1` API, which is accessed through the action context inside of data actions or the `props.context` context object in modules.

```
export interface ISecretManager {
  getSecretValue(secretKey: string, baseRetailServerUr1: string): Promise<ISecretValue>;
}

export interface ISecretValue {
  value: string; // secret value
  id?: string; // secret ID (if applicable)
  error?: Error; // Error details (set if request to fetch secret value failed)
  expiresOn: number; // Unix timestamp (in seconds) when the secret value will expire
}
```

To import this into your code, add `msdyn365Commerce` to the import statement for the '@msdyn365-commerce/core' library as shown in the following example.

```
import msdyn365Commerce, { IRequestContext, ... } from '@msdyn365-commerce/core';
```

The following example shows how to use the `SecretManager` class to access the secret value:

```
const secretValue: ISecretValue | undefined = await
msdyn365Commerce.secretManager?.getSecretValue('secretKey', requestContext.apiSettings.baseUr1);
```

Note that `secretManager` is a nullable property on `msdyn365Commerce` because the `SecretManager` class can only fetch secrets when running server-side. This is to prevent leaking the secret value to your browser. If the `secretManager` property is undefined, it means that the code is running in the context of a browser (client-side).

As a developer, you should only use the `SecretManager` class on code that is ensured to run server-side (for example, data actions that will run only on server-side), because you will otherwise be unable to access the secret value. If you include this property in code that will run in both contexts (server-side and client-side), it is important to include a fallback option if the `secretManager` property is undefined.

If the request to fetch the secret value fails, the error property will be set. You can use this to debug any issues you may encounter when trying to fetch secret values.

## Local development

Your e-Commerce Node application is only able to communicate with Retail Server and request tokens need to securely communicate in a deployed App Service environment. This means that when developing locally, the `SecretManager` class will be unable to retrieve secrets from your Key Vault. Instead you can create a secrets directory in your Node application and add a `secrets.json` file, where you can configure `secretKeys` and `secretValues` that will only be used when developing locally.

### NOTE

Everything under the `secrets/` directory should be added to your `.gitignore` file to help prevent secrets from being leaked online.

The following example shows the contents of a "secrets/secrets.json" file.

```
{
  "secretKey": "secretValue!"
}
```

If you do not configure this file, during local development you may encounter errors as the `SecretManager` class attempts to communicate with your Key Vault but fails to do so.

# Data actions

2/18/2021 • 3 minutes to read • [Edit Online](#)

This topic covers data actions in Microsoft Dynamics 365 Commerce.

## Overview

Data actions are JavaScript functions that are used in the Dynamics 365 Commerce architecture to help fetch and map data that is required by modules across applications.

Data actions offer improved performance through the following features:

- Integrated application-level and request-level caches enable state sharing scenarios.
- Built-in utilities support batching to minimize the number of external requests that your application requires.
- Automatic deduplication helps guarantee that multiple data action calls aren't duplicated.

The Dynamics 365 Commerce platform includes a set of core data actions that can be called from modules to do typical data retrieval. For example, core data actions can return product details. You can also create custom data actions to fetch and process data that is required by modules.

## Anatomy of a data action

Here is an example of a template TypeScript file that is created for a new data action.

```

import * as Msdyn365 from '@msdyn365-commerce/core';

/**
 * GetProductReviews Input Action
 */

export class GetProductReviewsInput extends Msdyn365.CommerceEntityInput implements Msdyn365.IActionInput {

    // TODO: Determine if the results of this get action should cache the results and if so provide
    // a cache object type and an appropriate cache key
    constructor() {
        super({shouldCacheOutput: true, cacheObjectType: 'TODO', cacheKey: 'TODO'});
    }

    public getCacheKey = () => `TODO`;
    public getCacheObjectType = () => 'TODO';
    public dataCacheType = (): Msdyn365.CacheType => 'application';
}

// TODO: Create a data model here or import one to capture the response of the action
export interface IGetProductReviewsData {
    text: string;
}

/**
 * TODO: Use this function to create the input required to make the action call
 */
const createInput = (args: Msdyn365.ICreateActionContext): Msdyn365.IActionInput => {
    return new GetProductReviewsInput();
};

/**
 * TODO: Use this function to call your action and process the results as needed
 */
async function action(input: GetProductReviewsInput, ctx:
Msdyn365.IActionContext): Promise<IGetProductReviewsData> {
    // const apiSettings = Msdyn365.msdyn365Commerce.apiSettings;

    // TODO: Uncomment the below line to get the value from a service
    // const response = await Msdyn365.sendRequest<IGetProductReviewsData[]>('/get/example/id/1', 'get');
    return {text: 'Static data from action'};
}

export const IGetProductReviewsAction = Msdyn365.createObservableDataAction({
    action: <Msdyn365.IAction<IGetProductReviewsData>>action,
    input: createInput
});

```

### Key parts of a data action

- **Action function** – The main function that contains the logic that is run when the action is called. This function might involve making application programming interface (API) calls, reading cookies, or transforming data that was passed in.

```

async function action(input:GetProductReviewsInput, ctx:
Msdyn365.IActionContext):Promise<IGetProductReviewsData> {
    // const apiSettings = Msdyn365.msdyn365Commerce.apiSettings;

    // TODO: Uncomment the below line to get the value from a service
    // const response = await Msdyn365.sendRequest<IGetProductReviewsData[]>('/get/example/id/1',
'get');
    return {text: 'Static data from action'};
}

// TODO: Create a data model here or import one to capture the response of the action
export interface IGetProductReviewsData {
    text: string;
}

```

- **Action input class** – The class that is used to pass data into the action function. The "cacheObjectType" and "cacheKey" values indicate where in the cache the class should put the result of the action.

```

export class GetProductReviewsInput extends Msdyn365.CommerceEntityInput implements
Msdyn365.IActionInput {

    // TODO: Determine if the results of this get action should cache the results and if so provide
    // a cache object type and an appropriate cache key
    constructor() {
        super({shouldCacheOutput: true, cacheObjectType: 'TODO', cacheKey: 'TODO'});
    }

    public getCacheKey = () => `TODO`;
    public getCacheObjectType = () => 'TODO';
    public dataCacheType = (): Msdyn365.CacheType => 'application';
}

```

- **createInput method** – This optional method can be used to build an instance of an action input class that is used to load data when a page is first populated.

```

const createInput = (args: Msdyn365.ICreateActionContext): Msdyn365.IActionInput => {
    return new GetProductReviewsInput();
};

```

### Create a new custom data action

To create a new custom data action, follow this step.

- At a command prompt, go to your root software development kit (SDK) folder, and run the **yarn msdyn365 add-data-action DATA\_ACTION\_NAME** command-line interface (CLI) command to create a data action, as shown in the following example.

```

c:\repos\Msdyn365.Commerce.Online>yarn msdyn365 add-data-action get-product-reviews

```

TypeScript files for new custom data actions are created under the `\src\actions\` directory. The name of each file uses the name of the data action. For the preceding example, the path and name of the file for the new custom data action are `\src\actions\getProductReviews.ts`.

# Data action cache options

2/18/2021 • 3 minutes to read • [Edit Online](#)

This topic provides an overview of supported data action cache options in Dynamics 365 Commerce.

The Dynamics 365 Commerce online software development kit (SDK) supports caching entities at the application level, which enables caching of data action responses to improve rendering performance and reduce server load. For more information, see [Data actions overview](#).

## Caching a data action

A data action can save data in either the request or application cache, based on its action input. The **dataCacheType** property of `IActionInput` enables the underlying action runtime to make this decision on the action's behalf. By default, the action responses go into the request cache.

```
export class FullProductInput implements IActionInput {
  public productId: number;
  public channelId: number;
  public ProductDetailsCriteria: ProductDetailsCriteria;

  constructor(productId: number | string, channelId: number, criteria: ProductDetailsCriteria) {
    this.productId = typeof productId === 'string' ? parseInt(productId, 10) : productId;
    this.channelId = channelId;
    this.ProductDetailsCriteria = criteria;
  }

  public getCacheKey = () => `${this.productId.toString()}-${this.channelId.toString()}-${this.ProductDetailsCriteria}`;
  public getCacheObjectType = () => 'FullProduct';
  public dataCacheType = (): CacheType => 'request';
}
```

## Supported cache types

The following cache types are supported and can be set on the **dataCacheType** property:

- **request**: Action input caches the entity for the life cycle of the request. All of the subsequent data action inputs with the same cachekey (within the same request) will be served from the request cache.
- **application**: Action input caches the entity for the life cycle of the application (subject to time to refresh (TTR) and time to live (TTL) values as defined in cache settings. All of the subsequent data action inputs with the same cachekey will be served from the application cache.
- **instance**: Instance is a special cache type setting primarily used for aggregator data actions that do not make a request and extract information from other data actions, for example a categories hierarchy. Such data actions are run on server and client independently. If the instance is not specified, then such aggregator data actions would contain duplicate data.
- **none**: Used to skip or bypass the request cache. An action with cache type "none" skips the caching layer completely.

## Cache settings

Cache settings can be configured using the `\src\settings\cache-settings.json` file. The following example shows the format of a `cache-settings.json` file.

```
{
  "checkPeriodInSeconds": 120,
  "ttlInSeconds": {
    "entity-with-ttl": 4,
    "category": 60
  },
  "ttrInSeconds": {
    "entity-with-ttr": 2
  }
}
```

For more information, see [Data action cache settings](#).

#### **checkPeriodInSeconds**

This setting represents the time interval in seconds, at which the SDK will do a pass on the application cache to nudge TTL expired items from the cache. The default value is 600 seconds.

#### **ttlInSeconds - TTL (Time to Live)**

This setting indicates the duration an entity can stay in the application cache. This value is configurable at the application level and also per entity. The default value is 600 seconds.

#### **ttrInSeconds - TTR (Time to Refresh)**

TTR tells the action runtime to keep the data fresh, in the sense that the cache value is retained in the application cache but a fresh call is made to update the cache data. In the event of an unexpected error, you can still choose to return the data in the cache. The default value is 60 seconds.

#### **defaultTTLInSeconds**

This setting indicates the default time to live (in seconds) for all the cache items. The default value is 600 seconds.

#### **defaultTTRInSeconds**

This setting indicates the default time to refresh (in seconds) for all the cache items. The default value is 60 seconds.

# Test data actions with mocks

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic describes how to test data actions with mock data.

## Overview

By mocking data actions in Microsoft Dynamics 365 Commerce, you can replace the output of a data action with the data that is specified in the `actionmock.json` file that has been loaded. An action mock is useful if you want to test your module without invoking the actual action. You will have to use this approach if you haven't configured your Commerce server (`MSDyn365Commerce_BASEURL` property) in the `.env` file. For more information about `.env` files, see [Configure a development environment \(.env\) file](#).

## Action mock structure

To create a data action mock, create a new file under the `/src/module/<MODULE_NAME>/mocks/` directory for your module. The name of the new file should be in the format `<MODULE MOCK_NAME>.actionmock.json`, as in the following example.

```
/src/modules/product-feature/mocks/myModuleMock.actionmock.json
```

After the file is created, you can simulate the data action return object inside the file by specifying the `CacheObjectType` and `CacheKey` values that are defined in the data action. The `CacheKey` value can be set to `"*"` to accept any cache key. For more information, see [Data actions](#).

The following example shows how the `<MODULE MOCK_NAME>.actionmock.json` file should be structured.

```
{
  "CacheObjectType": "MyCacheObjectType",
  "CacheKey": "MyCacheKey",
  "Mock": {
    "foo": "bar"
  }
}
```

If no `CacheKey` value is specified, or if `"*"` is specified, all actions that have the corresponding `CacheObjectType` value will receive the mock output.

## Example

The following example shows a module definition file that uses a data action, and the corresponding data action mock that returns product data.

Example module definition file:

```

{
  "$type": "contentModule",
  "friendlyName": "Product Feature",
  "name": "product-feature",
  "description": "Feature module used to highlight a product.",
  "categories": [
    "storytelling"
  ],
  "tags": [
    ""
  ],
  "dataActions": {
    "products": {
      "path": "@msdyn365-commerce-modules/retail-actions/dist/lib/get-simple-products",
      "runOn": "server"
    }
  },
  "config": {
    "imageAlignment": {
      "friendlyName": "Image Alignment",
      "description": "Sets the desired alignment of the image, either left or right on the text.",
      "type": "string",
      "enum": {
        "left": "Left",
        "right": "Right"
      },
      "default": "left",
      "scope": "module",
      "group": "Layout Properties"
    }
  },
  "resources": {
    "resourceKey": {
      "comment": "resource description",
      "value": "resource value"
    }
  }
}

```

Example module mock file:

```
[
  {
    "CacheObjectType": "SimpleProduct",
    "CacheKey": "*",
    "Mock": {
      "RecordId": 22565423455,
      "ItemId": "2101",
      "Name": "Retro Horn-Rimmed Keyhole Sunglasses",
      "Description": "High-quality with the perfect blend of timeless classic and modern technology
with hint of old school glamor.",
      "ProductTypeValue": 3,
      "DefaultUnitOfMeasure": "Ea",
      "BasePrice": 15,
      "Price": 15,
      "AdjustedPrice": 14,
      "MasterProductId": null,
      "Components": null,
      "Dimensions": null,
      "Behavior": null,
      "LinkedProducts": null,
      "PrimaryImageUrl": "https://bit.ly/33cMGxr",
      "ExtensionProperties": null
    }
  }
]
```

#### NOTE

The **CacheObjectType** and **CacheKey** values should match the values in the data action that you're mocking. If no **CacheKey** value is specified, all actions that have the corresponding **CacheObjectType** value receive the mock output.

## Use an action mock in a preview

To use an action mock in your module preview, include the query string parameter for the action mock **actionMock=MODULE\_NAME:MOCK\_FILE\_NAME**, as shown in the following example.

```
https://localhost:4000/modules?type=product-feature&actionMock=product-feature:myModuleMock
```

Here is the syntax of the query string parameter.

```
{module-name}:{action-mock-file-name}
```

If no action mock file name is specified, the package name is used to search for the mock.

# Page load data actions

2/18/2021 • 4 minutes to read • [Edit Online](#)

This topic covers page load data actions in Microsoft Dynamics 365 Commerce.

## Overview

Every page that is rendered, whether it's a product details page, a department page, or a home page, requires data. Page load data actions are used to obtain that data.

## The createInput method

When a page is loaded, a data action can be called by using the `createInput` method. The following example shows the sample code that is created in the TypeScript file for a data action by using the `yarn d365 add-data-action DATA_ACTION_NAME` command-line interface (CLI) command.

```
const createInput = (args: Msdyn365.ICreateActionContext): Msdyn365.IActionInput => {
    return new GetProductReviewsInput();
};
```

The `ICreateActionContext` type represents an object that is passed to every `createInput` method. It contains three pieces of information:

- The request context (`inputData.requestContext`)
- The module's configuration (`inputData.config`)
- The module's data (`inputData.data`)

In the following example, notice that the `createInput` method in the TypeScript template file has been added to the `createDataAction` call. Therefore, the Dynamics 365 Commerce online software development kit (SDK) can determine that this data action can be run on page load.

```
export default Msdyn365.createObservableDataAction({
    action: <Msdyn365.IAction<IGetMyDataData>>action,
    input: createInput
});
```

### Example of the createInput method

For the following example of the `createInput` method, the module that calls the data action has a configuration string property that is named `productId`. The value of this property is a product ID that the data action will use as input.

```
/**
 * Creates a ProductInput using module configuration data
 */
const createInput = (inputData: ICreateActionContext<IGeneric<IAny>>): IActionInput => {
    // Ensure module has a config property 'productId'
    if(inputData.config && inputData.config.productId) {
        // Create and return an input for the data action using the module configuration data.
        return new ProductInput(inputData.config.productId);
    }
};
```

## Register the data action on a module

Before a module can call a data action on page load, the data action must be registered in the module definition file.

The following example shows a module that uses the data action earlier in this topic to get product information so that it can be shown inside the module.

```
{
  "$type": "moduleDefinition",
  "name": "product-module",
  "friendlyName": "Product module",
  "description": "Product module",
  "categories": ["Product"],
  "dataActions": {
    "product": {
      "path": "../../actions/get-product",
      "runOn": "server"
    }
  },
  ...
}
```

Here, the **dataActions** node indicates the data actions that should be run when a module is loaded on a page. The name of every key in the data actions object refers to the name of the property that the result will be assigned to in the module's data properties (in this case, the **this.props.data.product** property). Additionally, the **path** property of every data action points to a file that exports the data action that should be run. Generally, the data action is the default export of the file it was written in.

To help ensure that you have the correct typing for the module when you develop your module view, you must update the module data file with corresponding types, based on the data actions that you've registered. Here is an example.

```
import { AsyncResult } from '@msdyn365-commerce/retail-proxy';

// product-module.data.ts
export interface IProductModuleData {
  product: AsyncResult<SimpleProduct>;
}
```

Now, when you develop this module, you will have access to the product information via the **this.props.data.product** property.

## Client-side rendering

Dynamics 365 Commerce renders pages server side and [hydrates](#) the page on the client after the initial load. Data actions defined in a module definition are executed on the server by default, which causes modules to render server side. If a module explicitly needs to render on client, the **runOn** parameter value needs to be set to 'client' in the module definition file as shown below.

```
{
  "$type": "moduleDefinition",
  "name": "product-module",
  "friendlyName": "Product module",
  "description": "Product module",
  "categories": ["Product"],
  "dataActions": {
    "product": {
      "path": "../../actions/get-product",
      "runOn": "client"
    }
  },
  ...
}
```

#### NOTE

If a data action is being used in multiple modules with both server/client "runOn" configurations, the data action will run only on the server side. Therefore, it is important to avoid conflicting the **runOn** configurations if the module needs to be rendered explicitly on the client side.

## Register a core data action

The Dynamics 365 Commerce online SDK contains a set of core data actions that can be used to perform typical Commerce data tasks. Interfaces for core data actions can be found under the `\node_modules\@msdyn365-commerce-modules\retail-actions\dist\lib` directory. To register a core data action so that you can use it inside your module, use the following format in the **dataActions** node of your `MODULE_definition.json` file.

```

{
  "$type": "contentModule",
  "friendlyName": "Product Feature",
  "name": "product-feature",
  "description": "Feature module used to highlight a product.",
  "categories": [
    "storytelling"
  ],
  "tags": [
    ""
  ],
  "dataActions": {
    "products": {
      "path": "@msdyn365-commerce-modules/retail-actions/dist/lib/get-simple-products",
      "runOn": "server"
    }
  },
  "config": {
    "productIds": {
      "friendlyName": "Product ID",
      "description": "Provide a Product Id that the module will display",
      "type": "string",
      "scope": "module",
      "group": "Content Properties"
    }
  },
  "resources": {
    "resourceKey": {
      "comment": "resource description",
      "value": "resource value"
    }
  }
}

```

Notice that this example calls a core data action that is named **get-simple-products**. This data action uses the **productIds** config property to get the list of product IDs and returns an array of **SimpleProduct** results. The following example shows the module `data.ts` file that defines the return value. The interface for the **SimpleProduct** return type is defined in the `\node_modules\@msdyn365-commerce\commerce-entities\dist\types\commerce-entities` directory that is imported at the top of the example.

```

import { AsyncResult, SimpleProduct } from '@msdyn365-commerce/retail-proxy';

export interface IProductFeatureData {
  products: AsyncResult<SimpleProduct>[];
}

```

# Use event-based data actions

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic describes how to use event-based data actions.

## Overview

In some scenarios, you don't want a data action to run when a page is first loaded. Instead, you want it to run dynamically in response to some event on the client. For example, a product can be added to a customer's cart in response to a button click, search results can be shown in response to a change in the text input, or banner text can be updated in response to a time-based event.

## Example

In the following example, a very basic module loads product information when a user clicks a button.

The following code shows a **react** component that contains a button that users can click.

```
// product-button.tsx
import * as React from 'react';

/**
 * ProductAddToCart component
 */
class ProductButton extends React.Component {
  public render(): JSX.Element {
    return (
      <div>
        <button onClick={_getProductInfo}>Get Product Info!</button>
      </div>
    );
  }

  // On-Click handler function
  private _getProductInfo = () => {
    console.log('We need to get the product!');
  }
}

export default ProductButton;
```

Currently, this component just logs a message to the console when the button is clicked. To replace that behavior with the data action, you must do three things:

1. Import the data action and its input class.
2. Create an input for the data action.
3. Invoke the data action.

The following code shows an updated **react** component that makes a call for a product when the button is clicked.

```
// product-button.tsx
import * as React from 'react';

// Import our data action and input class
// NOTE: Generally the data action is the DEFAULT export of the file it was written in.
import getProductDataAction, { ProductInput } from '../actions/get-product';

/**
 * ProductAddToCart component
 */
class ProductButton extends React.Component {
  public render(): JSX.Element {
    return (
      <div>
        <button onClick={_getProductInfo}>Get Product Info!</button>
      </div>
    );
  }

  // On-click handler
  private _getProductInfo = async() => {
    // Create the input for our data-action
    const actionInput = new ProductInput('12345');

    // Run and await the result of the data action
    const product = await getProductDataAction(actionInput, {callerContext:
this.props.context.actionContext});

    // Log the result to the console
    console.log(product);
  }
}

export default ProductButton;
```

#### NOTE

This example uses a hard-coded **productId** value. However, it can be updated so that the **productId** value is read from text input or the module's configuration properties.

# Core data actions

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic covers the list of core data actions that are included with the Microsoft Dynamics 365 Commerce e-Commerce software development kit (SDK). You can find all core data actions in the `\node_modules\@msdyn365-commerce-modules\retail-actions\dist\lib` directory.

## NOTE

All core data actions are observable data actions that are wrapped in an `AsyncResult` class.

DATA ACTION	DESCRIPTION
add-address	Add a new address to an existing customer.
checkout	Initiate checkout for an order.
delete-address	Delete an existing customer address.
generic-data-action	A sample data action.
get-active-cart	Get the active cart, or create an active cart if none exists.
get-address	Return a list of customer addresses.
get-card-payment-accept-point	Return card payment information.
get-categories	Return a list of product categories.
get-categories-hierarchy	Return a list of product categories as a hierarchy.
get-checkout-cart	Return information about the current checkout cart.
get-current-category	Return a category hierarchy for a given category ID.
get-customer	Return customer information for a given customer account number.
get-customer-loyalty-cards	Return a list of loyalty cards for a given customer.
get-dimensions-for-selected-variant	Return a list of available product dimensions for a given product variant.
get-full-products	Get detailed product information, including prices and ratings, for a product.
get-full-products-by-category	Get detailed product information for the products in a specific category.

DATA ACTION	DESCRIPTION
get-full-products-by-refine-search-category	Get detailed product information for a category when refiners are applied.
get-full-products-by-refine-search-text	Get detailed product information, based on a given search term, when refiners are applied.
get-full-products-search-by-text	Get detailed product information, based on a given search term.
get-list	Return a list of products.
get-order-history	Return a list of past orders for a customer.
get-org-unit-configuration	Return organizational unit information.
get-products-by-category	Return a list of products for a specific category.
get-recommendations	Return a list of product recommendations.
get-refiners-by-category	Return a list of applicable refiners for a given category.
get-refiners-by-text	Return a list of applicable refiners for a given text search term.
get-related-products	Return a list of related products.
get-selected-variant	Return a specific variant for a given product.
get-simple-products	Return a list of products together with basic information for a list of product IDs.
get-wishlist-by-customer-id	Return a customer's wish list.
refine-search-by-category	Return a list of products, based on the selected category.
search-org-unit-locations	Return a list of store locations.
update-address	Update an existing customer address.
update-line-delivery-specifications	Update delivery information for line items in the cart.
update-primary-address	Update a customer's primary address.

# Call Retail Server APIs

2/18/2021 • 6 minutes to read • [Edit Online](#)

This topic explains how to call application programming interfaces (APIs) for Microsoft Dynamics 365 Retail Server from a data action or directly from module code.

## Overview

To call Retail Server APIs, you must use the Retail Server proxy library that Retail Server provides. This proxy library is also known as TypeScriptProxy or TSProxy. It allows for streamlined communication with Retail Server from JavaScript-based or TypeScript-based environments.

## Install the Retail Server proxy

The Retail Server proxy is available for download via the Dynamics 365 npm feed and should be added by default. If it isn't there, you can get it by adding a reference in the packages.json file.

To install the proxy in your software development kit (SDK) development environment, follow these steps.

1. Determine your current active version of Retail Server. This version will be the version of the Retail Server NuGet package that you use for back-end extensibility.
2. In the **package.json** file, add the following entry in the **dependencies** section. (This entry might already be present and have up-to-date version information.)

```
"@msdyn365-commerce/retail-proxy": "{RETAIL_SERVER_VERSION}"
```

3. Run **yarn install**.

You should now have access to the correct Retail Server proxy for your project. You might see that a reference is already included as part of the module library.

## Retail Server proxy data action managers

The Retail Server proxy contains a set of APIs that communicate internally with Retail Server via HTTP. These APIs are all available through a set of data action managers. To import the code for these data action managers, you can use the following import paths.

```
// Generic example
import {} from '@msdyn365-commerce/retail-proxy/dist/DataActions/{DATA_ACTION_MANAGER_NAME}.g';

// Specific example
import { getByIdsAsync } from '@msdyn365-commerce/retail-proxy/dist/DataActions/ProductsDataActions.g';
```

The following data action managers are available:

- CartsDataActions
- CatalogsDataActions
- CategoriesDataActions
- CommerceListsDataActions
- CustomersDataActions

- EmployeesDataActions
- OrgUnitsDataActions
- PickingListsDataActions
- ProductsDataActions
- PurchaseOrdersDataActions
- RecommendationsDataActions
- SalesOrdersDataActions
- ScanResultsDataActions
- ShiftsDataActions
- StockCountJournalsDataActions
- StoreOperationsDataActions
- SuspendedCartsDataActions
- TransferOrdersDataActions
- WarehousesDataActions

For a list of all the available Retail Server APIs in each data action manager, see [Retail Server Customer and Consumer APIs](#).

## Retail Server proxy data methods

The Retail Server proxy is closely linked to the [Data Action Framework](#). Therefore, for every Retail Server API, there are two exposed Retail Server proxy methods:

- **The createInput method** – This method creates an `IActionInput` class that can be used either to run a [page load data action](#), or to do a direct state update or fetch via the `actionContext.update()` or `actionContext.get()` methods. This method is always named `create{RETAIL_SERVER_API_NAME}Input`.
- **The action method** – This method can be invoked on its own as an [event-based data action](#), or it can be added inside another action method to create a [data action chain](#). This method is always named `{RETAIL_SERVER_API_NAME}Async`.

## Create a page load Retail Server proxy data action

When you want to attach a Retail Server proxy API call to a module so that it will run when a page is loaded, you must create a new data action. The process resembles the process for creating a standard page load data action.

In this example, you will create a module that uses the Retail Server proxy to get all the categories that are available for the configured channel when a page is loaded. To start, you must identify the correct Retail Server proxy API to use. For this example, this API is the `GetCategories` API that is provided by the `CategoriesDataActions` data action manager. You can then construct a data action that can be used in a module definition. In general, to complete this task, you must do two things:

- Provide a **createInput** method that calls the Retail Server proxy **createInput** method for the desired API and passes it any contextual data that you want (for example, the channel ID).
- Have the action method of the new data action be the **retailAction** method that is provided by the Retail Server proxy. The **retailAction** method is designed to parse the input that is passed to it and call the corresponding Retail Server proxy API.

Under the `src\actions` directory, create a file for a new data action. For this example, the file is named `get-category-list.ts`, and it contains the following code.

```

import { createObservableDataAction, IAction, ICreateActionContext } from '@msdyn365-commerce/core';
import { Category, retailAction } from '@msdyn365-commerce/retail-proxy';
import { createGetCategoriesInput } from '@msdyn365-commerce/retail-proxy/dist/DataActions/CategoriesDataActions.g';

/**
 * Get Org Unit Configuration Data Action
 */
export default createObservableDataAction({
  action: <IAction<Category[]>>retailAction,
  input: (context: ICreateActionContext) => {
    return createGetCategoriesInput({ Paging: { Top: 0 } },
    context.requestContext.apiSettings.channelId);
  }
});

```

The `get-category-list.ts` file exports a data action that can be registered on a module to get the list of all categories from whatever channel has been configured for the project. Because this approach requires much less custom code to make the HTTP call than manual communication with Retail Server, we recommend that you always call Retail Server by using the Retail Server proxy.

The following example shows how the `get-category-list` data action can be registered in the `"module" > "dataActions"` node in the module definition file.

```

{
  "$type": "contentModule",
  "friendlyName": "Product Feature",
  "name": "product-feature",
  "description": "Feature module used to highlight a product.",
  "categories": [
    "storytelling"
  ],
  "tags": [
    ""
  ],
  "dataActions": {
    "products": {
      "path": "@msdyn365-commerce-modules/retail-actions/dist/lib/get-simple-products",
      "runOn": "server"
    },
    "productReviews": {
      "path": "../../actions/getproductreviews",
      "runOn": "server"
    },
    "categories": {
      "path": "../../actions/get-category-list",
      "runOn": "server"
    }
  },
  "config": {
    "imageAlignment": {
      "friendlyName": "Image Alignment",
      "description": "Sets the desired alignment of the image, either left or right on the text.",
      "type": "string",
      "enum": {
        "left": "Left",
        "right": "Right"
      },
      "default": "left",
      "scope": "module",
      "group": "Layout Properties"
    },
    "productTitle": {
      "type": "string",
      "friendlyName": "Product Title".
    }
  }
}

```

```

    "friendlyName": "Product Placement",
    "description": "Product placement title"
  },
  "productDetails": {
    "type": "richText",
    "friendlyName": "Product Details",
    "description": "Rich text representing the featured product details"
  },
  "productImage": {
    "type": "image",
    "friendlyName": "Product Image",
    "description": "Image representing the featured product"
  },
  "buttonText": {
    "type": "string",
    "friendlyName": "Button Text",
    "description": "Text to show on the call to action button"
  },
  "productIds": {
    "friendlyName": "Product ID",
    "description": "Provide a Product Id that the module will display",
    "type": "string",
    "scope": "module",
    "group": "Content Properties"
  }
},
"resources": {
  "resourceKey": {
    "comment": "resource description",
    "value": "resource value"
  }
}
}

```

The module `data.ts` file also requires an entry for the return type of the data action. The following example shows a sample module `data.ts` file. After it's implemented, the property can be accessed from the module's view file by using the `this.props.data` object.

```

import { AsyncResult, Category, SimpleProduct } from '@msdyn365-commerce/retail-proxy';
export interface IProductFeatureData {
  products: AsyncResult<SimpleProduct>[];
  categories: AsyncResult<Category>[];
}

```

## Call a Retail Server proxy API directly in module code

The following example shows how to call the `getCategories` Commerce API by using the Commerce proxy `getCategoriesAsync` wrapper API. This API call returns a list of all categories, and the sample code logs them to the console.

```

import * as React from 'react';

import { getCategoriesAsync } from '@msdyn365-commerce/retail-
proxy/dist/DataActions/CategoriesDataActions.g';
import { IProductFeatureData } from './product-feature.data';
import { imageAlignment, IProductFeatureProps } from './product-feature.props.autogenerated';

export interface IProductFeatureViewProps extends IProductFeatureProps<{}> {
  productName: string;
}

/**
 *
 * ProductFeature component
 * @extends {React.PureComponent<IProductFeatureProps<IProductFeatureData>>}
 */
class ProductFeature extends React.PureComponent<IProductFeatureProps<IProductFeatureData>> {
  public render(): JSX.Element | null {
    const {
      config,
    } = this.props;

    // set default product info values from config values if available
    let ProductName = config.productTitle ? config.productTitle : 'No product name defined';

    getCategoriesAsync({ callerContext: this.props.context.actionContext },
this.props.context.request.apiSettings.channelId)
      .then(categoryList2 => {
        let categories2 = '';
        for (let i = 0; i < categoryList2.length; i++) {
          categories2 += `${categoryList2[i].Name}, `;
        }
        console.log(categories2);
      });

    const ProductFeatureViewProps = {
      ...this.props,
      productName: ProductName,
    };

    return this.props.renderView(ProductFeatureViewProps) as React.ReactElement;
  }
}

export default ProductFeature;

```

# Call Retail Server extension APIs

2/18/2021 • 5 minutes to read • [Edit Online](#)

This topic describes how to call Microsoft Dynamics 365 Retail Server extension application programming interfaces (APIs) from data actions or directly from module code.

## Overview

Dynamics 365 Retail Server extension APIs can be called from either the point of sale (POS) system or from e-Commerce modules and data actions. To call the APIs from e-Commerce modules and data actions, you must create proxy module TypeScript (.ts) files by using a tool that is provided as part of the Dynamics 365 Retail software development kit (SDK). You can then include these files in your e-Commerce configurations and use them to call the Retail Server extension APIs from e-Commerce modules and data actions.

### NOTE

This topic doesn't explain how to create Retail Server extensions. For more information, see [Create a new Retail Server extension](#).

It's assumed that the following prerequisites are in place:

- A Retail Server extension has already been deployed.
- You have access to the Retail Server extension dynamic-link libraries (DLLs) that are available.

In addition, make sure that the .env file **MSDyn365Commerce\_BASEURL** has a value that points to the environment that has the deployed Retail Server extension, so that you can test against it. If this option isn't available, you can use a mock-up instead.

If you're developing on the local Tier 1 Retail Server virtual machine (VM), you must point **MSDyn365Commerce\_BASEURL** to the local URL (`https://usnconeboxax1ret.cloud.onebox.dynamics.com/`), and make sure that **MSDyn365Commerce\_CHANNELID** and **MSDyn365Commerce\_OUN** are set to the appropriate online channel that you're using. Here is an example of an .env file.

```
...
MSDyn365Commerce_BASEURL=https://usnconeboxax1ret.cloud.onebox.dynamics.com/
MSDyn365Commerce_CHANNELID=68719478279
MSDyn365Commerce_CATALOGID=0
MSDyn365Commerce_OUN=128
...
```

For more information, see [Configure a development environment \(.env\) file](#).

You might also have to change the following setting in the Retail Server web.config file, so that the call can go through in the local development environment.

```
<add key="AllowedOrigins" value="*" />
<!-- <add key="AllowedOrigins"
value="https://usnconeboxax1pos.cloud.onebox.dynamics.com;https://usnconeboxax1ecom.cloud.onebox.dynamics.com" /> -->
```

# Create proxy files

You will need the Retail SDK to generate proxy files. If you are using a Tier 1 development VM environment, make sure that you have the latest Retail SDK installed. For more information, see [Migrate the Retail SDK from Visual Studio 2015 to Visual Studio 2017](#).

For information about how Retail extensions can be called from Retail POS, see [Typescript and C# proxies for Retail point of sale \(POS\)](#). That topic explains how to create a proxy file by using a command that resembles the following command.

```
K:\RetailSDK\References\microsoft.dynamics.commerce.tools.coreproxygenerator\10.14.20128.1\tools>CommerceProxyGenerator.exe
..\..\..\microsoft.dynamics.commerce.tools.extensionsproxygenerator\9.22.20167.4\tools\Microsoft.Dynamics.Retail.RetailServerLibrary.dll k:\WarrantySample\Contoso.RetailServer.WarrantySample.dll
/application:typescriptextensions
```

## NOTE

The SDK version that is referenced in the command might differ, depending on the version of Retail Server that you're running.

The process for creating proxy files for e-Commerce is similar, but the final `/application:typescriptextensions` option is replaced by `/application:typescriptmoduleextensions`, as shown in the following example.

```
K:\RetailSDK\References\microsoft.dynamics.commerce.tools.coreproxygenerator\10.14.20128.1\tools>CommerceProxyGenerator.exe
..\..\..\microsoft.dynamics.commerce.tools.extensionsproxygenerator\9.22.20167.4\tools\Microsoft.Dynamics.Retail.RetailServerLibrary.dll k:\WarrantySample\Contoso.RetailServer.WarrantySample.dll
/application:typescriptmoduleextensions
```

After you run the preceding command, two new files are generated: `DataActionExtension.g.ts` and `DataServiceEntities.g.ts`.

## Proxy data methods

The proxy is closely linked to the data action framework. For every Retail Server extension API, there are two exposed proxy methods:

- **createInput** – This method creates an `IActionInput` class that can be used either to run a page load data action, or to do a direct state update or fetch via the `actionContext.update()` or `actionContext.get()` methods. This method is always named `create{COMMERCE_SCALE_UNIT_EXTENSION_API_NAME}Input`.
- **action** – This method can be invoked on its own as an event-based data action, or it can be added inside another action method to create a data action chain. This method is always named `{RETAIL_SERVER_API_NAME}Async`.

## Call a proxy API with a data action

From the Dynamics 365 Commerce online SDK, include the two new files from the previous section in the `/src/actions/` directory. Then create a new data action .ts file, and paste in code that resembles the following example to call the Retail Server extension APIs from the data action.

The following example uses a file that is named `get-warranty-info.ts`. Notice that it imports the `DataActionExtension.g` and `DataServiceEntities.g` files that were generated earlier, and it calls the

createGetWarrantyByProductIdInput Retail Server extension API as defined in the proxy file.

```
import { createObservableDataAction, IAction, ICreateActionContext } from '@msdyn365-commerce/core';
import { retailAction } from '@msdyn365-commerce/retail-proxy';
import { createGetWarrantyByProductIdInput } from './DataActionExtension.g';
import { IProductWarranty } from './DataServiceEntities.g';
/**
 * Get Warranty Info Data Action
 */
export default createObservableDataAction({
  action: <IAction<IProductWarranty[]>>retailAction,
  input: (context: ICreateActionContext) => {
    return createGetWarrantyByProductIdInput({Paging:{Top:250}}, '12345');
  }
});
```

You can now call the data action just as you might call any other data action, by declaring it in the **dataActions** node of your `module.definition.json` file, as shown in the following example. The data action will be called at page load time.

```
{
  "$type": "contentModule",
  "friendlyName": "Warranty List",
  "name": "warrantylist",
  "description": "Provides a list of available warranty services available for purchase.",
  "categories": [
    "warranty"
  ],
  "tags": [
    ""
  ],
  "dataActions": {
    "productWarranties": {
      "path": "../../actions/get-warranty-info",
      "runOn": "server"
    }
  },
  "resources": {
    "warrantyName": {
      "value": "Warranty Name",
      "comment": "Text for the warranty name header"
    },
    "warrantyDescription": {
      "value": "Description",
      "comment": "Text for the warranty description header"
    },
    "warrantyPrice": {
      "value": "Price",
      "comment": "Text for the warranty price header"
    },
    "warrantyBuyButton": {
      "value": "Buy now",
      "comment": "Text for the warranty action button"
    }
  }
}
```

You must also add the return data type to the module's `data.ts` file, as shown in the following example.

```
import { AsyncResult } from '@msdyn365-commerce/retail-proxy';
import { IProductWarranty } from '../actions/DataServiceEntities.g';

export interface IWarrantylistData {
  productWarranties: AsyncResult<IProductWarranty[]>;
}

```

Finally, you can access the data from your module React component by using the **this.props.data.productWarranties** property. The following example shows a sample module view.tsx file that renders data coming back from the Retail Server extension API.

```
import * as React from 'react';
import { IWarrantylistsampleViewProps } from './warrantylistsample';
export default (props: IWarrantylistsampleViewProps) => {
  const {
    data: { productWarranties }
  } = props;
  if (productWarranties && productWarranties.result) {
    return (
      <table className='table'>
        <thead>
          <tr>
            <th>Warranty</th>
            <th>Price</th>
          </tr>
        </thead>
        <tbody>
          {productWarranties.result.map(warranty => (
            <tr>
              <td>{warranty.Description}</td>
              <td>${warranty.Price}</td>
              <button type='button' className='btn btn-primary'>Buy Now</button>
            </tr>
          ))}
        </tbody>
      </table>
    );
  } else {
    return <div>No warranty info returned</div>;
  }
};

```

## Call proxy APIs directly

The following example shows a Retail Server API being called directly inside of a module's typescript React view code without using a data action.

```
import * as React from 'react';
import { getWarrantyByProductIdAsync } from '../actions/DataActionExtension.g';
import { IWarrantyListViewProps } from './warrantylist';
export default (props: IWarrantyListViewProps) => {
  const _getWarrantyOnClick = async() => {
    getWarrantyByProductIdAsync({ callerContext: props.context.actionContext }, '12345').then( result =>
    {
      ...
    });
  }

  return (
    <div>
      <button onClick={_getWarrantyOnClick}>Get Warranty Info</button>
    </div>
  );
};
```

# Chain data actions

2/18/2021 • 3 minutes to read • [Edit Online](#)

This topic describes how to chain data actions.

## Overview

To create a maintainable and compact codebase, you will often need a suite of composable data actions that can easily use each another to create more complex code flows. The Microsoft Dynamics 365 Commerce Online Software Development Kit (SDK) lets you seamlessly chain data actions but still provide all the out-of-box benefits of the data action architecture (caching, batching, and deduplicating).

## Examples

The following examples show data action chaining. First, a product information call is made. This call is followed by an inventory call.

The first example shows a data action that gets product information.

```

// get-product.ts
import { IAction, IActionInput } from '@msdyn365-commerce/action';
import { SimpleProduct } from '@msdyn365-commerce/commerce-entities';
import { CommerceEntityInput, createObservableDataAction, IAny, ICreateActionContext, IActionContext,
IGeneric, IHTTPError, IHTTPResponse, sendCommerceRequest } from '@msdyn365-commerce/core';
import { ProductInput } from './inputs/product-input';

/**
 * Product Action Input Class
 * This class is used by our Action Function, so that it has access to a productId
 */
export class ProductInput implements IActionInput {
  public channelId: number;
  public productId: number;
  constructor(productId: number, channelId: number) {
    this.channelId = channelId;
    this.productId = productId;
  }
  public getCacheKey = () => `${this.channelId}-${this.productId}`;
  public getCacheObjectType = () => 'Product';
  public dataCacheType = (): Msdyn365.CacheType => 'application';
}

/**
 * Action Function which calls the Retail API and returns the product based on the passed ProductInputs
productId
 */
async function getSimpleProductAction(input: ProductInput, ctx: IActionContext): Promise<SimpleProduct> {
  const { apiSettings } = ctx.requestContext;

  // Construct our HTTP request using information available in actionContext (ctx), and our Action Input
(input)
  const requestUrl = `${apiSettings.baseUrl}/Products/${input.productId}`;

  // Make the HTTP Request
  return sendCommerceRequest<SimpleProduct>(requestUrl, 'get')
    .then((response: IHTTPResponse) => {
      if(response.data) {
        return response.data;
      }
      ctx.trace('[getSimpleProductAction] Invalid response from server');
      return <SimpleProduct>[];
    })
    .catch((error: IHTTPError) => {
      ctx.trace(error.message);
      ctx.trace(error.stack || '');
      ctx.trace(`Unable to Fetch Product.`);
      return <SimpleProduct>{};
    });
}

/**
 * This exports the action Data Action, which the result of passing your action method and createInput
method (if used)
 * to the createDataAction method.
 */
export default createObservableDataAction({
  action: <IAction<SimpleProduct>>getSimpleProductAction
});

```

The second example shows a data action that gets inventory information.

```

// check-inventory.ts
import { IAction, IActionInput } from '@msdyn365-commerce/action';
import { ProductAvailableQuantity } from '@msdyn365-commerce/commerce-entities';
import { createObservableDataAction, IAny, IActionContext, IGeneric, IHTTPError, IHTTPResponse,
sendCommerceRequest } from '@msdyn365-commerce/core';

// Because this API also only needs a productId, we can re-use the ProductInput we created earlier here.
import { ProductInput } from './get-product.ts';

/**
 * Calls the Retail API and returns the Availability information for the passed Product
 */
async function getProductAvailabilityAction(input: ProductInput, ctx: IActionContext):
Promise<ProductAvailableQuantity> {
    const { apiSettings } = ctx.requestContext;

    // Construct our HTTP request using information available in actionContext (ctx), and our Action Input
    (input)
    const requestUrl = `${apiSettings.baseUrl}/Products/GetProductAvailabilities`;
    const requestBody = {
        productId: input.productId;
    }

    // Make the HTTP Call and handle the response
    return sendCommerceRequest<ProductAvailableQuantity>(requestUrl, 'post', requestBody)
        .then((response: IHTTPResponse) => {
            if(response.data) {
                return response.data;
            }
            ctx.trace('[getProductAvailabilityAction] Invalid response from server');
            return <ProductAvailableQuantity>[];
        })
        .catch((error: IHTTPError) => {
            ctx.trace(error.message);
            ctx.trace(error.stack || '');
            ctx.trace(`Unable to Fetch Product Availability.`);
            return <ProductAvailableQuantity>{};
        });
}

export default createObservableDataAction({
    action: getProductAvailabilityAction
})

```

Now that you have actions for getting the product data and the **ProductAvailableQuantity** value of a product, you can create a new chain data action. Chain data actions are just data actions that invoke other data actions as part of their execution.

The following example shows the **getProductWithAvailability** chain data action, which uses both the preceding actions.

```

import getProduct, { ProductInput } from './get-product';
import getProductAvailability from './check-inventory';

/**
 * This interface will be the return type of our chain data action.
 * This contains both the basic product information in addition to the product's availability information.
 */
export interface SimpleProductWithAvailability extends SimpleProduct {
  availability: ProductAvailableQuantity
}

/**
 * Calls the Retail API and returns the Availability information for the passed Product
 */
async function getProductWithAvailabilityAction(input: ProductInput, ctx: IActionContext):
Promise<SimpleProductWithAvailability> {
  // First we get the product
  const product: SimpleProductWithAvailability = await <SimpleProductWithAvailability>getProduct(input,
ctx);

  // If we successfully get the product, then we try to get its availability information.
  if(product) {
    // Get the availability information
    product.availability = await getProductAvailability(input, ctx)
  } else {
    return <SimpleProductWithAvailability>{};
  }
}

export default createObservableDataAction({
  action: getProductWithAvailabilityAction
})

```

You can now use the new chain data action wherever you need both the basic product information and the product's current inventory status. In addition, the calls that exist in the chain data action are still run through the cache. They are also batched and deduplicated together with other actions that are run on the same page.

# Batch data actions

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic describes how to batch data actions.

## Overview

Often you'll have an application that requires many calls to the same application programming interface (API) during the load of a single page. An example is a product feature page that showcases information about many products instead of just one product. In a typical approach, multiple calls are made to the data action to get products. However, because this approach uses many individual HTTP requests to get the product information, it might not be efficient. To solve this issue, the data action architecture supports batchable data actions.

## Examples

The main difference between a batch data action and a standard data action is the batch data action's support for an array of action inputs. In the following example of a standard data action, notice that the `getSimpleProductAction` action method accepts only one `ProductInput` class.

```
async function getSimpleProductAction(input: ProductInput, ctx: IActionContext): Promise<SimpleProduct>
```

To change this data action to a batch data action, modify the method signature so that the method can accept an array of `ProductInput` classes and return an array of `SimpleProduct` objects. The following example shows how the data action method must be updated so that it can process an array of inputs and return an array.

```
async function getSimpleProductsAction(inputs: ProductInput[], ctx: IActionContext):  
Promise<SimpleProduct[]> {  
    const { apiSettings } = ctx.requestContext;  
  
    // Construct our HTTP request using information available in actionContext (ctx), and our Action Input  
    (input)  
    const requestUrl = `${apiSettings.baseUrl}/Products`;  
  
    // Construct our request context from all the passed inputs  
    const requestBody = {  
        productIds: inputs.map(input => input.productId);  
    }  
  
    // Get the SimpleProducts  
    return sendCommerceRequest<SimpleProduct[]>(requestUrl, 'post', requestBody)  
        .then((response: IHTTPResponse) => {  
            if(response.data) {  
                return response.data;  
            }  
            ctx.trace('[getSimpleProductsAction] Invalid response from server');  
            return <SimpleProduct[]>[];  
        })  
        .catch((error: IHTTPError) => {  
            ctx.trace(error.message);  
            ctx.trace(error.stack || '');  
            ctx.trace(`Unable to Fetch Products.`);  
            return <SimpleProduct[]>[];  
        });  
}
```

Now that the data action method has been updated so that it can handle an array of inputs, the `isBatched` property in the action creation call must be set to `true`.

```
export default createObservableDataAction({
  action: <IAction<SimpleProduct[]>>getSimpleProductsAction,
  input: createInput,
  isBatched: true
});
```

Because this action now supports batching, if the action is called in multiple places during a page load, the data action framework automatically groups the requests together. That's why this approach helps minimize the number of HTTP requests that are required and helps maximize performance.

#### NOTE

Some APIs might not support batching on their side. So when you create a batch data action, you should confirm that the service that you're using can support the action.

# Create an observable data action

2/18/2021 • 3 minutes to read • [Edit Online](#)

This topic describes how to create an observable data action in Microsoft Dynamics 365 Commerce.

## Overview

Observable data actions are used to track the status of a data action as it's running. This capability is helpful if you must run logic or render a user interface (UI) in response to the current status of a data action. Observable data actions use a special promise-like class that is named **AsyncResult**. This class adds "observer" functionality to a standard promise.

The following example shows how to take advantage of an **AsyncResult** class. This data action waits three seconds before it returns a string.

```
// test-action.ts
/**
 * Test action method for TestAsync action
 * @param input The action input
 * @param context The action context
 */
const testAction = async (input: TestAsyncActionInput, context: IActionContext): Promise<string> => {
  await new Promise(resolve => {
    setTimeout(
      () => {
        resolve();
      }, 3000);
  });

  // Flag-based error scenario
  if (input.shouldError) {
    throw new Error('Oops');
  }
  return 'foo';
};

/**
 * Test Action Input
 */
export class TestAsyncActionInput implements IActionInput {
  public shouldError: Boolean = false;
  constructor(shouldError?: Boolean) {
    this.shouldError = shouldError || this.shouldError;
  }
  public getCacheKey = () => `test`;
  public getCacheObjectType = () => 'test';
  public dataCacheType = (): Msdyn365.CacheType => 'none';
}

/**
 * Test createInput method for TestAsync Action
 */
const createInput = () => {
  return new TestAsyncActionInput();
};
```

In this example, the data action simulates an outgoing application programming interface (API) call. It also includes a flag that can be set to allow a failure simulation. In some scenarios, you might want to create a

module that can send updates about the status of a data action. You can't use a regular data action for that purpose.

## Create the observable data action

To create the observable data action, use the new `createObservableDataAction` utility method for data action creation.

```
export default createObservableDataAction({
  input: createInput,
  action: <IAction<string>>testAction
});
```

The `createObservableDataAction` method is equivalent to the `createDataAction` method, but returns an `IObservableAction` interface instead of an `IAction` interface. The `IObservableAction` interface returns an `AsyncResult` class instead of the `Promise` class that a standard `IAction` interface returns. The `AsyncResult` class provides additional data including the `status` and `error` properties of the data action.

A mock can be created to test the data action, as shown in the following example.

```

// test-module.tsx
import { observer } from 'mobx-react';
import * as React from 'react';
import { IAsyncTestModuleData } from './async-test-module.data';
import { IAsyncTestModuleProps } from './async-test-module.props.autogenerated';
import testAction, { TestAsyncActionInput } from './actions/async-test-action';

/**
 * TestModule Component
 * @extends {React.PureComponent<IAsyncTestModuleProps<IAsyncTestModuleData>>}
 */
@observer
class AsyncTestModule extends React.PureComponent<IAsyncTestModuleProps<IAsyncTestModuleData>> {
  constructor(props: IAsyncTestModuleProps<IAsyncTestModuleData>) {
    super(props);
  }
  public render(): JSX.Element {
    return (
      <div className='row'>
        <div className='col'>
          <h1>Status: { this.props.data.testResult.status }</h1>
          <h1>Result: { this.props.data.testResult.result }</h1>
          { this.props.data.testResult.error &&
            <h1>Error: { this.props.data.testResult.error.message }</h1>
          }
          <button
            // tslint:disable:jsx-no-lambda
            // tslint:disable-next-line:react-this-binding-issue
            onClick={(e) => this._clientCall(e)}
          > Run on client
          </button>
          <button
            // tslint:disable:jsx-no-lambda
            // tslint:disable-next-line:react-this-binding-issue
            onClick={(e) => this._clientCall(e, true)}
          > Error on client
          </button>
        </div>
      </div>
    );
  }
}
export default AsyncTestModule;

```

The following example shows a sample module definition that registers the sample observable data action that was created earlier.

```

// test-module.definition.json
{
  "$type": "contentModule",
  "friendlyName": "test-module",
  "name": "test-module",
  "description": "Module for testing observable data actions",
  "categories": ["test-module"],
  "tags": ["samples"],
  "dataActions": {
    "testResult": {
      "path": "./actions/test-action",
      "runOn": "client"
    }
  }
}

```

When adding a data action inside the module data.ts file, ensure that every data action that returns an

**observableDataAction** object is wrapped by an **AsyncResult** class. This will guarantee the correct typings when a module is written.

```
// test-module.data.ts
import { AsyncResult } from '@msdyn365-commerce/retail-proxy';
export interface IAsyncTestModuleData {
  testResult: AsyncResult<string>;
}
```

When a data action is wrapped in an **AsyncResult** class (as in the above example), the module will now have access to the **status**, **result**, and **error** properties. The **status** property contains the current state of the data action, which can be one of: **'Success'**, **'Loading'** or **'Failed'**. The **result** property contains the data that is returned by the action if it succeeds. If the data action throws an error, the **result** property won't be filled in. Instead, the **error** property can be used to see the error details.

By taking advantage of the **status**, **result**, and **error** properties that are provided by observable data actions, complicated scenarios can be better handled in a module. Examples include showing a loading screen while a data action call runs and providing contextual error messages in response to a failed data action.

# Share state across modules

2/18/2021 • 4 minutes to read • [Edit Online](#)

This topic describes how to share state across multiple modules by using data actions in Dynamics 365 Commerce.

## Overview

Data actions perform the important role of state management in situations where you must share state across multiple modules on the same page. In general, state is shared within the application state of the running Node application.

## Examples

In this example, two modules share basic interaction. One module (**sample-button**) has a button, and the other module (**sample-message**) shows a message when that button is selected.

First, you must have a data action that returns an object that contains the number of times that the button has been selected. Here is what the code looks like.

```

// sample-state.ts
import { CacheType, createObservableDataAction, IAction, IActionContext, IActionInput, IAny,
ICreateActionContext, IGeneric } from '@msdyn365-commerce/core';
export interface ISampleState {
  clickCount: number;
}

/**
 * SampleState - action input
 */
export class SampleStateInput implements IActionInput {
  public getCacheKey = () => `SampleState`;
  public getCacheObjectType = () => 'SampleState';
  public dataCacheType = (): CacheType => 'request';
}

/**
 * SampleState - action
 */
export async function sampleStateAction(input: SampleStateInput, ctx: IActionContext): Promise<ISampleState>
{
  return { clickCount: 0 };
}

/**
 * SampleState - create new input for create action
 */
const createInput = (inputData: ICreateActionContext<IGeneric<IAny>>): IActionInput => {
  return new SampleStateInput();
};

/**
 * SampleState - create action
 */
export default createObservableDataAction<ISampleState>({
  action: <IAction<ISampleState>>sampleStateAction,
  input: createInput
});

```

In its current state, this data action has no implementation. It just creates a place to store an object in the cache. Because the two modules in this example must communicate with each other, it's helpful if they both observe this object. To give modules access to this object, you must make sure that the modules register the data action that you created earlier as a page load data action.

Here is the code for the **sample-button** module.

```

// sample-button.definition.json
{
  "$type": "contentModule",
  "friendlyName": "Sample Button",
  "name": "sample-button",
  "description": "Sample Button",
  "categories": ["sample-button"],
  "tags": ["samples"],
  "module": {
    "view": "./sample-button",
    "dataActions": {
      "sampleState": {
        "path": "../..actions/sample-state/sample-state"
      }
    }
  }
}

```

Here is the code for the **sample-message** module.

```
// sample-message.definition.json
{
  "$type": "contentModule",
  "friendlyName": "Sample Message",
  "name": "sample-message",
  "description": "Sample Message",
  "categories": ["sample-message"],
  "tags": ["samples"],
  "dataActions": {
    "sampleState": {
      "path": "../actions/sample-state/sample-state"
    }
  }
}
```

Both modules are now registered to the data action. Therefore, they both observe the same object in the application state. The next step is to update the application state when the **sample-button** module has a user click event. All modules that observe the application state should then be automatically updated. Here is the code for the **sample-message** module.

```
// sample-message.data.ts
import { AsyncResult } from '@msdyn365-commerce/retail-proxy';
import { ISampleState } from '../actions/sample-state/sample-state';
export interface ISampleMessageData {
  sampleState: AsyncResult<ISampleState>;
}
```

```
// sample-message.tsx
import * as React from 'react';
import { ISampleMessageData } from './sample-message.data';
import { ISampleMessageProps } from './sample-message.props.autogenerated';

/**
 * SampleMessage Module used for showcasing cross-module communication
 * @extends {React.Component<ISampleMessageProps<ISampleMessageData>>}
 */
export default class SampleMessage extends React.Component<ISampleMessageProps<ISampleMessageData>> {
  constructor(props: ISampleMessageProps<ISampleMessageData>) {
    super(props);
  }
  public render(): JSX.Element {
    if(this.props.data.sampleState.result) {
      return (<h3>The Button has been clicked {this.props.data.sampleState.result.clickCount} times.
</h3>>);
    }
    return (<h3>Error: No Sample State Detected</h3>>);
  }
}
```

The **sample-message** module is very straightforward. It asks for the **ISampleState** value by using a page load data action. Then, based on the data that is returned, it renders a simple message. Because the application state is internally powered by **MobX**, this module can automatically react when the data that it's observing changes.

Finally, here is the code for the **sample-button** module that updates the application state in response to on a user click event.

```

// sample-button.data.ts
import { AsyncResult } from '@msdyn365-commerce/retail-proxy';
import { ISampleState } from '../actions/sample-state/sample-state';
export interface ISampleButtonData {
  sampleState: AsyncResult<ISampleState>;
}

```

```

// sample-button.tsx
import * as React from 'react';
import { ISampleButtonData } from './sample-button.data';
import { ISampleButtonProps } from './sample-button.props.autogenerated';
import { SampleStateInput } from '../actions/sample-state/sample-state';

/**
 * SampleButton component used for showcasing cross-module communication
 * @extends {React.Component<ISampleButtonProps<ISampleButtonData>>}
 */
export default class SampleButton extends React.Component<ISampleButtonProps<ISampleButtonData>> {
  constructor(props: ISampleButtonProps<ISampleButtonData>) {
    super(props);
    this._onClick.bind(this);
  }
  public render(): JSX.Element {
    return (
      <button onClick={this._onClick}>
        Click Me!
      </button>
    );
  }

  // onClick Handler should update application state
  private _onClick = (e: React.MouseEvent): void => {
    if (this.props.data.sampleState.result) {
      // This will directly update our application state, which should trigger all modules observing
      the state to update
      this.props.context.actionContext.update(new SampleStateInput(), { clickCount:
this.props.data.sampleState.result.clickCount + 1 });
    }
  }
}

```

As you can see, the `onClick` handler makes a call to the `actionContext.update()`. This method lets you directly change the application state. When the state is changed, MobX takes over and re-renders all the modules that are observing the state that includes the `sample-message` module.

# Data action cache settings

2/18/2021 • 6 minutes to read • [Edit Online](#)

This topic covers cache settings for data actions in Microsoft Dynamics 365 Commerce.

The software development kit (SDK) \src\settings\cache.settings.json file holds cache settings for entities that are returned from data actions calls. After these entities are cached, they are returned from the cache for all data action requests that have the same cache key, provided that their time to refresh (TTR) and time to live (TTL) values are valid.

For core data actions that are provided in the SDK, the cache key is implicitly set within the data action itself. (For information about how to determine the cache key from the SDK, see the [Determine cache keys for data actions](#) section later in this topic.) For custom data actions, the cache key can be defined in the action input by overriding the `getCacheKey()` method.

For all entities, the default TTR is 60 seconds, and the default TTL is 600 seconds.

The following example shows a JavaScript Object Notation (JSON) file that includes a section for TTR and TTL settings. Each section contains name of the entity for the data action's cache key followed by the time in seconds.

```
{
  "ttlInSeconds": {
    "AttributeValue": 1800,
    "Category": 1800,
    "CategoryHierarchy": 1800,
    "ChannelConfiguration": 1800,
    "FullProduct": 1800,
    "ProductRating": 1800,
    "OrgUnit": 1800,
    "ProductCatalog": 1800,
    "SimpleProduct": 1800
  },
  "ttrInSeconds": {
    "AttributeValue": 900,
    "Category": 900,
    "CategoryHierarchy": 1800,
    "ChannelConfiguration": 1800,
    "FullProduct": 900,
    "OrgUnit": 1800,
    "Product": 900,
    "ProductCatalog": 300,
    "ProductDimensionValue": 900,
    "ProductRating": 900,
    "SimpleProduct": 900
  }
}
```

## Determine cache keys for data actions

You can find the data cache key for a specific core data action by looking at the source code under the SDK \node\_modules\@msdyn365-commerce-modules\retail-actions\dist\lib directory.

For example, to find the code for the "get-simple-products" data action, look in the get-simple-products.js file. By examining the source code of this file in the following example, you can find the entity name **SimpleProduct**. You can then add this entity to the JSON file for cache settings in the previous example.

```

...
export class ProductInput {
  constructor(productId, apiSettings, channelId) {
    this.getCacheKey = () => buildCacheKey(`RecordId-${this.productId.toString()}`, this.apiSettings);
    this.getCacheObjectType = () => 'SimpleProduct';
    this.dataCacheType = () => 'application';
    this.apiSettings = apiSettings;
    this.productId = +productId;
    this.channelId = channelId || apiSettings.channelId;
  }
}
...

```

## Cache settings for specific entities

The following table provides cache setting descriptions for specific data action cache key entities.

ENTITY	DESCRIPTION
AttributeValue	Contains the metadata of the product attributes information shown on a product details page. For better performance, and to reduce round trips to Retail Server, we recommended that you cache the entity with optimum TTR and TTL values. Longer TTR affects the freshness of the product attributes shown. For information about the APIs returning this entity, see <a href="#">Products controller</a> .
Category	Contains the metadata of the category information shown in a navigation module. For better performance, and to reduce round trips to Retail Server, it is recommended to cache the entity with optimum TTR and TTL values. Longer TTR affects the freshness of the category information shown. For information about the APIs returning this entity, see <a href="#">Categories controller</a> .
CategoryHierarchy	Contains the metadata of the hierarchy of available categories shown in a navigation module. For better performance, and to reduce round trips to Retail Server, we recommended that you cache the entity with optimum TTR and TTL values. Longer TTR affects the freshness of the categories hierarchy information shown. For information about the APIs returning this entity, see <a href="#">Categories controller</a> .
OrgUnit	Contains metadata of the organization unit used in "buy online, pick up in store" (BOPIS) scenarios and the store locator module. For better performance, and to reduce round trips to Retail Server, we recommended that you cache the entity with optimum TTR and TTL values. For information about the APIs returning this entity, see <a href="#">Org units controller</a> .
ProductDimensionValue	Contains the metadata of the product dimensions information shown on a product details page. For better performance, and to reduce round trips to Retail Server, we recommended that you cache the entity with optimum TTR and TTL values. Longer TTR affects the freshness of the product dimensions shown. For information about the APIs returning this entity, see <a href="#">Products controller</a> .

ENTITY	DESCRIPTION
ProductList-Recommendations	Contains the list of recommended products on a homepage or product details page. For better performance, and to reduce round trips to Retail Server, we recommended that you cache the entity with optimum TTR and TTL values. Longer TTR affects the freshness of the product list recommendations.
ProductList-RelatedProducts	Contains the list of related products, shown on product details page. For better performance, and to reduce round trips to Retail Server, we recommended that you cache the entity with optimum TTR and TTL values. Longer TTR affects the freshness of the related products.
ProductRating	Contains the metadata of the product rating information shown on a product details page. For better performance, and to reduce round trips to Retail Server, we recommended that you cache the entity with optimum TTR and TTL values. Longer TTR affects the freshness of the product rating information shown. For information about the APIs returning this entity, see <a href="#">Products controller</a> .
ProductRefiner	Contains the metadata of the product refiners shown on a product list page. For better performance, and to reduce round trips to Retail Server, we recommended that you cache the entity with optimum TTR and TTL values. Longer TTR affects the freshness of the product refiners shown. For information about the APIs returning this entity, see <a href="#">Products controller</a> .
ProductSearchResult	Contains the metadata of the product search results shown on a product list page. For better performance, and to reduce round trips to Retail Server, we recommended that you cache the entity with optimum TTR and TTL values. Longer TTR affects the freshness of the product list in search results. For information about the APIs returning this entity, see <a href="#">Products controller</a> .
SimpleProduct	Contains the metadata of the product shown on a product details page. For better performance, and to reduce round trips to Retail Server, we recommended that you cache the entity with optimum TTR and TTL values. Longer TTR affects the freshness of the product information shown. For information about the APIs returning this entity, see <a href="#">Products controller</a> .

## Inline cache options

The Dynamics 365 Commerce online SDK's data action layer provides flexibility for controlling how a data action response should be cached and what its scope should be (application or request). For all custom data actions, the cache type can be defined as part of the [action input](#). A common scenario is for data actions to invoke a Retail Server proxy data action, or module business logic that will invoke a Retail Server proxy data action. An example of such a scenario would be when a user selects a "find store" button. For these scenarios, a module can set the "bypassCache" option on the action context when invoking the Retail Server proxy data action. This setting tells the SDK to honor the module's given cache preferences. For more information about Retail Server proxy data actions, see [Call Retail Server APIs](#).

Supported values for bypassCache are:

- **get** - Ignores cache while performing read and fetches the latest information from Retail Server.
- **none** - Action response is cached per request. If `byPassCache` is not specified runtime defaults to this value.

In general, for custom data actions and Retail Server proxy actions that read data from Retail Server (calling APIs with names that start with "get," "search," or "read"), the value of "bypassCache" is set to "none" by default. For all other Retail Server proxy actions configured to fetch the latest data from Retail Server, the value of "bypassCache" is set to "get" by default. These values can be overridden if needed.

The following is an example of usage.

```
if (checkoutCartId) {
  try {
    checkoutCart = await readAsync({ callerContext: ctx, bypassCache: 'get' }, checkoutCartId);
  } catch {
    ctx.telemetry.error('Error getting checkout cart based on saved checkout cart ID');
    ctx.telemetry.exception(error);
  }
}
```

# Data action overrides

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic describes how to override default data actions with custom data actions in Dynamics 365 Commerce.

## Overview

The modules included with the Dynamics 365 Commerce software development kit (SDK) module library use pre-existing data actions to fetch data for the modules to use. There may be times when you want to use a custom data action to alter the business logic, but do not want to clone the module because you won't be changing the UX rendered by the module. With data action overrides, you can override the registered action by creating a new action with the same action ID. Overriding a data action will cause all previous uses of the data action, either through import or inclusion in the module definition.json file, to use your new data action.

## Data action ID naming convention

Each data action has a data action ID that's used when the `createObservableDataAction` method is called through the "id" property. The data action ID should follow the naming convention of `[package name]/[module name]/[action name]`, as in the following example.

```
export default createObservableDataAction({
  id: '@msdyn365-commerce-modules/retail-actions/get-address',
  action: <IAction<Address[]>>getAddressAction,
  input: <(args: ICreateActionContext) => IActionInput>createGetAddressInput
});
```

## Data action override example

To override the get-address data action, you need to create a new data action that uses the get-address ID in the `/src/actions` directory.

The following command creates a new data action in the `\src\actions` directory.

```
yarn msdyn365 add-data-action custom-get-address
```

Next, you replace the default template code with your code. In the example below, the data action ID is the same as used in the `...\Msdyn365.Commerce.Online\node_modules@msdyn365-commerce-modules\retail-actions\dist\lib\get-address.js` data action `@msdyn365-commerce-modules/retail-actions/get-address`.

```

import { CacheType, IAction, IActionContext, IActionInput, ICommerceApiSettings } from '@msdyn365-commerce/core';
import { createObservableDataAction, ICreateActionContext } from '@msdyn365-commerce/core';
import { Address } from '@msdyn365-commerce/retail-proxy';

import { readAsync } from '@msdyn365-commerce/retail-proxy/dist/DataActions/CustomersDataActions.g';

/**
 * Input class for the getAddress data action
 */
export class AddressInput implements IActionInput {
    public userAccountNumber: string;
    private apiSettings: ICommerceApiSettings;

    constructor(userAccountNumber: string, apiSettings: ICommerceApiSettings) {
        this.userAccountNumber = userAccountNumber;
        this.apiSettings = apiSettings;
    }

    public getCacheKey = () => this.userAccountNumber
    public getCacheObjectType = () => 'GetAddress';
    public dataCacheType = (): CacheType => 'request';
}

/**
 * createInput method for the getAddress method
 * @param inputData The input data passed to the createInput method
 */
export const createGetAddressInput = (inputData: ICreateActionContext): IActionInput => {
    const { requestContext } = inputData;
    if (!requestContext.user.isAuthenticated || !requestContext.user.customerAccountNumber) {
        throw new Error('Unable to create address input. User is not authenticated.');
```

# Data action hooks

2/18/2021 • 2 minutes to read • [Edit Online](#)

## IMPORTANT

The data action hooks feature has been deprecated. To avoid performance issues, we strongly recommend that you use [data action overrides](#) to modify business logic in the data action layer.

This topic describes how to hook into pre- and post- data action events to further process data if needed.

## Overview

The modules included with the Dynamics 365 Commerce software development kit (SDK) use pre-existing actions to fetch data for the modules to use. You may have scenarios where you want to change some business logic in the data action layer. In addition to support for data action overrides, the Commerce platform also has the ability to hook into pre- and post- data action events.

## Supported data action hook events

The following data action hook events are supported:

- **preHook**: Runs before the action starts to modify the data action input. This event is only applied to uncached data actions.
- **preReadOnlyHook**: Runs before the action starts but cannot modify the data action input. This event can be applied to both cached and uncached data actions.
- **postHook**: Runs after the data action completes and can modify the data action output. This event is only applied to uncached data actions.
- **postReadOnlyHook**: Runs after the data action completes but cannot modify the data action output. This event is supported on both cached and uncached data actions.

## Use data action hooks

To use a data action hook, you can leverage the **add-data-action** command-line interface (CLI) command to create the file. The following example creates a data action file named "get-address-hook.action.ts" under the "\\src\\actions" directory.

```
yarn msdyn365 add-data-action get-address-hook
```

Next, you replace the code in the data action file with the following template code and then add appropriate code to the event you are interested in.

```
import { createDataActionHook, IActionInput } from '@msdyn365-commerce/core';
// import { Cart } from '@msdyn365-commerce/retail-proxy';

const beforeCart = async (inputs: IActionInput | IActionInput[]) => {
  // tslint:disable-next-line: no-console
  console.info('Pre Hook');
};

const afterCart = async (_inputs: IActionInput | IActionInput[], cartName: string | string[]) => {
  // tslint:disable-next-line: no-console
  console.info('Post Hook');
};

const preReadOnlyCart = async (inputs: IActionInput | IActionInput[]) => {
  // tslint:disable-next-line: no-console
  console.info('Pre ReadOnly Hook');
};

const postReadOnlyCart = async (_inputs: IActionInput | IActionInput[], cartName: string | string[]) => {
  // tslint:disable-next-line: no-console
  console.info('Post ReadOnly Hook');
};

createDataActionHook({
  actionId: 'Action_ID',
  postHook: afterCart,
  preHook: beforeCart,
  preReadOnlyHook: preReadOnlyCart,
  postReadOnlyHook: postReadOnlyCart
});
```

#### NOTE

You'll need to change the **Action\_ID** to the data action ID you are adding event hooks to. The module library list of data actions can be found in the ...\\Msdyn365.Commerce.Online\\node\_modules@msdyn365-commerce-modules\\retail-actions\\dist\\lib directory of the SDK.

# Theming overview

2/18/2021 • 5 minutes to read • [Edit Online](#)

This topic presents an overview of online site theming in Microsoft Dynamics 365 Commerce.

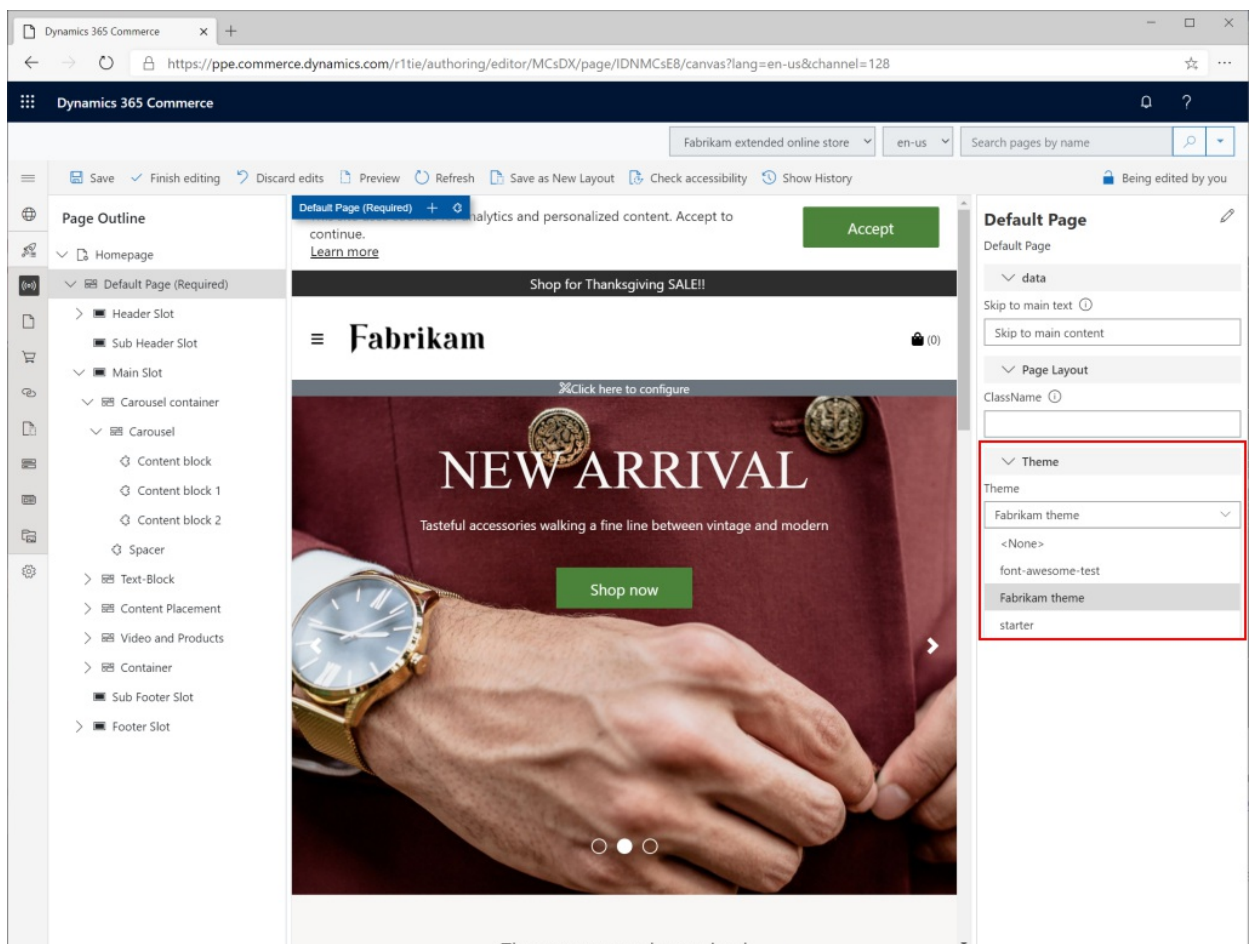

## Overview

Dynamics 365 Commerce lets you apply a theme to your whole online site, individual templates, or individual pages. For example, you might have a default theme that is set for the whole online site and a campaign theme that is applied to just a subset of the pages on the site.

Themes include Sassy Cascading Style Sheets (SCSS) files that you can use to format your site pages and modules. They can optionally also contain module view and definition extensions, so that modules can render different views, depending on the theme that is selected.

After a theme is created and uploaded to your production site, you can use the Commerce site builder tool to set the theme for the site. You can set the site's theme in a template, in a layout, or on a single page. When an online page is rendered, the appropriate theme is applied, so that all the modules on that page have a consistent look and feel. The site builder tool also lets you upload additional Cascading Style Sheets (CSS) overrides. In that way, you can make changes on top of the selected theme.

The following illustration shows how a theme is selected for a page in Dynamics 365 Commerce. Notice that the page container (**Default page**) is selected, and the **Theme** field for the page appears in the properties pane on the right.

The screenshot shows the Dynamics 365 Commerce site builder interface. The main content area displays a page titled "Default Page (Required)" with a promotional banner for "NEW ARRIVAL" featuring a watch. The banner includes the text "Tasteful accessories walking a fine line between vintage and modern" and a "Shop now" button. The left sidebar shows the "Page Outline" with various slots and containers. The right sidebar shows the "Default Page" properties pane, where the "Theme" field is highlighted with a red box, showing "Fabrikam theme" selected from a dropdown menu. Other options in the dropdown include "<None>", "font-awesome-test", and "starter".

A theme can be set on the master page in a similar manner. In this case, the theme is applied to all pages that are

derived from the master page. Note that if the **locked** property is turned off, individual pages can override the theme.

## General guidelines for creating a custom theme

- Create a new theme by using the `yarn msdyn365 add-theme NEW_THEME_NAME` command-line interface (CLI) command. This command will create a theme in the `/src/themes/` folder.
- Under the `styles` directory, you will find the SCSS entry point file for the theme. This file uses the naming pattern `THEME_NAME.theme.scss`.
- Themes are created as special modules. They contain definition files that include the theme's friendly name and description, and also a template React component.
- There is no limit to the number of `.scss` files that your theme can contain.
- Your theme entry point can import other `.scss` files by using relative paths.

## Best practices

- Module library modules are built by using Bootstrap 4 classes. Therefore, we recommend that every theme include either Bootstrap 4 or Bootstrap 4 RTL as the SCSS framework.
- If you want to take advantage of module library modules that are built by using Font Awesome glyph icons, you should include **font-awesome** in the SCSS file. The following example shows how to include **Bootstrap** and **font-awesome** in a SCSS file.

```
$fa-font-path: 'https://use.fontawesome.com/releases/v5.2.0/webfonts' !default;  
@import "bootstrap/scss/bootstrap";  
...
```

## Recommended structure for a custom theme

This section shows the recommended structure for any custom theme.

Import or define the following items:

- Fonts and glyph icons
- Mix-ins and functions:
  - **Bootstrap**: Dependencies, excluding components and utilities
  - **Shared components**: Dependencies, excluding components and utilities
  - Custom theme mix-ins and functions
- Theme variables:
  - Custom theme variables
  - **Bootstrap**: Default theme variables (fallbacks)
- SCSS for components and modules:
  - **Shared components**: Components
  - Custom components and modules
- Utilities:
  - Bootstrap, shared component, and custom utilities

## Hooks for module theming

For every module, a class name is defined that matches the module name. In this way, any theme can target the module. This class name should be the first class name that is applied to the outermost element that is rendered by the React component. To allow for more granular theme options, developers can provide additional class names on elements or features of a module. In that way, custom themes can target those elements or features.

## Custom themes

Custom themes can be created by using the Dynamics 365 Commerce online SDK. They can then be stored in the `/src/themes/` folder. For more information, see [Create a theme](#).

## RTL and LTR support within a theme

You may have requirements to support both right-to-left (RTL) and left-to-right (LTR) languages on your e-Commerce site. Themes support the ability to specify different RTL and LTR SCSS files.

### NOTE

RTL and LTR support within a theme is available in Dynamics 365 Commerce release 10.0.15.

Each theme has a `styles\THEME_NAME.theme.scss` file that is created using the `yarn msdyn365 add-theme` command-line interface (CLI) command. For example, using the command `yarn msdyn365 add-theme spring` to create a new theme called "spring" will create the file `"\src\themes\spring\styles\spring.theme.scss"`, which contains the SCSS code for the theme. SCSS files are compiled into CSS files when using the `yarn start` or `yarn pack` commands, and are then used to render site pages.

To support specific RTL or LTR versions of a SCSS file, you can provide additional files using the following file naming convention: `THEME_NAME.rtl.theme.scss` for RTL support and `THEME_NAME.ltr.theme.scss` for LTR support. When a page renders, the appropriate CSS file will be referenced according to the browser language setting. If you only need support for a single language, use the default `THEME_NAME.theme.scss` file.

## RTL and LTR best practices

Because the CSS code used in RTL and LTR layouts is generally the same except for a few properties, those differing properties can be specified in their respective "theme" files and a "base-style" file can be created to be shared (and imported) by both the RTL and LTR SCSS files.

- `THEME_NAME-rtl.theme.scss` - Contains specific properties for the RTL layout.
- `THEME_NAME-ltr.theme.scss` - Contains specific properties for the LTR layout.
- `base-style.scss` - Contains shared styles and is imported in the two `THEME_NAME` files.

# Create a new theme

2/18/2021 • 3 minutes to read • [Edit Online](#)

This topic describes how to create a new theme for a Microsoft Dynamics 365 Commerce online site.

## Overview

The Dynamics 365 Commerce online software development kit (SDK) lets you create custom themes that can be applied to your online site. They can also be shared across the sites in a single tenant if desired.

After a theme is created and uploaded to your sandbox or production environment, you can use Commerce site builder to set the theme on your site (or sites). Then, when an online page is rendered, the appropriate theme is applied. In this way, modules will have a consistent look and feel across site pages.

Themes contain Sassy Cascading Style Sheet (SCSS) files that you can use to style your online site and individual modules. They can also optionally contain the following extensions:

- Module view extensions that provide new layout views on a module
- Definition extensions to change a module's configurations

## Create a new theme

The online software development kit (SDK) provides the **add-theme** command-line interface (CLI) command. To create a new theme in Commerce, you run the command as shown in the following example, replacing **THEME\_NAME** with the name that you want to give to the new module.

```
yarn msdyn365 add-theme THEME_NAME
```

The following example shows how to create a theme that is named **spring**.

```
yarn msdyn365 add-theme spring
```

The new theme will be created in a new directory under the `...\src\themes` directory. For example, the `spring-time` theme is created under the `...\src\themes\spring` directory.

### Theme naming conventions

Theme names are case-insensitive. The theme's friendly name and description can be added to the theme definition file in the new theme directory.

## Theme definition file

A theme is created as a special module. Each theme has a theme definition file in JavaScript Object Notation (JSON) format that contains the theme's friendly name and description. The **\$type** property will be set to **"themeModule"**.

The following example shows a theme definition file.

```
{
  "$type": "themeModule",
  "friendlyName": "Spring theme",
  "name": "spring",
  "description": "This is default theme."
}
```

## Theme styles

SCSS files are stored under the `...\src\themes\THEME_NAME\styles` directory. By default, this directory includes a `THEME_NAME.theme.scss` file. This file is the entry point SCSS file. You can add other SCSS files and directories to the directory as you require.

For example, the file name and path of the `spring` theme might be `...\src\themes\spring\styles\spring.theme.scss`.

## Test a theme

You can easily test a theme in your development environment by using the `?theme=THEME_NAME` query string parameter.

To test your theme, follow these steps.

1. At a command prompt, under the directory of your local code repository, run `yarn start`.
2. In a web browser, load a module test page, and add the `?theme=THEME_NAME` query string parameter, as shown in the following example.

```
https://localhost:4000/modules?type=product-feature&theme=spring
```

If your `.env` file's `MSDyn365_HOST` entry points to your production site, you can also use the following URL to preview what your site looks like when a custom theme is applied.

```
https://localhost:4000?theme=spring
```

### Mock new configuration values in a theme

If new configuration fields are added to a module in a theme, mock data can be added to the module's mock file. For example, if you modify a module library module's view and definition files, you can add new configuration mocks to the module library mock files that are under the `...\node_modules\@msdyn365-commerce-modules` directory in the module library module.

In a similar way, if you're mocking data for a custom module, you can add new mock data in the module's mock JSON file. Alternatively, you can create new mock files under the same module mock directory.

# Configure theme settings

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic describes how to configure theme settings in Microsoft Dynamics 365 Commerce.

## Overview

The Dynamics 365 Commerce e-Commerce extensibility software development kit (SDK) lets theme designers specify various layouts for each module. Theme designers can then control specific layout options for images. The layouts are specified in the theme.settings.json file in /src/settings/src/settings.

## Example theme.settings.json file

The following example shows how module layouts that have specific size values for image settings can be added to the theme.settings.json file. Each layout will be exposed in the authoring tool when the module is configured. The **productFeature** module is configured so that it has two layouts: **layout1** and **layout2**. The **layout1** layout specifies height and width image settings for the **sm** and **lg** viewport sizes.

```

{
  "modules": {
    "productFeature": {
      "properties": {
        "layout1": {
          "friendlyName": "Default Layout",
          "description": "Default Hero Layout",
          "type": "layout",
          "properties": {
            "image": {
              "friendlyName": "Feature Image",
              "description": "Feature Image Settings",
              "type": "imageSizes",
              "properties": {
                "sm": {
                  "width": 767,
                  "height": 431
                },
                "lg": {
                  "width": 1259,
                  "height": 472
                }
              }
            }
          }
        },
        "layout2": {
          "friendlyName": "Banner Layout",
          "description": "Banner Layout without image",
          "type": "layout"
        }
      }
    }
  },
  "gridSettings": {
    "xs": 576,
    "sm": 576,
    "md": 768,
    "lg": 992,
    "xl": 1200
  }
}

```

Default grid breakpoint settings can also be set in the `theme.settings.json` file (see `gridSettings` in the preceding example).

# Configure theme style presets

2/18/2021 • 6 minutes to read • [Edit Online](#)

This topic explains how to add style variables that are known as style presets to custom themes in Microsoft Dynamics 365 Commerce site builder.

## Overview

A style preset is a stored set of all authorable style values across a site theme. Style presets can be used to immediately change the look of a site from within site builder. Style presets let site builder authors quickly change, preview, and activate a set of style values across their site, without having to use Cascading Style Sheets (CSS) or deploy new themes. Font styles, button styles, and site colors are typical examples of style variables that can be managed through style presets.

For more information about how style presets work in site builder, see [Work with style presets](#).

## Default style presets

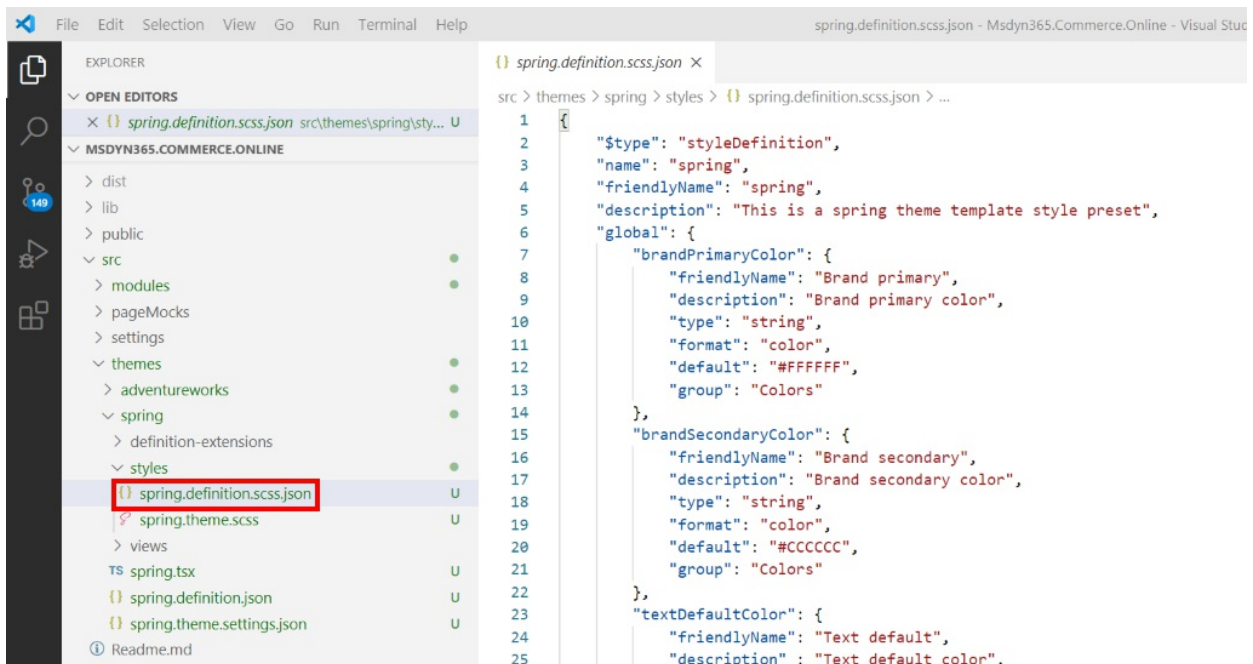

Themes that have authorable style presets must have a default style preset. They can also have additional optional preset settings that are known as preset instances. For example, a theme that has a default "modern light" style might also have optional preset instances such as "modern dark" and "vintage dark."

### Style preset definition files

Each theme contains a style presets definition file that provides metadata for site builder, such as the friendly name and description of the style preset. This definition file also includes the global and module-specific styles that will be available for customization in site builder.

When the **add-theme** [command line interface \(CLI\)](#) command is used to create a theme, a style preset definition file is automatically created under the theme's **styles** directory. The naming convention for the definition file is **THEME\_NAME.definition.scss.json**.

The following illustration shows an example (in Visual Studio Code) of a theme style definition file that was created by using the **add-theme** CLI command.

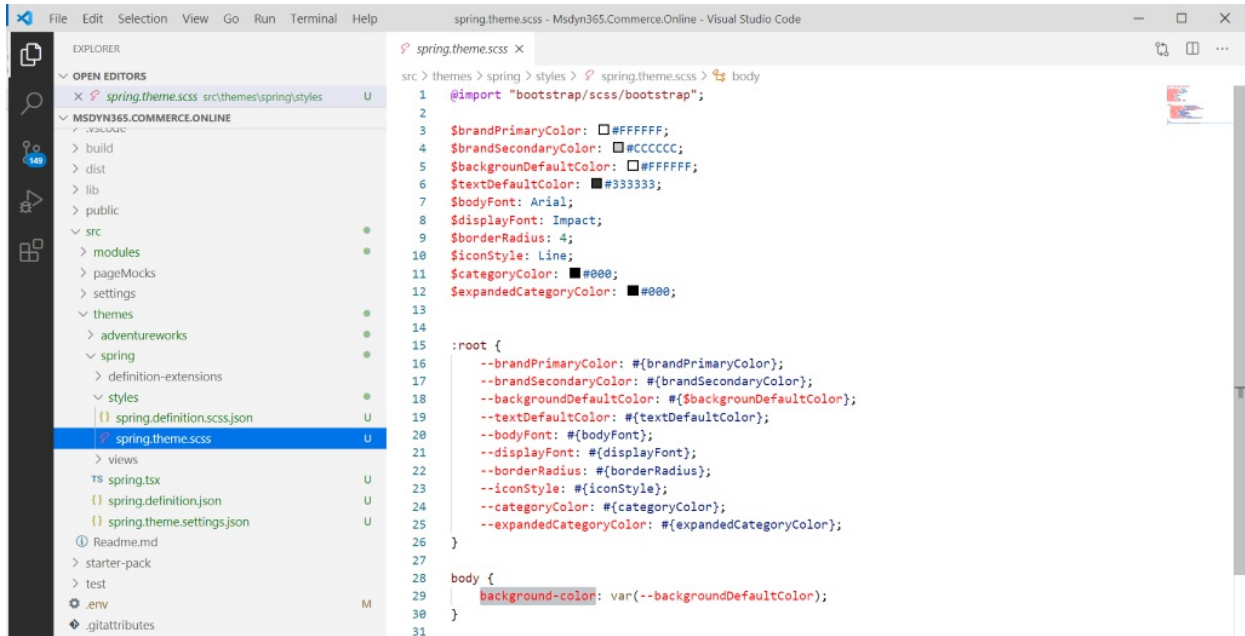

The screenshot shows the Visual Studio Code interface. On the left, the Explorer pane shows a project structure with a 'styles' directory containing a file named 'spring.definition.scss.json', which is highlighted with a red box. The main editor area displays the content of this file, which is a JSON object defining a style preset. The file content is as follows:

```
1 {
2   "$type": "styleDefinition",
3   "name": "spring",
4   "friendlyName": "spring",
5   "description": "This is a spring theme template style preset",
6   "global": {
7     "brandPrimaryColor": {
8       "friendlyName": "Brand primary",
9       "description": "Brand primary color",
10      "type": "string",
11      "format": "color",
12      "default": "#FFFFFF",
13      "group": "Colors"
14    },
15    "brandSecondaryColor": {
16      "friendlyName": "Brand secondary",
17      "description": "Brand secondary color",
18      "type": "string",
19      "format": "color",
20      "default": "#CCCCCC",
21      "group": "Colors"
22    },
23    "textDefaultColor": {
24      "friendlyName": "Text default",
25      "description": "Text default color",
```

Each style that is defined under the **global** and **module** sections should also be defined in the theme's Sassy CSS (SCSS) file. The naming convention for that file is **THEME\_NAME.scss**

In the example in the following illustration, SCSS variables have been defined for **brandPrimaryColor** in the **theme.scss** file. The default color is **#FFFFFF**. When the style preset is turned on, the color value is replaced with the default color value that is defined in the style preset definition file. Although both colors happen to be the same in this example, a site builder author can choose to override this property with any color. Modules that use this global SCSS variable will then automatically pick up the color change when the user applies the setting from within site builder.

```
1 @import "bootstrap/scss/bootstrap";
2
3 $brandPrimaryColor: #FFFFFF;
4 $brandSecondaryColor: #CCCCCC;
5 $backgroundDefaultColor: #FFFFFF;
6 $textDefaultColor: #333333;
7 $bodyFont: Arial;
8 $displayFont: Impact;
9 $borderRadius: 4;
10 $iconStyle: Line;
11 $categoryColor: #000;
12 $expandedCategoryColor: #000;
13
14
15 :root {
16   --brandPrimaryColor: #{brandPrimaryColor};
17   --brandSecondaryColor: #{brandSecondaryColor};
18   --backgroundDefaultColor: #{backgroundDefaultColor};
19   --textDefaultColor: #{textDefaultColor};
20   --bodyFont: #{bodyFont};
21   --displayFont: #{displayFont};
22   --borderRadius: #{borderRadius};
23   --iconStyle: #{iconStyle};
24   --categoryColor: #{categoryColor};
25   --expandedCategoryColor: #{expandedCategoryColor};
26 }
27
28 body {
29   background-color: var(--backgroundDefaultColor);
30 }
31
```

### Style preset definition schema

The following style preset definition schema is used for top-level section properties in the style presets definition file:

- **\$type** - The type of definition file. The value of this property must be **"styleDefinition"**.
- **name** – The name of the theme. This property must match the theme name in the theme definition file.
- **friendlyName** – The friendly name of the style preset. This name is shown in site builder when style presets are configured. The minimum length is three characters.
- **description** – The description of the style preset. The description provides a friendly string that is shown in site builder when style presets are configured.
- **global** – The **global** section is used to add style presets that are globally scoped across the theme. CSS property names are used as children of this node to define styles for the CSS style.
- **module** – The **module** section is used to add style presets for specific modules. Module names are used as children of this node to define module-specific style presets.

### Style preset property schema

The following style preset property schema is used for each style property that is defined in the **global** and **module** sections of the style presets definition file:

- **friendlyName** – The friendly name of the individual style preset property. This name is shown in site builder when style presets are configured. The minimum length is three characters.
- **description** – The description of the style preset property. The description provides a friendly string that is shown in site builder when style presets are configured.
- **type** – This property is used as metadata for site builder. The only supported value is **"string"**.
- **format** – This property provides extra metadata to site builder, so that it can present specific user experience (UX) configuration scenarios. This property is optional and currently supports only the value **"color"**, which

is used to open the color picker in site builder.

- **default** – The default CSS style value that is set for this property.
- **group** – This property is used to group similar properties in site builder.
- **enum** – This property is optional and provides a set of hard-coded values that site builder authors can select among.

## Style preset instances

Together with the default style preset settings, a theme can contain one or more optional style preset instances. To create a preset instance file, you must manually create additional style preset definition files under the **styles** directory. The contents of these style preset definition files resemble the contents of the default style preset definition file. However, the default values for the properties in the **global** and **module** sections typically differ. The naming convention for the preset instance file is **PRESET\_INSTANCE\_NAME.scss.json**.

The following example shows a style preset instance file for a dark theme. The file name is **modern-dark.scss.json**.

### NOTE

The value of the **name** property must be unique. It must differ from the name of the default theme and other style preset instances.

```

{
  "$type": "styleDefinition",
  "name": "modern-dark",
  "friendlyName": "modern dark",
  "description": "This is a spring modern light theme template style preset",
  "global": {
    "brandPrimaryColor": {
      "friendlyName": "Brand primary",
      "description": "Brand primary color",
      "type": "string",
      "format": "color",
      "default": "#AAAAAA",
      "group": "Colors"
    },
    "brandSecondaryColor": {
      "friendlyName": "Brand secondary",
      "description": "Brand secondary color",
      "type": "string",
      "format": "color",
      "default": "#CCCCCC",
      "group": "Colors"
    },
    "textDefaultColor": {
      "friendlyName": "Text default",
      "description": "Text default color",
      "type": "string",
      "format": "color",
      "default": "#555555",
      "group": "Colors"
    },
    "backgroundDefaultColor": {
      "friendlyName": "Background default",
      "description": "Background default color",
      "type": "string",
      "format": "color",
      "default": "#000000",
      "group": "Colors"
    },
    ...
  }
}

```

## Localize style preset names and descriptions

Property names and descriptions for the style preset and style preset instance files can be localized by using the **themes** node in the global.json file. The process resembles the process for localizing the module config properties. For more information, see [Localize a module](#).

The following example shows a global.json file that sets various localized style preset properties.

```

{
  "settings" : {...},
  "modules" : {...},
  "themes" : {
    "spring": {
      "friendlyName": {
        "value": "Spring",
        "_value.comment": "Spring theme name"
      },
      "description": {
        "value": "This is the spring theme.",
        "_value.comment": "Spring theme description"
      },
      "styles": {
        "definition": {
          "description": {

```

```

        "value": "This is the Spring theme style preset",
        "_value.comment": ""
    },
    "global": {
        "brandPrimaryColor": {
            "friendlyName": {
                "value": "Primary brand color",
                "_value.comment": ""
            },
            "description": {
                "value": "The primary brand color used across the site.",
                "_value.comment": ""
            },
            "group": {
                "value": "Colors",
                "_value.comment": ""
            }
        },
        "HeaderFontSize": {
            "friendlyName": "Header text size",
            "description": "This is the text default size for header elements",
            "type": "string",
            "enum": {
                "5px": "Small",
                "10px": "Medium",
                "15px": "Large"
            },
            "group": "Typography"
        }
    },
    "modules"
        "header": {
            "categoryColor" : {
                "friendlyName": {
                    "value": "Header background",
                    "_value.comment": ""
                },
                "description": {
                    "value": "This is the background color for the module",
                    "_value.comment": ""
                },
                "group": {
                    "value": "Color",
                    "_value.comment": ""
                }
            }
        }
    },
    "presets": {
        "dark-theme": {
            "description": {
                "value": "This is the dark theme style preset",
                "_value.comment": ""
            }
        },
        "light-theme": {
            "description": {
                "value": "This is the dark theme style preset",
                "_value.comment": ""
            }
        }
    }
}

```

# Extend a theme to add module extensions

2/18/2021 • 6 minutes to read • [Edit Online](#)

This topic describes how to extend a theme to add module extensions in Microsoft Dynamics 365 Commerce.

## Overview

Dynamics 365 Commerce e-Commerce themes can optionally contain the following module extensions to either the set of modules in the Commerce module library or custom modules:

- Module view extensions that provide new layout views on a module
- Definition extensions that change a module's configurations
- Data action extensions that call additional data actions

## Theme module view extensions

Themes let you include customized module view extensions, which are generally used to change the default layout of a module for a selected theme. These customized module view extensions are supported for both module library modules and custom modules. For example, you might want to add a new button to a module library module to support additional features. By creating a view extension, you can avoid having to use the `clone` command-line interface (CLI) command to create a full copy of the module library module. In some cases, you might want to extend the module definition, and also add more configuration properties, slots, or resources. For more information about how to create module view extensions, see the [Create a module view extension](#) section of this topic.

View extensions are stored under the `...\src\themes\THEME_NAME\views` directory and follow a naming pattern that resembles the naming pattern for module views (`MODULE_NAME.view.tsx`). For example, a view extension might be named `product-feature.view.tsx`. If a view extension exists in the selected theme, the React component will call it instead of the default view file. Therefore, view extensions can be written exactly like a module view that is used for a module.

In general, you might want to examine the existing view file for one of the module library modules before you create a new view on it. You might also want to copy and paste additional code into the existing view file. To view the source code of a module library module view, open the `...\node_modules\@msdyn365-commerce-modules` directory, and look for the module that you're interested in. You might have to fix the file path references for relative path imports.

### Create a module view extension

The online software development kit (SDK) provides the `add-view-extension` CLI command. To create a new module view extension in Commerce, you run the command `yarn msdyn365 add-view-extension THEME_NAME MODULE_NAME`, replacing `THEME_NAME` with the name of the theme that you want to add the view extension to and `MODULE_NAME` with the name of the module that you're extending.

For example, run the following command to add a new file that is named `product-feature.view.ts` under the `spring-theme` theme's view directory.

```
yarn msdyn365 add-view-extension spring product-feature
```

The following example shows a view file extension that was created by using the preceding command.

```
import * as React from 'react';
import { ISampleModuleViewProps } from '../../modules/product-feature/./product-feature';

export default (props: IProductFeatureViewProps) => {
  return (
    <div className='row'>
      <h2>Config Value: {props.config.showText}</h2>
      <h2>Resource Value: {props.resources.resourceKey}</h2>
    </div>
  );
};
```

## Theme definition extensions

You might have scenarios where you must extend the **config**, **slots**, **dataActions**, or **resources** section of a module definition, and then access those sections from the module view extension. Although you can add new configurations, slots, and resources, you can't modify existing ones. However, by using a **disableConfigProperties** section, you can disable the inheritance of some configurations.

Definition extensions are stored under the **definition-extensions** folder. They follow the naming pattern **MODULE\_NAME.definition.ext.json**, where **MODULE\_NAME** is the name of the module that you're extending.

### Create a module definition extension

To create a new definition extension, create a new file under the **/src/themes/THEME\_NAME/definition-extensions** folder that matches the module that you're extending. For example, the path of a definition extension might be **/src/themes/spring-theme/definition-extensions/product-feature.definition.ext.json**.

The following example shows a theme definition extension file where several configurations, slots, and resources have been added, in addition to a new data action. Notice that the **\$type** property must be set to **"definitionExtension"**. In the definition file, you can declare new properties under the **dataActions**, **config**, **slots**, and **resources** nodes, as shown in this example.

```

{
  "$type": "definitionExtension",
  "dataActions": {
    "products": {
      "path": "@msdyn365-commerce-modules/retail-actions/dist/lib/get-simple-products",
      "runOn": "server"
    },
    "cartNameExtension": {
      "path": "../../actions/cart-extension.action",
      "runOn": "server"
    }
  },
  "config": {
    "subTitle": {
      "type": "string",
      "friendlyName": "Sub Title",
      "description": "Sub Title for additional information"
    },
    "favoriteIcon": {
      "type": "image",
      "friendlyName": "Favorite icon",
      "description": "Favorite icon"
    },
    "favoriteIconSettings": {
      "friendlyName": "Favorite icon Settings",
      "description": "Image settings for the favorite icon property",
      "type": "imageSettings"
    }
  },
  "slots": {
    "content": {
      "friendlyName": "Content Slot",
      "description": "This is the content slot",
      "allowedCategories": ["container"],
      "max": 10,
      "min": 0
    }
  },
  "resources": {
    "recommendedLocations": {
      "value": "Recommended Locations"
    }
  },
  "disableConfigProperties": ["subTitle", "imageAlignment"]
}

```

The `disableConfigProperties` section can be used to define configuration fields that should be disabled. Configuration fields that have been disabled don't appear as configurable options in Commerce site builder for the selected module when the theme is set.

When the `yarn start` command is run, a new props file is automatically generated and appears in the definition extension directory. This file includes the merge of the parent module and the extended module, based on the properties and rules that are defined in the definition extension file.

If you're using a definition extension together with a module view extension, you must add the reference to the new automatically generated file in your view file to take advantage of the new definition changes.

The following example shows the addition of the new automatically generated file. This example also imports the module data file if it's required.

```

import * as React from 'react';
import { IProductFeatureViewProps } from '../../modules/product-feature/./product-feature';
import { IProductFeatureProps } from '../../definition-extensions/product-feature.ext.props.autogenerated';

export default (props: IProductFeatureViewProps & IProductFeatureProps<{}>) => {
  return (
    <div className='row'>
      <h2>Config Value: {props.config.showText}</h2>
      <h2>New Config SubTitle Value: {props.config.subTitle}</h2>
      <h2>Resource Value: {props.resources.resourceKey}</h2>
    </div>
  );
};

```

## Data action extensions

After a theme is selected, any additional data actions that are added to the module theme definition extension file are triggered when pages that use the module are loaded. Any data actions that are added to a module theme extension are called before data actions that are defined on the original module.

The return data from a data action call must be declared in a **THEME\_NAME.data.ts** file under the theme's **/views** directory. The following example shows the file structure of a theme that calls a data action that is named **cart-extension.action**. Notice that the new data action is included in the **actions** folder. The example definition extension file that was shown earlier includes an additional data action, **cart-extension**, that is called by using a relative path from within the **\*.definition.ext.json** file.

```

src
├── __actions
│   └── __cart-extension.action.ts
├── __modules
├── __themes
│   └── __spring
│       └── __definition-extensions
│           └── __product-feature.definition.ext.json
│               └── __styles
│                   └── __view
│                       └── __product-feature.data.ts
│                           └── __product-feature.view.tsx

```

Data that is returned from a data action must be assigned to a variable that is declared in the **MODULE\_NAME.data.ts** file under the **views** directory. The name of the variable must match the name that is provided in the **dataAction** section of the module definition extension file. In the following example, notice that the variable name **cartNameExtension** matches the variable name that is provided in the example definition extension file that was shown earlier.

```

import { AsyncResult } from '@msdyn365-commerce/retail-proxy';

export interface ICartExtensionData {
  cartNameExtension: AsyncResult<string>;
  products: AsyncResult<SimpleProduct>[];
}

```

To consume the data that is returned from the new data action, the module view file can now import the new interface, as shown in the following example for **product-feature.view.tsx**.

```
import * as React from 'react';
import { ICartExtensionData } from './product-feature.data';
import { IProductFeatureViewProps } from '../../modules/product-feature./product-feature';
import { IProductFeatureProps } from '../definition-extensions/product-feature.ext.props.autogenerated';

export default (props: IProductFeatureViewProps & IProductFeatureProps<ICartExtensionData>) => {
  return (
    <div className='row'>
      <h2>Config Value: {props.config.showText}</h2>
      <h2>New Config SubTitle Value: {props.config.subTitle}</h2>
      <h2>Resource Value: {props.resources.resourceKey}</h2>
      <h2>Cart Extension Value: {props.data.cartName}</h2>
    </div>
  );
};
```

# Override a module library component in a theme

2/18/2021 • 3 minutes to read • [Edit Online](#)

This topic describes how to override module library components to allow for customizations in a theme.

## Overview

The Microsoft Dynamics 365 Commerce module library contains a set of TypeScript components that various module library modules use, and that can be overridden. These components consist of helper APIs that contain business logic and other logic to help render the HTML for the module HTML, handle events, and make server-side calls.

If you must change any logic in a component, you can use the command-line interface (CLI) [add-component-override](#) command to override the component for a selected theme. For example, if you want to change the logic for strikethrough pricing, you can override the Price component. Other changes, such as [module view overrides](#), can also be used for visual changes. In rare cases, you might have to [clone a module](#) to make all the changes that you require.

## Component list

To get a list of components, you can use the following CLI command.

```
yarn msdyn365 add-component-override --list-components
```

Component source code can be found under `\node_modules\@msdyn365-commerce\components\src\` inside the directory for the online software development kit (SDK) that is installed. You might want to browse the source code to see what options are available in each component.

The following table lists the components that included as part of the module library. The components might vary, depending on the version of the module library that you use.

COMPONENT	DESCRIPTION
AddToCart	This component is used to add a product to the cart. It works in combination with the cart state that is present in the global state package. This component is rendered as a button on a product details page (PDP). When the button is selected, it validates the inventory check for the product and calls the Retail Server addcartline API to add the product to the cart.
AddToWishlist	This component is used to add a product to, or remove a product from, the wishlist. It works in combination with the wishlist state that is present in the global state package. This component renders the user interface (UI) for the add/remove wishlist button. It also handles the onclick event. The onclick event will ensure that the user is signed in.

COMPONENT	DESCRIPTION
CartIcon	This component is used to render the HTML to show the cart icon in the header module. When the cart icon is selected, this component opens the cart page. The module library also has a CartIcon module that is separate from this component. If the CartIcon module isn't configured in a header module, this component is used as a fallback.
CartLineItem	This component is used to render the HTML to show a single line item in the cart. It consists of a product image, the product details that are selected in the buy box module on the PDP, the product quantity, and the product price with discounts.
Price	This component is used to render the HTML to show the product price across the site in the correct format. It doesn't make any API calls.
Product	This component is used to render the HTML to show the products in a card format across the site. It consists of a product image, title, description, price, and rating.
PromoCode	This component is used to apply promotional codes or discount codes to the cart. It works in combination with the cart state that is present in the global state package to apply or remove a promotion in the cart.
Rating	This component is used to render the HTML to show the product rating across the site. It doesn't make any API calls. This component also handles the click event to update the rating.
SocialMedia	This component is used to render the social media icons for sharing a product from the buy box module. It currently supports Facebook, LinkedIn, Mail, Pinterest, and Twitter.
WishlistIcon	This component is used to render the HTML to show the wishlist icon in the header module. It also handles the click event to open the wishlist page.

## Override a component in a theme

To override a component in a theme, you can run the following CLI command: `yarn msdyn365 add-component-override [themeName] [componentName] [--list-components]`. After this command is run, you should find a new TypeScript file under the theme's `\view\components` directory. You can then modify the file in that directory as you require.

### Example

```
yarn msdyn365 add-component-override spring add-to-cart
```

# Extend a theme from a base theme

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic describes how to extend a theme from a base theme for a Microsoft Dynamics 365 Commerce online site.

## Overview

By using the Dynamics 365 Commerce online store extensibility software development kit (SDK), you can create either themes that are standalone themes or themes that are extended from a base theme. For example, you can have a base theme that defines Cascading Style Sheets (CSS) styles for modules, module view extensions, and module definition extensions. You can then have a different theme, or even a set of themes, that adds changes on top of the base theme. This capability is helpful when a single Dynamics 365 environment has multiple online sites that use different theme branding.

## Specify a base theme

To specify the base theme for a theme, edit the theme definition file, and add a **\$ref** section that points to the base theme.

In the following example, the **\$ref** section references the **fabrikam** sample theme that is included as part of the module library.

```
{
  "$ref": "@msdyn365-commerce-modules/fabrikam-design-kit/dist/lib/modules/fabrikam/fabrikam.definition.json",
  "$type": "themeModule",
  "description": "This is SDK template theme module",
  "friendlyName": "adventureworks",
  "name": "adventureworks"
}
```

## Examples

In the following example, the **add-theme** command-line interface (CLI) command is used to create a base theme.

```
yarn msdyn365 add-theme base
```

Here is the definition file for the base theme that is created.

### basetheme.definition.json

```
{
  "$type": "themeModule",
  "description": "This is SDK template theme module",
  "friendlyName": "base",
  "name": "base"
}
```

Next, the CLI command is used to create a theme that is named **extended**.

```
yarn msdyn365 add-theme extended
```

The definition file for the extended theme can now reference the base theme by using a relative path, as shown here.

### extended.definition.json

```
{
  "$ref": "../base/base.definition.json",
  "$type": "themeModule",
  "description": "This is SDK template theme module",
  "friendlyName": "extended",
  "name": "extended"
}
```

### Include base theme styles

By default, base theme styles aren't included in the extended theme. To include the base theme styles, you can add a reference in the **extended.theme.scss** file, as shown here. This example also shows how to add other styles.

### extended.theme.scss

```
@import "../base/styles/base.theme.scss";

body {
  background-color: red;
}
```

The following example resembles the previous example. It shows that you can also add a reference to the base theme in the **extended.definition.scss.json** file, if you want.

### extended.definition.scss.json

```
{
  "$ref": "../base/styles/base.definition.scss.json",
  "name": "extended"
}
```

# Add custom resources to your customization code

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic describes how to add custom static resources such as font, image, and Cascading Style Sheet (CSS) files to your software development kit (SDK) customization code so that they can be accessed from within your theme.

Some scenarios require adding custom static resources such as font, image, or CSS files that can be accessed from within a module or a theme. These static files can be added to a `/public` folder within your SDK customization code so that they will be included in the configuration package generated with the [CLI `pack` command](#). Relative paths can then be used to access the resources.

## Example

Resources can be added to the `/public` directory or any subdirectory under this directory. For example, adding a font called "NewFont-Regular" could include adding multiple font files such as "NewFont-Regular.eot", "NewFont-Regular.woff", "NewFont-Regular.ttf", and "NewFont-Regular.svg" to the `/public` directory.

After adding files to the `/public` directory, relative paths in the Sassy CSS (SCSS) file can then be used to point to them. The following SCSS example is taken from a theme that is located in the `/src/themes/spring` folder. When the command-line interface (CLI) command `pack` is used, the SCSS code is compiled into a zip file created in the `/build/public/static/css/spring` directory. A relative path is then used to access the font.

```
@import "bootstrap/scss/bootstrap";

@font-face {
  font-family: 'NewRocker-Regular';
  src: url('.././././NewFont-Regular.eot');
  src: url('.././././NewFont-Regular.eot?#iefix') format('embedded-opentype'),
        url('.././././NewFont-Regular.woff') format('woff'),
        url('.././././NewFont-Regular.ttf') format('truetype'),
        url('.././././NewFont-Regular.svg#NewFont-Regular') format('svg');
}

body {
  font-family: 'NewFont-Regular', Fallback, sans-serif;
}
```

## Dynamic access to the public path

When you deploy your e-Commerce customizations using Microsoft Lifecycle Services (LCS), the physical paths to any files stored in the `/public` directory will change, so you cannot provide static physical paths to these files from within your code. However, there is a helper API named `getAsset` that is available to help you obtain the path.

The following example from a custom module `.tsx` file shows how to use the `getAsset` API to generate a URL to a font file stored in the `/public/webfonts` directory.

```
import { getAsset } from '@msdyn365-commerce/core';

const url = `${getAsset('webfonts/fa-solid-900.woff', this.props.context.request)}`;
```

# Script injectors

2/18/2021 • 4 minutes to read • [Edit Online](#)

This topic covers script injectors that can be used to add scripts to online pages in Microsoft Dynamics 365 Commerce.

## Overview

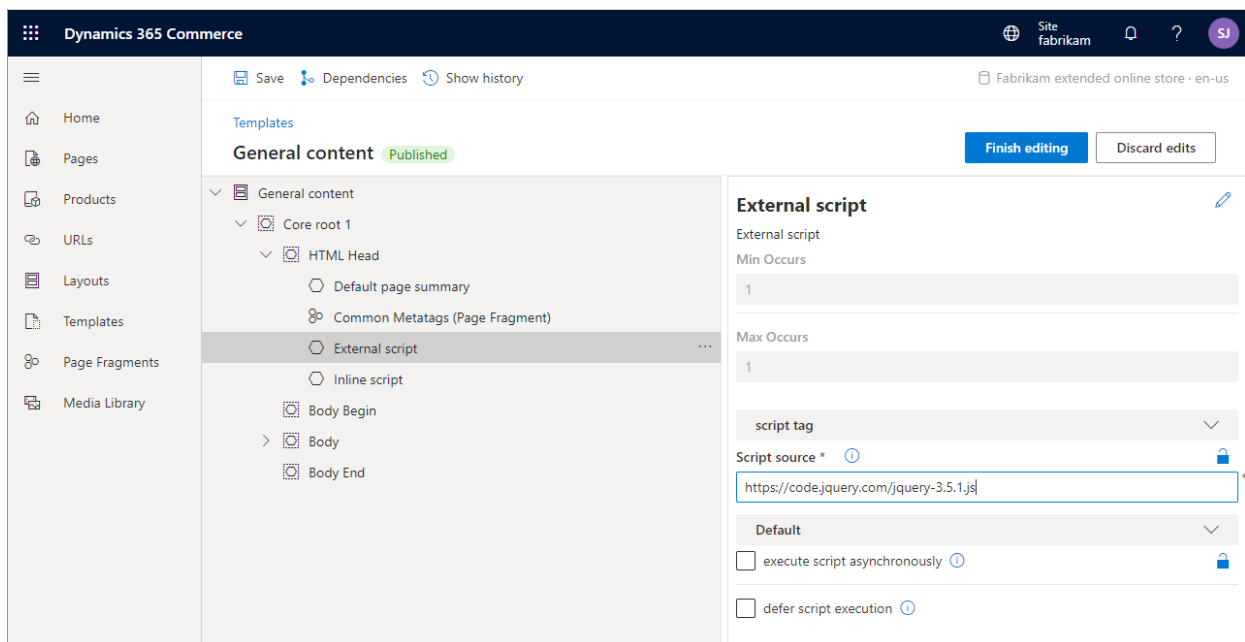

The Dynamics 365 Commerce module library provides two prebuilt script injector modules: **external script** and **inline script**. You can add these modules to a page or page template to inject inline or external scripts into the HTML head, body begin, or body end of a page as needed. For example, you can add a script for integration with third-party analytics, or other service scripts.

## External script module

The external script module allows you to add JavaScript from external sources by providing a URL that points to a valid JavaScript file. After the module is added using Commerce site builder, the script URL can be added to the **Script source** property.

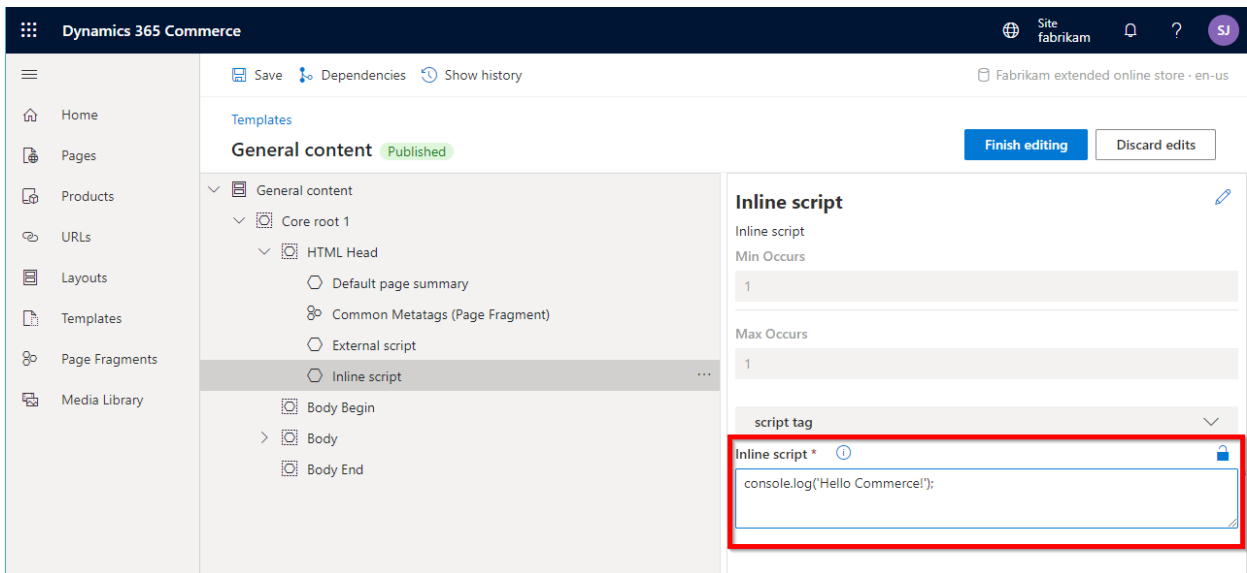

The external script module includes the **execute script asynchronously** and **defer script execution** configuration properties. The **execute script asynchronously** property specifies whether the script should be executed asynchronously. The **defer script execution** property specifies whether the script should be executed when the page has finished parsing configuration properties.

The following illustration shows an external script injector module that is being configured on a page template. The **Script source** property box is where you add the URL that points to the script source code that will be injected into the HTML for the rendered page.

## Inline script module

The inline script module allows you to add inline JavaScript code directly to a page template or page. After the module is added using Commerce site builder, the script can be pasted into the **Inline script** property box, as highlighted in the following illustration.

#### NOTE

When adding script to the **Inline script** property box, you do not need to add the outer `<script>` tags, just the inline JavaScript code.

## Custom script injector modules

In some cases, you might have to inject scripts into your site or site pages, but the prebuilt script injector modules from the module library aren't flexible as you require. For example, you might want additional configuration fields to be exposed in the authoring tools. In these cases, you can extend the prebuilt script injector modules into new custom script injector modules. You can put a custom script injector module on a page, in a shared template, or in a master template.

### Create a custom script injector

To create a custom script injector, use the following command to create a new module.

```
C:\repos\MySite>yarn msdyn365 add-module my-script-injector
```

Next, open the `my-script-injector.definition.json` file and change the `"$type"` property to `"scriptModule"`. After providing a friendly name and description, add the `"Script"` and `"HTML head"` categories, and `"script"` to the `"tags"` property. These categories and tags will allow the script injector to access the applicable page slots already defined inside a page template.

Script modules contain a special `"attributes"` section that defines where the module can be placed. The attributes include `"allowInBodyBegin"`, `"allowInBodyEnd"`, and `"allInHead"`, and the attribute values can be `true` or `false`. The default values for all three attributes are `false`, so it's important to specify where the module can be loaded.

Configurations can also be added to allow the script to be added from within Commerce site builder.

The following example shows a configured custom script injector definition file.

```

{
  "$type": "scriptModule",
  "friendlyName": "My Script Injector",
  "name": "my-script-injector",
  "description": "Used to add custom script to a page.",
  "categories": [
    "Script",
    "HTML head"],
  "tags": ["script"],
  "attributes": {
    "allowInBodyBegin": true,
    "allowInBodyEnd": true,
    "allowInHead": true
  },
  "dataActions": {
  },
  "config": {
    "scriptSource": {
      "friendlyName": "Script source",
      "description": "The script source. Can be an external URL or a relative URL. Relative URLs are
resolved from the public folder",
      "type": "string",
      "group": "script tag",
      "required": true
    },
    "async": {
      "friendlyName": "execute script asynchronously",
      "description": "specifies that the script is executed asynchronously",
      "type": "boolean",
      "default": false
    },
    "defer": {
      "friendlyName": "defer script execution",
      "description": "Specifies that the script is executed when the page has finished parsing",
      "type": "boolean",
      "default": false
    }
  }
}

```

### Modify the script injector view file

You can modify the `my-script-injector.tsx` React file and the `my-script-injector.view.tsx` `Analytics.tsx` view file, if needed.

To create a custom script injector you can use `HtmlHeadInclude`, which is a React [Higher-Order Component](#) that allows you to insert elements into the head of the page. It is simple to use, and you can add any elements you want in your view file between the `<HtmlHeadInclude>` tags, as shown in the following example.

```
import { HtmlHeadInclude } from '@msdyn365-commerce/core-internal';
import * as React from 'react';
import { IMyScriptInjectorViewProps } from './my-script-injector';

export default (props: IMyScriptInjectorViewProps) => {
  const scriptContents = `window.ga=window.ga||function(){(ga.q=ga.q||[]).push(arguments)};ga.l=+new
Date;ga('create', 'UA-XXXX-Y', 'auto');ga('send', 'pageview')`;
  return (
    <HtmlHeadInclude>
      <script data-load-point='headStart'>
        {scriptContents}
      </script>
      <script data-load-point='headStart' async src={props.config.scriptSource} />
    </HtmlHeadInclude>
  );
};
```

#### NOTE

Inline script content should be saved as a string and then inserted into the script, and the **data-load-point** attribute must be specified on script tags. This attribute controls where the script tag should be placed. Possible values include **headStart**, **headEnd**, **bodyStart**, and **bodyEnd**.

The **HtmlHeadInclude** component can also be used to insert **<title>**, **<meta>**, **<link>**, and **<style>** tags into the head of an HTML document. Unlike scripts, these elements do not need a **data-load-point** attribute as they will always be placed in the head.

After a custom script injector module is deployed to a Dynamics 365 Commerce environment, it will appear in site builder.

# Configure and enable connectors

2/18/2021 • 11 minutes to read • [Edit Online](#)

This topic describes connectors and explains how to configure and enable them in Microsoft Dynamics 365 Commerce.

Connectors let you connect your Dynamics 365 Commerce site to external third-party services to perform tasks such as capturing analytics, logging, and experimenting. Some third-party service providers require a paid license for their service before it can be used. For more information, contact your service provider.

As of Commerce release version 10.0.13, the only supported type of connector is the experimentation connector. As of Commerce release version 10.0.17, support for the geoLookup connector has been added. In future versions, you will be able to configure and enable other types of connectors.

## Configure and enable connectors

You can add connectors to your Commerce site by adding them as a dependency in your `package.json` file. Alternatively, you can implement them directly in your configuration package code under the `\src\connectors` directory.

### Connector settings file

Connectors are configured and enabled in the `connector.settings.json` file under the `\src\settings` directory. If no `connector.settings.json` file exists, you can manually create one. In this file, you can specify the experimentation connector that you want to use and configure it as you require. Only one experimentation connector can be used at a time.

The following example shows the contents of the `connector.settings.json` file that defines an experimentation connector.

```
{
  "experimentation": {
    "name": "msdyn365-exp-test-2",
    "config": {
      "sdkKey": "EXPERIMENTATION_PROVIDER_KEY",
      "key2": "value2"
    },
    "cacheConfig": {
      "ttlInSeconds": {
        "experimentation": 1800,
        "experimentationDataFile": 300
      },
      "ttrInSeconds": {
        "experimentation": 10
      }
    }
  }
}
```

### Connector settings file schema

- **experimentation** – This object contains all the information that is required to start and enable your experimentation connector.
- **name** – This setting specifies the name of the experimentation connector that is used. You can find the name of the connector in the connector's definition file. The type of the connector must be `experimentationConnector`.

- **config** – This section allows for any configuration object that the connector requires for initialization and to start to communicate with the third-party service. To learn what information is required, look in the **configSchema** section of the connector's definition file or in the connector's README file.
- **cacheConfig** – You can specify the timings that are used when some experimentation-related entities are cached. In this section, **tllInSeconds** refers to the amount of time that an entity can remain in the cache before it's considered stale, and **ttrInSeconds** refers to the amount of time before an entity is refreshed. The connector's README file should include a list of recommended cache timings.
- **experimentation** – This setting controls the cache timings for getting the list of available experiments that are configured in your third-party provider during **getExperiments()**. The default TTL (time to live) is 1,800 seconds, and the default TTR (time to refresh) is 60 seconds.
- **experimentationDataFile** – This setting controls the cache timings for having the configuration passed down to the client during **getConfigForClientSideInit()**. The default TTL is 1,800 seconds, and the default TTR is 60 seconds.

## Experimentation connector

An experimentation connector lets you connect your application to an external experimentation service provider. By adding this type of connector to your application, configuring it, and enabling it, you can create and run experiments in Commerce site builder, and track outcomes, to provide the best experience for your customers.

An experimentation connector consists of three parts:

- A connector definition file (in JavaScript Object Notation [JSON] format)
- A provider file
- A listener file

### Connector definition file

A connector definition file is used to register and provide configuration metadata data to your application. This metadata includes the type of connector, the name of the connector, a description of the connector, and the configuration schema. The name of the connector definition file is in the format **<CONNECTOR\_NAME>.connector.json**.

The following example shows the contents of a connector definition file.

```
{
  "$type": "experimentationConnector",
  "name": "msdyn365-exp-test",
  "description": "Test connector implementation",
  "configSchema": {
    "type": "object",
    "properties": {
      "projectId": {
        "type": "string",
        "description": "The project ID to use for experimentation"
      }
    },
    "required": ["projectId"]
  }
}
```

### Connector definition file schema

- **\$type** – The type of connector. Because the definition file in the preceding example is for an experimentation connector, the type is **experimentationConnector**.
- **name** – The name of the connector. This name must be unique across all connectors.
- **description** – The description of the connector.
- **configSchema** – The configuration schema. A configuration schema lets you provide a JSON schema that

validates the configuration that is given to you at application startup, so that your connector can be initialized correctly. For example, when you initialize your connector, you need the **projectId** value to make an API call that is required for communication with the third-party experimentation service. You can specify this value in the preceding JSON file to ensure that the configuration that is provided matches your connector's requirements.

### **Provider file**

An experimentation provider file is required to initialize a connector. It also enables the connector to interact with Commerce site builder to present a list of available experiments that are configured in your third-party experimentation service. The name of the provider file is in the format **<CONNECTOR\_NAME>.provider.ts**.

The provider file should implement the following interface.

```

export interface IExperimentationProvider {
  /**
   * Allows the experimentation connector to do any startup related tasks
   * using the config provided by the partner.
   *
   * This method is only called once during server startup.
   * @param config The configuration provided in connector.settings.json
   */
  initialize(config: any): Promise<boolean>;

  /**
   * Returns the configuration that should be passed to the experimentation connector
   * when it is initialized client-side
   */
  getConfigForClientSideInit(): Promise<any>;

  /**
   * Initializes the experimentation provider on the browser (client-side) so that
   * it may activate experiments for a user.
   *
   * @param config The config that is required to initialize the experimentation connector
   * client-side. The result of getConfigForClientSideInit() is passed into this method
   */
  initializeClientSide(config: any): boolean;

  /**
   * Returns a list of all the experiments currently configured whether active or not.
   * This list will be cached and periodically refreshed.
   * @param page Optional argument that specifies the page to return.
   * @param items Optional argument that specifies the maximum number of objects to return per request.
   */
  getExperiments(page?: string, items?: string): Promise<IExperiments[]>;

  /**
   * Returns a list of experiments and variants a user will be a part of based
   * off the userId. Optional attributes can provide the connector with additional criteria
   * to determine which experiments a user should be a part of.
   *
   * @param userId userId unique to a user if signed in or unique to a session if user is anonymous.
   * userId will be generated from hash if user is signed-in to deterministically generate sanitized
   * userIds.
   * @param attributes Optional user related attributes
   */
  getVariantsForUser(userId: string, attributes?: {
    [index: string]: string;
  }): IVariants[];

  /**
   * Activates experiment(s) a user is currently being served. This call will be made
   * client-side after the connector has been initialized client-side
   *
   * @param userId userId unique to a user if signed in or unique to a session if user is anonymous.
   * userId will be generated from hash if user is signed-in to deterministically generate sanitized
   * userIds.
   * @param experiments The experiments the user is participating in.
   * @param attributes Optional user related attributes
   */
  activateExperiment(userId: string, experiments: IVariants[], attributes?: {
    [index: string]: string;
  }): boolean;
}

```

In addition, some of the functions use the following types for their return types and arguments.

```

/**
 * Variations on each experiment
 */
export interface IVariations {
  friendlyName: string;
  id: string;
  status: State;
  weight?: string;
}

/**
 * Experiments
 */
export interface IExperiments {
  friendlyName: string;
  id: string;
  status: State;
  variations: IVariations[];
  createdAt?: string;
  lastModifiedDate?: string;
  lastModifiedBy?: string;
  description?: string;
  type?: string;
  link?: string;
  resultLink?: string;
}

/**
 * Experiments
 */
export interface IVariants {
  variantId: string;
  experimentId: string;
  moduleId?: string;
}

```

### Listener file

An experimentation listener file is required to track user conversion events. The listener file implements a logger interface that hooks into the event logging framework of the software development kit (SDK) to subscribe to specific user actions. The name of the listener file is in the format `<CONNECTOR_NAME>.listener.ts`.

The listener file should implement the following interface.

```

export interface IExperimentationListener {
  /**
   * Initializes the experimentation listener on the browser (client-side) so that
   * it may keep track of any conversion events related to the current experiments.
   *
   * @param config The config that is required to initialize the experimentation connector
   * client-side. The result of the provider file's getConfigForClientSideInit() is passed into this
   method
   * @param userId The user ID of the current user being served the experiment
   */
  initializeClientSide(config: any, userId: string): boolean;
  /**
   * Tracks a successful user conversion event.
   *
   * @param eventType The name of the event that occurred
   * @param payload Any additional tags or data related to the conversion event
   * @param attributes Optional parameter containing user attributes pertaining to the user that triggered
   the event
   */
  trackEvent(eventType: string, payload: any, attributes?: any): void;
}

```

## GeoLookup connector

A geoLookup connector lets you connect to an external geolocation service provider. By adding this type of connector to your e-commerce site and configuring it, you can generate geolocation information for e-commerce site users.

### Enable and configure a geoLookup connector

Connectors are enabled and configured in the `connector.settings.json` file under the `\src\settings` directory of the SDK.

The following example shows a geoLookup connector being enabled in the `connector.settings.json` file.

```

{
  "geoLookup": {
    "name": "GeoLocationTest",
    "config": {
      "apiKey": "GEOLOCATION_SERVICE_PROVIDER_API_KEY"
    },
    "cacheConfig": {
      "ttlInSeconds": {
        "geoLookup": 10
      }
    }
  }
}

```

- **geoLookup** – This object contains all the information that is required to start and enable a geoLookup connector.
- **name** – This setting specifies the name of the geoLookup connector. You can find the name of the connector in the geoLookup connector's definition file. The connector type must be `geoLookupConnector`.
- **config** – This section allows for any configuration object that the connector requires for initialization and communication with the third-party service. To learn what information is required, look in the `configSchema` section of the geoLookup connector's definition file, or in the connector's README file. Change the `apiKey` value to a value that is provided by the service provider.
- **cacheConfig** – Here, you can specify the timings that are used when geolocation entities are cached. The `ttlInSeconds` value specifies the amount of time, in seconds, that an entity can remain in the cache before

it's considered stale. The **ttrInSeconds** value specifies the amount of time, in seconds, before an entity is refreshed. The geoLookup connector's README file should include a list of recommended cache timings.

- **geoLookup** – This setting controls the cache timings for getting geolocation information that is generated by the third-party service provider. The default TTL is 120 seconds.

### Anatomy of a geoLookup connector

A geoLookup connector consists of two parts:

- A connector definition file in JSON format
- A provider file

#### Connector definition file

The connector definition file is used to register and provide configuration metadata data to your application. The name of the provider file is in the format **<CONNECTOR\_NAME>.connector.json**. The metadata includes the type of connector, the connector's name, a description of the connector, and the configuration schema, as shown in the following example of a connector definition file.

```
{
  "$type": "geoLookupConnector",
  "name": "msdyn365-geoLookup-test",
  "description": "Test connector implementation",
  "configSchema": {
    "type": "object",
    "properties": {
      "apiKey": {
        "type": "string",
        "description": "Api key for using the geoLookup API"
      }
    },
    "required": ["apiKey"]
  }
}
```

#### Connector definition file schema

- **\$type** – The type of connector. Because the definition file in the preceding example is for a geoLookup connector, the type is **geoLookupConnector**.
- **name** – The name of the connector. This name must be unique across all connectors.
- **description** – The description of the connector.
- **configSchema** – The configuration schema. A configuration schema lets you provide a JSON schema that validates the configuration that is given to you at application startup, so that your connector can be initialized correctly. For example, when you initialize your connector, you need the **projectId** value to make an API call that is required for communication with the third-party service. You can specify this value in the preceding JSON file to ensure that the configuration that is provided matches your connector's requirements.

#### Provider file

A provider file is required to initialize a connector. The name of the provider file is in the format **<CONNECTOR\_NAME>.provider.ts**.

The provider file should implement the following interface.

```

export interface IGeoLookupProvider {
  /**
   * Allows the geoLocation connector to do any startup related tasks
   * using the config provided by the partner.
   *
   * This method is only called once during server startup.
   * @param config The configuration provided in connector.settings.json
   */
  // tslint:disable:no-any
  initialize(config: any): Promise<boolean>;

  /**
   * Geolocation lookup connector will get location information based on the ip address
   * @param ip The ip address
   */
  getGeoInformation(ip: string): Promise<IGeoLocation>;
}

```

In addition, some of the functions use the following types for their return types and arguments.

```

export interface IGeoLocation {
  country?: string;
  region?: string;
  city?: string;
  zipCode?: string;
  [otherProperty: string]: string | undefined;
}

```

Geolocation information that is generated will be saved in the `requestContext.geoLocation` object.

# Telemetry logger

2/18/2021 • 5 minutes to read • [Edit Online](#)

This topic covers the telemetry logger in Dynamics 365 Commerce.

## Overview

The Dynamics 365 Commerce online software development kit (SDK) includes a custom telemetry logger that you can use to log to multiple resources at various levels but also maintain a unified context on both the server and the client.

## Access the telemetry logger

By default, the telemetry logger is available to all react components. It can be accessed with the `this.props.telemetry` property from the module view code file.

Sometimes you will want to access the telemetry logger in a shared component instead of having to pass it down through the properties of every component in your module. The SDK repository includes a `WithContext()` utility that lets you inject the telemetry logger directly into your component.

When the telemetry logger runs in a development environment, all logs are also shown in the console.

## Trace logging

The messages that are logged can range in importance from debug statements to critical errors. This logging is available through the trace logging feature of the telemetry logger. The trace logger uses the following logging methods and levels.

```
enum LogLevel {
    Trace = 'trace',
    Debug = 'debug',
    Information = 'information',
    Warning = 'warning',
    Error = 'error',
    Critical = 'critical',
    None = 'none'
}
```

### Trace logging APIs

The following example shows the primary application programming interface (API) that is used to log a trace message.

```
telemetry.log(
    logLevel: LogLevel,           // One of the log levels listed in the enum above
    messageTemplate: string,     // A string that follows a message template format (see below for
more info)
    logOptions?: TelemetryLogOptions // Object wrapping up the optional parameters for the log statement
)
```

The trace logging system uses message templates to enforce a structured logging system for telemetry. Therefore, the logs can be captured and rendered in both human-friendly and machine-friendly formats. The `messageTemplate` argument of the `.log` call uses what are known as *named holes* for any event data. When

you're writing trace log messages, you can write human-readable messages that include event data. To include event data, mark the place in the message template by using `{<name>}`, where `<name>` is the name that you want to use for the event data. The actual value that will fill that named hole is provided in the `logOptions.values` parameter. The `logOptions` parameter contains any optional parameters that should be included for a trace log. Here is an example.

```
type TelemetryLogOptions = {
  values?: unknown[]; // Holds any arguments that are meant for placeholders in the message template
  customTags?: string[]; // Array of custom tags to add to log. Custom tags can be used to group
  message in the telemetry back-end
  exception?: Error; // Exception that can be attached to the log. Will contain details like stack
  trace info
};
```

The benefit of this structured logging system is that when log messages are rendered so that a human can read them, the system can replace the named holes with the values that have been provided. However, when the messages are sent and stored, or when the telemetry is processed by a machine, the event data can be kept separate. Event data can be used, for example, to aggregate or filter specific messages without requiring any string parsing. For more information about structured logging and message templates, see [Message Templates](#).

The following examples show some trace log calls.

```
telemetry.log(LogLevel.Debug, "{user} says {word}", {values: ["Bill", "Hi!"]});
// Output: "Bill says Hi!"

telemetry.log(LogLevel.Debug, "Customer {customer} purchased item {productID}", {values: [12345, 321]});
// Output: "Customer 12345 purchased item 321"

telemetry.log(LogLevel.Debug, "Module {id} threw error {code} while rendering", {values: [123, 404],
  customTags: ["Module Error"], exception: error});
// Output: "Module 123 threw error 404 while rendering"
// The customTags and exception will be attached to the log call, and can be viewed in the telemetry back-
end
```

There are also wrapper methods that simplify the logging calls. However, these wrapper methods can log only strings. There is one wrapper method for each log level, as the following example shows.

```
this.props.telemetry.trace("This will log at log level 'trace'");
this.props.telemetry.debug("This will log at log level 'debug'");
this.props.telemetry.information("This will log at log level 'information'");
this.props.telemetry.warning("This will log at log level 'warning'");
this.props.telemetry.error("This will log at log level 'error'");
this.props.telemetry.critical("This will log at log level 'critical'");
```

If you want to include additional strings or other objects in the wrapper methods, you can add them to the message by passing them as arguments at the end of the call. All additional arguments will be converted to strings, joined to the first string message, and separated by a comma. Here is an example.

```
this.props.telemetry.trace("This is the first message", "This is the second message", {some object})

// Output will be: "This is the first message,This is the second message,{.toString result of {some
object}}"
```

The console logs are controlled by the `?debug=true` query string.

## Exception logging

Logging of **Error** objects (and classes that inherit from them) can be done through the `.exception(Error)` API. Here is an example.

```
this.props.telemetry.exception(new Error("Something is broken!"));
```

### **.error vs. .exception**

You might be confused about when you should use `.error()` to log an error in your application, and when you should use `.exception()`. This confusion can arise because the names are similar, and because you can use `.error()` to log **Error** objects, by passing the **Error** objects as additional parameters.

The best guidance is to use `.exception()` to log actual **Error** objects and `.error()` to log string messages that state that an error has occurred in the business logic. Generally, `.exception()` logs are more easily correlated with issues and allow for faster debugging when real issues arise. The messages from `.error()` are treated as another trace log, and more detailed analysis might be required to find the issue than if you use `.exception()`. Therefore, it can take more time to recognize that an issue has occurred. In addition, `.exception()` allows for better tracking across different requests. Therefore, it supports features such as automatic alerting when an issue begins to affect many requests.

# Package configurations and deploy them to an online environment

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic describes how to package configurations and deploy them to your Microsoft Dynamics 365 Commerce online environment.

## Overview

When your local site configurations (modules, data actions, and themes) are ready to be deployed to your online environment, you must package and deploy them by using Microsoft Dynamics Lifecycle Services (LCS).

## Package the local site configurations for upload

The `yarn msdyn365 pack` command creates a package of the local site configurations. You can then use the package to upload the configurations to an online environment via LCS.

The command should be run from the root directory of your local online software development kit (SDK) files. The output of the command is a new zip file in the same directory.

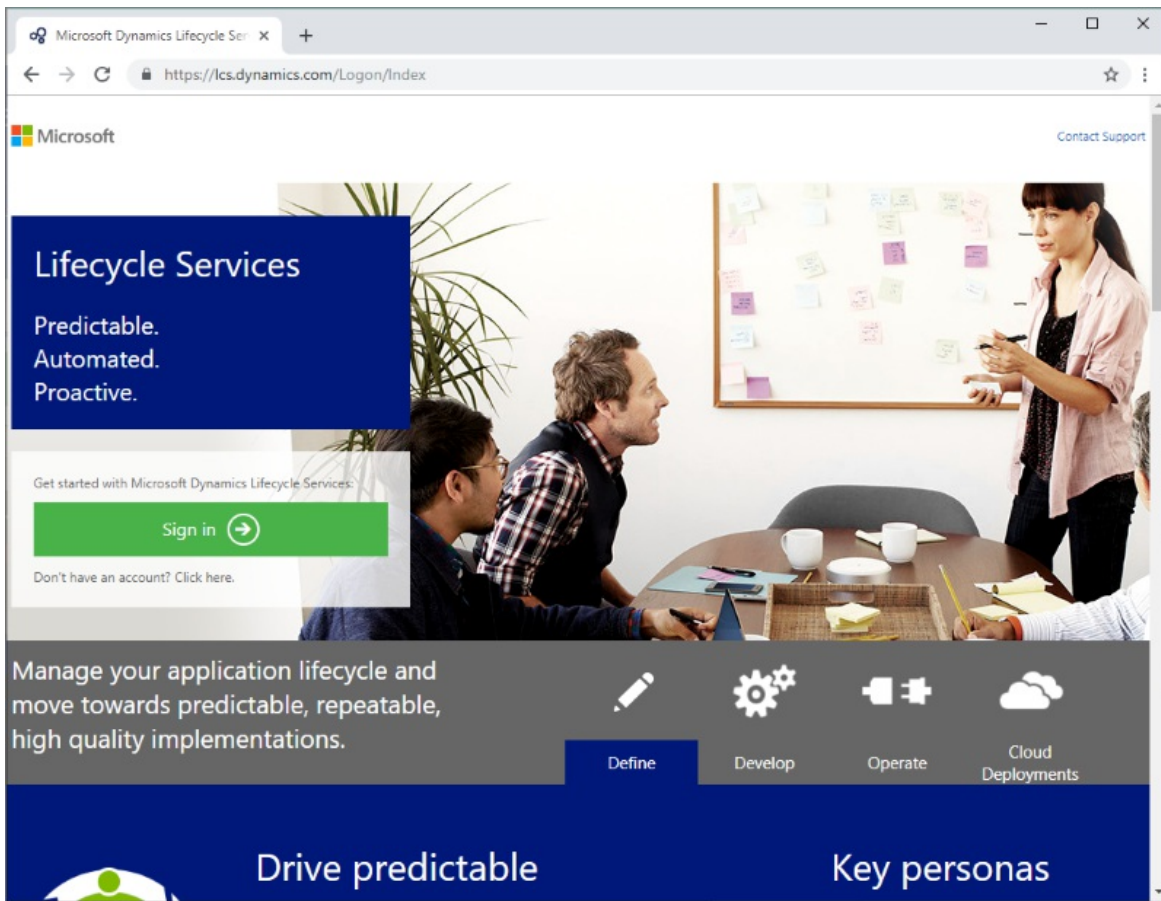

Here is an example.

```
c:\repos\D365.Commerce.Fabrikam>yarn msdyn365 pack
```

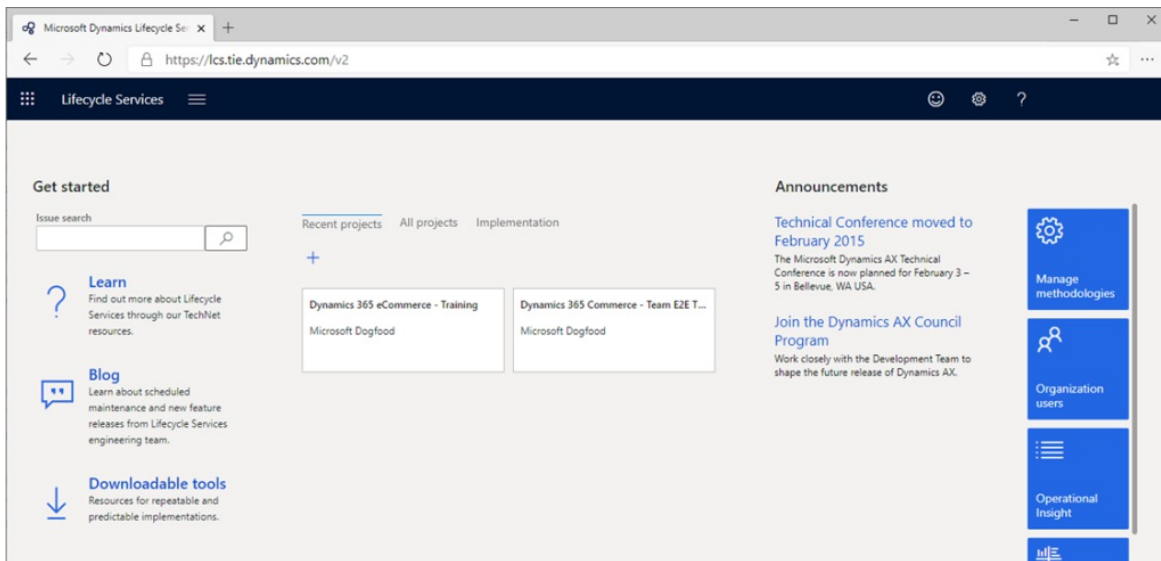

## Upload a package by using LCS

To upload a site configuration package by using LCS, follow these steps.

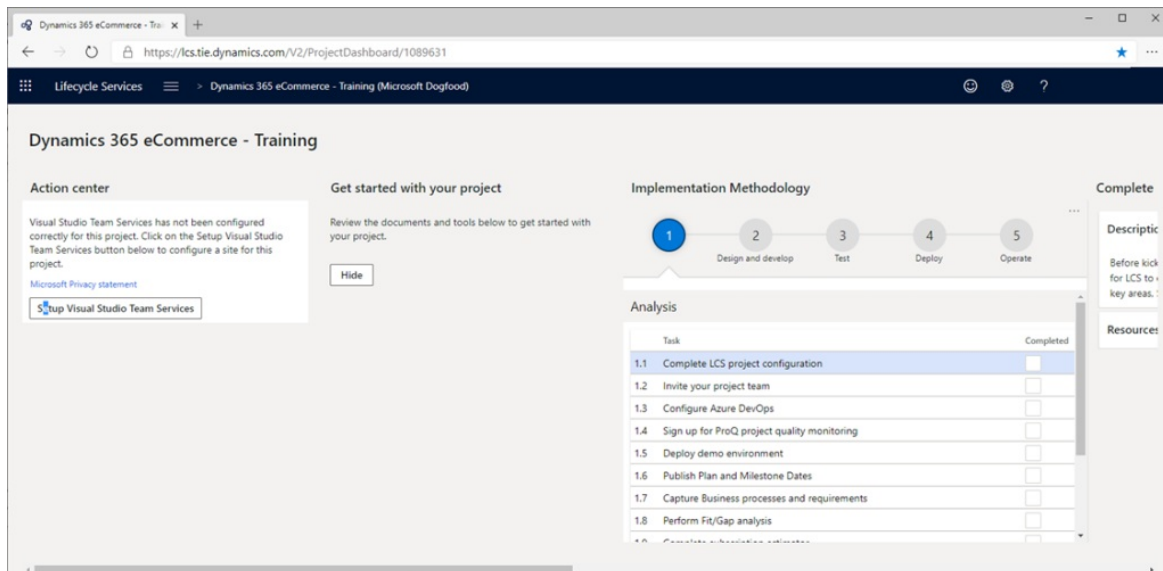

1. Go to <https://lcs.dynamics.com>. (Alternatively, if you're using the test integration LCS server, go to <https://lcs.tie.dynamics.com>). You should see a sign-in page that resembles the following illustration.

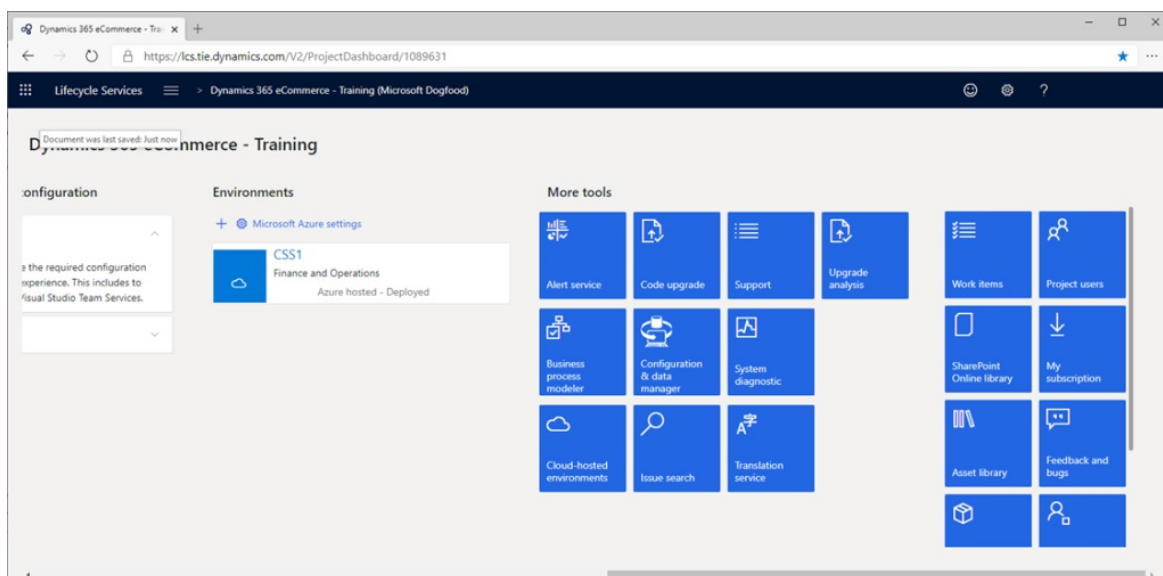

2. Select **Sign in**, and enter your LCS-provided account credentials. The main dashboard appears.

3. Select the e-Commerce project that you will be using. The project dashboard appears.

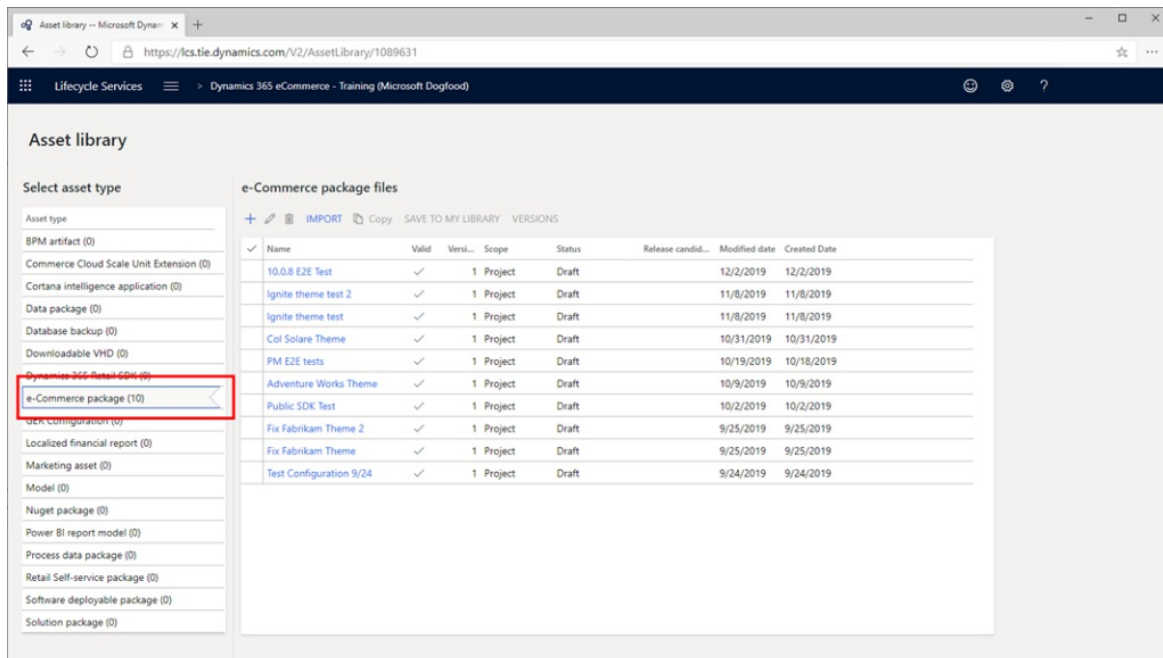

4. Scroll to the right to see more options.

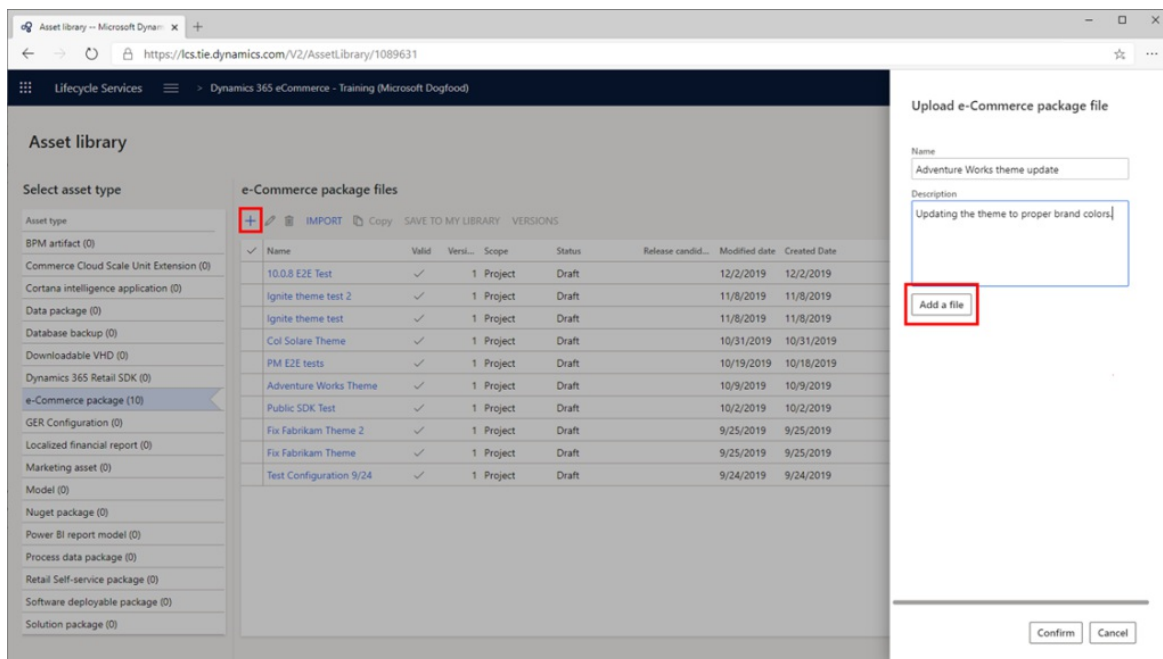

5. To upload the package, in the **More tools** section, select the **Asset Library** tile.

6. On the **Asset library** page, in the left pane, select the **e-Commerce package** tab. If you don't see the **e-Commerce package** tab, you must enable e-Commerce features. Contact your Microsoft Commerce representative to obtain the required code.

7. Select the plus sign (+).
8. In the **Upload e-Commerce package file** dialog box, enter a name and description for the package, and then select **Add a file**.

9. In the **Upload file asset** dialog box, select **Browse**, and browse to the location of the package zip file that you created earlier. Select the file, and then select **Upload**.

10. When the upload is completed, you're returned to the **Upload e-Commerce package file** dialog box. Select **Confirm** to process the upload.

## Upload e-Commerce package file

Name

Description

Upload successful

[Add a file](#)

[Confirm](#) [Cancel](#)

While the upload is being processed, you might have to refresh the page to see status updates. The processing can take between 45 and 50 minutes. When it's completed, a success or failure message is shown.

<a href="#">Configuration Package</a>	🔄	1	Project	Draft		3/19/2019	85 KB

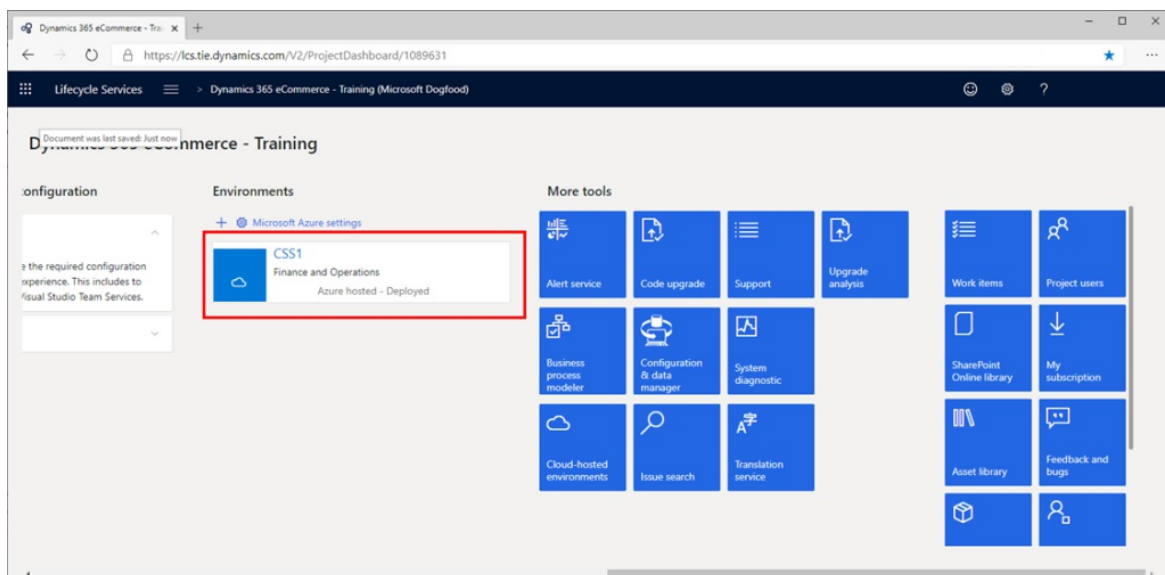

If the processing was successfully completed, a check mark appears in the **Valid** column.

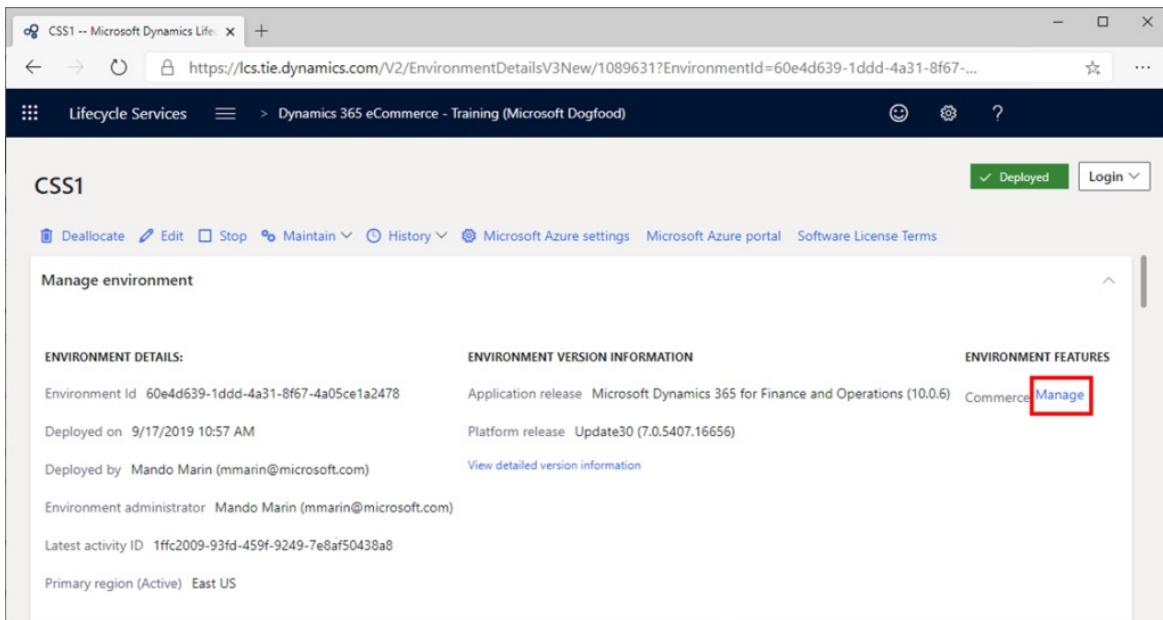

## Deploy a package

To deploy a package, follow these steps.

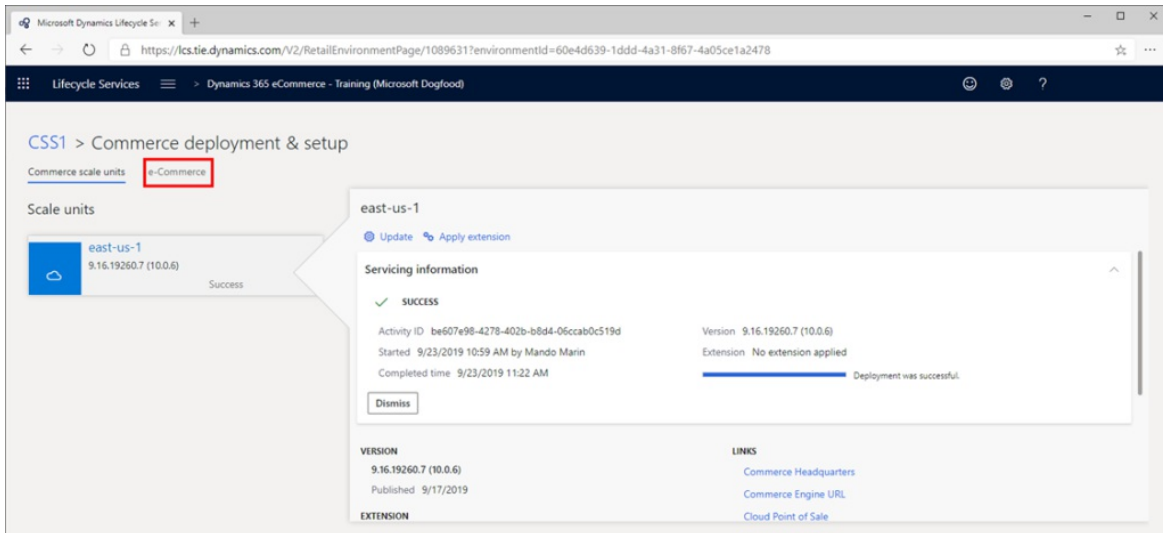

1. In LCS, go to the project dashboard, and select the environment that you want to deploy a package to. For example, in the following illustration, the **RushE2E-TIE-SB3** pre-production environment is selected.

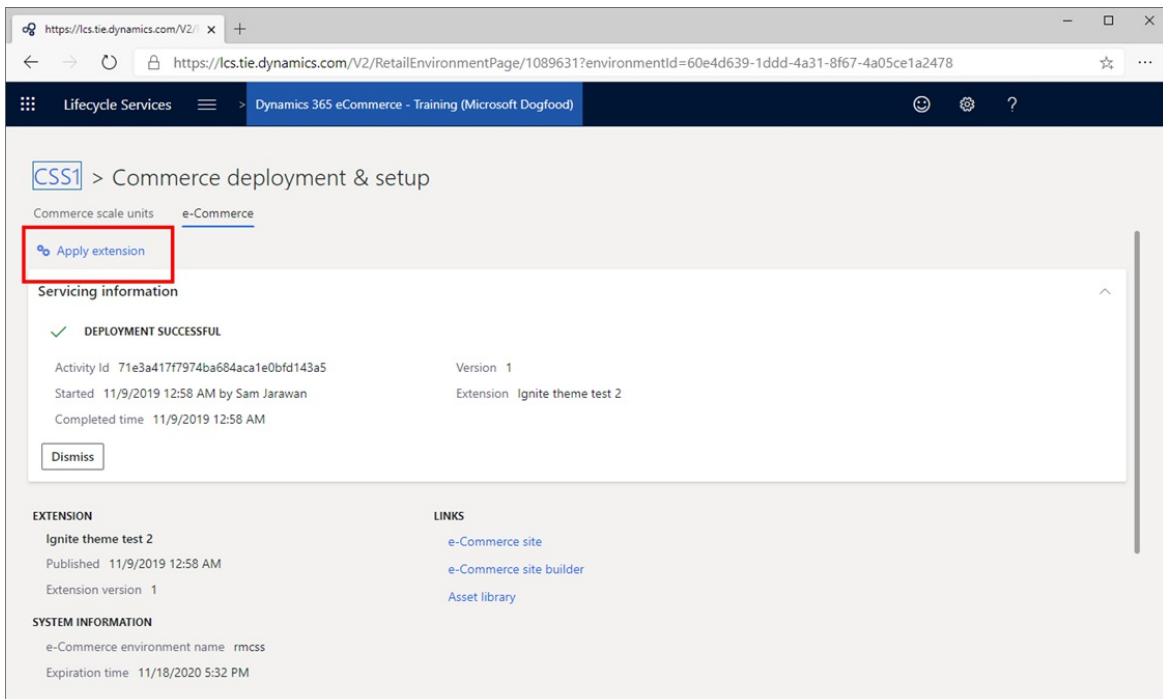

2. In the **Environment features** section on the right side of the page, select **Manage**.

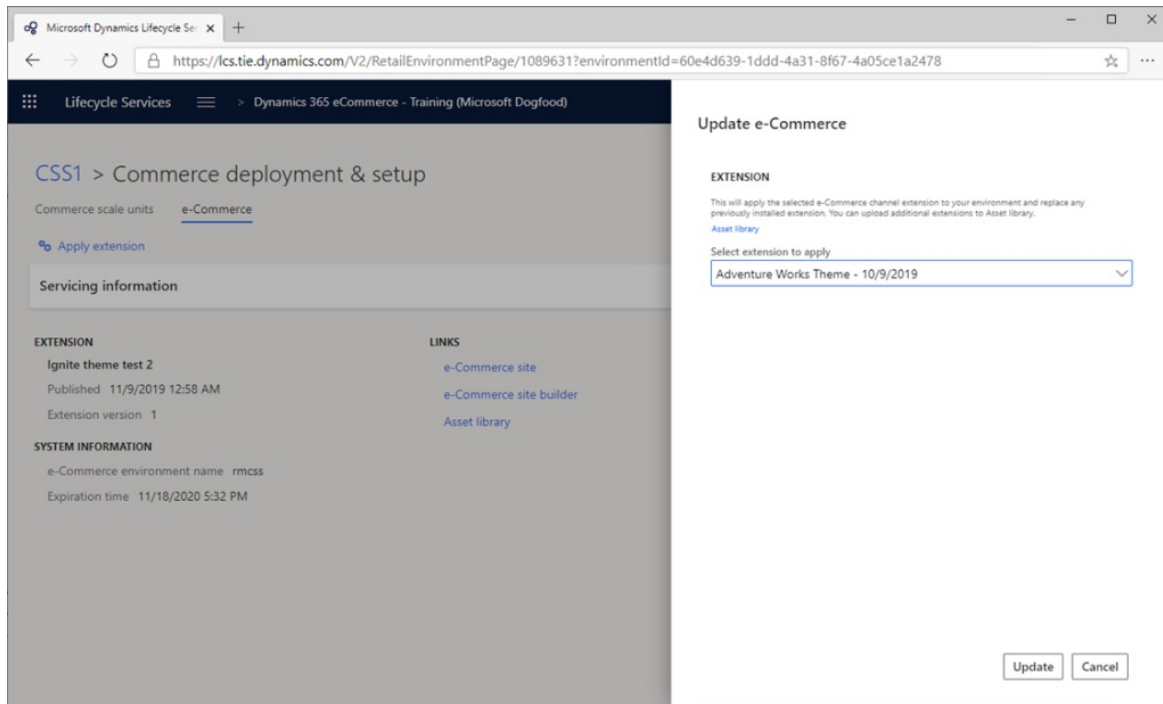

3. Select the E-Commerce (Preview) tab.

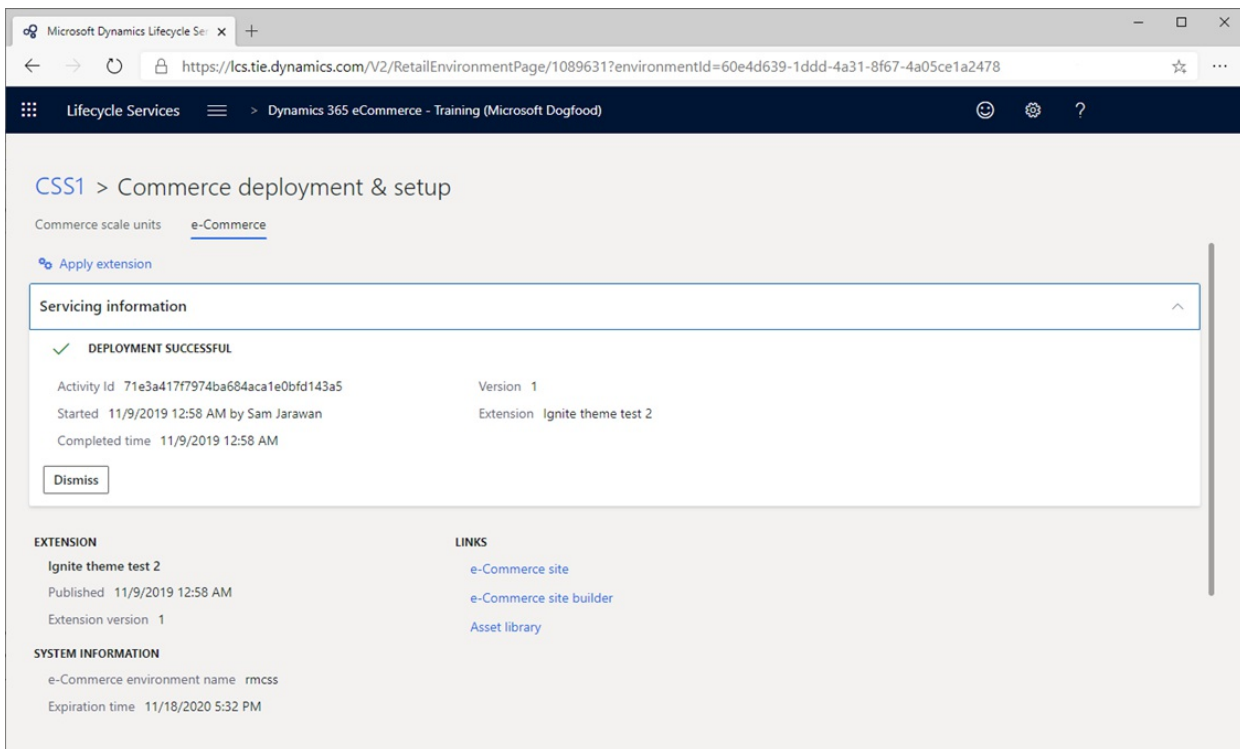

4. Select Apply extension to select the package to deploy.

5. In the **Update e-Commerce** dialog box, select the package that you uploaded earlier, and then select **Update**.

You can now track the deployment status in the **Details** section.

After the deployment is completed, you should see your changes in the authoring tools or on pages that are rendered. For example, new modules or themes will be available to page authors, or changes are rendered and will appear in the online environment.

# SDK and module library updates

2/18/2021 • 5 minutes to read • [Edit Online](#)

This topic covers regular updates that will be released as part of the Microsoft Dynamics 365 Commerce online software development kit (SDK).

## Overview

Regular updates will be released as part of the Dynamics 365 Commerce online SDK and module library. These updates might include new features or product fixes. Product release notes will be provided for all changes.

## Dependency versions in the packages.json file

The SDK packages.json file that is included in the SDK root directory controls which versions of the SDK, module library, Fabrikam design kit, and Retail Server proxy are downloaded. The specific entries can be found in the "dependencies" section, as shown in the following example. Note that the version numbers might differ, depending on when the SDK was acquired.

```
...
"dependencies": {
  "@msdyn365-commerce-modules/starter-pack": "9.25",
  "@msdyn365-commerce-modules/fabrikam-design-kit": "9.25",
  "@msdyn365-commerce/bootloader": "^1.0.0",
  "@msdyn365-commerce/retail-proxy": "9.25",
}
...
```

- **@msdyn365-commerce-modules/starter-pack** – This entry represents the module library, which includes the set of starter modules and data actions. The preceding example is configured to pull down only the specified version.
- **@msdyn365-commerce-modules/fabrikam-design-kit** – This entry represents the Fabrikam design kit, which includes the Fabrikam theme. The Fabrikam theme defines specific Cascading Style Sheets (CSS) and module view overrides for the set of modules in the module library. The preceding example is configured to pull down only the specified version.
- **@msdyn365-commerce/retail-proxy** – This entry represents the Retail Server proxy, which is used to access the set of APIs for the Commerce Scale Unit. The preceding example is configured to pull down only the specified version.
- **@msdyn365-commerce/bootloader** – This entry represents the SDK. The caret (^) symbol ensures that the **yarn** command always pulls down the latest released version.

The version numbers that are used in the preceding example are in the format *X.Y.Z*, where *X* is the major version, *Y* is the minor version, and *Z* is the patch version.

SDK dependencies are backward-compatible and can be pulled down at any time. The module library minor versions are dependent on the Commerce Scale Unit. Therefore, they can't be higher than the versions that are shown in the table that follows.

Patch versions won't change dependencies on the Commerce Scale Unit. Therefore, they can be updated at any time. The tilde (~) symbol can be used with version numbers to ensure that any patch versions that might include software updates are always pulled down. The following example shows how the tilde is used to pull down the latest patch version.

```

...
"dependencies": {
  "@msdyn365-commerce-modules/starter-pack": "~9.26.0",
  "@msdyn365-commerce-modules/fabrikam-design-kit": "~9.26.0",
  "@msdyn365-commerce/bootloader": "^1.0.0",
  "@msdyn365-commerce/retail-proxy": "~9.26.0",
}
...

```

The following table maps module library versions to Commerce Scale Unit versions. The same module library versions that are mapped to the Commerce Scale Unit should be used for the Retail Server proxy and Fabrikam design kit. The table lists current supported versions as of **January 25, 2021**.

COMMERCE SCALE UNIT VERSION	MAXIMUM MODULE LIBRARY VERSION
10.0.10	9.20.x
10.0.11	9.21.x
10.0.12	9.22.x
10.0.13	9.23.x
10.0.14	9.24.x
10.0.15	9.25.x
10.0.16	9.26.x

## Pull updates

The SDK, module library, and other dependency updates are optional and can be pulled down to a local development environment by using the **yarn** command in the SDK source code. When this command is run, the latest dependencies are pulled down, based on the versions that are specified in the `packages.json` file. Before you run the **yarn** command, you should delete the `yarn.lock` file from the root directory. Optionally, you can also delete the `/node_modules` folder to get a clean set of dependency files.

After the latest dependencies are pulled down, you can run **yarn start** to run the Node server on your development environment and test the new SDK and module library components.

When a configuration package is created by using the **yarn msdyn365 pack** command-line interface (CLI) tool, all dependencies are updated to their local versions during the packaging process. The package that is created can then be uploaded to an online site by using Microsoft Dynamics Lifecycle Services (LCS).

## Determine the latest released versions of the dependency packages

To determine the latest released versions of the dependency packages, follow these feed links:

- [Module library feed](#)
- [SDK feed](#)
- [Retail Server proxy feed](#)

## Determine the versions deployed on an e-Commerce site

To determine the deployed versions of the SDK, module library, and Retail Server proxy that are used on an e-Commerce site, right-click a site page, select **View page source**, and then search for the following strings to find the version number:

- **commerceSDKVersion** – The SDK version.
- **commerceSSKVersion** – The module library version.
- **retailServerProxyVersion** – The Retail Server proxy version.

## Update the app.settings.json file

In the SDK `/src/settings` directory, there's a file called **app.settings.json**. This file surfaces global settings to Commerce site builder that are used by the module library set of modules and can contain additional settings for custom modules. The settings are located in site builder at **Site Settings > Extensions**.

When upgrading the module library, there may be new settings that are applicable and need to be added manually. The latest app.settings.json file can be found in the [online SDK GitHub settings directory](#). This file contains settings for the latest available module library. If you haven't made any additions to the app.settings.json file, you can copy the contents of this file to your version or do a diff and merge the new settings manually. If you're updating to an older module library, you can find the specific app.settings.json file under the specific build branch located on the [GitHub branches page](#). You'll need to manually merge the contents to your app.settings.json file.

When a local configuration package is created by using the **yarn msdyn365 pack** command-line interface (CLI) tool, the local app.settings.json file updates will be included. The package that is created can then be uploaded to an online site by using Microsoft Dynamics Lifecycle Services (LCS). You will then see the new settings in the site builder tool.

# Best practices for Dynamics 365 Commerce development

2/18/2021 • 7 minutes to read • [Edit Online](#)

## IMPORTANT

Some or all of the functionality noted in this topic is available as part of a preview release. The content and the functionality are subject to change. For more information about preview releases, see [One version service updates FAQ](#).

This topic describes some best practices to follow when developing Dynamics 365 Commerce customizations.

The Dynamics 365 Commerce platform provides a rich online software development kit (SDK) for developer extensibility. Custom modules, data actions, and themes can be created, or modules from the Commerce [module library](#) can be extended. It is important to consider web site performance when building Commerce customizations. Standard best practices used for website development are applicable including minimizing HTML, JavaScript, and CSS files, and optimizing images.

## Infrastructure setup

The [Dynamics 365 Commerce ecosystem](#) comprises various subsystems including Commerce headquarters, Commerce Scale Unit, the web storefront that includes the Node rendering service, Commerce site builder, and the product recommendations services. For best performance, the various components should all be deployed to the same region. The specific region decision should be made in accordance with the customer's regional location.

## NOTE

Commerce Scale Unit allows you to select a specific region during setup.

## Minimize HTML, CSS, and JavaScript file sizes

The Dynamics 365 Commerce online SDK provides development extensions that use TypeScript and Sassy Cascading Style Sheets (SCSS) files. When a configuration package is built by using the [yarn msdyn365 pack](#) command, or when the Node server is started in a local development environment by using the [yarn start](#) command, the TypeScript files are compiled down to JavaScript files, and the SCSS files are compiled down to Cascading Style Sheets (CSS) files. These files are also minified to help reduce network bandwidth. You should make sure that extra, unused JavaScript and CSS files aren't included in your extension package.

### Reduce JavaScript by excluding unused modules

Dynamics 365 Commerce comes with a large set of modules referred to as the Commerce [module library](#). If there are modules that won't be used on an e-Commerce site, they can be excluded to reduce the JavaScript chunk size. The excluded modules will not be rendered on the live e-Commerce site or available within Commerce site builder when authoring pages.

Modules can be excluded by adding the module name to the **excludeModules** property in the SDK's `"/src/settings/platform.settings.json"` file, as shown in the following example.

```
{
  "excludeModules": ["<EXCLUDED_MODULE_NAME1>", "<EXCLUDED_MODULE_NAME2>"]
}
```

You can verify that the module was successfully excluded by comparing the chunk size displayed after a build, or by testing the module in a development environment. For the latter method, you can confirm that the excluded module is not rendered by using the URL `http://localhost:4000/modules?type=<your-module-name>` (after running the Node server by using the "yarn start" command).

## Optimize images

One of the biggest performance hits to a web page can be the downloading of images. You should use CSS whenever possible to generate images for items such as buttons, but in cases where you need marketing or product images you should upload images to the Commerce site builder [Media Library](#). Images uploaded to the Media Library should be of high quality and resolution to cover all web site usage scenarios. Images served from the Media Library will automatically be resized using an image resizer service.

### Image resizer service

When rendered inside of a module, served images are processed by an image resizer service included in the Commerce rendering engine. This is important for responsive design because as the screen size gets smaller, images will automatically be scaled down to the optimum size for each particular module.

It's important to follow some guidelines to ensure that images are resized correctly. Modules can specify image sizes for particular view ports in the `theme.settings.json` file. For more information, see [Configure theme settings](#).

When building modules with images, the HTML should always include the width and height parameters. If the width and height are not provided, image caching will not be optimized through the image resizer.

### Image types and file sizes

There are three aspects that are important when determining the file size of an image:

- The resolution of the image (width and height).
- How the image is encoded (JPEG, GIF, or PNG).
- The quality parameter (JPEG only).

JPEG uses lossy compression that decreases the file size by discarding image detail. The amount of detail discarded is controlled by the quality parameter, which is a number between 0 and 100, with 100 being the best quality. A lower-quality parameter number results in a lower-quality image, but also a smaller file size.

PNG is a lossless format, so no image detail is lost but the image file size will be larger. For images with text, sharp lines, or color gradients, PNG may be a better choice because the JPEG format may show undesirable artifacts as a result of the lossy compression.

GIF is also a lossless format, but it only supports 256 colors in a single image. For images with text or sharp lines that also don't have many colors, GIF may be a better format choice over PNG or JPEG. GIF also has support for simple animations.

Ultimately, the goal is to find the right balance to maintain image quality while keeping the image size as small as possible.

## Cache configuration

Caching is often used on static content that doesn't often change, such as images, product content, and JavaScript and CSS files. Some scenarios may require custom cache settings to achieve the best performance

results.

### Image caching

The default content delivery network (CDN) cache time for images is set to 5 minutes. This means that after 5 minutes the next request to get a specific image will need to be retrieved from the origin, and so will be slower. Increasing the cache time setting is possible, but it must be done by opening a support ticket.

### Data caching

Product-specific data is cached in the e-Commerce rendering Node layer. Caching times are different for each entity type and can be configured inside of the `cache.settings.json` file in the SDK `"/src/settings/"` directory. For more information, see [Data cache settings](#).

## Browser hint meta tags

Browser hint meta tags such as `preconnect` and `dns-prefetch` can be used to tell browsers what resources are needed ahead of time to render a page. Such tags will cause a browser to initiate network connections before it typically would, to make time-expensive network calls earlier. This is useful for adding additional rendering of image, font, or file endpoints used within a page.

The `preconnect` browser hint meta tag can be used if a page relies on resources coming from external origins or domains to initiate a TCP connection. This will cause DNS lookup, TCP handshake, and TLS negotiation to happen before the reference in the HTML document.

The following is an example of a `preconnect` meta tag hint used in HTML.

```
<link rel="preconnect" href="https://<DOMAIN_TO_PRECONNECT>">
```

The `dns-prefetch` browser hint meta tag can be used if a resource is likely to be navigated to or used on a page. DNS prefetching can resolve a domain's address earlier than usual to avoid this time-expensive step later.

The following is an example of a `dns-prefetch` browser hint meta tag used in HTML.

```
<link rel="dns-prefetch" href="https://<DOMAIN_TO_PREFETCH>">
```

Adding meta tags to a page can be done in Commerce site builder using the **Metatags** module. The **Metatags** module should be added to a page template's "HTML Head" section. For more information, see [Work with templates](#).

## Performance analysis

It's very important that e-commerce site pages be performance tested before they go live. You can use a wide range of existing webpage performance testing tools for this purpose. At a minimum, you can use your web browser's F12 Developer Tools to examine the network loads for individual parts of a page. This approach can help identify any performance bottlenecks so that you can investigate them further.

## Restrict your e-commerce website from loading inside external website HTML iframe elements

The `frame-ancestors` directive can be used to restrict the loading of your e-commerce site inside external website HTML iframe elements. For more information on how to configure this feature in Commerce site builder, see [Manage Content Security Policy](#).

# Dynamics 365 Commerce online SDK FAQ

2/18/2021 • 3 minutes to read • [Edit Online](#)

## IMPORTANT

Some or all of the functionality noted in this topic is available as part of a preview release. The content and the functionality are subject to change. For more information about preview releases, see [One version service updates FAQ](#).

This topic summarizes answers to questions frequently asked by users of the Dynamics 365 Commerce online software development kit (SDK).

### **After upgrading to module library version 9.27 (Commerce version 10.0.17 release), buy box module view extensions might generate a compilation error.**

The compilation error is caused by code sharing that is related to the product quick view module that was introduced in the Commerce version 10.0.17 release. Because the quick view module shares lots of functionality with the buy box module, some common components were moved to a common folder, so that the buy box and quick view modules can share the code.

To fix the compilation error, update any import references in the buybox.tsx view file, as shown in the examples that follow.

This example shows the old code for imports in buybox.view.tsx.

```
import { IBuyboxViewProps } from '../..';
import {
  IBuyboxAddToCartViewProps,
  IBuyboxAddToOrderTemplateViewProps,
  IBuyboxAddToWishlistViewProps,
  IBuyboxFindInStoreViewProps,
  IBuyboxKeyInPriceViewProps,
  IBuyboxProductConfigureDropdownViewProps,
  IBuyboxProductConfigureViewProps,
  IBuyboxProductQuantityViewProps,
  IBuyboxShopSimilarLookViewProps
} from './components';
```

This example shows the new code for imports in buybox.view.tsx.

```
import { IBuyboxAddToCartViewProps, IBuyboxAddToOrderTemplateViewProps, IBuyboxAddToWishlistViewProps,
  IBuyboxKeyInPriceViewProps, IBuyboxProductConfigureDropdownViewProps, IBuyboxProductConfigureViewProps,
  IBuyboxProductQuantityViewProps, IBuyboxShopSimilarLookViewProps } from '../..common';
import { IBuyboxViewProps } from './buybox';
import { IBuyboxFindInStoreViewProps } from './components/buybox-find-in-store';
```

### **After upgrading to module library version 9.24 (10.0.14 release), cloned modules that use data actions may display the error, "UserAuthorizationException. Customer account number on the request was wrong".**

The following list of [core data actions](#) have a signature change that moves the user account number parameter to the second parameter (instead of the first) and is now set as an optional parameter. In most scenarios where the user account number is no longer needed, the data action will execute in the context of the current signed-in user. In some custom scenarios where the user account number is different than the user account number of the signed-in user, you can fetch the user account number by using the [get-customer](#) data action and passing it to the data action.

Core data actions with signature changes include:

- **add-address**
- **get-address**
- **get-customer**
- **get-loyalty-card**
- **get-loyalty-transaction-estimation**
- **issue-loyalty**

The module library modules have been updated with the correct calling pattern to the above data actions, so you won't receive any errors in these modules. However, if one of the modules was previously [cloned](#) it will still have the older data action signature and display this error at runtime, "UserAuthorizationException. Customer account number on the request was wrong". The signatures will need to be updated accordingly. One way to resolve this issue is to temporarily clone the module library module again with a new name, then differentiate the new module code with the previously cloned custom module and merge the changes. The temporary module can then be deleted.

**After upgrading to module library version 9.23 (10.0.13 release), cloned modules or view extensions that import "CartlineComponent" or "WishListIconComponent" components may display the errors "export 'CartlineComponent' was not found in '@msdyn365-commerce/components'" or "export 'WishListIconComponent' was not found in '@msdyn365-commerce/components'".**

The "CartlineComponent" and "WishListIconComponent" components have been renamed to "CartLineItemComponent" and "WishListIconComponent" respectively. If the previous component names are used in either a cloned module or a view extension, the build errors mentioned above will be displayed. To fix these issues, update the previous component names to the new component names in the cloned module or view extension code.

# Retail software development kit (SDK)

2/18/2021 • 15 minutes to read • [Edit Online](#)

This topic provides an overview of the Retail software development kit (SDK). Microsoft Dynamics 365 Commerce provides a rich SDK that developers can use to customize and add new features to the product. The multi-tier architecture of the Dynamics 365 Commerce provides simplified options for customizing and extending the client, business logic, and data layers independently of each other. The Retail SDK includes libraries, NuGet packages, a point of sale (POS) application, code samples, templates, and tools. You can use it to create extensions apps, add features, and change existing functionality of Commerce.

## Retail SDK overview

The Retail SDK includes the code, code samples, templates, and tools that are required to extend or customize existing Commerce functionality. The SDK supports rapid development, full MSBuild integration, and package generation. The following image shows the relationship between the development environment and the cloud components.

### NOTE

The Retail SDK supports the Transport Layer Security (TLS) 1.2 standard. Any customization that you build by using the Retail SDK should follow the TLS 1.2 standard.

## Download the Retail SDK

The Retail SDK is available in development environments that are provisioned via Microsoft Dynamics Lifecycle Services (LCS), in the virtual hard disks (VHDs) that are downloaded from LCS, and in hotfix packages that are deployed to the LCS environment. For more information, see [Deploy and access development environments](#) and

## [Apply updates to cloud environments.](#)

To access the Retail SDK, sign in to the development virtual machine (VM), and go to the K:\RetailSDK folder. You can obtain new versions of the Retail SDK by applying any Commerce binary hotfix from LCS to the development environment. After hotfix deployment is completed, you can find the new version of the SDK inside the K:\RetailSDK\Update folder.

If the current version of the Retail SDK contains extensions, the configuration files and extension projects must be merged from the previous version of the SDK to the new version after an upgrade. This merge is required only if your previous version of the SDK includes extensions, and those extensions must be migrated to the new version. For more information and detailed instructions, see [Upgrade the Retail channel extension to the latest Retail SDK](#). We recommend that you integrate the SDK with a source control system such as Git or Azure.

## Full MSBuild integration

The Retail SDK is a build system. A simple MSBuild command from the root of the SDK folder builds everything. This functionality eliminates questions about how you should build and where you should build from. It also ensures consistency and reproducibility. Therefore, the Retail SDK can easily be integrated with a build pipeline such as Azure Pipelines. For more information, see [Set up Commerce SDK build pipeline](#).

## Prerequisites

To develop or build extensions by using the Retail SDK, you must have the following components:

- Visual Studio 2017 Community, Professional, or Enterprise edition (VM) that has the following components:
  - .NET Desktop development
  - Universal Windows Platform development
  - ASP.NET and web development
  - Azure development
  - Node.js development
  - .NET Core cross-platform development
  - Mobile development with .NET (required for hybrid app development)
- The following runtimes:
  - [sdk-2.1.202-windows-x64-installer](#)
  - [sdk-2.1.513-windows-x64-installer](#)
  - [runtime-2.0.9-windows-x64-installer](#)
  - [runtime-2.1.17-windows-x64-installer](#)
  - TypeScript version 2.2.2

Visual Studio 2017 has TypeScript 3.1 as the default version. You must install version 2.2.2, because the POS app is based on that version. In Visual Studio, select **Tools > Get Tools and Features**. On the **Individual components** tab, select the **TypeScript 2.2 SDK from SDKs, libraries, and frameworks** section, and install it.

## Build the Retail SDK

Before you start development via the Retail SDK, you must restore all the packages by using MSBuild to do a full build from the root of the SDK folder.

1. Open the developer Command Prompt window for Visual Studio 2017 or the MSBuild 15.0 Command

Prompt window.

2. In the Command Prompt window, go to the Retail SDK folder.
3. Run the **msbuild /t:rebuild** command from the root of the SDK folder. The `dirs.proj` file in the root of the SDK folder (`RetailSDK\dirs.proj` or `RetailSDK\Code\dirs.proj`) contains all the details that are required to build the full SDK.

Administrator: Developer Command Prompt for VS 2017

```
K:\RetailSDK>msbuild /p:Configuration=Release_
```

## Retail SDK components

The following table shows the folders that the Retail SDK contains to help with extension development. The folder structure and descriptions in this table are based on Retail SDK version 10.0.13.

FOLDER OR FILE	DESCRIPTION
Assets	This folder contains scripts and configuration files that are required for packaging. Only these configuration files ( <code>HardwareStation.Extension.config</code> , <code>RetailProxy.MPOSOffline.ext.config</code> , <code>CommerceRuntime.Ext.config</code> , and <code>CommerceRuntime.MPOSOffline.Ext.config</code> ) can be edited so that they include extension binary details for packaging. <ul style="list-style-type: none"><li>• <b>manifest.json</b> – The SDK binary version.</li></ul>
BuildTools	This folder contains scripts, sample certificates, and a <code>Customization.settings</code> (packaging metadata) file. Don't change any files in this folder, except <code>Customization.settings</code> .
Database	This folder contains shared database scripts. Extensions must copy the extension scripts to the <code>Database\Upgrade\Custom</code> folder.
Documents	This folder contains instructions for running some of the samples.
OnlineStore	This folder contains the end-to-end sample e-Commerce storefront solution that was built by using the Retail proxy.
Packages	The Retail deployable package that is generated after the SDK build for packaging will be copied to this folder ( <code>Packages\RetailDeployablePackage</code> ). The Retail deployable package is deployed to different environments (test, sandbox, and production) by using LCS.

FOLDER OR FILE	DESCRIPTION
PaymentExternals	<p>Extension payment assemblies must be copied. The following three subfolders hold various payment files:</p> <ul style="list-style-type: none"> <li>• <b>IPaymentProcessor Assemblies</b> – This folder contains the assembly that implements the <b>IPaymentProcessor</b> interface and its dependent assemblies.</li> <li>• <b>Payment Web Files</b> – This folder contains the callback HTML, JavaScript, or Cascading Style Sheets (CSS) files that are required to make the payment accepting page available. Payment connector developers will provide these web files if their payment accepting page requires them.</li> <li>• <b>IPaymentDevice Assemblies</b> – This folder contains the assembly that implements the <b>IPaymentDevice</b> interface and payment request handlers, and the interface's dependent assemblies. These assemblies are used in Retail Hardware station and Retail Modern POS to communicate with payment terminal devices.</li> </ul> <p>Additionally, all extensions that are related to payment connectors should be put in this folder before you create the deployment packages.</p>
Payments	<p>The folder contains the sample Payment Connector project for E-Commerce Add-in for Dynamics 365 Commerce.</p>
pkgs	<p>This folder contains all the NuGet packages (reference libraries) that are required to build the extension projects and tools for packaging and Retail proxy generation.</p>
POS	<p>This folder contains the POS app and extension project:</p> <ul style="list-style-type: none"> <li>• <b>App</b> – Modern POS–specific views and other items.</li> <li>• <b>Contracts</b> – Public contracts for POS extensions. Extension can consume only these contracts for POS extensions.</li> <li>• <b>Extensions</b> – Sample Extension projects and POS.Extension project that extension can consume.</li> <li>• <b>Folder SharedApp</b> – POS views that are shared between Cloud POS and Modern POS.</li> <li>• <b>Folder Web</b> – Cloud POS–specific views and other items.</li> <li>• <b>CloudPos.sln</b> – The Cloud POS solution file.</li> <li>• <b>ModernPos.sln</b> – The Modern POS solution file.</li> </ul>
References	<p>This folder serves as the single location where all binaries are stored. It's used to resolve every project's binary references. The list of files includes external non-Commerce binaries and also Microsoft Commerce binaries. Additionally, this folder serves as the global drop location for any binaries that are built from the Retail SDK.</p>

FOLDER OR FILE	DESCRIPTION
SampleExtensions	<p>This folder contains the sample projects and templates for extensions:</p> <ul style="list-style-type: none"> <li>• <b>CommerceRuntime</b> – Sample extension projects for business logic extensions (Commerce runtime [CRT] triggers, handlers, and new service extension).</li> <li>• <b>HardwareStation</b> – Sample Hardware station extension projects.</li> <li>• <b>HybridApp</b> – Android and iOS shell apps for the POS. Extension can build these apps and deploy them to the Android and iOS platforms.</li> <li>• <b>OnlineStore</b> – The sample online storefront app.</li> <li>• <b>RetailProxy</b> – The sample C# proxy project for POS offline mode. As of version 10.0.11, the C# proxy is obsolete (deprecated). The Retail server extension libraries can be used directly in offline mode. You don't have to have separate proxy libraries.</li> <li>• <b>RetailServer</b> – Sample Retail server extension projects.</li> <li>• <b>SampleExtensionsTest</b> – The sample project for creating an extension test project.</li> <li>• <b>ShoppingApp</b> – The sample mobile app (Retailer shopping app) for users in Android and iOS.</li> <li>• <b>TypeScriptProxy</b> – Sample proxy projects that show how to generate TypeScript for the POS.</li> </ul>
dirs.proj	This project file directs the build order.
Microsoft-version.txt	This file includes the Microsoft application version of the Retail SDK.

## Extension components in the Retail SDK

The following tables provide information about the components in the Retail SDK that must be customized for different scenarios. Only the sample projects inside the RetailSDK\SampleExtensions folder can be changed for extension purposes. No other files or projects/scripts in the Retail SDK should be changed.

### Client (POS)

SCENARIO	Extend the POS for user experience (UX) changes, client logic, workflows, and simple validations.
COMMERCE SDK REFERENCE	<p>\RetailSDK\POS</p> <p>Open the ModernPos.sln or CloudPos.sln file, and add an extension to the POS.Extension project. Don't change anything in the core POS app/web projects.</p>
TECHNOLOGY	TypeScript, HTML, and CSS
DOCUMENTATION	<a href="#">Run the point of sale (POS) samples</a>

### CRT

SCENARIO	Extend CRT to add or change business logic (for example, logic for calculating tax, prices, or discounts).
COMMERCE SDK REFERENCE	\RetailSDK\SampleExtensions\CommerceRuntime Open the CommerceRuntimeSamples.sln file.
TECHNOLOGY	C#
DOCUMENTATION	<a href="#">Commerce runtime (CRT) and Retail Server extensibility</a>

### Retail server

SCENARIO	Create a Retail server extension to expose new Commerce APIs to the client.
COMMERCE SDK REFERENCE	\RetailSDK\SampleExtensions\RetailServer Open any of the sample extensions inside the RetailServer folder.
TECHNOLOGY	Open Data Protocol (OData) and C#
DOCUMENTATION	<a href="#">Create a new Retail Server extension API (Retail SDK version 10.0.11 and later)</a> <a href="#">Create a new Retail Server extension API (Retail SDK version 10.0.10 and earlier)</a>

### TypeScript proxy

SCENARIO	A TypeScript proxy is required if new Retail server extensions must be consumed in the POS or E-Commerce clients.
COMMERCE SDK REFERENCE	\RetailSDK\SampleExtensions\RetailServer Open any of the sample extensions inside the RetailServer folder.
TECHNOLOGY	OData and C#
DOCUMENTATION	<a href="#">Create a new Retail Server extension API (Retail SDK version 10.0.11 and later)</a> <a href="#">Create a new Retail Server extension API (Retail SDK version 10.0.10 and earlier)</a>

### Hardware station

SCENARIO	A Hardware station is required to add or change logic that is related to peripherals.
COMMERCE SDK REFERENCE	\RetailSDK\SampleExtensions\HardwareStation Open the HardwareStationSamples.sln file.
TECHNOLOGY	C#

DOCUMENTATION	<a href="#">Integrate POS with a new hardware device</a>
---------------	--

### Payment connector

SCENARIO	Integrate the POS with a new payment connector.
COMMERCE SDK REFERENCE	<pre>\RetailSDK\SampleExtensions\HardwareStation\Extension.PaymentSample</pre> <p>Open the HardwareStation.Extension.PaymentSample.sln file.</p>
TECHNOLOGY	C#
DOCUMENTATION	<a href="#">Create an end-to-end payment integration for a payment terminal</a>

## Best practices for naming

The C# source code in the Retail SDK uses the Contoso namespace. Therefore, it's easier to distinguish Microsoft types and extension types. If your extension code references a type from the Microsoft binary, use **Microsoft.Dynamics** for the reference, to distinguish between Microsoft libraries and the libraries from the extension. The extension libraries must not begin with the **Microsoft.Dynamics** name.

## Deployment packages

After extension development (CRT, Retail Server, database scripts, POS, and Hardware station), you can use the Retail SDK to generate deployment packages. Packages can be deployed to test, sandbox, and production environments. For more information, see [Create deployable packages](#).

## Dependencies, build order, and full builds

You should build all the extensions and required out-of-box projects. ([Use MSBuild to do a full build from the root of the SDK folder](#).)

- You should build your extension, POS, and packaging projects, but you don't have to build the sample projects that are included in the Retail SDK. You can edit the dirs.proj file in the Retail SDK to remove unwanted sample projects, but don't remove the packaging and POS projects from the list.
- Include the extension project in the dirs.proj file of the appropriate folder. In that way, when you run MSBuild from the root of the SDK folder, all the extension and required out-of-box projects are built.
- The dirs.proj file in the root of the SDK folder is sequenced in the correct order to build all the required projects and then the packaging project. The sequence must be correct. Otherwise, the project and dependencies won't be built correctly.

## Regular configuration/code signing

For Modern POS, create an app package signing certificate to build correctly, or use Cloud POS. For information about how to create a PFX file, see [Create a certificate for package signing](#). Then copy the PFX file to the BuildTools folder, and update the BuildTools\Customization.settings file with the correct name by using the **ModernPOSPackageCertificateKeyFile** element.

The BuildTools\Customization.settings file holds most of the configuration values for the Retail SDK.

```

<!-- This section is for global settings and code signing. Any build file will inherit these values if
applicable.
also use these values during package generation. -->
<AssemblyNamePrefix>MyCompany</AssemblyNamePrefix>
<CustomAssemblyVersion Condition="'$(CustomAssemblyVersion)' == ''>1.0.0.0</CustomAssemblyVersion>
<CustomVersion Condition="'$(CustomVersion)' == ''>1.0.0.1</CustomVersion>
<CustomName Condition="'$(CustomName)' == ''>MyCompany Retail Customization</CustomName>
<CustomDescription Condition="'$(CustomDescription)' == ''>MyCompany Retail
Customization</CustomDescription>
<CustomPublisher Condition="'$(CustomPublisher)' == ''>MyCompany Ltd.</CustomPublisher>
<CustomCopyright Condition="'$(CustomCopyright)' == ''>MyCompany (c) 2015</CustomCopyright>

<SignAssembly Condition="'$(SignAssembly)' == ''>true</SignAssembly>
<DelaySign Condition="'$(DelaySign)' == ''>>false</DelaySign>
<AssemblyOriginatorKeyFile Condition="'$(AssemblyOriginatorKeyFile)' == '' and '$(SignAssembly)' == 'true'">
  $(MSBuildThisFileDirectory)\StrongNameSigningCert-Contoso.snk</AssemblyOriginatorKeyFile>

<ModernPOSPackageCertificateKeyFile Condition="'$(ModernPOSPackageCertificateKeyFile)' == ''>
  $(MSBuildThisFileDirectory)\ModernPOSAppxSigningCert-Contoso.pfx</ModernPOSPackageCertificateKeyFile>

<RetailServerLibraryPathForProxyGeneration Condition="'$(RetailServerLibraryPathForProxyGeneration)' == ''>
  $(SdkReferencesPath)\Microsoft.Dynamics.Retail.RetailServerLibrary.dll</RetailServerLibraryPathForProxyGener
ation>

```

The following values are the global values. These values control how the build manages binaries, components, and how packages are named, versioned, and code-signed.

- **AssemblyNamePrefix**
- **CustomAssemblyVersion**
- **CustomVersion**
- **CustomName**
- **CustomDescription**
- **CustomPublisher**
- **CustomCopyright**
- **SignAssembly**
- **AssemblyOriginatorKeyFile**
- **ModernPOSPackageCertificateKeyFile**
- **RetailServerLibraryPathForProxyGeneration**

It's a good practice to sign your assemblies by using a strong name, even though a strong name isn't required. For information about how to create your own key file if you don't already have one, see [How to: Create a public-private key pair](#).

The installer files that are generated for self-service components such as Modern POS, Hardware station, and Store scale unit can be signed by using [SignTool.exe](#).

Both the key file for the strong name and the app package signing certificate can be stored inside the BuildTools folder or in Azure Key Vault. For a password-protected or secured certificate, use Azure Key Vault.

## Customizing the build

### Adding new projects

It's easy to add new projects to the Retail SDK's build system. You can either clone one of the many existing projects or start a new project. You just have to make some adjustments in a text editor, as shown in the following illustration. The relative path of the **Import** elements should be adjusted, and the **AssemblyName** element should use the predefined **AssemblyNamePrefix** property. These adjustments are required to get

various tasks for free, such as versioning, code signing, uniform assembly naming, and automatic dropping to the References folder.

```
1 <?xml version="1.0" encoding="utf-8"?>
2 <Project ToolsVersion="14.0" DefaultTargets="Build" xmlns="http://schemas.microsoft.com/d
3 <Import Project="..\..\..\BuildTools\Microsoft.Dynamics.RetailSdk.Build.props" />
4 <Import Project="$(MSBuildExtensionsPath)\$(MSBuildToolsVersion)\Microsoft.Common.props"
5 <Import Project="..\..\..\BuildTools\Microsoft.Dynamics.RetailSdk.Build.settings" />
6 <PropertyGroup>
7 <Configuration Condition="'$(Configuration)' == ''">Debug</Configuration>
8 <Platform Condition="'$(Platform)' == ''">AnyCPU</Platform>
9 <ProjectGuid>{2CB843E4-8BEB-4A57-A72B-66D1849FFED6}</ProjectGuid>
10 <OutputType>Exe</OutputType>
11 <RootNamespace>Contoso.Retail.Ecommerce.Publishing</RootNamespace>
12 <AssemblyName>$(AssemblyNamePrefix).Retail.Ecommerce.Publishing</AssemblyName>
13 <ShippingSourceCode>true</ShippingSourceCode>
14 <TargetFrameworkProfile />
15 <TargetFrameworkVersion>v4.5.1</TargetFrameworkVersion>
16 <DefaultLanguage>en-US</DefaultLanguage>
17 </PropertyGroup>
18 <PropertyGroup Condition="'$(Configuration)|$(Platform)' == 'Debug|AnyCPU' ">
27 <PropertyGroup Condition="'$(Configuration)|$(Platform)' == 'Release|AnyCPU' ">
35 <ItemGroup>
11 <ItemGroup>
16 <ItemGroup>
22 <ItemGroup>
39 <ItemGroup>
49 <Import Project="$(MSBuildToolsPath)\Microsoft.CSharp.targets" Condition="'$(WindowsApp
50 <Import Project="$(SdkRootPath)\BuildTools\Microsoft.Dynamics.RetailSdk.Build.targets" /
51 </Project>
```

### Changing the build order or adding to the build

MSBuild traversal files (dirs.proj files) are used to build the whole directory tree of the Retail SDK. The following illustration shows the main traversal file of the Retail SDK. Similar files might also exist in subdirectories. Notice that Visual Studio solution files (.sln files) are similar to traversal files. Both types of file direct the MSBuild engine to process other build scripts.

```
1 <Project ToolsVersion="14.0" DefaultTargets="Build" BuildInParallel="false" xmlns
2 <Import Project="BuildTools\Microsoft.Dynamics.RetailSdk.Build.props" />
3 <Import Project="BuildTools\Microsoft.Dynamics.RetailSdk.Build.settings" />
4 <ItemGroup>
5 <ProjectFiles Include="CommerceRuntime\CommerceRuntime.sln" />
6 <ProjectFiles Include="HardwareStation\HardwareStation.sln" />
7 <ProjectFiles Include="OnlineStore\OnlineStore.sln" />
8 <ProjectFiles Include="Payments\PaymentSdk.sln" />
9 <ProjectFiles Include="SampleExtensions\dirs.proj" />
10 <ProjectFiles Include="Extensions\dirs.proj" />
11 <ProjectFiles Include="Proxies\dirs.proj" />
12 <ProjectFiles Include="Pos\ModernPos.sln" />
13 <ProjectFiles Include="Pos\CloudPos.sln" />
14 <ProjectFiles Include="Packages\dirs.proj" />
15 </ItemGroup>
16 <Import Project="$(SdkRootPath)\BuildTools\Microsoft.Dynamics.RetailSdk.Buil
17 </Project>
```

After new code is added, most of it should be put in a new folder. You must also add it to the traversal structure by adding it to one or more dirs.proj files. In the previous illustration, the Extensions folder is highlighted on line 10. The quickest way to get started with a new dirs.proj file is to copy an existing file, correct the paths in the Import elements, and update the ProjectFiles elements in the ItemGroup element.

### Customizing build scripts

When you must implement new build steps, remember that the existing scripts might be updated by a Retail SDK update later. The best practice is to minimize edits to any file, or to add new files instead. If you require new global MSBuild properties, the BuildTools\Microsoft.Dynamics.RetailSDK.Build.props file is a good place to add them. Likewise, the BuildTools\Microsoft.Dynamics.RetailSDK.Build.targets file can be used to add new build processing targets.

If only one project requires special handling, it's better to explicitly make the change there. If you require new

local MSBuild properties, add a local.props file in the same directory. Alternatively, if you require local build processing targets, add a local.targets file.

## Developer productivity

The **CommerceRuntime** and **RetailServer** extension dynamic-link libraries (DLLs) must be copied into the bin folder of the locally installed RetailServer web application. Users can configure the Customization.setting file so that the DLLs are automatically copied into the bin folder of the local RetailServer web application whenever new versions of these files are built from the extension project.

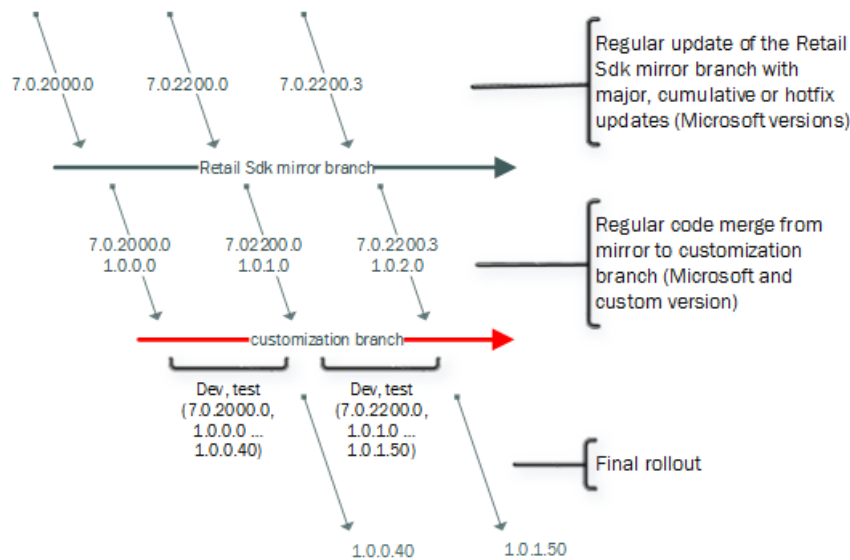

```
47 <!-- This section is for development only features -->
48 <PropertyGroup>
49 <RetailServerDropBinariesOnBuild Condition="'$(RetailServerDropBinariesOnBuild)' == ''>true</RetailServerDropBinariesOnBuild>
50 <RetailServerInstallationLocalBinariesPath Condition="'$(RetailServerInstallationLocalBinariesPath)' == ''>I:\RetailServer\WebRoot\bin</RetailServerInstallationLocalBinariesPath>
51 </PropertyGroup>
52 </Project>
```

## Application Lifecycle Management

A good Application Lifecycle Management (ALM) solution provides version control, builds, automated builds, planning tools, tracking tools, dashboards, customization, and more. The organization of the Retail SDK supports these tasks.

### Branching and versioning

To work efficiently in a team, or even just to be able to go back and look at some changes that were made earlier, you must have a good branching strategy and versioning discipline. The following illustration shows a simple branching strategy that might work well for most teams. The version numbers are fictitious. For more information, see, [Adopt a Git branching strategy](#).

### Retail SDK mirror branch

It's important to emphasize that the non-customized Retail SDK should be stored in your source control. You don't have to store every version, but the versions that your team wants to snap to should be added. (Those versions might be cumulative updates or hotfixes.) Only a simple merge of all changes (that is, additions, changes, and deletions) should be done. No other development work should occur in this branch. The Retail SDK has its own version. All Commerce binaries and packages that are included have the same version. The version can also be found in the root of the SDK folder, in a file that is named Microsoft-version.txt.

### Customization branch

For development, a new customization branch should be created. At the beginning of the initial branch-out, this branch will be an exact copy of the Retail SDK mirror branch. It's the branch that will be used for the team's

development. The version of the customization branch must be incremented at least every time that a build is created for testing. It can even be incremented every day. The file version to increment is defined by using the **CustomVersion** property in the Customization.setting file. If you update the version and rebuild, all binaries, packages, and manifest files are updated accordingly.

The **CustomAssemblyVersion** property should be updated only when the update isn't backward-compatible and/or for major new releases. In other words, you should rarely update this property. In the previous illustration, the current file version of the customization branch is 1.0.2.\* (based on Microsoft version 7.0.2200.3). The file version of the first rolled-out release was 1.0.0.40 (based on Microsoft version 7.0.2000.0). When a testing phase is completed, and the final packages are being deployed with that version, it's important that you either increment the version or create a source control label.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Upcoming changes in the Retail SDK

2/18/2021 • 4 minutes to read • [Edit Online](#)

In a future release of Dynamics 365 Commerce, a new set of features is planned to simplify the development and servicing process for commerce channel customization. To uptake some of these features, you may need to upgrade, recompile, or do some minor code changes in the extensions that you've built. No changes will be required in the extension logic files or manifest that you've created. However, you will have to move your extension files to the new templates, update the packaging model, and recompile Commerce runtime, proxy, and Commerce Scale Unit extensions to map to the new library reference model and integrated development environment (IDE).

Microsoft is publishing this topic before the new features are released, so that you can plan and prepare to uptake them.

Here is the list of new features that are planned for enhancement of the Retail software development kit (SDK), and that will require some work on your side before you uptake them.

## Independent packaging model

Microsoft is developing a new feature that is named the *independent packaging model*. This packaging model helps separate the extensions from the core and services independently. Microsoft plans eventually to support separate packages for extensions too. If there are independent software vendor (ISV) solutions and partner extensions, they can be packaged and serviced separately. ISV solutions and partner extensions no longer have to be combined.

To enable Retail Modern POS to support this new packaging model, Microsoft is changing the point of sale (POS) framework so that it supports the Microsoft Windows optional package extension model. The way that extensions are developed won't change. Only the way that extensions are packaged and deployed will change. In the new model, all Modern POS extensions will be created as separate .appx files. Core POS will load those files as add-ins, and it will run under the core Modern POS app identity. Previously, core POS and extensions were packaged as one .appx file. Now, there will be .appx files for both core and extension add-ins, so that developers can independently service just your extension .appx files. The extensions that are developed will work for both Cloud POS and Modern POS. Although the template might differ, the code is shared between both apps.

### NOTE

When you uptake the new feature, changes are required in the extensions that you previously built. You must move your extension files to the new project type in a separate package and then complete a configuration update. No change is required in the extension logic files or the manifest that you created. However, you must move your extension logic files and manifest to the new template, and then rebuild, test, and validate them.

Independent package model development is not supported in Windows server operating system or LCS development box, you must use your own Windows 10 box.

## Prerequisites

- Visual Studio 2017, version 15.1
- Windows 10, version 1703
- Windows 10, version 1703 SDK

## Development tools

Currently, the Retail SDK samples and other templates inside the Retail SDK work only with Microsoft Visual Studio 2015. To support some of the upcoming changes in the Retail SDK and the new independent packaging model, Microsoft is planning to upgrade from Visual Studio 2015 to either Microsoft Visual Studio 2017 or the latest version.

The new templates and Retail SDK samples can be compiled only in Visual Studio 2017 or the latest supported version. **Therefore, you should plan to upgrade from Visual Studio 2015 to Visual Studio 2017 on your development virtual machines (VMs) when this new feature is released. Starting 10.0.11, Retail SDK components can be developed and compiled only in VS 2017, it will not work in VS 2015.**

## Retail SDK reference folder to NuGet Gallery

All the reference binaries for the Commerce runtime, Commerce Scale Unit, Commerce proxy, commerce tool, and so on, are published in the Retail SDK\Reference folder. Currently, your extensions reference that folder. However, Microsoft is planning to move away from this model and publish the SDK references in the NuGet Gallery instead.

### NOTE

For this new model, you should change your extension project so that it references the NuGet Gallery instead of the Retail SDK\reference folder. This change will require a reference update and recompilation in your extension project.

This new model will simplify the update process. For example, if you require any updated references in the Retail SDK, you must currently go to Microsoft Dynamics Lifecycle Services (LCS), apply the latest binaries updates, and so on. In the NuGet approach, you can just right-click to get the updated version.

## Commerce packaging tool

The channel installers are being enhanced so that you can use them to install just the extensions. You will be able to decide whether to use one combined installer for core and all extensions, or whether to install extensions and core separately.

## Retail SDK samples to GitHub

Microsoft is planning to move the samples from the Retail SDK to GitHub. Because the samples are published only as sample code, this change won't affect your extensions. GitHub makes it easy to get the latest samples. You will no longer have to go through the LCS process.

### NOTE

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Development and ALM changes from version 10.0.10 to 10.0.13

2/18/2021 • 7 minutes to read • [Edit Online](#)

It's common for admins of Microsoft Dynamics 365 Commerce environments to pause updates and then leapfrog to the current version. This topic will help ensure that you land safely. There are significant changes and updates to the development and build tools.

Microsoft tries to provide updates that include no breaking changes, and you won't have to refactor your customizations because of these changes. Customizations that follow best practice patterns and that were developed on earlier versions can be deployed on the latest service update.

## Who should read this topic

If you're in a technical role (developer, administrator, or manager) and work with Dynamics 365 Commerce, continue to read this topic. There have been substantial improvements and changes, and there is a wealth of information and documentation that describes what has changed and what other changes are coming. The purpose of this topic is to bring all that information together into a single place, so that you have a better understanding of specific changes that you will have to make to update your development environments or adjust your Application Lifecycle Management (ALM) processes.

## Overall improvements, changes, and notes

The following features are available across products and users. Some features apply to all versions, whereas others apply only to version 10.0.10 and later.

- [All-in-one deployable packages](#) for X++ will merge all your custom code and independent software vendor (ISV) models into a single custom package.
  - In version 10.0.10 and later, custom payment connectors for card-not-present can be included in your deployable package.
  - In version 10.0.13, all-in-one packages will be **mandatory**.
- The commerce deployable package that is created by using the [Retail software development kit \(SDK\)](#) is no longer deployed to Application Object Server (AOS). Instead, you upload your self-service installers to Microsoft Dynamics Lifecycle Services (LCS) and use synchronization. For more information, see [Synchronize self-service installers in Dynamics 365 Commerce](#).
- Use a Microsoft-hosted build agent instead of a dedicated build machine for these purposes:
  - To build [application deployable packages](#)
  - To build [commerce deployable packages](#)

### NOTE

By using a build agent, you will increase your Azure consumption. However, you should see cost savings if you can decommission your dedicated build server.

For a general overview of each application release, always check the "What's new or changed" topics:

- [What's new or changed in Finance and Operations apps home page](#)

- [What's new or changed in Dynamics 365 Commerce](#)
- [What's new and changed in Platform updates](#)

## What's changed in the 10.0.10 release

- Custom payment connectors for card-not-present can be included natively in your X+ + application deployable package. For more information, see [All-in-one deployable packages](#).
- Upload your self-service installers to LCS, and use synchronization. For more information, see [Synchronize self-service installers in Dynamics 365 Commerce](#).

### NOTE

The process for uploading the installer is a manual process. However, Microsoft is working to incorporate the new Commerce asset types into the [DevOps pipeline tools for Dynamics 365 Finance and Operations](#), so that you will be able to automate the upload to LCS.

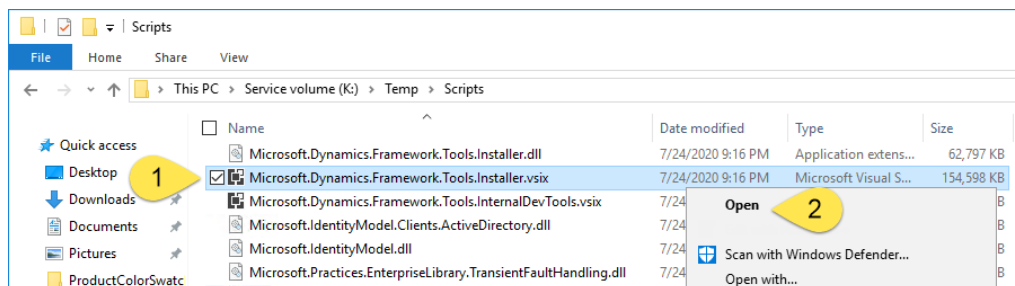

- Custom retail deployable packages no longer have to include the Adyen payment dynamic-link libraries (DLLs).

## What's changed in the 10.0.11 release

- The Retail SDK has been updated to Visual Studio 2017. Visual Studio 2015 is installed on the templates for preconfigured virtual machines (VMs) for developers. However, to build the Retail SDK, you must have Visual Studio 2017 installed. Therefore, you will have to [manually update Visual Studio](#) and rebuild the Retail SDK.

Microsoft is working to rebuild the virtual hard disk (VHD) templates that are used to provision developer and test environments. When this work is completed, the VHD templates will automatically include Visual Studio 2017. Although there is no confirmed date for when the rebuilt templates will be available, Microsoft expects them to be ready soon after version 10.0.13 is generally available in September 2020. For more information, see [Action Required - .NET version and Visual Studio 2017](#).

- Install the Visual Studio tools by installing the Visual Studio extension. To download the extension, follow these steps:
  1. Download the latest service update package from the Shared asset library in LCS. This package is a zip file.
  2. Open the zip file, and find the **DevToolsService\Scripts** folder.
  3. Extract the **Scripts** folder to your local computer (for example, **K:\Temp\Scripts**).
  4. Find the **Microsoft.Dynamics.Framework.Tools.Installer.vsix** file. The size of this file should be about 150 megabytes (MB).
  5. Right-click the file, and then select **Open**.

For more information, see [Update the Visual Studio development tools](#).

- Rebuild the Retail SDK.
  1. Go to the folder that contains your unmodified version 10.0.11 Retail SDK.
  2. Create a backup copy of the Retail SDK for safekeeping.
  3. Open Visual Studio 2017 as an admin, and then open each standard solution file in the SDK folder. You will probably receive a message that states that Visual Studio will close and reopen, and that a computer restart might be required. Select **Continue**.
  4. Open the Visual Studio 2017 Command Prompt window as an admin, and verify that you're using the correct version of the Visual Studio developer command prompt. Visual Studio 2017 uses version 15 of the developer command prompt (whereas Visual Studio 2015 uses version 14). The version number appears in the command window when it opens.
  5. Verify that the standard SDK can be compiled. Go to the root of the **RetailSDK** folder, and run the following command.

```
msbuild /t:rebuild
```

If the build fails, you probably skipped one of the earlier steps.

- References to `PackageReference` (NuGet package reference) are updated. Because of this change, project references are much easier to maintain. Additionally, because of this change, you must manually update *every* custom project in the Retail SDK. Expect to spend about five minutes per project. Look at how the standard projects were updated, and use those updates as a model.
  1. Make sure that everything can be compiled, and that a package can be created from your local developer machine.
  2. Make sure that your build server is updated to Visual Studio 2017.

#### WARNING

Your build server will probably fail, because the names of the NuGet reference folders are very long and will exceed the file path limit of 260 characters.

- Retail SDK file size: The size of an unmodified retail deployable package is now about 340 MB. If customizations are included, the file size might increase to 350 MB. If you try to deploy the file to your Commerce Scale Unit (cloud) (previously known as Retail Cloud Scale Unit [RCSU]), you will receive an error message that states that you can't deploy [packages that are larger than 300 MB](#). Follow these steps to fix this issue:
  1. Follow the instructions in [Deploy the deployable packages](#), and manually remove the self-service installer files.
  2. Upload the much smaller package to LCS, and then continue your deployment as usual.

#### NOTE

The build and deployment scripts that are embedded in the deployable package are hard-coded to check for the self-service installers.

## What's changed in the 10.0.12 release

- It's easier to generate the [Commerce proxy](#).

## What's changed in the 10.0.13 release

- In version 10.0.13, application development that uses X++ requires Visual Studio 2017. If you haven't yet updated to Visual Studio 2017, review the section about version 10.0.11 earlier in this topic.
- Microsoft is working to rebuild the VHD templates that are used to provision developer and test environments. When this work is completed, the VHD templates will automatically include Visual Studio 2017. Although there is no confirmed date for when the rebuilt templates will be available, Microsoft expects them to be ready soon after version 10.0.13 is generally available in September 2020. For more information, see [Action Required - .NET version and Visual Studio 2017](#).

## Where to go for help

1. First, double-check and triple-check to make sure that you followed every step in the relevant topics that are listed earlier in this topic.
2. Check with your partner. Your partner is familiar with your business and setup. Your setup might involve a unique customization that your partner can quickly identify and address.
3. Check the [Retail SDK FAQ](#). It's updated as common issues are identified.
4. Submit a support request through LCS. Provide as much information as you can about the issue. When you submit the request, send a copy to your FastTrack solution architect.
5. Expect to share your screen with your partner, the support specialist, your solution architect, or even a combination of the three. Be prepared to reproduce the error.

### NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Merge the build systems for Commerce and Finance

2/18/2021 • 3 minutes to read • [Edit Online](#)

This topic describes the steps for merging the build systems for Dynamics 365 Commerce and Dynamics 365 Finance. The Lifecycle Services (LCS)-integrated build experience supports both code upgrades and new projects. The Commerce software development kit (SDK) is a self-contained MSBuild-based build system. Many customizers want to make productive changes in both Microsoft Commerce and Finance components. This topic outlines the manual steps for merging both build systems using Azure DevOps.

## Enable the build system

To get started, you must follow all the steps to get a full continuous build system up and running. For information, see [Developer topology deployment with continuous build and test automation](#). After deployment, you create the build definition and build steps. Build at least one time, so that you become familiar with it and are sure that you can build without errors. Then move to the next step.

## Prepare the Retail SDK

### Getting the Retail SDK

If you don't already have the Retail SDK in the same Microsoft Azure DevOps project, add it now. You will find the SDK in any developer or build topology. Follow the branching documentation in [Retail software development kit \(SDK\) architecture](#). We recommend that you create your Retail SDK mirror and your SDK customization branch at this time. After your SDK customization branch is ready, and it has been submitted in the same Azure DevOps project as Commerce, you can start.

## Install NuGet.exe

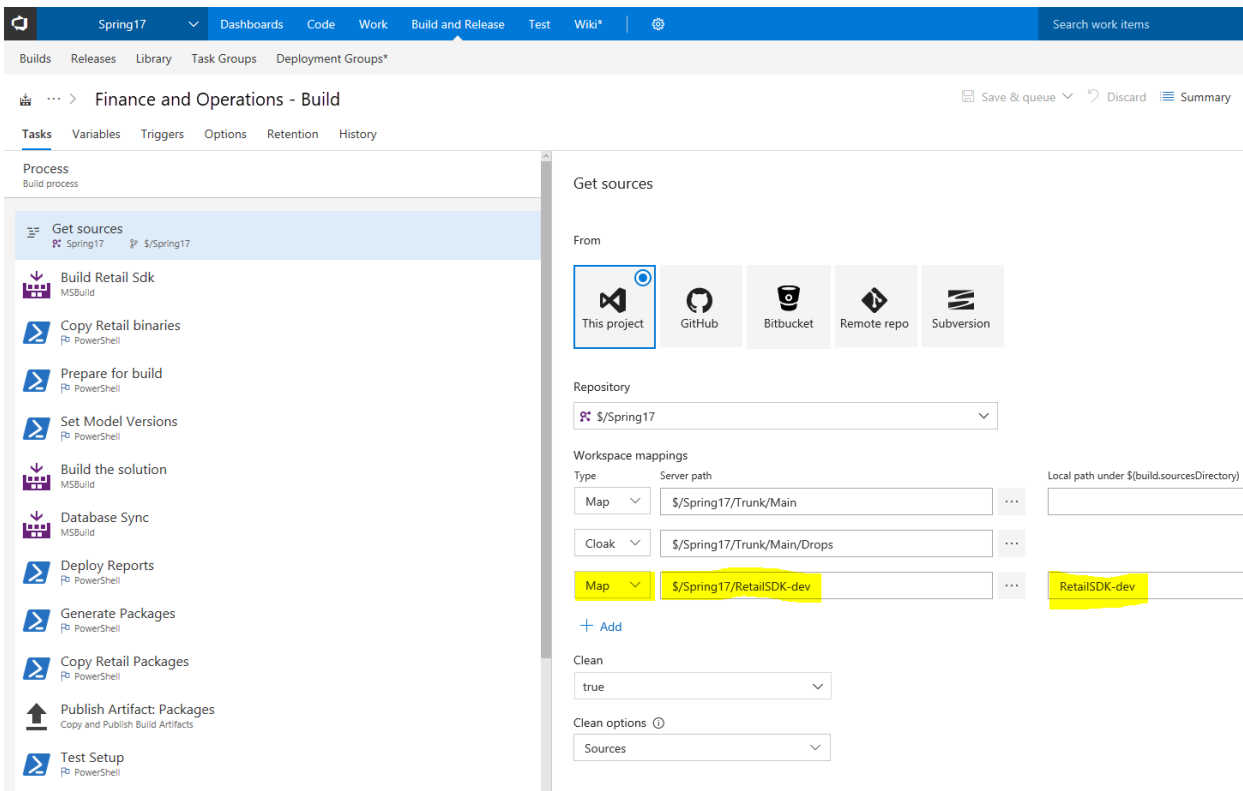

Some of the dependency packages and references have moved to NuGet packages to minimize the file merge and the size of the SDK. These are available for download from the NuGet.org. When you build the Retail SDK these dependencies are automatically pulled from the NuGet.org based on the packages.config file. For this to work, you need to install the [NuGet command line interface](#) and add the nuget to the Windows path after downloading nuget.exe from NuGet.org. The following steps show how to add the nuget to the Windows path:

1. Open the Windows menu and type **Path**. The **Edit the system environment variables** will be available.
2. In that menu, click **Environment variables** on the lower right.
3. In the next window, under **System variables**, select **Path** and click **Edit**.
4. Add an entry for the folder where you would like to store the nuget.exe file or store the nuget.exe file in a folder that is already listed.

## Add a repository mapping for the Retail SDK

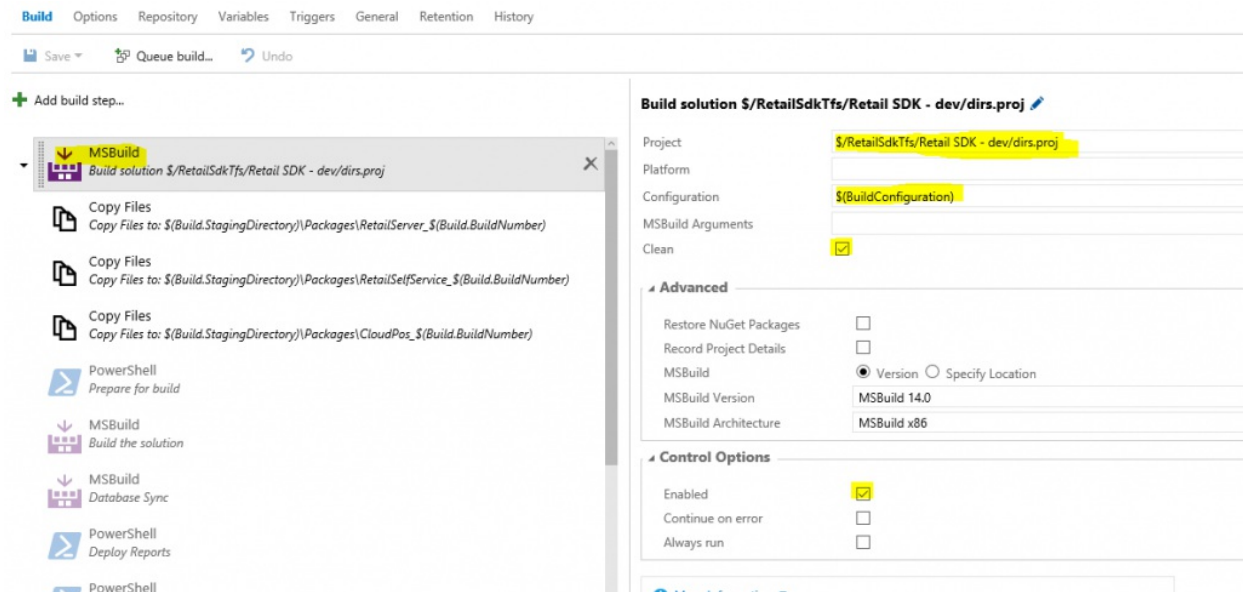

Edit the build definition so that it includes the location of the Retail SDK. (In other words, add a map.)

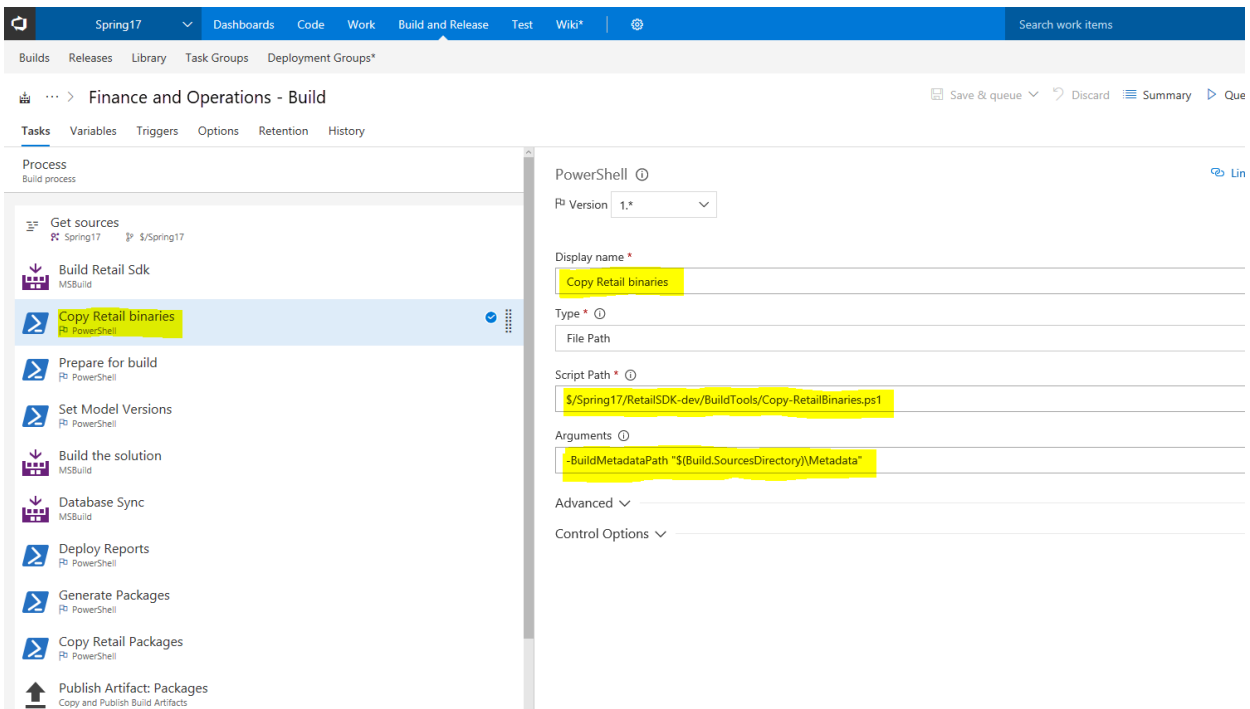

## Add a new build step to build the Retail SDK

Add a new step at the beginning of the build pipeline, as shown in the following screen shot.

## Add a copy step for binaries from the Retail SDK to the Commerce build

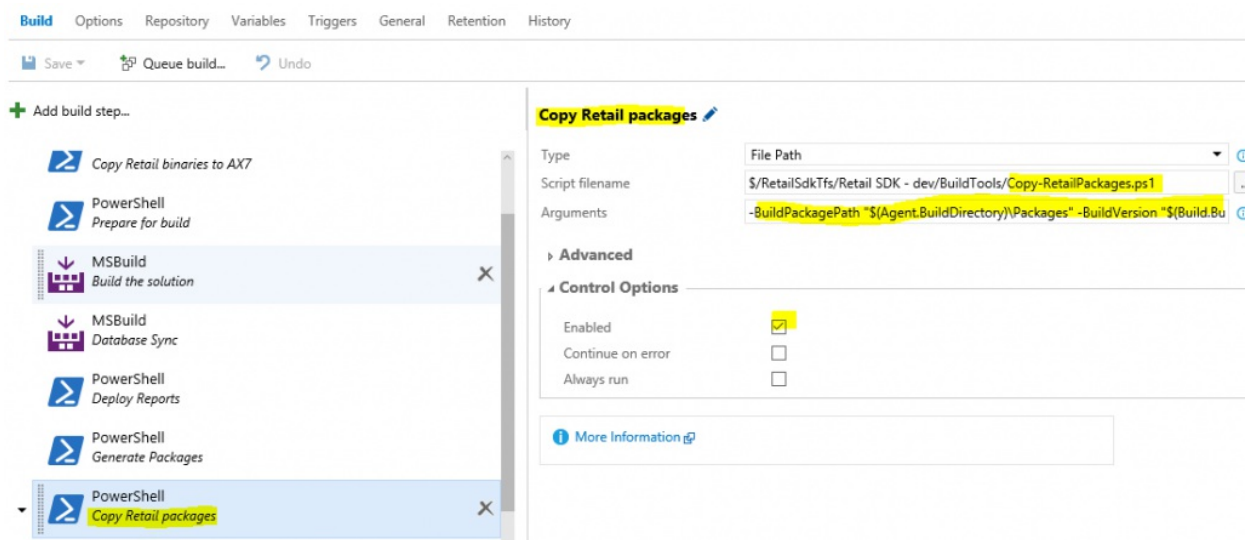

This build step enables Microsoft to copy the latest built Commerce binaries to the Commerce bin folder, if Microsoft shares files/binaries. Make sure that you complete this step immediately after you add a build step for the Retail SDK, as described in the previous section.

## Add a copy step for all Commerce packages

Make sure that this step occurs after the "PowerShell: Generate packages" step (see image below). Here are the arguments.

```
-BuildPackagePath "$(Agent.BuildDirectory)\Packages" -BuildVersion "$(Build.BuildNumber)"
```

## Optional: Referencing a Commerce DLL

You must complete this task only if you must add built Retail binaries to the package. In this case, you must follow these three steps:

1. Use a normal AXReference in your Commerce project.
2. Add the corresponding AXReference folder and the XML file inside it to Azure DevOps.
3. Update the Copy-RetailBinaries.ps1 file with the appropriate file commands to get the binary file from the Retail SDK to the Retail bin folder. The Microsoft Windows PowerShell file includes a sample that copies the PricingEngine.dll file into the ApplicationSuite bin folder. Depending on the modules that you're building, the files and folders must be changed so that they are in a different location.

**NOTE**

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Migrate the Retail SDK from Visual Studio 2015 to Visual Studio 2017

2/18/2021 • 6 minutes to read • [Edit Online](#)

This topic explains what has changed in the 10.0.11 release of the Retail software development kit (SDK), how to migrate it to Visual Studio 2017, and how to update an extension project reference library to NuGet.

## What has changed in the 10.0.11 release

- The Retail SDK has been updated to Visual Studio 2017.
- References have been updated to PackageReference (NuGet package reference).

## Retail SDK updated to support Visual Studio 2017

The Retail SDK now runs on Visual Studio 2017. In release 10.0.11 and later, all Retail SDK components, including Modern POS (MPOS), Cloud POS (CPOS), the Commerce runtime (CRT), Retail Server, the proxy, and Hardware station (HWS), can be built and compiled only in Visual Studio 2017. You can't use Visual Studio 2015.

## References updated to PackageReference

The Retail SDK reference libraries use PackageReference. All the SDK samples use the PackageReference model. All the SDK reference libraries are converted to NuGet packages, and libraries are removed from the RetailSDK\Reference folder. The NuGet packages are in the ..\RetailSDK\Code\pkgs or ..\RetailSDK\pkgs folder. The following example shows the reference to **Microsoft.Dynamics.Commerce.Runtime**.

```
<ItemGroup>
  <PackageReference Include="Microsoft.Dynamics.Commerce.Runtime" Version="9.21.x" />
</ItemGroup>
```

## What is affected

- If you want to deploy a new merged package (that is, an extension and out-of-box changes) on version 10.0.11 or later, you must migrate your solution to the SDK on Visual Studio 2017. No code changes are required to migrate and build your solution.
- Hard-coded references in extension projects must be migrated to PackageReference (NuGet reference).

### Migrate to the SDK for Visual Studio 2017

There are two ways to migrate:

- Deploy a new development and build environment from Microsoft Dynamics Lifecycle Service (LCS), and manually install the Visual Studio 2017. LCS developer VM with Visual Studio 2017 will be available in a future release.
- Update extensions to Visual Studio 2017 in an existing development environment:
  - Install Visual Studio 2017 Community, Professional, or Enterprise edition on the existing build and development virtual machine (VM) with the following workloads:
    - .NET Desktop development
    - Universal Windows Platform development

- ASP.NET and web development
- Azure development
- Node.js development
- .NET Core cross-platform development
- Mobile development with .NET (required for hybrid app development)
- If you manually install Visual Studio 2017, install the following prerequisites on the development VM. If you don't install these prerequisites, compilation will fail, and .NET SDK and runtime errors will be generated:
  - [sdk-2.1.202-windows-x64-installer](#)
  - [sdk-2.1.513-windows-x64-installer](#)
  - [runtime-2.0.9-windows-x64-installer](#)
  - [runtime-2.1.17-windows-x64-installer](#)
  - Install Typescript version 2.2.2. In Visual Studio, go to **Tools > Get Tools and Features**. Select the **Individual components** tab and select the **TypeScript 2.2 SDK from SDKs, libraries, and frameworks** section and install it. VS 2017 has Typescript 3.1 as default, please include 2.2.2 also because the POS app is built based on Typescript 2.2.2.

## Build the Retail SDK

Follow these steps to build the Retail SDK.

1. Open the Developer command prompt for Visual Studio 2017 or the MSBuild 15.0 command prompt. Build the out-of-box Retail SDK by running `msbuild /t:rebuild` from the root of the SDK folder (where you can find the `dirs.proj` file). The folder is `RetailSDK\dirs.proj` or `RetailSDK\Code\dirs.proj` in most installations.
2. Merge your extension to the new SDK folder. For information about how to merge extension with the SDK, see [Upgrade the Retail channel extension to the latest Retail SDK](#).
3. After the extensions have been merged, update all the hard-coded references to `PackageReference` by using the NuGet packages.

## Update the reference in the CRT and Retail Server extension projects

1. a. Use any of the sample CRT projects in the Retail SDK (`..\RetailSDK\SampleExtensions\CommerceRuntime`) as a template and migrate your CRT extension to this new format. The new samples uses the Visual Studio 2017 formats for project dependencies (NuGet references).
2. In the NuGet Package Manager, add the local NuGet repository folder. For information about how to create a local NuGet repository, see [Install and manage packages in Visual Studio using the NuGet Package Manager](#).

### NOTE

All the SDK reference libraries are converted to NuGet packages, and libraries are removed from the `RetailSDK\Reference` folder. The NuGet packages can be found in the `..\RetailSDK\Code\pkgs` or `..\RetailSDK\pkgs` folder.

3. To add the NuGet package reference to the project, right-click the **Dependencies** node in the project, and then select **Manage NuGet Packages**.
4. In the NuGet Package Manager, add the required packages. For example, if the project requires the CRT library reference, add the `Microsoft.Dynamics.Commerce.Runtime` NuGet package. After the NuGet

package reference is added, the project file will be updated with the package reference, as shown in the following example.

```
<ItemGroup>
  <PackageReference Include="Microsoft.Dynamics.Commerce.Runtime" Version="9.21.x" />
</ItemGroup>
```

#### NOTE

PackageReference also supports floating versions, where the version is updated with the floating version number. For more information about floating versions, see [How NuGet resolves package dependencies](#). When the floating version is used, extensions no longer have to update the reference for every update, because NuGet will automatically resolve to the latest version. For example, the package reference might resemble `<PackageReference Include="Microsoft.Dynamics.Commerce.Runtime" Version="9.21.x" />`.

In a similar way, update the references for all the Retail Server, proxy, and Hardware station extension projects.

### Retail Server and Proxy extensions

Migrate the Retail Server and Proxy extensions to the new extension model released in version 10.0.12. Starting in version 10.0.12, the same Retail Server extension library can be used for offline use, no separate C# proxy library is needed, however a client typescript proxy is still required. For more information, see [Create a new Retail Server extension API](#). This step is recommended but not required, as the Retail Server and proxy extension libraries will continue to work until the old extension model is deprecated.

## What isn't affected

You don't have to change the extensions code that was written in previous versions of the Retail SDK. You must update references and recompile only for the new SDK.

If you have existing pipelines in Azure Pipelines not based on build machine agent that are set up for the Retail SDK build will continue to work. In the MSBuild task step, change the MSBuild version to 15.0, if this change is required.

Follow the steps to set up a build pipeline in Azure DevOps without using build VM and build agent from the build machine. For more information, see [Set up Commerce SDK build pipeline](#).

## Azure DevOps pipeline using build machine agent

The same build machine used for MSBuild with the Azure DevOps pipeline can be used with SDK version 10.0.11. Perform the following steps on the build machine for the SDK:

1. Install Visual Studio 2017 on the build machine.
  2. Optionally, run msbuild (msbuild version 15.0) from the developer command prompt for Visual Studio 2017 on the build machine. Open the developer command prompt for Visual Studio 2017 and navigate to the Retail SDK root folder. Type `msbuild dirs.proj` and make sure that the MSBuild completes successfully.
  3. On the build machine, add an environment variable for the MSBuild 15.0. Go to **System Properties > Environment Variables > System variables**. Select the **Path** variable, and then select **Edit**. In the **Edit environment variable** window, select **New** and add the path variable for MSBuild 15.0. Move it to the top of the list of PATH variables. For example, the path will be something like - C:\Program Files (x86)\Microsoft Visual Studio\2017\Enterprise\MSBuild\15.0\Bin. The path will change based on where you installed Visual Studio 2017. To get the path for MSBuild from the developer command prompt for Visual Studio 2017, type **where MSBuild**.
- To validate the config information

- Open a regular "CMD" window (not the Visual Studio command prompt).
  - Run **msbuild /version**.
  - Verify that the first result in the list is MSBuild version is 15.9.\* or greater.
4. Restart the Azure DevOps build agent on the build machine.
  5. In Azure DevOps pipeline, change the MSBuild version to 15.0 or later.

If the build from Azure DevOps pipeline fails with a NuGet error, the Azure pipeline may not be not using MSBuild version 15.0 for NuGet restore or the extension projects are not upgraded to use the package reference model.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Retail software development kit (SDK) extensibility samples

2/18/2021 • 3 minutes to read • [Edit Online](#)

The Retail software development kit (SDK) includes extensibility samples. These samples are a good way to learn about different ways to customize Dynamics 365 Commerce.

The Retail SDK includes extensibility samples. You can also use these projects as boilerplate projects to get started with a specific customization. For example, to start a new commerce runtime (CRT) extension, you can just copy one of the CommerceRuntime sample projects into a new folder, adjust the project import paths, and then start working in the project. For most of the samples, additional step-by-step instructions are available in the Retail SDK\Documents folder. The following table provides a high-level list of the samples.

SAMPLE NAME	DESCRIPTION	TASKS THAT ARE DEMONSTRATED
CrossLoyalty	This sample includes two retailers, AdventureWorks and Contoso. The Contoso retailer accepts loyalty points that customers earn from AdventureWorks. The sample shows how to create a simple new CRT service and call it when a button in Retail Modern POS is clicked. It simulates the cross-loyalty scenario. There are changes to the configuration, CRT, Commerce Scale Unit, Commerce Proxy, and point of sale (POS) (both Modern POS and Cloud POS). This sample supports offline mode for Modern POS.	<ul style="list-style-type: none"><li>• Create a new CRT and Commerce Scale Unit extension, or a new service.</li><li>• Create a new operation as a separate project.</li></ul>
EmailPreference	This sample shows how to use extension properties to extend an entity. The extended entity is persisted in both the Commerce and channel databases, and the POS client enables access to the value. The new value is written synchronously to Commerce via the RetailRealtimeTransaction service. No customization is required in the CRT or Commerce Scale Unit, because extension properties flow automatically. There are changes to pages, tables, the Real-time Service (RTS) client, Commerce Data Exchange (CDX), the channel database, and the POS (both Modern POS and Cloud POS). This sample doesn't support offline mode.	<ul style="list-style-type: none"><li>• Modify an existing Modern POS/Cloud POS view or page.</li><li>• Extend the Real-time Service.</li><li>• Use extension properties to store custom field values in the database.</li></ul>

SAMPLE NAME	DESCRIPTION	TASKS THAT ARE DEMONSTRATED
StoreHours	<p>This sample shows how to create a new business entity (StoreHours) across both Commerce and the channel. There are changes to tables, CDX, the channel database, the CRT, Commerce Scale Unit, and the POS (both Modern POS and Cloud POS). This sample supports offline mode for Modern POS.</p>	<ul style="list-style-type: none"> <li>• Create a new CRT and Commerce Scale Unit extension, or a new service.</li> <li>• Modify an existing MPOS/Cloud POS view or page.</li> <li>• Send the custom table data to the channel by using CDX.</li> </ul>
HealthCheck	<p>This sample shows how to expand an existing CRT service by adding functionality. In this case, the health of some other system can be checked as part of the RunHealthCheckServiceRequest service that already exists. There are changes to the CRT and CRT Test Host.</p>	
ExtensionProperties	<p>This sample shows the following customization strategies for the CRT:</p> <ul style="list-style-type: none"> <li>• Extension properties for service, entity, request, and response</li> <li>• Triggers</li> <li>• Notifications</li> <li>• Notification handlers</li> </ul>	<p>Use extension properties to store custom field values in a database.</p>
CommerceRuntime Test Host	<p>This tool mimics a typical CRT host that resembles Commerce Scale Unit. It supports simple testing of CRT extensions that doesn't require changes in Commerce Scale Unit or UI clients. You just register the services that are required for the CRT and run it.</p> <p><b>Note:</b> RealTimeTransaction service calls that might be part of a CRT extension won't work correctly. To test these service calls, use the RetailServer Test Client sample instead.</p>	
RetailServer Test Client	<p>You can use this simple application to make Commerce Scale Unit calls, offline mode calls through the Commerce Proxy, or both. This sample application acts as a client. It resembles the POS clients but requires no UI changes. Therefore, it supports rapid testing and development. You can use this tool to verify customizations of the channel database, RTS, CRT, and/or Commerce Scale Unit before you hand them off to the UI team.</p>	

SAMPLE NAME	DESCRIPTION	TASKS THAT ARE DEMONSTRATED
OnlineStore	This sample is an ASPNET implementation that showcases the use of the Ecommerce SDK. It includes both a store front and a publishing job.	
OpenIdConnectUtility	This sample lets you call Commerce Scale Unit in a customer context (C2) by using a Google Identity.	
CashDispenser (HardwareStation)	This sample shows how to customize Retail Hardware Station so that a cash dispenser can be integrated.	Create a new Hardware Station project and support for new peripherals.
Rambler (HardwareStation)	This sample shows how to customize Hardware Station so that a Rambler Mobile Card Reader can be integrated.	Create a new Hardware Station project and support for new peripherals.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Create deployable packages

2/18/2021 • 15 minutes to read • [Edit Online](#)

This topic explains how to create a Commerce deployable package (which is a package that contain all the extensions) for the following components and deploy the package to your environment by using Microsoft Dynamics Lifecycle Services (LCS):

- Commerce runtime (CRT)
- Commerce proxy
- Commerce Scale Unit
- Modern POS
- Cloud POS
- Hardware station
- Channel database scripts
- Payment connector
- Hybrid app (IOS and Android POS app)

## Deployable package types

The following table lists Commerce package types for deployment:

PACKAGE TYPE	DESCRIPTION	APPLIES TO
Retail deployable package	Combined package that contains Commerce scale unit (CRT, RS, DB) extension, CPOS, and self-service packages.	Commerce scale unit environment
Commerce cloud scale unit package	Commerce scale unit (CRT, RS, DB) extension.	Commerce scale unit environment
All in one deployable package	Payment extension for Finance and Operations.	Finance and Operations environment

## Retail deployable package

Retail deployable package is one combined package that contains all your customizations together with all the metadata that is required for deployment. You can use this deployable package to deploy your customizations to various environments. You can do the deployment by using the automated flow in LCS, or you can do it manually by using the scripts that are provided inside the package. This topic guides you through the process of generating the deployable package.

### IMPORTANT

All customizations for the Commerce components are packaged as a single deployable package. Separate packages for individual components, such as Modern POS, Cloud POS, Commerce Scale Unit, CRT are not supported. You must package all extensions as a single deployable package, even if you must merge or combine extensions from independent software vendors (ISVs) or various partners.

If your customizations were built and packaged as individual component packages by using a version of the Retail software development kit (SDK) that is older than application version 7.1.1541.3036, the packages are no longer supported for deployment in LCS. You must uptake the hotfix in [KB 4015062](#), and then rebuild and repackage your customizations.

For detailed information about the Retail SDK, see [Retail software development kit \(SDK\) architecture](#).

## Generate a separate package for Commerce Cloud Scale Unit (CSU)

If you have only CSU extension (CRT, RS, and channel database) then you can generate the separate CSU package instead of generating the full Retail Deployable package, which includes both CSU and self-service packages (MPOS, CPOS, RSSU and HWS).

Retail SDK version 10.0.16 or later supports generating a separate package for Commerce Cloud Scale Unit. This package can be uploaded to LCS > **Asset library** > **Commerce Cloud Scale Unit Extensions** and deployed to CSU.

### Steps to generate a CSU package

#### Option 1

1. Clone or download the Scale unit packaging project from [Dynamics365 Commerce ScaleUnit Samples](#).

Select the correct release branch version according to your SDK/application release. Detailed steps to clone can be in [Download Retail SDK samples and reference packages from GitHub and NuGet](#).

2. Add the extension Commerce runtime, Retail server, and channel database extension project as a Project reference to the scale unit packaging project.
3. Build the scale unit project. This project will generate the **CloudScaleUnitExtensionPackage.zip** output package in the project bin output folder. CloudScaleUnitExtensionPackage.zip package can be uploaded to LCS and deployed to CSU.

Select the correct version of the **Microsoft.Dynamics.Commerce.Sdk.ScaleUnit** NuGet version in the NuGet package manager in Visual Studio according to your SDK/application version.

#### Option 2

1. Create a new C# class library project with Target framework .NET Standard 2.0.
2. Add the **Microsoft.Dynamics.Commerce.Sdk.ScaleUnit** NuGet package as a dependency to the project.

Select the correct version of the Microsoft.Dynamics.Commerce.Sdk.ScaleUnit NuGet version according to your SDK/application version.

Consume the Microsoft.Dynamics.Commerce.Sdk.ScaleUnit package from [https://pkgs.dev.azure.com/commerce-partner/Registry/\\_packaging/dynamics365-commerce/nuget/v3/index.json](https://pkgs.dev.azure.com/commerce-partner/Registry/_packaging/dynamics365-commerce/nuget/v3/index.json). You can add the package source location in the nuget.config file of your extension project file.

```
<packageSources>
  <add key="dynamics365-commerce" value="https://pkgs.dev.azure.com/commerce-
partner/Registry/_packaging/dynamics365-commerce/nuget/v3/index.json" />
  <add key="nuget.org" value="https://api.nuget.org/v3/index.json" />
</packageSources>
```

3. Add the extension Commerce runtime, Retail server, and channel database extension projects as a Project reference to the scale unit packaging project.
4. Build the scale unit project. This project will generate the **CloudScaleUnitExtensionPackage.zip** output package in the project bin output folder. CloudScaleUnitExtensionPackage.zip package can be uploaded to LCS and deployed to CSU.

The Commerce runtime extension config, Web.Config, will be generated by the scale unit packaging project. You do not have to create the extension config files manually.

### Deploy the package to CSU

1. Go to <https://lcs.dynamics.com/v2>.
2. Sign in to LCS and open a project. Then, on the hamburger menu, select Asset library.
3. Select the Commerce **Cloud Scale Unit Extension** asset type, and then select the + button to upload the package. Provide a package name and description and then add the package file by selecting Add file.
4. After the upload is complete, select Confirm to complete the upload process.
5. The package will be validated by LCS in a few minutes. After validation is complete, mark the package as Release candidate.
6. After upload, the package needs to be deployed to the environment. For more information, follow the steps outlined in Apply updates and extensions to Commerce Scale Unit (cloud).

## Finance and Operation payment package

To create a payment package, follow the steps in [Create Commerce payment packaging for Finance and Operations deployment](#).

## Steps to create a combined Retail deployable package

There are two ways to generate a commerce deployable package. You can use the Commerce build automation, or you can generate the package manually by using the build tools in the Retail SDK. This topic focuses on the manual method.

1. Customize or add functionality to the Commerce stack.
2. Use the build tools to identify the customized installation package, code-sign it, and specify the customized CRT, Commerce Scale Unit, and Hardware station assemblies, and customized database scripts.
3. After all the settings have been specified in the **Customization.settings** file in the ...\**Retail SDK\BuildTools** folder, run **msbuild /t:rebuild** on the root of the Retail SDK folder. You can use either the MSBuild build tool or the Microsoft Visual Studio developer command-line tool to generate the deployable packages. Before you build the package, put all the customized assemblies in the ...\**Retail SDK\References** folder. Additionally, put the modified configuration files, such as **CommerceRuntime.Ext.config**, **CommerceRuntime.MPOSOOffline.Ext.config**, **HardwareStation.Extension.config**, and **RetailProxy.MPOSOOffline.ext.config**, in the ...\**Retail SDK\Assets** folder.

## Retail SDK build tools – Customization settings

Most of the configuration values that the Retail SDK uses to build and package customizations are set in the BuildTools\Customization.settings files. These values define metadata that controls how binaries, components, and packages are named, versioned, and code-signed. After you define this metadata, the Retail SDK build

system uses it to identify the customization assets and package them for all the Commerce components.

The following configuration settings are available in the Customization.settings file:

- **AssemblyNamePrefix** – Specify the prefix name for the assembly. When you build the Retail SDK, all the assemblies are prefixed with this name.
- **CustomAssemblyVersion** – Specify the custom assembly version for all assemblies that are built by using the Retail SDK.
- **CustomVersion** – Specify the custom file version for all assemblies that are built by using the Retail SDK.
- **CustomName** – Specify the custom name for the assembly.
- **CustomDescription** – Specify the description for the assembly.
- **CustomPublisher** – Specify the publisher for the assembly.
- **CustomPublisherDisplayName** – Specify the publisher display name.
- **SignAssembly** – Specify **True** to sign the assembly during the build.
- **DelaySign** – Specify **True** to delay signing of the assets during the build.
- **AssemblyOriginatorKeyFile** – Specify the strong name key to use to sign the assembly.
- **ModernPOSPackageCertificateKeyFile** – Specify the Personal Information Exchange (PFX) file to use to sign Modern POS and Hardware station.
- **RetailServerLibraryPathForProxyGeneration** – Specify the customized Commerce Scale Unit assembly to use for proxy generation (both TypeScript and C# proxies).

For Retail SDK version 7.1 and earlier versions, you must specify the name of the Retail Server assembly here.

For Retail SDK version 7.2 and later versions, use the commerce generator tool for proxy generation. However, if you're using the proxy on the e-Commerce client side, specify the assembly name here.

- The **ItemGroup** section includes the following settings:
  - **ISV\_CommerceRuntime\_CustomizableFile** – Specify the details of all the customized CRT and dependent assemblies. You can have multiple entries, one for each assembly.

#### NOTE

If the extension depends on Newtonsoft.Json.Portable or some other assemblies, then explicitly include it. Don't assume that these assemblies will be included by default in the packaging or Commerce Scale Unit folder because the out-of-band (OOB) Commerce Scale Unit or CRT is using this. In the future, if the OOB functionalities don't use these assemblies, it could be removed. As a result, you should always explicitly include all of the extension dependent assemblies in order to package and place them in the correct folder.

#### Example

```
ISV_CommerceRuntime_CustomizableFile Include="$(SdkReferencesPath)\MyCrtExtension.dll"
```

- **ISV\_RetailServer\_CustomizableFile** – Specify the details of all the customized Commerce Scale Unit assemblies. You can have multiple entries, one for each assembly.

#### Example

```
ISV_RetailServer_CustomizableFile Include="$(SdkReferencesPath)\MyRetailServerExtension.dll"
ISV_RetailServer_CustomizableFile Include="$(SdkReferencesPath)\MyRetailServerExtension2.dll"
```

- **ISV\_RetailProxy\_CustomizableFile** – Specify the details of all the customized Commerce proxy assemblies. You can have multiple entries, one for each proxy assembly.

#### Example

```
ISV_RetailProxy_CustomizableFile Include="$(SdkReferencesPath)\MyRetailProxyExtension.dll"
```

- **ISV\_HardwareStation\_CustomizableFile** – Specify the details of all the customized Hardware station assemblies. You can have multiple entries, one for each customized Hardware station assembly.

#### Example

```
ISV_HardwareStation_CustomizableFile Include="$(SdkReferencesPath)\MyHardwareStationExtension.dll"
```

- **ISV\_CustomDatabaseFile\_Upgrade\_Custom** – Specify the details of all the customized database scripts.

#### Example

```
ISV_CustomDatabaseFile_Upgrade_Custom Include="$(SdkRootPath)\Database\Upgrade\Custom\SqlUpdatev1.sql"
```

#### IMPORTANT

Before you start the build process, you must put extension assemblies in ...Retail SDK\References and custom database scripts under ...RetailSDK\Database\Upgrade\Custom.

### Database scripts

Database scripts are packaged together with the Commerce Scale Unit and Modern POS Offline packages, and are run when Commerce Scale Unit and Modern POS are installed. If there are multiple custom database scripts, they are run in alphabetical order. Therefore, to run the scripts in a specific order, you must name them accordingly. The CRT.RETAILUPGRADEHISTORY table tracks the scripts that are already applied to the database. Therefore, the next package upgrade runs only the upgrade scripts that don't have an entry in the CRT.RETAILUPGRADEHISTORY table.

For more details about Channel database extensions, see [Channel database extensions](#).

## Update the extension configuration files

If you have any new extensions in CRT, Commerce Scale Unit, Hardware station, or Retail proxies, you must register the details of the extension assemblies in the <composition> section of the relevant extension configuration file. You can find all the extension configuration files in the ...RetailSDK\Assets folder. Because all extensions are loaded based on the information in the extension configuration files, you must register your assemblies there.

Before you generate the package, you must update the following configuration files if you have any customization in that area:

- **CommerceRuntime.Ext.config** – Register all your CRT extensions and dependent assemblies. Also this is where you need to include the Commerce Scale Unit extension dependent assemblies.

## NOTE

If the extension depends on Newtonsoft.Json.Portable or some other assemblies, then explicitly include it. Don't assume that these assemblies will be included by default in the packaging or Commerce Scale Unit folder because the out-of-band (OOB) Commerce Scale Unit or CRT is using this. In the future, if the OOB functionalities don't use these assemblies, it could be removed. As a result, you should always explicitly include all of the extension dependent assemblies in order to package and place them in the correct folder.

## Example - How to register extension assemblies and extension key value pair configurations

```
<?xml version="1.0" encoding="utf-8"?>
<commerceRuntimeExtensions>
  <composition>
    <!-- Register your own assemblies here. -->
    <add source="assembly" value="my custom library" />
  </composition>
</commerceRuntimeExtensions>
<?xml version="1.0" encoding="utf-8"?>
<commerceRuntimeExtensions>
  <composition>
    <!-- Register your own assemblies here. -->
    <add source="assembly" value="my custom library" />
  </composition>

  <settings>
    <add name="ext.myCustomKey1" value="myCustomValue1" />
    <add name="ext.myCustomarea.myCustomKey2" value="myCustomValue2" />
  </settings>
</commerceRuntimeExtensions>
```

- **CommerceRuntime.MPOSOffline.Ext.config** – Register all your CRT extensions, dependent assemblies and extension Key Value pair configurations. The key name for the extension configuration values must be prefixed with "ext." as the CommerceRuntime initialization will enforce this convention and will not load otherwise, additional prefixes can be added to represent the sub-area they control. Ex: "ext.CusomStorageConfig.CustomKeyCart"

## Example - How to register extension assemblies and extension key value pair configurations

```
<?xml version="1.0" encoding="utf-8"?>
<commerceRuntimeExtensions>
  <composition>
    <!-- Register your own assemblies or types here. -->
    <add source="assembly" value=" my custom library" />
  </composition>
</commerceRuntimeExtensions>
<?xml version="1.0" encoding="utf-8"?>
<commerceRuntimeExtensions>
  <composition>
    <!-- Register your own assemblies or types here. -->
    <add source="assembly" value=" my custom library" />
  </composition>

  <settings>
    <add name="ext.myCustomKey1" value="myCustomValue1" />
    <add name="ext.myCustomarea.myCustomKey2" value="myCustomValue2" />
  </settings>
</commerceRuntimeExtensions>
```

- **HardwareStation.Extension.config** – Register all your Hardware station extensions.

## Example

```
<?xml version="1.0" encoding="utf-8"?>
<hardwareStationExtension>
  <composition>
    <!-- Register your own assemblies or types here. -->
    <add source="assembly" value=" my custom library" />
  </composition>
</hardwareStationExtension>
```

- **RetailProxy.MPOSOOffline.ext.config** – Register all your commerce proxy extensions.

## Example

```
<?xml version="1.0" encoding="utf-8"?>
<retailProxyExtensions>
  <composition>
    <!-- Register your own proxy extension assemblies. -->
    <add source="assembly" value=" my custom library" />
  </composition>
</retailProxyExtensions>
```

## Commerce Scale Unit extension assemblies

Before you start the package, you must add an entry for the Commerce Scale Unit extension assemblies in the <extensionComposition> of the Commerce Scale Unit web.config file, so that the assemblies are loaded and used. You can find the web.config file in the Retail SDK\Packages\RetailServer\Code folder.

The following illustration shows an example of a web.config file.

```
<retailServer>
  <!-- Please specify comma separated versions. -->
  <version supportedVersions="7.0" deprecatedVersions="" />
  <endpoints commerceEndpoint="Commerce" authenticationEndpoint="Auth"/>
  <authentication UserTokenLifetime="24:0:0" Issuer="https://commerce.dynamics.com/auth" AllowInsecureHttp="true" CertTI
  <!-- if maxPageSize is set to 0 request size is uncapped. -->
  <pagingConfiguration maxPageSize="1000" />
  <extensionComposition>
    <!-- Please use fully qualified assembly names for ALL if you need to support loading from the Global Assembly Cache
    if you host in an application with a bin folder, this is not required. -->
    <add source="assembly" value="MyRetailServerExtension" />
  </extensionComposition>
</retailServer>
<system.serviceModel>
  <bindings>
    <ws2007FederationHttpBinding>
      <binding name="SamlBearerTokenBindingConfig"
        closeTimeout="00:01:00"
        openTimeout="00:01:00"
        receiveTimeout="00:10:00"
        sendTimeout="00:10:00"
        maxBufferPoolSize="67108864"
        maxReceivedMessageSize="67108864">
```

## Shared Hardware station web.config

If you are not using the legacy payment connector, then comment the legacy payment connector and enable the non-legacy connector in the web.config file. By default, the legacy payment connector is enabled in the shared hardware station web.config.

## Example

To disable the legacy connector, open the web.config file from \RetailSDK\References\Microsoft.Dynamics.Retail.HardwareStation.WebHost.x.x.x.x\Pkg\bin and comment the legacy connector. Enable the non-legacy connector under the composition section, as shown in the following sample code.

#### NOTE

x.x.x.x in the web.config folder path

(\RetailSDK\References\Microsoft.Dynamics.Retail.HardwareStation.WebHost.x.x.x.x\Pkg\bin) is the version number. This will vary based on your Retail SDK version number.

```
<composition>
  <!-- Defaulting to legacy payment devices.
  <add source="assembly"
  value="Microsoft.Dynamics.Commerce.HardwareStation.Peripherals.Legacy.PaymentDeviceAdapter"/>
  -->
  <add source="assembly"
  value="Microsoft.Dynamics.Commerce.HardwareStation.Peripherals.PaymentDeviceAdapter" />
</composition>
```

#### NOTE

Do not add or change any custom settings in the above mentioned example or in any of the channel config files. The only supported modification is to add custom assemblies details in the composition section.

As part of your extension or package, do not edit any of the following config files. These config files will be updated with the latest file from core Microsoft package during deployment and your changes will be lost.

- CommerceRuntime.config
- dllhost.exe.config
- HardwareStation.Dedicated.config
- HardwareStation.Shared.config
- workflowFoundation.config
- Hardware station - Web.config

## Install NuGet.exe

Some of the dependency packages and references have moved to NuGet packages to minimize the file merge and the size of the SDK. These are available for download from the NuGet.org. When you build the Retail SDK these dependencies are automatically pulled from the NuGet.org based on the packages.config file. For this to work, you need to install the [NuGet command line interface](#) and add the nuget to the Windows path after downloading nuget.exe from NuGet.org. The following steps show how to add the nuget to the Windows path:

1. Open the Windows menu and type **Path**. The **Edit the system environment variables** will be available.
2. In that menu, click **Environment variables** on the lower right.
3. In the next window, under **System variables**, select **Path** and click **Edit**.
4. Add an entry for the folder where you would like to store the nuget.exe file or store the nuget.exe file in a folder that is already listed.

## Generate a Retail deployable package

To generate the Retail deployable package, open the MSBuild command prompt or Developer command prompt for Visual Studio 2017 (for SDK version lower than 10.0.11 use MSBuild command prompt or Developer command prompt for Visual Studio 2015). On the developer virtual machine, search for **msbuild** or **Developer command prompt for VS 2017** on the **Start** menu and navigate to the root of the SDK folder. Run the following command. MSBuild will find the dirs.proj file in the SDK root folder and build all the projects included in the dirs.proj (remove the sample projects include in the dirs.proj file). If you want to build your extension project, then update the dirs.proj file with your extension projects.

```
msbuild /p:Configuration=Release
```

## Packages

After the build is completed, deployable packages are generated as a zip file (RetailDeployablePackage.zip) in the Retail SDK\Packages\RetailDeployablePackage folder.

### NOTE

There won't be separate packages for the various Commerce components. All the packages will be combined into one bundle package that is named RetailDeployablePackage.

## Deploy the packages

1. Go to <https://lcs.dynamics.com/v2>.
2. Sign in to LCS, and open a project. Then, on the hamburger menu, select Asset library.
3. Select the **Software deployable package** asset type, and then select the + button to upload the package. Provide a package name and description and then add the package file by selecting **Add file**.
4. After the upload is complete, select **Confirm** to complete the upload process.
5. The package will be validated by LCS in a few minutes. After validation is complete, mark the package as Release candidate.
6. After upload, the package needs to be deployed to the environment. For more information, follow the steps outlined in [Apply updates and extensions to Commerce Scale Unit \(cloud\)](#).

For information about how to deploy the packages either manually or by using the automated flow in LCS, see [Apply a deployable package](#) and [Install a deployable package](#).

LCS has a 300 MB limitation on the package size. If the package size is greater than 300 MB, LCS will not allow deployment of the package. To reduce the size and deploy to RCSU, remove any of the self-service exes (ModernPOSSetup, StoreSystemSetup, or HardwareStationSetup installers). Unzip the package and remove any of the self-service exes and zip the package again. The self-service packages are not deployed to Cloud Commerce scale unit. Sync the self-service package to AOS following the steps in [Synchronize self-service installers in Dynamics 365 Commerce](#).

## Upload self-service installers to LCS and synchronize to Dynamics 365 Commerce

After the Retail deployable package is generated, go to the RetailSDK\Packages\RetailDeployablePackage\content.folder\RetailSelfService\Packages folder and upload all the self-service installers found in that folder to LCS **project > Asset library > Retail Self-service package**. Synchronize the package to Dynamics 365 Commerce by navigating to **Retail and Commerce > Headquarters setup > Parameters > Commerce parameters** and select the **Channel deployment** tab and then select **Check for package updates** to perform synchronization.

For detailed information, see [Synchronize self-service installers in Dynamics 365 Commerce doc](#).

### NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Development in cloud-hosted environments without admin access

2/18/2021 • 4 minutes to read • [Edit Online](#)

As of Microsoft Dynamics 365 for Finance and Operations, Enterprise edition, Platform update 12, customers will no longer have access to virtual machine (VM) administrator accounts on development or build environments that are running in Microsoft subscriptions. This restriction only applies to new deployments of Platform update 12 (or newer) environments. Environments that were deployed before this update, and have been updated to Platform update 12, will still have administrator access.

You can use a remote desktop (RDP) to access these restricted environments using the non-admin user provided on the Lifecycle Services (LCS) environment page. For more information about environments that don't allow administrator access, see [Development and build VMs that don't allow administrator access FAQ](#).

If you deploy an environment using Microsoft Azure subscription in LCS, then you will not have admin access in this environment. If you need admin access in your environment, use your Azure subscription and deploy the environment using LCS. You can also use the downloadable VHD and deploy it in your Azure virtual machine (VM) or host it locally to get full admin access.

If you don't have admin access in the environment, you will not be able to test and debug using Modern POS. You can still do all commerce customization for POS if you are testing the customization, you must use Cloud POS in that environment. From a customization perspective, there is no difference between Cloud POS and Modern POS - any customization will work both in Cloud POS and Modern POS. There is no additional logic or code for customization completed in Cloud POS in order to work in Modern POS or vice versa, unless you added logic that is browser-specific or UWP app-specific for Hardware and other scenarios. Another option is to do all development work in the environment using Modern POS and test it in some other environment where you have admin access to install MPOS. In most cases, you should be able to test using Cloud POS, expect if you want to test for offline scenarios. If you want to test offline scenarios, you can create a Modern POS installer using the build script, and then test it in your test environment or some other POS registers.

## If you are using Cloud POS for development, set up the following configuration before opening the Cloud POS project

1. Open Visual Studio and go to **View > Application Explorer**. Wait for Internet Information Services (IIS) Express to start with all the Commerce websites deployed. You should see the IIS tray icon in the task bar with all the websites running, such as Cloud POS and Commerce Scale Unit.
2. To debug CRT/RS extensions, attach the CRT/RS project to the IIS Express process.
3. When you open the Cloud POS project from the Retail SDK, IIS Express may fail with the following error.

```
Filename: redirection.config
Error: Cannot read configuration file
```

## To resolve this issue

1. Close Visual Studio.
2. Copy the `aspnet.config` and `redirection.config` files to `%userprofile%\Documents\IISExpress\config`.
3. Open the `applicationhost.config` file in the `%userprofile%\Documents\IISExpress\config` folder.

- In **applicationhost.config**, change the physicalPath of RetailCloudPos to point to your SDK location. For example, physicalPath="K:\RetailSDK\POS\Web". The overall section will look like the following:

```
<site name="RetailCloudPOs" id="4" serverAutoStart="true">
  <application path="/" applicationPool="Dynamics365">
    <virtualDirectory path="/" physicalPath="K:\RetailSDK\POS\Web" />
  </application>
</site>
```

- Save the changes to **applicationhost.config**
- Rename the %userprofile%\Documents\IISExpress\config folder. Do not delete the files because you will copy the **applicationhost.config** file to a new location in **step 8**.
- Start Visual Studio again with the Cloud POS project. The %userprofile%\Documents\IISExpress\config folder will be recreated with the default config files.
- Copy the **applicationhost.config** file from the folder that you renamed in **step 6**, to the folder created in **step 7**.
- Edit ..\RetailSDK\POS\Web\Pos.Web.csproj and change the default **IISURL** node value to your Cloud POS URL and set **UseIIS** to false.

```
Ex:
<UseIIS>False</UseIIS>
<IISUrl>https://YourCPOSURL.com</IISUrl>
```

- Right-click the Pos.Web project and select **Properties**.
- In the **Properties** window, select the **Web** tab. Select the **Start URL** radio option and set the start URL as your Cloud POS URL and under the **Servers** section select **IIS Express as the server** from the drop down menu and set the **Project URL** as your cloud POS URL.

If you are using IIS for development (VMs with admin access), then you need to set the UseIIS node value to False and select Local IIS from the Server drop-down menu.

For example, `https://usnconeboxax1pos.cloud.onebox.dynamics.com`.

- Save the changes.
- Right-click the Pos.Web project and select **Set as StartUp Project**.
- Press F5 to run the Pos.Web Project or click the **Run** button in the Visual Studio menu.

## Install the Developer topology prerequisites

Cloud-hosted development environments do not include Typescript version 2.2.2 by default, and the default Windows host file does not contain the Cloud POS URL to use for local debugging. The **Developer topology prerequisites** package installs Typescript 2.2.2 and updates the Windows host file with your Cloud POS URL. Deploying the package will take a few minutes.

To install the Developer topology prerequisites:

- Go to Lifecycle Services (<https://lcs.dynamics.com>) and sign in.
- Under **Projects**, select the project where your dev environment is deployed.
- In the **More tools** section, click the **Asset library** tile.
- Select **Software deployable package** for the Asset library type and click **Import**.
- In the **Shared asset library list**, select **Developer topology prerequisites** and click **Pick**.
- Go to the **Environments** section, and click your development environment.

7. Click the **Maintain** tab and select **Apply updates**.
8. Select **Developer topology prerequisites** and click **Apply**.

**NOTE**

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Set up Commerce SDK build pipeline

2/18/2021 • 3 minutes to read • [Edit Online](#)

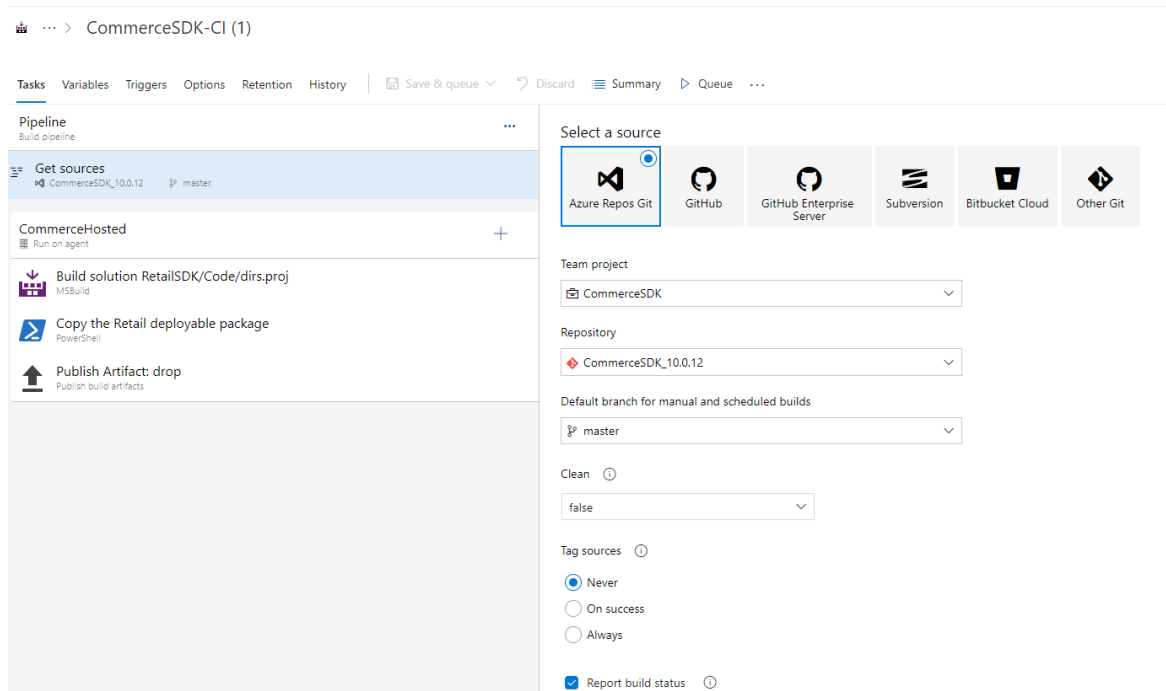

This topic shows how to set up the Azure DevOps build pipeline for the Retail SDK, by using the Azure DevOps build agent (a Microsoft-hosted agent). To generate the build for Retail SDK, a dedicated build machine isn't required. The setup works with the Azure DevOps build agent. This topic applies to Retail SDK version 10.0.11 or greater.

## Prerequisites

The Retail SDK must be added to Azure Repos (Git repository), GitHub, or Azure DevOps. The Retail SDK is available in the service volume drive of the development virtual machine (VM) from Lifecycle Services (LCS). To provision a development VM in LCS, follow the steps in [Deploy and access development environments](#).

## Set up a build pipeline in Azure DevOps

1. Sign in to your Azure DevOps organization.
2. Select **Pipeline** and click **New pipeline**.
3. Select your source repo.
4. Click the pipeline and provide a name for your pipeline. For **Agent pool**, choose **Azure Pipelines**. For **Agent Specification**, enter **vs2017-win2016**.
5. On the **Get sources** tab, select your Retail SDK repo.

6. In the **Agent job** panel, provide a display name. For **Agent pool**, select **<inherit from pipeline>**.

Tasks Variables Triggers Options Retention History | Save & queue Discard Summary Queue ...

Pipeline Build pipeline

- Get sources CommerceSDK\_10.0.12 master
- CommerceHosted Run on agent
- Build solution RetailSDK/Code/dirs.proj MSBuild
- Copy the Retail deployable package PowerShell
- Publish Artifact: drop Publish build artifacts

Agent job CommerceHosted View YAML

## Sample YAML script for the pipeline

The following YAML script specifies the pipeline.

```

pool:
  name: Azure Pipelines
  demands: msbuild

steps:
- task: MSBuild@1
  displayName: 'Build solution RetailSDK/Code/dirs.proj'
  inputs:
    solution: RetailSDK/Code/dirs.proj
    msbuildVersion: 15.0

- powershell: |
  # Script to copy the Retail deployable package with Build number.

  Copy-Item
"$$(Build.SourcesDirectory)\RetailSDK\Packages\RetailDeployablePackage\RetailDeployablePackage.zip" -
Destination
"$$(Build.ArtifactStagingDirectory)\RetailDeployablePackage_$$$(Build.BuildNumber).zip"

  displayName: 'Copy the Retail deployable package'

- task: PublishBuildArtifacts@1
  displayName: 'Publish Artifact: drop'

```

## Set up an Azure DevOps build pipeline that uses a build machine

If the build machine uses MSBuild with the Azure DevOps pipeline, follow these steps in the build machine to enable it for the Retail SDK, version 10.0.11:

1. Install Visual Studio 2017 on the build machine.
2. Optional, run **msbuild** (version 15.0) from the developer command prompt for Visual Studio 2017 in the build machine. Open the developer command prompt for Visual Studio 2017, navigate to the Retail SDK root folder, and run `msbuild dirs.proj`. Make sure that the **msbuild** command finishes successfully.
3. In the build machine add an environment variable for **msbuild**, version 15.0. Open **System Properties > Environment Variables > System variables**. Select **Path**, click **New**, and add the path variable for **msbuild**. An example of the path is `C:\Program Files(x86)\Microsoft Visual Studio\2017\Enterprise\MSBuild\15.0\Bin\`. The path depends on where you installed Visual Studio 2017. To get the path for **msbuild**, open the **Developer Command Prompt for Visual Studio 2017**, and run the command `where msbuild`.
4. Restart the Azure DevOps build agent in the build machines.
5. In the Azure DevOps pipeline, set the **Agent Pool** to **Default** and change the msbuild version to 15.0 or latest.

## Troubleshooting

If the build from Azure DevOps fails with a NuGet error, check for these issues:

- The Azure pipeline isn't using **msbuild**, version 15.0, for NuGet restore.
- The extension projects haven't been upgraded to use the package reference model.

### NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Download Retail SDK samples and reference packages from GitHub and NuGet

2/18/2021 • 4 minutes to read • [Edit Online](#)

This topic explains to how to download Retail software development kit (SDK) samples from GitHub and reference packages from NuGet. The Retail SDK includes the code samples, templates, and tools that are required to extend or customize Microsoft Dynamics 365 Commerce functionality. The SDK is published in different repositories (repos) in GitHub, depending on the extension components.

This topic applies to Retail SDK version 10.0.16 or later. For more information about how to download earlier versions of the Retail SDK, see [Retail software development kit \(SDK\)](#).

## Commerce.ScaleUnit repo

The **Commerce.ScaleUnit** repo contains the sample code for customizing the Commerce runtime (CRT), Retail Server, and the channel database.

Clone or download the repo from [Dynamics365 Commerce ScaleUnit Samples](#).

The repo contains multiple branches for each release. The release branch that you should use depends on your go-live version, as shown in the following table. The repo contains only samples, so cloning this repo is optional.

RELEASE BRANCH NAME	VERSION	APPLICATION RELEASE VERSION
<a href="#">Release/9.26</a>	9.26.*	10.0.16
<a href="#">Release/9.27</a>	9.27.*	10.0.17

To clone a single branch, use the following command.

```
git clone --single-branch --branch release/9.26
https://github.com/microsoft/Dynamics365Commerce.ScaleUnit.git
```

This will clone the release/9.26 into your current directory.

### Commerce.ScaleUnit repo folders and projects

FOLDER	PROJECT	CONTENTS	DESCRIPTION
Channel Database	ChannelDatabase.csproj	Contoso.ExampleTable.ChannelDatabase.sql	A sample database extension.

FOLDER	PROJECT	CONTENTS	DESCRIPTION
CommerceRuntime	CommerceRuntime.csproj	<ul style="list-style-type: none"> <li>• <b>Controller</b> – Sample code for implement new Retail Server APIs.</li> <li>• <b>Entities, messages, and request handlers</b> – Sample code for implementing the new CRT service.</li> </ul>	Sample CRT extensions.
ScaleUnit	ScaleUnit.csproj	The project that is required to generate the Commerce Scale Unit (CSU) package	The project that is required to generate the CSU package.

#### NOTE

Repos aren't currently available for in-store components such as Modern point of sale (POS), Cloud POS, Hardware station, Retail scale unit, and other samples. However, Microsoft plans to make them available in later releases.

## Download reference packages for creating APIs, and for consuming messages, request, entities, and contracts

Contracts, messages, entities, and request packages are published in the public NuGet feed. You can use the extension code to consume and customize existing functionalities, or to build new functionalities.

Consume the packages from [https://pkgs.dev.azure.com/commerce-partner/Registry/\\_packaging/dynamics365-commerce/nuget/v3/index.json](https://pkgs.dev.azure.com/commerce-partner/Registry/_packaging/dynamics365-commerce/nuget/v3/index.json). You can add the package source location in the nuget.config file of your extension project file.

```
<packageSources>
  <add key="dynamics365-commerce" value="https://pkgs.dev.azure.com/commerce-partner/Registry/_packaging/dynamics365-commerce/nuget/v3/index.json" />
  <add key="nuget.org" value="https://api.nuget.org/v3/index.json" />
</packageSources>
```

## Reference packages that are available in the public NuGet feed

### Microsoft.Dynamics.Commerce.Sdk.Runtime package

This meta package contains all the required packages for implementing the CRT and Retail Server extensions. All the required contracts, messages, requests/responses, and entities are included in this package.

#### Dependencies:

- Microsoft.Dynamics.Commerce.Diagnostics
- Microsoft.Dynamics.Commerce.Runtime.Data
- Microsoft.Dynamics.Commerce.Runtime.DataServices.Messages
- Microsoft.Dynamics.Commerce.Runtime.Entities
- Microsoft.Dynamics.Commerce.Runtime.Framework
- Microsoft.Dynamics.Commerce.Runtime.Hosting.Contracts
- Microsoft.Dynamics.Commerce.Runtime.Messages

- Microsoft.Dynamics.Commerce.Runtime.RealtimeServices.Messages
- Microsoft.Dynamics.Commerce.Runtime.Services.Messages

### Microsoft.Dynamics.Commerce.Sdk.ScaleUnit package

This package is required to generate the CSU package for deployment.

#### Dependencies:

- CSU packaging dependencies

### Microsoft.Dynamics.Commerce.Sdk.ChannelDatabase package

This package is required to generate the database packages with CSU.

#### Dependencies:

- Channel database packaging dependencies

### Package versioning

PACKAGE VERSION	APPLICATION RELEASE
9.26.x_Preview	10.016 PEAP release
9.26.x	10.0.16 Customer preview
9.26.x	10.016 GA

An extension project can consume the correct version if you add the package reference to the project and include the full version number. Alternatively, to make the extension project always get the latest version, use a wildcard character. We recommend that you use the full version number, and that you update the version, based on your go-live version. There are two options:

- Without a wildcard character:

```
<PackageReference Include="Microsoft.Dynamics.Commerce.Sdk.Runtime" Version="9.26" />;
```

- With a wildcard character:

```
<PackageReference Include="Microsoft.Dynamics.Commerce.Sdk.Runtime" Version="9.26.*" />;
```

For every hotfix and new application release, a new version of the package will be published in the same public feed. Consume the package version that is based on the version that is required for your go-live. If the version of the package that is consumed is higher than the version of your go-live application, runtime and deployment failures will occur.

## Best practices and branching strategies

For detailed information about the Git branching strategy, see [Git branching strategy](#).

Keep your branch strategy simple, and follow these best practices:

- Use feature branches for all new features and software updates.
- Merge feature branches into the main branch by using pull requests.
- Keep a high-quality, up-to-date main branch.

The following branching strategies are based on the way that Microsoft uses Git. For more information, see [How](#)

we use Git at Microsoft.

## Create a new feature branch for development and software updates

Create a new feature branch that is based on the Dynamics 365 Commerce release/x.x.x branch. Clone the release/x.x.x branch, and then create a new branch. Be sure to use the correct naming convention for the new branch. For more information, see [Git branching doc for sample naming convention](#).

### Clone the release/x.x.x branch and create a new branch

1. Create the clone.

```
git clone --single-branch --branch release/9.26
https://github.com/microsoft/Dynamics365Commerce.ScaleUnit.git

git checkout -b private/{username}/{feature/description}
```

2. Add and commit new changes to the development branch.

```
git -add .
git commit -m"commit message"
```

3. After the development is completed, tested, and validated, push the changes to the main branch by using **git push <remote> <branch>**.

```
git push origin {private branch name}
```

## Create a release branch after development

1. After you push the development changes to the main branch, create a new release branch, and then create the deployable packages from it.

```
git checkout -b release/x.x.x
```

2. If any changes are made in the release branch, merge them from the release branch back to main branch.

```
git checkout master git merge release/x.x.x
```

## Create an extension hotfix branch

As you did for the release branch, create a hotfix branch for extension from the main branch, and then release the hotfix. Later, merge the changes back to the main branch.

## Merge the new SDK release branch to the main and development branches

After a new version of the SDK samples is released, you must merge it with your new branch. Because the SDK contains only samples, you don't have to get the updated changes from the new SDK release branch.

```
git checkout master git merge release/x.x.x
```

### NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Retail SDK FAQ

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic summarizes answers to questions that are frequently asked by users of the Retail SDK.

## How do I handle a runtime error thrown when using `ISupportedTypesAware` in SDK version (10.0.420.10003~10.0.420.10033)?

This error might occur when you use `ISupportedTypesAware`.

*Exception: System.MissingMethodException: Method not found:  
'System.Collections.Generic.IEnumerable`1<System.Type>  
Microsoft.Dynamics.Commerce.Runtime.ISupportedTypesAware.get\_SupportedRequestTypes()'*

When extending or implementing CRT handlers, use `IRequestHandlerAsync` instead of `ISupportedTypesAware`. `ISupportedTypesAware` is not supported and if used in extension it may cause this runtime error. Additionally, don't use explicit implementations.

The following example shows the recommended approach using `IRequestHandlerAsync`.

```
public class MyHandler : IRequestHandlerAsync
{
    public IEnumerable<Type> SupportedRequestTypes
    {
        get
        {
            return new[]
            {
                typeof(MyRequest)
            };
        }
    }

    public Task<Response> Execute(Request request)
    {
        // Return response.
    }
}
```

The following example, which is not recommended, uses `ISupportedTypesAware`.

```
// NOT RECOMMENDED
public class MyHandler : IRequestHandlerAsync, ISupportedTypesAware
{
    public IEnumerable<Type> SupportedRequestTypes
    {
        get
        {
            return new[]
            {
                typeof(MyRequest)
            };
        }
    }

    Task<Response> IRequestHandlerAsync.Execute(Request request)
    {
        return null;
    }
}
}
```

## How do I handle a ReadOnly CartValidationException error in SDK version (10.0.0 and later)?

This error will occur if the following read-only properties are updated in SDK version 10.0.9 or earlier. These properties are made read only in SDK version 10.0.0 to avoid miscalculations in the cart total:

- ExtendedPrice
- TaxAmount
- ItemTaxGroupID
- TaxAmountExclusive
- TaxAmountInclusive
- TotalAmount
- NetAmountWithoutTax
- IsInvoiceLine
- InvoiceAmount

To resolve this issue, remove the code in the client/server. Setting this value and OOB code will calculate these values or keep the logic in the read-only fields. You can follow the example shown below, however be sure to modify the code according to the best practice, as this option is not recommended.

In HQ Commerce **parameters > Configuration parameters > Create a new config** with a name/value like the following pattern:

**RetailReadOnlyExempt\_[EntityName] : [ColumnName]**

For example, in the error at the top of this page, ITEM TAXGROUPID is the read-only property with the error. You can search to see this is part of CartLine and CartLineData. The configuration name/value pair would look like this:

**RetailReadOnlyExempt\_CartLineData : ITEM TAXGROUPID**

Additionally, to exempt more than one column for a given entity, use a comma as the separator for column names. The configuration name/value pair in this case would look like this:

**RetailReadOnlyExempt\_CartLineData : TAXAMOUNT,TOTALAMOUNT, ExtendedPrice, ItemTaxGroupID, TaxAmountExclusive, TaxAmountInclusive, TotalAmount, NetAmountWithoutTax, IsInvoiceLine, InvoiceAmount**

#### NOTE

ITEMTAXGROUPID, TAXAMOUNT, TOTALAMOUNT are the column names of the properties in the examples above, not the actual property names. The entity name for the CartLine is CartLineData.

After adding the config run job 1110 to push this change.

## - Deployment failed with error - Could not load file or assembly Microsoft.Dynamics.Commerce.RetailServer.Extensibility.Contracts

Deployment of the new retail deployable package fails with the message:

*An unhandled exception occurred during the execution of the current web request. Please review the stack trace for more information about the error and where it originated in the code. Could not load file or assembly "Microsoft.Dynamics.Commerce.RetailServer.Extensibility.Contracts, Version=7.0.0.0, Culture=neutral, PublicKeyToken=31bf3856ad364e35" or one of its dependencies. The system cannot find the file specified.*

This error may occur if the extension project upgraded from Retail SDK version 10.0.10 or 10.0.11 to Retail SDK version 10.0.12 or later, and there are extension projects referencing Microsoft.Dynamics.Commerce.RetailServer.Extensibility.Contracts.

To fix this issue, remove the reference to Microsoft.Dynamics.Commerce.RetailServer.Extensibility.Contracts in the extension project and regenerate the package and deploy again. Removing this reference library will not impact extension code/functionality because it's not needed for extension solutions. Starting in version 10.0.11, extensions can refer to Microsoft.Dynamics.Commerce.Hosting.Contracts for Retail server APIs.

#### NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# POS user interface visual configurations

2/18/2021 • 12 minutes to read • [Edit Online](#)

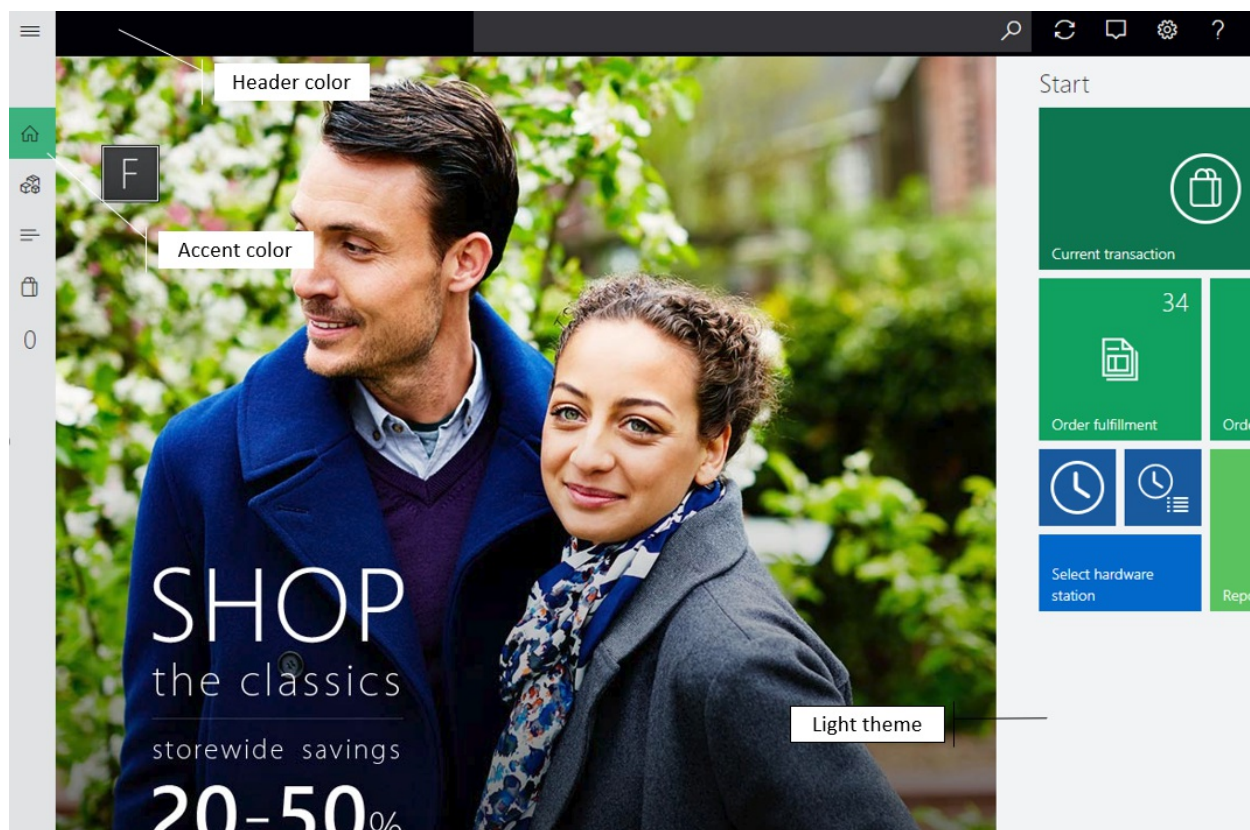

The user interface (UI) of the Microsoft Dynamics 365 Commerce point of sale (POS) can be configured by using a combination of visual profiles and screen layouts that are assigned to stores, registers, and users. This topic provides information about those configuration options.

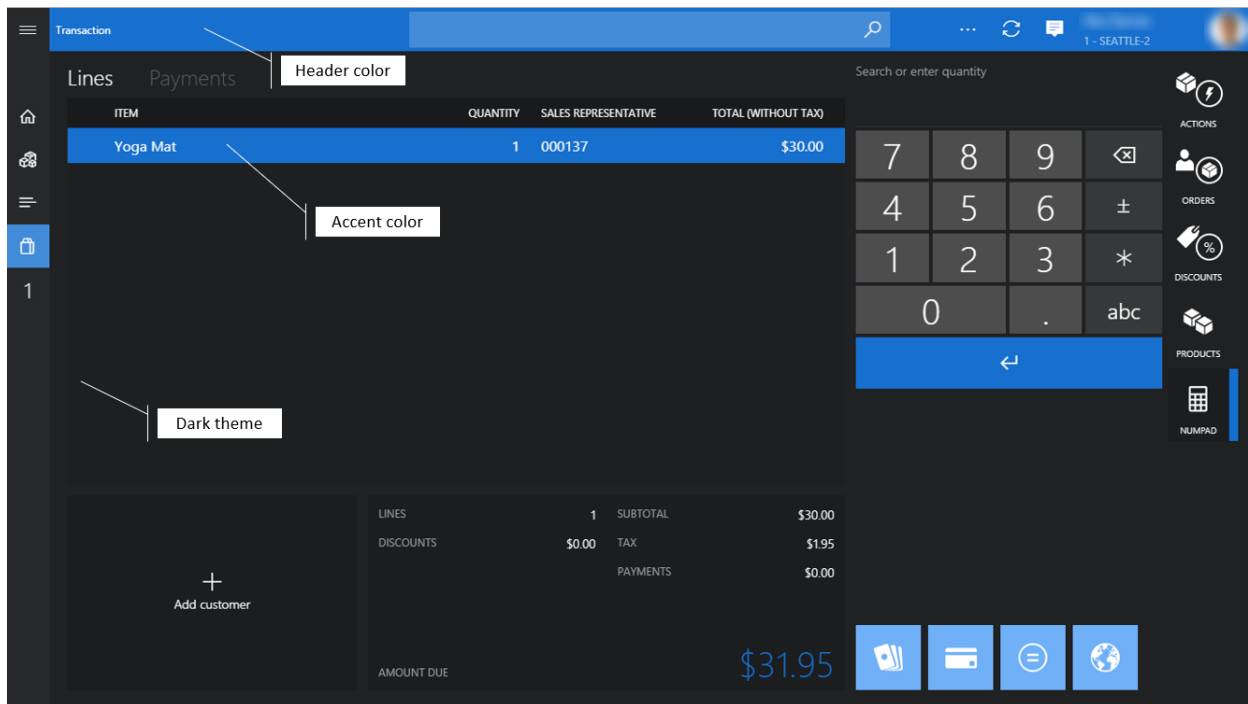

The following illustration shows the relationships among the various entities that make up the configurable aspects of the POS UI.

## Visual profile

Visual profiles are assigned to registers, and they specify the visual elements that are register-specific and shared across users. Every user who signs in to the register sees the same theme, layout, colors, and images.

- **Profile number** – The profile number is the unique identifier of the visual profile.
- **Description** – You can specify a meaningful name that will help identify the correct profile for your situation.
- **Theme** – You can select between the **Light** and **Dark** application themes. The theme affects the font and background colors throughout the application.
- **Accent color** – The accent color is used throughout the POS to differentiate or highlight specific visual elements, such as tiles, command buttons, and hyperlinks. Typically, these elements are actionable.
- **Header color** – You can configure the color of the page header to meet the retailer's branding requirements.
- **Font scheme** – You can select between the **Standard** and **Large** font schemes. The font scheme affects the font size throughout the application. The default selection is **Standard**.
- **Always show application bar labels** – When this option is turned on, the label text is always visible under the application bar buttons.
- **Layout** – You can select between the **Centered** and **Right** layouts. The layout affects the alignment of the sign-in box on the sign-in screen. The default selection is **Centered**.
- **Show date/time** – When this option is turned on, the current date and time are shown in the POS header and on the sign-in screen.
- **Keyboard** – You can select between **Default to OS keyboard** and **Show number pad** to specify the default keyboard that is used for input on the sign-in screen. The number pad is a virtual keyboard that is used primarily for touch-based devices. The default selection is **Default to OS keyboard**.
- **Logo image** – You can specify a logo image that is shown on the sign-in screen. We recommend that you use an image that has a transparent background. The file size should be kept as small as possible, because application behavior and performance can be affected when large files are stored and loaded.
- **Login background** – You can specify a background image for the sign-in screen. The file size of background images should be kept as small as possible.
- **Background** – You can specify a background image that is used instead of the solid theme color throughout the application. As for background images for the sign-in screen, the file size should be kept as small as possible.

#### NOTE

The **Right** layout and date/time display don't apply to the sign-in screen in compact view.

You need to run the **1090 (Registers)** distribution schedule job to synchronize the latest visual profile

configurations to the channel database.

## Screen layouts

Screen layout configurations determine the actions, content, and placement of UI controls on the POS **Welcome** screen and **Transaction** screen.

The screenshot shows the Dynamics 365 Retail POS setup interface for configuring screen layouts. The left sidebar lists various roles and their associated screen layouts, such as F3.1CSH (Fabrikam Cashier) and F3.MGR (Fabrikam Manager). The main area displays the 'Screen layouts' configuration page for the 'F3.MGR' role, showing a table of layout sizes and button grids.

Screen layout ID	Name	Default start screen
F3MGR	Fabrikam Manager	Welcome screen

Name	Layout type	Width	Height
1024x768 - Full	Modern POS - Full	1024	768
1280x720 - Full	Modern POS - Full	1280	720
1366x768 - Full	Modern POS - Full	1366	768
1440x960 - Full	Modern POS - Full	1440	960
480x853 - Compact	Modern POS - Compact	480	853

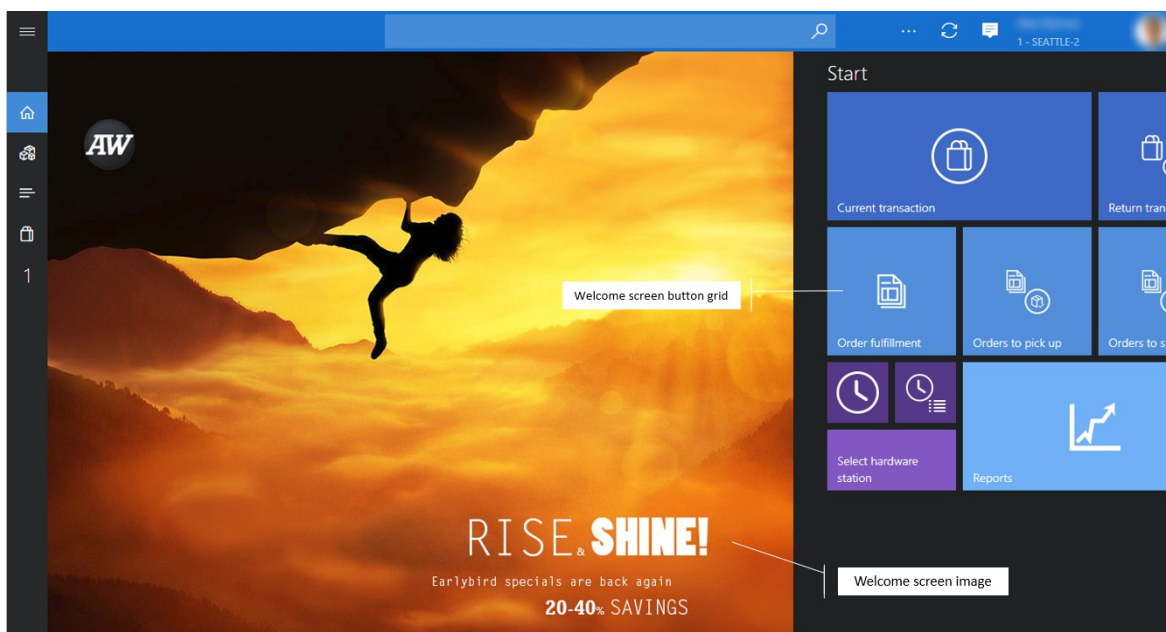

Layout zone	Button grid ID	Name
Welcome screen 1	F2W1M	Start
Welcome screen 2	F2W2	Products
Welcome screen 3	F2W3	Inventory
Welcome screen 4	F2W4M	Shift and drawer
Welcome screen 5	F2W5M	Operations
Transaction screen 1	F2T1M	Actions
Transaction screen 2	F2T2	Customer orders

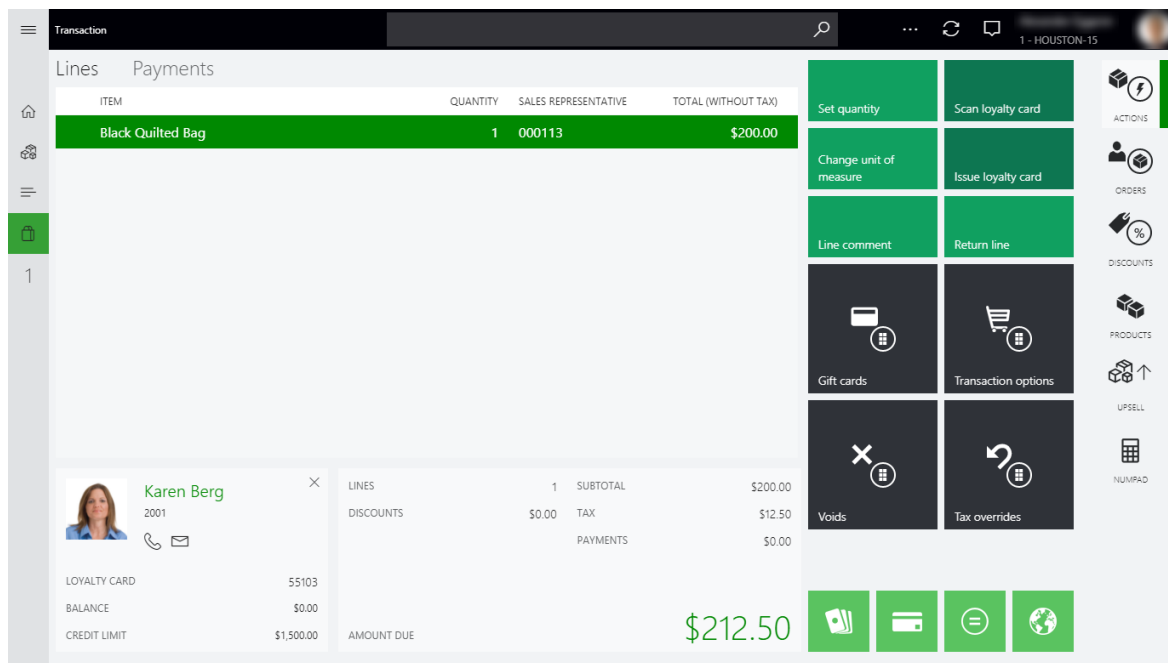

Layout zone	Image
Image 1	2506
Image 2	2507
Image 3	2508

Annotations in the image point to 'Screen layout' (the sidebar), 'Layout sizes' (the table), 'Button grids' (the table), and 'Images' (the table).

- **Welcome screen** – In most cases, the welcome screen is the page that users see when they first sign in to the POS. The welcome screen can consist of a branding image and button grids that provide access to POS operations. Typically, operations that aren't specific to the current transaction are put on this screen.

- **Transaction screen** – The **Transaction** screen is the main screen in the POS for processing sales transactions and orders. The content and layout are configured by using the screen layout designer.

- **Default start screen** – Some retailers prefer that cashiers go directly to the **Transaction** screen after sign-in. The **Default start screen** setting lets you specify the default screen that appears after sign-in for each screen layout.

### Assignment

Screen layouts can be assigned at the store, register, or user level. The user assignment overrides the register and store assignments, and the register assignment overrides the store assignment. In a simple scenario where all users use the same layout, regardless of register or role, the screen layout can be set only at the store level. In scenarios where specific registers or users require specialized layouts, those layouts can be assigned.

Depending on which level the screen layouts are assigned, you need to run the **1070 (Channel configuration)**, **1090 (Registers)**, and/or **1060 (Staff)** distribution schedule jobs to synchronize the latest screen layout configurations to the channel database.

### Layout sizes

Most aspects of the POS UI are responsive, and the layout is automatically resized and adjusted based on the screen size and orientation. However, the POS **Transaction** screen must be configured for every screen resolution that is expected.

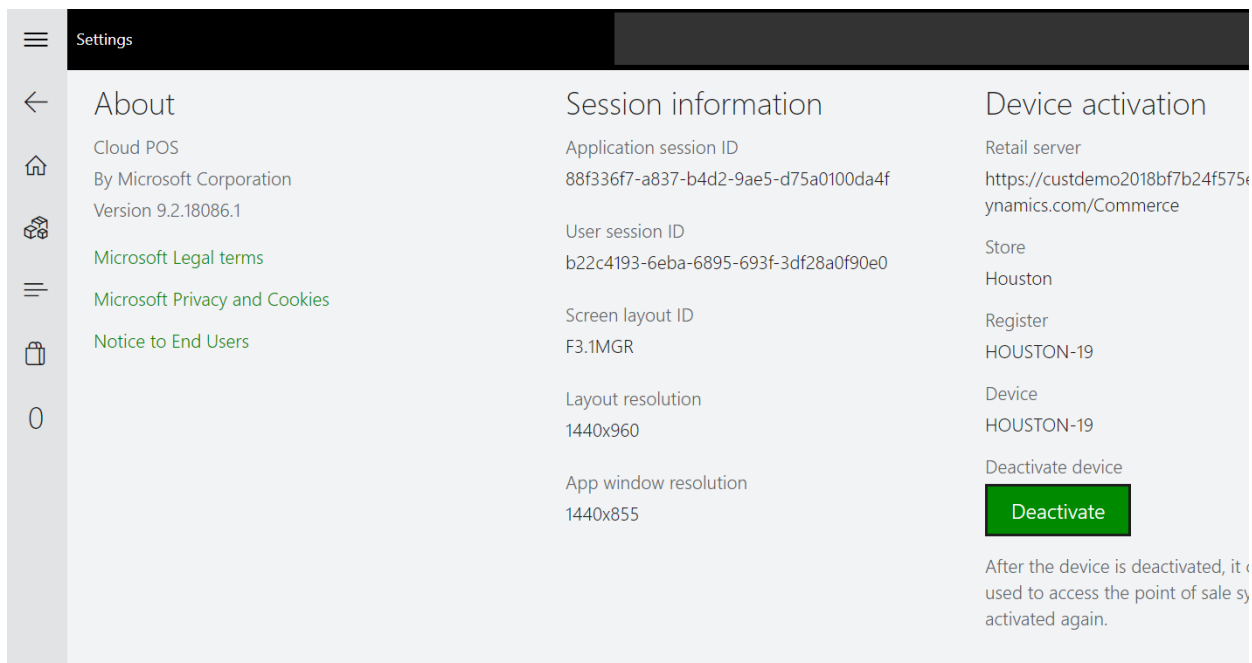

At startup, the POS application automatically selects the closest layout size that is configured for the device. A screen layout can also contain configurations for both landscape and portrait modes, and for both full-size and compact devices. Therefore, users can be assigned to a single screen layout that works across various sizes and form factors that are used in the store.

- **Name** – You can enter a meaningful name to identify the screen size.
- **Layout type** – The POS application can show its UI in various modes to provide the best user experience on a given device.
  - **Modern POS – Full** – Full layouts are typically best for larger displays, such as desktop monitors and tablets. You can select the UI elements to include, specify the size and placement of those elements, and configure their detailed properties. Full layouts support both portrait and landscape configurations.
  - **Modern POS – Compact** – Compact layouts are typically best for phones and small tablets. The design possibilities for compact devices are limited. You can configure the columns and fields for the receipt and totals panels.
- **Width/Height** – These values represent the effective screen size, in pixels, that is expected for the layout. Remember that some operating systems use scaling for high-resolution displays.

**TIP**

You can learn the layout size that is required for a POS screen by viewing the resolution in the app. Start the POS, and go to **Settings > Session information**. POS shows the screen layout that is currently loaded, the layout size, and the resolution of the app window.

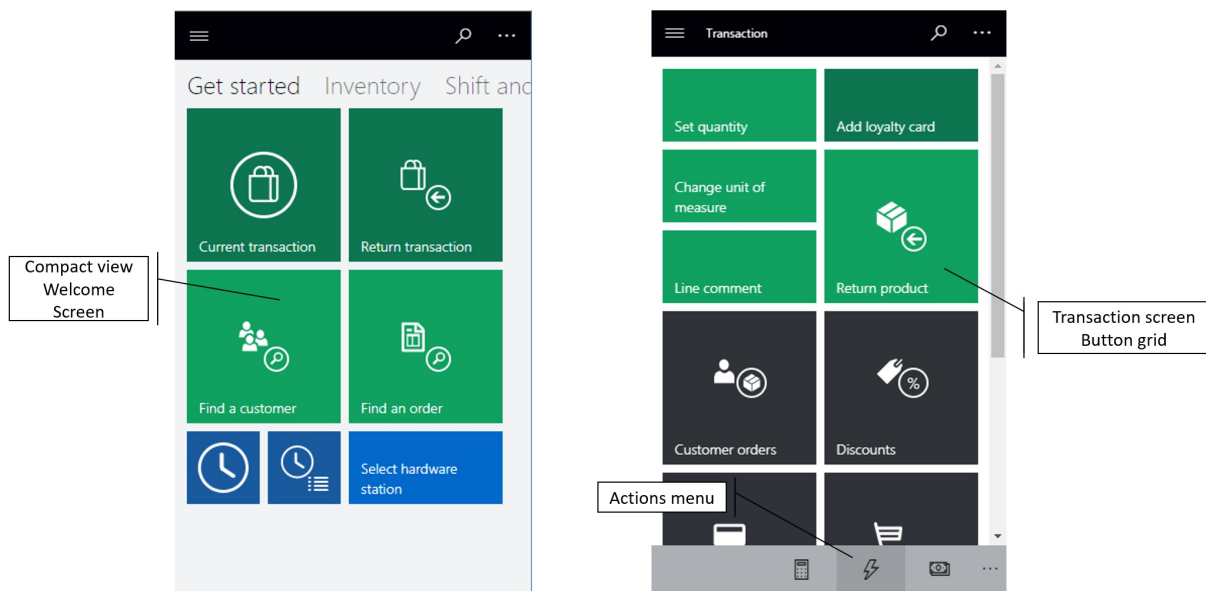

## Button grids

For each layout size in a screen layout, you can configure and assign button grids for the POS welcome screen and **Transaction** screen. Button grids for the welcome screen are automatically laid out from left to right, from the lowest number (Welcome screen 1) to the highest number.

In Full POS layouts, the placement of button grids is specified in the screen layout designer.

In Compact POS layouts, the button grids are automatically laid out from top to bottom, from the lowest number (Transaction screen 1) to the highest number. They can be accessed on the **Actions** menu.

### NOTE

The button sizes in the designer will scale to fit the size of the window, therefore they may not accurately reflect the actual buttons rendered in POS. To best simulate the button grid layout, adjust the designer windows to the same size as the POS.

## Images

For each layout size in a screen layout, you can specify images to include in the POS UI. For Full POS layouts, a

single image can be specified for the welcome screen. This image appears as the first UI element on the left. On the **Transaction** screen, images can be used as tab images or as a logo. Compact POS layouts don't use these images.

## Screen layout designer

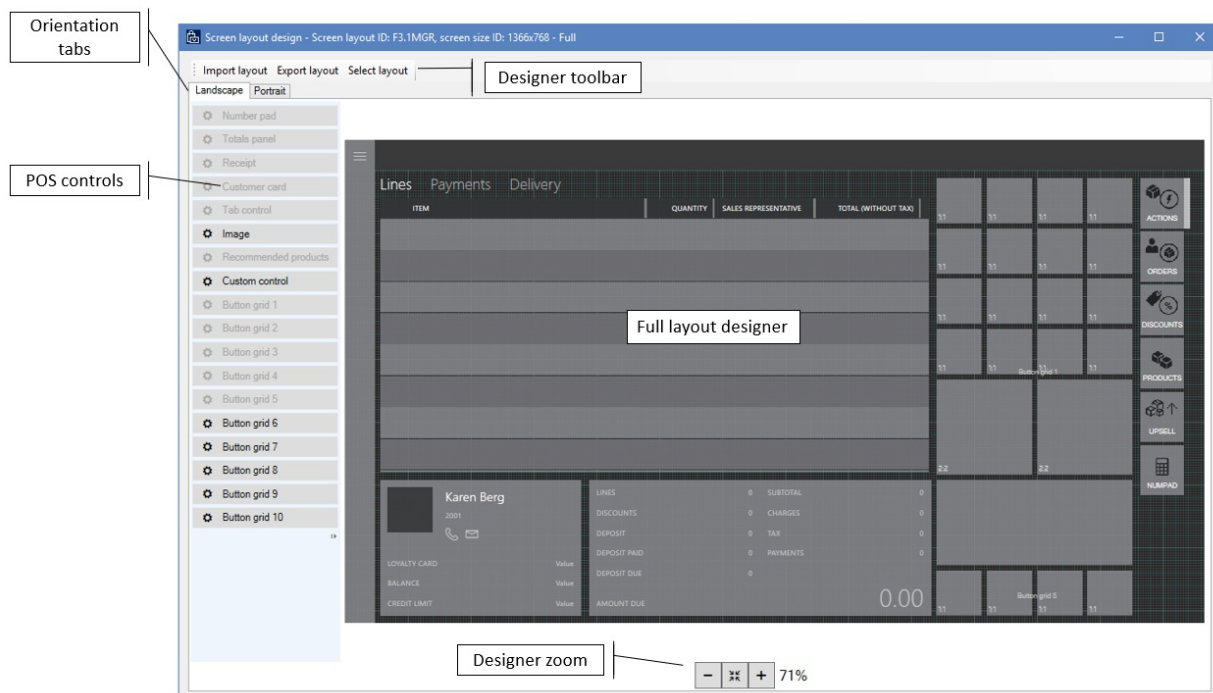

The screen layout designer lets you configure various aspects of the POS **Transaction** screen for each layout size, in both portrait and landscape modes, and for both Full and Compact layouts. The screen layout designer uses the ClickOnce deployment technology to download, install, and start the latest version of the application every time that users access it. Be sure to check the browser requirements for ClickOnce. Some browsers, such as Google Chrome, require extensions.

### IMPORTANT

You must configure a screen layout for each layout size that is defined and that is used by the POS.

## Full layout designer

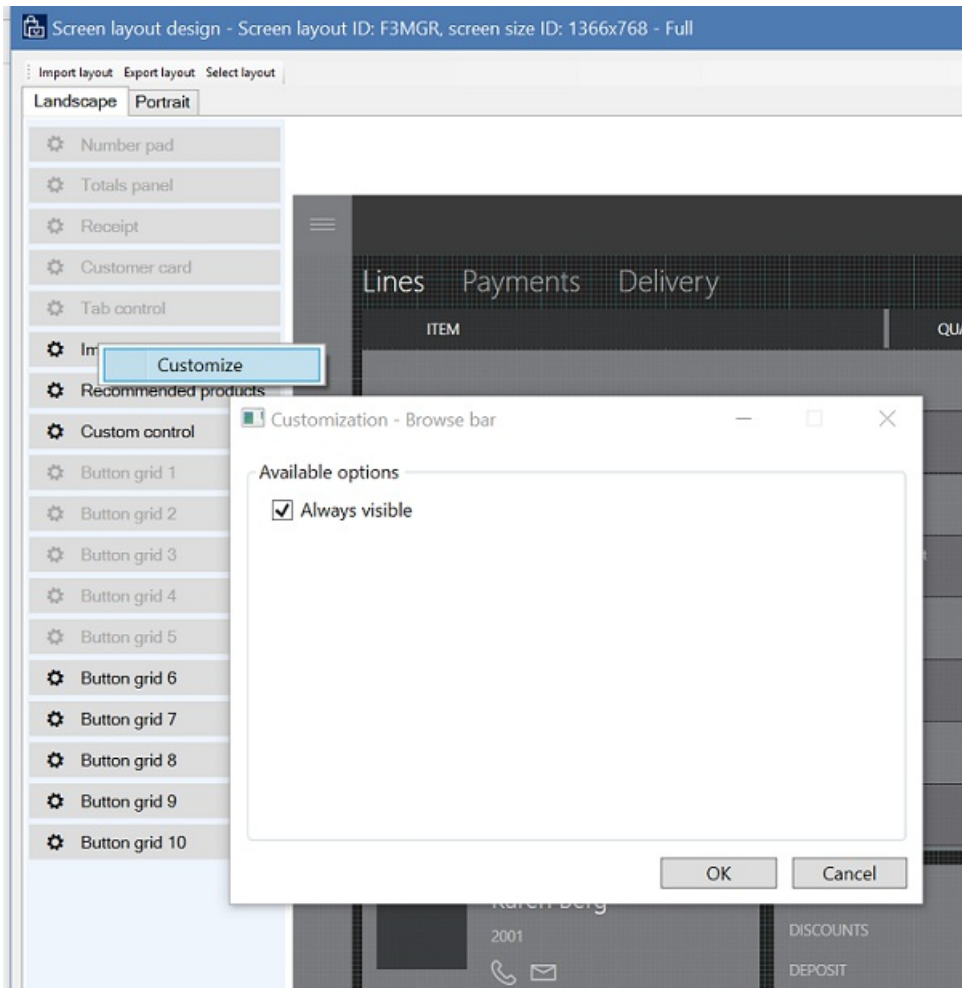

The Full layout designer lets users drag UI controls onto the POS **Transaction** screen and configure the settings of those controls.

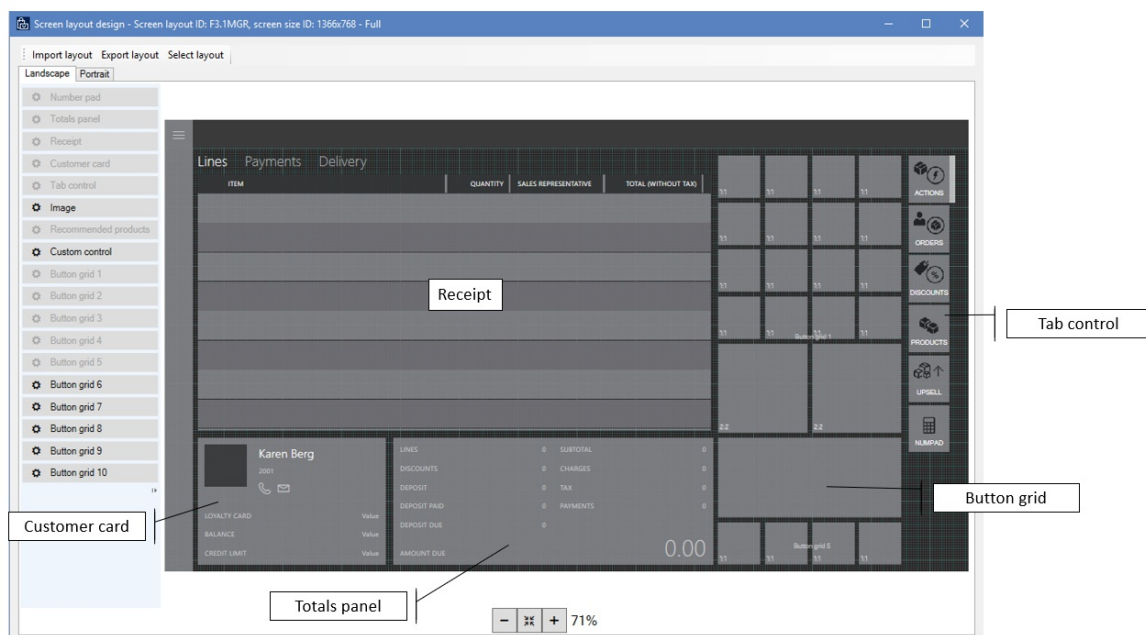

- **Import layout/Export layout** – You can export and import POS screen layout designs as XML files, so that you can easily reuse and share them across environments. It's important that you import layout designs for the correct layout sizes. Otherwise, UI elements might not fit correctly on the screen.
- **Landscape/Portrait** – If the POS device lets users switch between landscape and portrait modes, you must define a screen layout for each mode. The POS automatically detects screen rotation and shows the correct layout.
- **Layout grid** – The POS layout designer uses a 4-pixel grid. UI controls "snap" to the grid to help you correctly align the content.
- **Designer zoom** – You can zoom the designer view in and out to better view the content on the POS screen. This feature is useful when the screen resolution on the POS differs greatly from the resolution of the screen that is used in the designer.
- **Show/hide navigation bar** – For Full POS layouts, you can select whether the left navigation bar is visible on the **Transaction** screen. This feature is helpful for displays that have a lower resolution. To set

the visibility, right-click the navigation bar in the designer, and select or clear the **Always visible** check box. If the navigation bar is hidden, POS users can still access it by using the menu in the upper left.

- **POS controls** – The POS layout designer supports the following controls. You can configure many controls by right-clicking and using the shortcut menu.

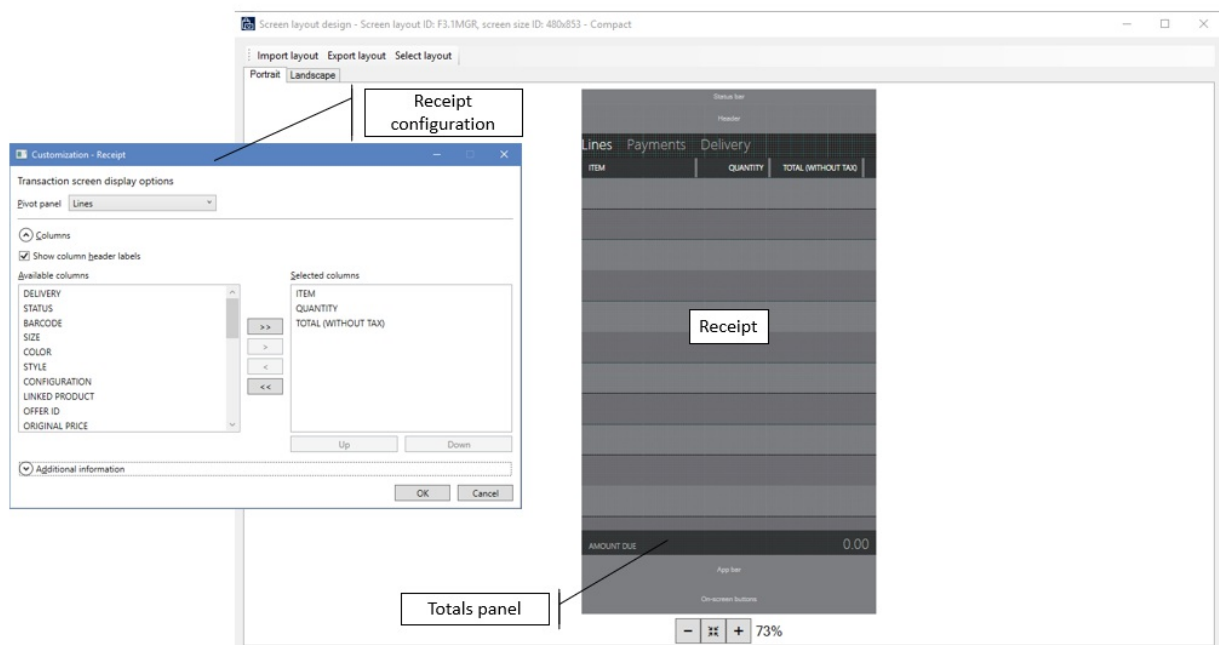

- **Number pad** – The number pad is the main mechanism for user input on the POS Transaction screen. You can configure the control so that the full number pad is shown. This option is ideal for touchscreen devices. Alternatively, you can configure it so that only the input field is shown. In this case, a physical keyboard is used for input. The number pad settings are available only for Full layouts.

For Compact layouts, the full number pad is always shown on the **Transaction** screen.

- **Totals panel** – You can configure the totals panel in either one column or two columns, to show values such as the line count, discount amount, charges, subtotal, and tax. Compact layouts support only a single column.
- **Receipt panel** – The receipt panel contains the sales lines, payment lines, and delivery information for the products and services that are processed in the POS. You can specify columns, widths, and placement. In Compact layouts, you can also configure additional information that appears in the row under the main line.
- **Customer card** – The customer card shows information about the customer who is associated with the current transaction. You can configure the customer card to hide or show additional information.
- **Tab control** – You can add the tab control to a screen layout, and then put other controls, such as the number pad, customer card, or button grids, in it. The tab control is a container that helps you fit more content on the screen. The tab control is available only for Full layouts.
- **Image** – You can use the image control to show the store's logo or another branding image on the **Transaction** screen. The image control is available only for Full layouts.
- **Recommended products** – If the recommended products control is configured for the environment, it shows product suggestions, based on machine learning.
- **Custom control** – The custom control acts as a placeholder in the screen layout and lets you reserve space for custom content. The custom control is available only for Full layouts.

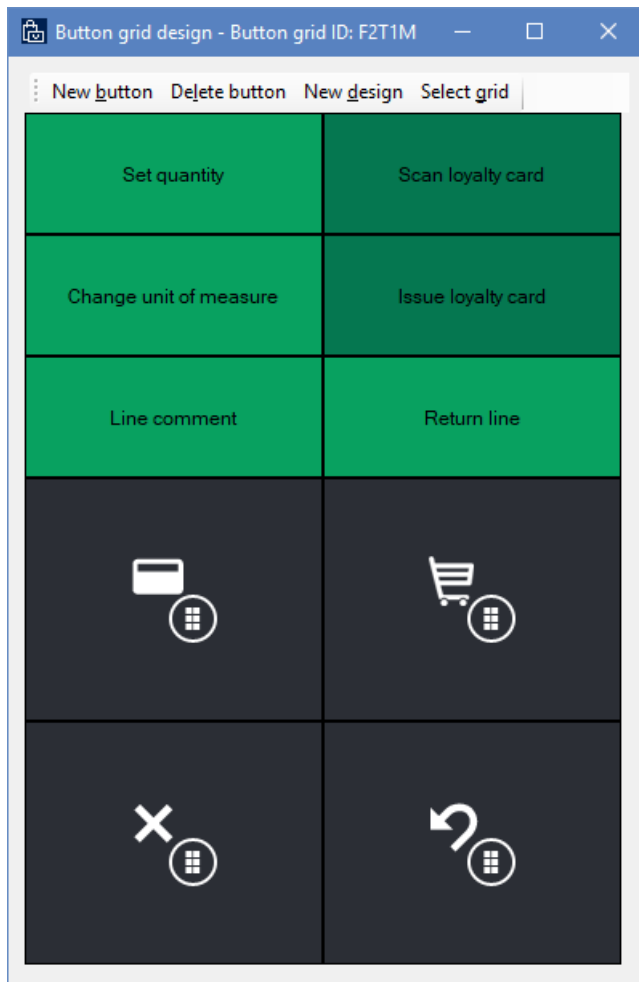

## Compact layout designer

Like the Full layout designer, the Compact layout designer lets you configure the POS screen layout for phones and small tablets. However, in this case, the layout itself is fixed. You can configure the controls in the layout by right-clicking and using the shortcut menu. However, you can't use drag-and-drop operations for additional content.

## Button grid designer

The button grid designer lets you configure button grids that can be used on the POS welcome screen and **Transaction** screen for both Full and Compact layouts. The same button grid can be used across layouts and layout types. Like the screen layout designer, the button grid designer uses the ClickOnce deployment technology to download, install, and start the latest version of the application every time that users access it. Be sure to check the browser requirements for ClickOnce. Some browsers, such as Google Chrome, require extensions.

- **New button** – Click to add a new button to the button grid. By default, new buttons appear in the upper-left corner of the grid. However, you can arrange buttons by dragging them in the layout.

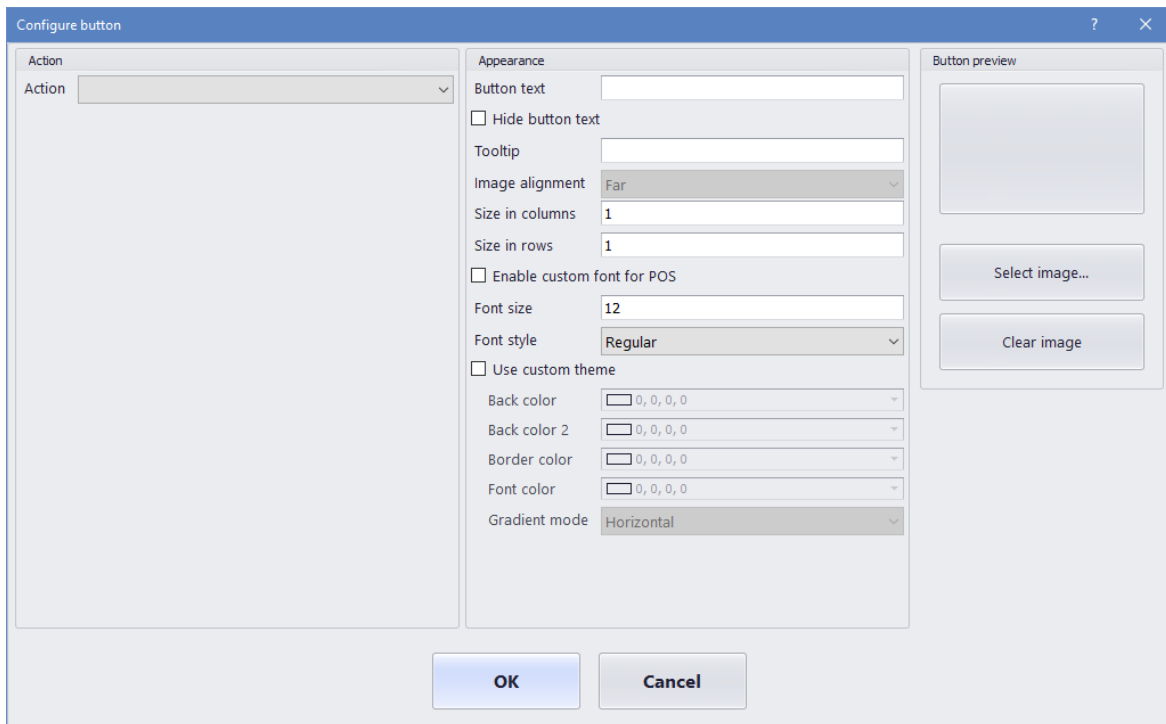

**IMPORTANT**

The contents of the button grid can overlap. When you arrange buttons, make sure that they don't hide other buttons.

- **New design** – Click to automatically set up a button grid layout by specifying the number of buttons per row and column.
- **Button properties** – You can configure button properties by right-clicking the button and using the shortcut menu.

**IMPORTANT**

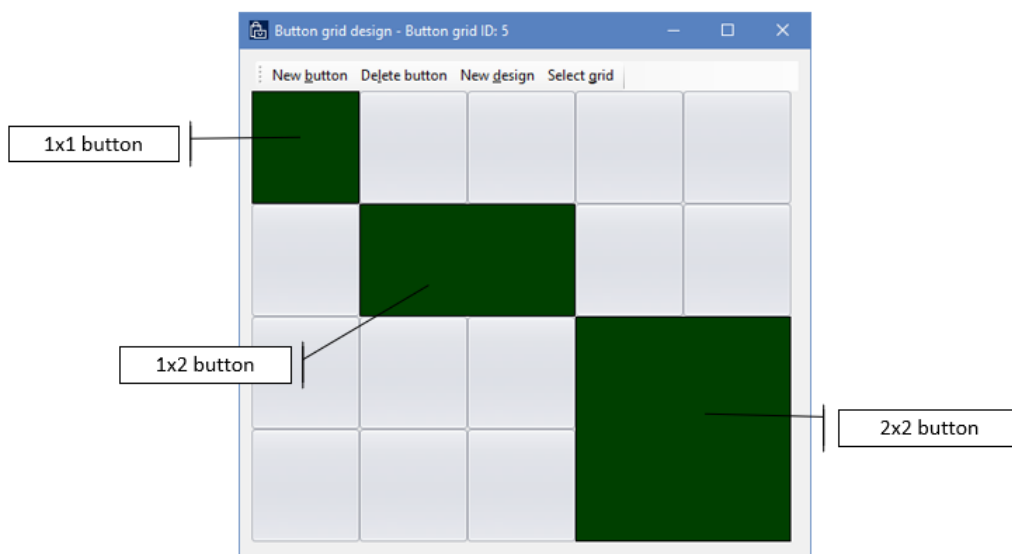

Some button grid settings apply only to Enterprise POS, not to Modern POS or Cloud POS.

- **Action** – In the list of applicable POS operations, select the operation that is invoked when the button is clicked in the POS.

For the list of supported POS operations, see [Online and offline point of sale \(POS\) operations](#).

- **Action parameters** – Some POS operations use additional parameters when they are invoked. For example, for the Add product operation, users can specify the product to add.
- **Button text** – Specify the text that appears on the button in the POS.
- **Hide button text** – Use this check box to hide or show the button text. Button text is often hidden for small buttons that show only an icon.
- **Tooltip** – Specify additional Help text that appears when users mouse over the button.
- **Size in columns/Size in rows** – You can specify how tall and wide the button is.

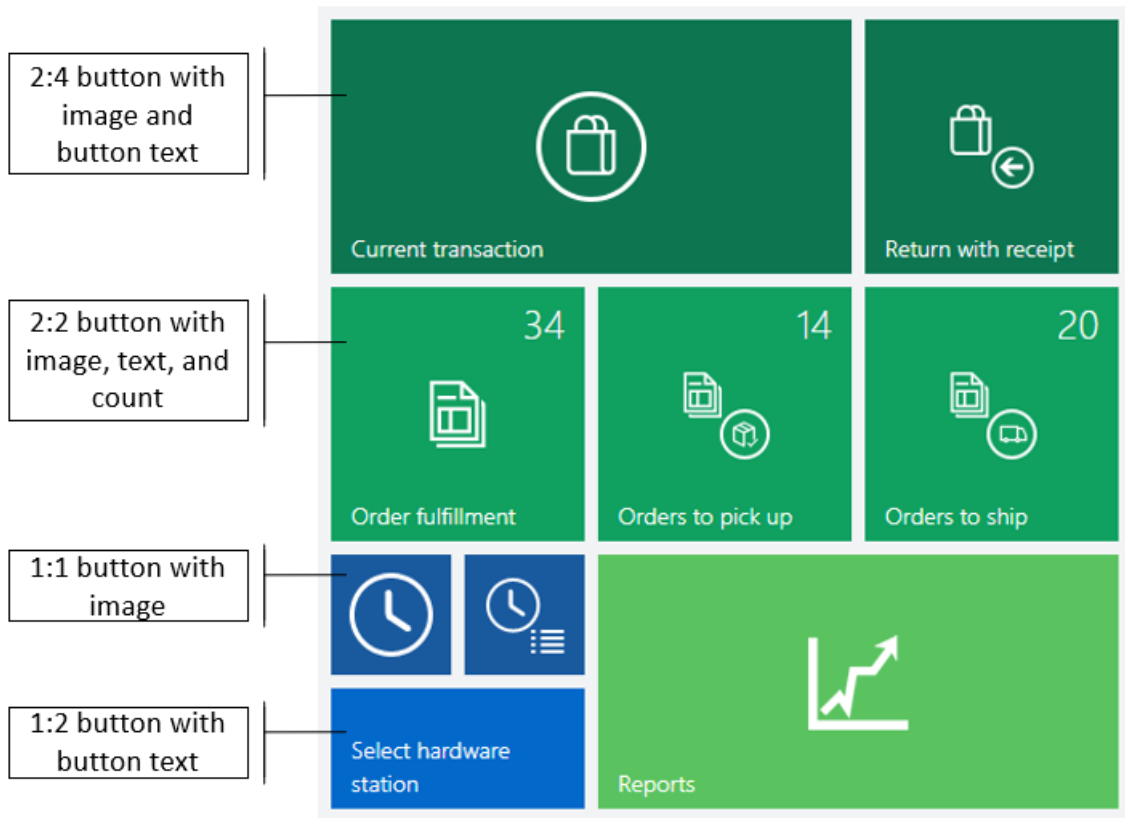

- **Custom font** – When you select the **Enable custom font for POS** check box, you can specify a font other than the default system font for the POS.

- **Custom theme** – By default, POS buttons use the accent color from the visual profile. When you select the **Use custom theme** check box, you can specify additional colors.

**NOTE**

Modern POS and Cloud POS use only the **Back color** and **Font color** values.

- **Button image** – Buttons can include images or icons. Select among the available images that are specified at **Retail and Commerce > Channel setup > POS setup > POS > Images**.

[Install the Retail point of sale \(POS\) layout designer](#)

**NOTE**

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Open URL in POS

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic describes how you can configure a button in Retail point of sale (POS) to open a URL. This feature does not require a code customization, and can be configured by someone in a non-developer role.

This feature allows configuration of a button in POS, using the button grid designer to open a URL. Currently, this is supported in the following configurations:

- Open in new window.
- Open within POS.
- Open a native app.

## Open in new window

This configuration defines whether to open the URL in a new window or within the app. When configured to open a web URL within the app, the side navigation panel and top bar of POS are visible and available for user interaction. When configured to open in a new window, the URL will open in a new app window on Modern POS for Windows, and in a new browser tab in all other POS clients. To enable this, you must configure the URL with the **Open in new window** option selected.

## Open within POS

Opening a web URL within POS is currently only supported for Modern POS on Windows. On other clients, this capability is under development and planned for release in future updates. To enable this, you must configure the URL with the **Open in new window** option not selected.

## Open a native app

This feature also allows you to specify non-web URLs to open a native app. For example, you can specify URL protocols such as MailTo, SIP, IM, or MSTEAMS, which can then be handled by respective native apps on the host device. To enable this, you must configure the URL with the **Open in new window** option selected.

- For Windows computers, see [Export or Import Default Application Associations](#) to set the default protocol associations if you are setting up your computer using Deployment Image Servicing and Management (DISM).
- If you are using MDM, such as Intune to manage your Windows computers, see [Policy CSP - ApplicationDefaults](#).
- If you are a developer building a custom website, see [Launch the default app for a URI](#).

## Open a native app seamlessly

Windows, iOS, and Android also allow opening of apps more seamlessly, based on app protocol association. If your app is not already configured to handle opening from a web browser, you may need a developer to configure this.

- For Windows, see [Enable apps for websites using app URI handlers](#).
- For iOS, see [Universal Links for Developers](#).
- For Android, see [Handling Android App Links](#).

CLIENT	OPEN IN NEW WINDOW	OPEN NATIVE APP	OPEN WITHIN POS	DETAILS
Modern POS on Windows	✓*	✓	✓	* Opens in new Modern POS window
Cloud POS	✓*	✓	X	* Opens in new browser tab
Modern POS on iOS	✓*	✓	X	* Opens in new browser tab
Modern POS on Android	✓*	✓	X	* Opens in new browser tab

## Before you begin

Before you begin, review how to configure [Screen layouts for the point of sale \(POS\)](#).

## Open URL in POS

To configure a URL to be opened in POS, perform the following steps.

1. In head office, go to **Retail and Commerce > Channel Setup > POS Setup > POS > Screen Layouts**.
2. Select **Button Grids > Designer**.
3. Create a new button.
4. Select **Button** properties.
5. Select **Open URL** as the action.
6. Enter the URL that you want to use.
7. Configure whether to open the URL in a new window.

### NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Install the POS layout designer

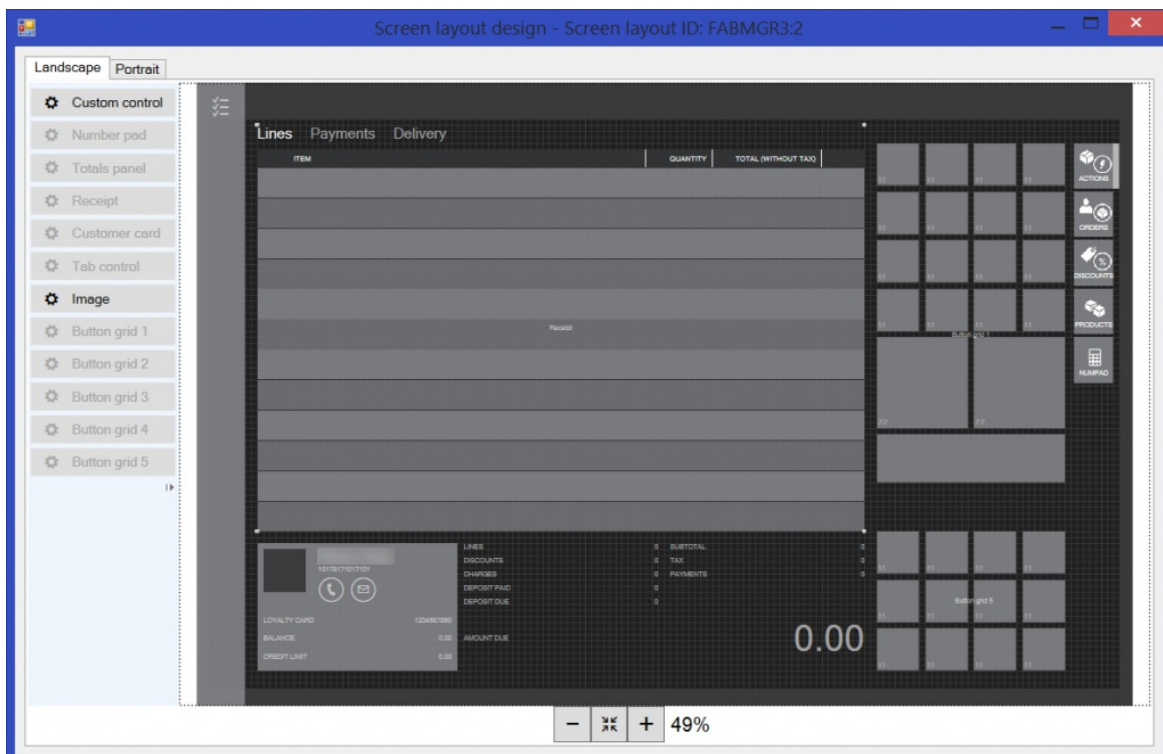

2/18/2021 • 2 minutes to read • [Edit Online](#)

You can use the one-click designer to design different Modern POS (MPOS) and Cloud POS layouts, in either Landscape mode or Portrait mode, for stores, registers, cashiers, and managers.

The graphical design interface for MPOS or Cloud POS is controlled by the till layout. A layout controls the position of various objects. Examples include the total layout, the item grid layout, the customer layout, the payment layout, and the layout of various menu buttons. Layouts also include the overall appearance of the sales interface that is presented to workers.

## Install the one-click designer

1. In Commerce, use the menu in the upper left to navigate to **Retail and Commerce > Channel setup > POS setup > POS > Screen layouts**.
2. Select any layout that has an application type of **Modern POS for Windows** or **Cloud POS**, and then click **Layout designer**.
3. On the notification bar that appears at the bottom of the Internet Explorer window, click **Open** to install the one-click designer. (The notification bar might appear in a different place in other browsers.)
4. In the **Application Run - Security Warning** message box that appears, click **Run** to install the Retail designer host. A progress indicator shows the progress of the installation.
5. After the installation is completed, on the **Sign in** page, enter your Commerce user name and password, and then click **Sign in** to start the designer.
6. After your credentials are validated and the designer starts, you can design your own layout or modify the existing layout.

# Troubleshoot the installation of the Layout designer

- When you click **Designer**, the prompt to download (or run) the installer doesn't appear, or your current security settings don't allow you to download the file.

## Solutions:

- In Internet Explorer, make sure that the pop-up blocker is disabled for this site. Click **Settings > Options > Privacy > Find Pop-up Blocker**, and change the setting, if a change is required.
- In Internet Explorer, add the Commerce URL to your trusted sites. Click **Settings > Options > Security > Trusted sites > Sites > Add**.
- The program doesn't start, and you're instructed to contact the vendor.

**Solution:** In Internet Explorer, add the Commerce URL to your trusted sites. Click **Setting > Options > Security > Trusted sites > Sites > Add**.

**Known issue:** The designer doesn't work correctly in the Google Chrome and Mozilla Firefox browsers. We are working to fix this issue.

## Additional resources

[Configure, install, and activate Retail Modern POS \(MPOS\)](#)

### NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Extend the point of sale (POS) Dual display view

2/18/2021 • 10 minutes to read • [Edit Online](#)

This topic explains how to extend the point of sale (POS) Dual display view so that it shows custom information. This topic is applicable to Microsoft Dynamics 365 for Finance and Operations 7.2 or Microsoft Dynamics 365 Retail 7.2 with KB 4091080, and later versions.

You can extend the POS Dual display view by adding a custom control. In the custom control, you can add images, POS data lists, labels, and so on, to show custom information.

## NOTE

You can extend the POS Dual display view only by adding a custom control. The custom control will override the standard content that is shown in the POS Dual display view. The dual display custom control and other extension details information related to dual display will not be shown in the extension details view.

## Required steps

Here is an overview of the steps that are required in order to customize the POS Dual display view.

1. Configure the hardware profile to enable dual display.
2. Create a folder in the POS.Extensions project for extension of the POS Dual display view.
3. Add a new custom control that includes custom information.
4. Update the manifest.json and extensions.json files with the extension of the POS Dual display view.
5. Deploy the changes, and validate the customization.

## Scenario or business problem

You will add a custom control column in the POS Dual display view to show the cart details and information about the customer and the store employee.

## Configure the hardware profile to enable dual display

1. Sign in to the client.
2. Go to **Retail and Commerce > Channel setup > POS setup > POS profiles > Hardware profiles**.
3. Select the hardware profile that is linked to your register.
4. On the **Dual display** tab, set the **Dual display in use** option to **Yes**.
5. Go to **Retail and Commerce > Retail and Commerce IT > Distribution schedule**.
6. Select the **Registers (1090)** job, and then select **Run now**.

## NOTE

You can find the end-to-end (E2E) sample in ...RetailSDK\POS\Extensions\DualDisplaySample.

## Add a new custom control for extension of the POS Dual display view

1. Start Microsoft Visual Studio 2015 in Administrator mode.
2. Open the **ModernPOS** solution from ...RetailSDK\POS.

3. Under the POS.Extensions project, create a folder that is named **DualDisplayExtension**.
4. Under the **DualDisplayExtension** folder, create a folder that is named **CustomControl**.
5. In the **CustomControl** folder, create a HTML file that is named **DualDisplayCustomControl.html**.

In the HTML file, you will add a data list control to show the cart details, and text controls to show the total amount, customer name, employee name, and sign-in status.

6. Copy the following code, and paste it into the **DualDisplayCustomControl.html** file.

```
<!DOCTYPE html>
<html lang="en" xmlns="http://www.w3.org/1999/xhtml">
<head>
<meta charset="utf-8" />
<title></title>
</head>
<body>
<!-- Note: The element ID is different from the ID generated by the POS extensibility framework. This
'template' ID is not used by the POS extensibility framework. -->
<script id="Microsoft_Pos_Extensibility_Samples_DualDisplay" type="text/html">
<div class="height100Percent width100Percent">
  <div class="height700 width100Percent no-shrink col marginBottom20">
    <div class="col grow marginBottom48">
      <div id="dualDisplayDataListSample" data-bind="msPosDataList: cartLinesDataList">
      </div>
    </div>
  </div>
  <div class="marginBottom20">
    <h2 class="marginLeft8" data-bind="text: cartTotalAmountLabel">Total Amount:</h2>
    <h2 class="marginLeft8" data-bind="text: cartTotalAmount"></h2>
    <h2 class="marginLeft8" data-bind="text: customerNameLabel">Customer Name:</h2>
    <h2 class="marginLeft8" data-bind="text: customerName"></h2>
    <h2 class="marginLeft8" data-bind="text: customerAccountNumberLabel">Customer Account Number:
  </h2>
    <h2 class="marginLeft8" data-bind="text: customerAccountNumber"></h2>
    <h2 class="marginLeft8" data-bind="text: isLoggedInOn() ? 'logged in' : 'logged out'"></h2>
    <h2 class="marginLeft8" data-bind="text: employeeNameLabel">Employee Name:</h2>
    <h2 class="marginLeft8" data-bind="text: employeeName"></h2>
  </div>
</div>
</script>
</body>
</html>
```

Next, you will add the resource file that is used to localize the field name.

7. Under the **DualDisplayExtension** folder, create a folder that is named **Resources**.
8. Under the **Resources** folder, create a folder that is named **Strings**.
9. Under the **Strings** folder, create a folder that is named **en-US**.
10. In the en-US folder add a new resources file and and change the file extension and name to resources.resjson and inside the resources.resjson file copy paste the below resource strings.

```

//=====
===
//===== Sample comment.
=====
//=====
===

{
  //===== extensions strings. =====

  "string_0" : "ID",
  "_string_0.comment" : "Item ID label text",

  "string_1" : "Name",
  "_string_1.comment" : "Item name label text",

  "string_2" : "Quantity",
  "_string_2.comment" : "Item cost label text",

  "string_3" : "Discount",
  "_string_3.comment" : "Total amount label text",

  "string_4" : "Cost",
  "_string_4.comment" : "Item cost label text",

  "string_5" : "Total Amount:",
  "_string_5.comment" : "Total amount label text",

  "string_6" : "Customer Name:",
  "_string_6.comment" : "Customer name label text",

  "string_7" : "Customer Account Number:",
  "_string_7.comment" : "Customer account number label text",

  "string_8" : "Employee Name:",
  "_string_8.comment" : "Employee name label text"
}

```

11. In the **CustomControl** folder, create a TypeScript file (.ts file) that is named **DualDisplayCustomControl.ts**.
12. Copy the following code, and paste it into the **DualDisplayCustomControl.ts** file. This code imports the relevant entities and context.

```

import {
  DualDisplayCustomControlBase,
  IDualDisplayCustomControlState,
  IDualDisplayCustomControlContext,
  CartChangedData,
  CustomerChangedData,
  LogOnStatusChangedData
} from "PosApi/Extend/DualDisplay";
import { DataList, IDataListState, SelectionMode } from "PosUISdk/Controls/DataList";
import { ObjectExtensions, StringExtensions } from "PosApi/TypeExtensions";
import { ProxyEntities } from "PosApi/Entities";

```

13. In the **DualDisplayCustomControl.ts** file, create a class that is named **DualDisplayCustomControl**, and extend it from the **DualDisplayCustomControlBase** class. You extend from the **DualDisplayCustomControlBase** class to get all the events that are exposed for dual display.

```

export default class DualDisplayCustomControl extends DualDisplayCustomControlBase { }

```

14. Inside the `DualDisplayCustomControl` class, add the following variables to get the cart, customer, and employee details.

```
private static readonly TEMPLATE_ID: string = "Microsoft_Pos_Extensibility_Samples_DualDisplay";

// The data list to bind against and display with cart line information.

public readonly cartLinesDataList: DataList<ProxyEntities.CartLine>;

// Computed values for binding against.

public readonly cartTotalAmount: Computed<number>;
public readonly customerName: Computed<string>;
public readonly customerAccountNumber: Computed<string>;
public readonly isLoggedInOn: Computed<boolean>;
public readonly employeeName: Computed<string>;

// Labels for binding against.

public readonly cartTotalAmountLabel: string;
public readonly customerNameLabel: string;
public readonly customerAccountNumberLabel: string;
public readonly employeeNameLabel: string;

// Observable values used for keeping track of state.

private readonly _cart: Observable<ProxyEntities.Cart>;
private readonly _cartLinesObservable: ObservableArray<ProxyEntities.CartLine>;
private readonly _customer: Observable<ProxyEntities.Customer>;
private readonly _loggedOn: Observable<boolean>;
private readonly _employee: Observable<ProxyEntities.Employee>; private _selectedTenderLines:
ProxyEntities.TenderLine[];
```

15. Create a class constructor method to initialize all the variables.

```
constructor(id: string, context: IDualDisplayCustomControlContext) {
    super(id, context);

    // Initializes labels.

    this.cartTotalAmountLabel = this.context.resources.getString("string_5");
    this.customerNameLabel = this.context.resources.getString("string_6");
    this.customerAccountNumberLabel = this.context.resources.getString("string_7");
    this.employeeNameLabel = this.context.resources.getString("string_8");

    // Initializes observable and computed values.

    this._cart = ko.observable(null);
    this._cartLinesObservable = ko.observableArray([]);
    this._customer = ko.observable(null);
    this._loggedOn = ko.observable(false);
    this._employee = ko.observable(null);
    this.cartTotalAmount = ko.computed(() => {
        return ObjectExtensions.isNullOrUndefined(this._cart()) ? 0.00 : this._cart().TotalAmount;
    });
    this.customerName = ko.computed(() => {
        return ObjectExtensions.isNullOrUndefined(this._customer()) ? StringExtensions.EMPTY :
this._customer().Name;
    });
    this.customerAccountNumber = ko.computed(() => {
        return ObjectExtensions.isNullOrUndefined(this._customer()) ? StringExtensions.EMPTY :
this._customer().AccountNumber;
    });
    this.isLoggedInOn = ko.computed(() => {
        return this._loggedOn();
    });
}
```

```

    },
    this.employeeName = ko.computed(() => {
        return ObjectExtensions.isNullOrUndefined(this._employee()) ? StringExtensions.EMPTY :
this._employee().Name;
    });
    this.cartChangedHandler = (data: CartChangedData) => {
        this._cart(data.cart);
        this._cartLinesObservable(ObjectExtensions.isNullOrUndefined(data.cart) ? [] :
data.cart.CartLines)
    };
    this.customerChangedHandler = (data: CustomerChangedData) => {
        this._customer(data.customer);
    };
    this.logOnStatusChangedHandler = (data: LogOnStatusChangedData) => {

        // Displays the busy indicator here, even though it's not necessary, in order to showcase and
test the scenario.

        this.isProcessing = true;
        window.setTimeout(() => {
            this.isProcessing = false;
        }, 1000);
        this._loggedOn(data.loggedOn);
        this._employee(data.employee);
    }

    // Initializes the cart lines data list

    let cartLinesDataListOptions: IDataListState<ProxyEntities.CartLine> = {
        selectionMode: SelectionMode.None,
        itemDataSource: this._cartLinesObservable,
        columns:[
            {
                title: context.resources.getString("string_0"), // ID
                ratio: 20,
                collapseOrder: 2,
                minWidth: 50,
                computeValue: (cartLine: ProxyEntities.CartLine): string => {
                    return ObjectExtensions.isNullOrUndefined(cartLine.ItemId) ?
StringExtensions.EMPTY : cartLine.ItemId;
                }
            },
            {
                title: context.resources.getString("string_1"), // Name
                ratio: 50,
                collapseOrder: 4,
                minWidth: 100,
                computeValue: (cartLine: ProxyEntities.CartLine): string => {
                    return ObjectExtensions.isNullOrUndefined(cartLine.Description) ?
StringExtensions.EMPTY : cartLine.Description;
                }
            },
            {
                title: context.resources.getString("string_2"), // Quantity
                ratio: 10,
                collapseOrder: 3,
                minWidth: 50,
                computeValue: (cartLine: ProxyEntities.CartLine): string => {
                    return ObjectExtensions.isNullOrUndefined(cartLine.Quantity) ?
StringExtensions.EMPTY : cartLine.Quantity.toString();
                }
            },
            {
                title: context.resources.getString("string_3"), // Discount
                ratio: 10,
                collapseOrder: 1,
                minWidth: 50,
                computeValue: (cartLine: ProxyEntities.CartLine): string => {
                    return ObjectExtensions.isNullOrUndefined(cartLine.DiscountAmount) ?
StringExtensions.EMPTY : cartLine.DiscountAmount.toString();
                }
            }
        ]
    };

```

```

StringExtensions.EMPTY : cartLine.DiscountAmount.toString();
    }
    },
    {
        title: context.resources.getString("string_4"), // Cost
        ratio: 10,
        collapseOrder: 5,
        minWidth: 50,
        computeValue: (cartLine: ProxyEntities.CartLine): string => {
            return ObjectExtensions.IsNullOrEmpty(cartLine.TotalAmount) ?
StringExtensions.EMPTY : cartLine.TotalAmount.toString();
        }
    }
    ]
};
this.cartLinesDataList = new DataList(cartLinesDataListOptions);

// Logs the completion of constructing the DualDisplayCustomControl.

this.context.logger.logInformational("DualDisplayCustomControl constructed",
this.context.logger.getNewCorrelationId());
}

```

16. Add the **onReady** method to bind the control to the specified HTML element.

```

/**
 * Binds the control to the specified element.
 * @param {HTMLElement} element The element to which the control should be bound.
 */
public onReady(element: HTMLElement): void {
    ko.applyBindingsToNode(element, {
        template: {
            name: DualDisplayCustomControl.TEMPLATE_ID,
            data: this
        }
    });
}

```

17. Add the **init** method to initialize all the controls.

```

/**
 * Initializes the control.
 * @param {IDualDisplayCustomControlState} state The initial state of the page used to initialize the
control.
 */
public init(state: IDualDisplayCustomControlState): void {
    this._cart(state.cart);
    this._customer(state.customer);
    this._loggedOn(state.loggedOn);
    this._employee(state.employee)
}

```

Here is what the overall class should look like.

```

import {
    DualDisplayCustomControlBase,
    IDualDisplayCustomControlState,
    IDualDisplayCustomControlContext,
    CartChangedData,
    CustomerChangedData,
    LogOnStatusChangedData
} from "PosApi/Extend/DualDisplay";

```

```

import { DataList, IDataListState, SelectionMode } from "PosUISdk/Controls/DataList";
import { ObjectExtensions, StringExtensions } from "PosApi/TypeExtensions";
import { ProxyEntities } from "PosApi/Entities";
export default class DualDisplayCustomControl extends DualDisplayCustomControlBase {
    private static readonly TEMPLATE_ID: string = "Microsoft_Pos_Extensibility_Samples_DualDisplay";

    // The data list to bind against and display with cart line information.

    public readonly cartLinesDataList: DataList<ProxyEntities.CartLine>;

    // Computed values for binding against.

        this._customer(data.customer);
    };
    this.logOnStatusChangedHandler = (data: LogOnStatusChangedData) => {

        // Displays the busy indicator here, even though it's not necessary, in order to showcase
and test the scenario.

        this.isProcessing = true;
        window.setTimeout(() => {
            this.isProcessing = false;
        }, 1000);
        this._loggedOn(data.loggedOn);
        this._employee(data.employee);
    }

    // Initializes the cart lines data list

    let cartLinesDataListOptions: IDataListState<ProxyEntities.CartLine> = {
        selectionMode: SelectionMode.None,
        itemDataSource: this._cartLinesObservable,
        columns:[
            {
                title: context.resources.getString("string_0"), // ID
                ratio: 20,
                collapseOrder: 2,
                minWidth: 50,
                computeValue: (cartLine: ProxyEntities.CartLine): string => {
                    return ObjectExtensions.isNullOrUndefined(cartLine.ItemId) ?
StringExtensions.EMPTY : cartLine.ItemId;
                }
            },
            {
                title: context.resources.getString("string_1"), // Name
                ratio: 50,
                collapseOrder: 4,
                minWidth: 100,
                computeValue: (cartLine: ProxyEntities.CartLine): string => {
                    return ObjectExtensions.isNullOrUndefined(cartLine.Description) ?
StringExtensions.EMPTY : cartLine.Description;
                }
            },
            {
                title: context.resources.getString("string_2"), // Quantity
                ratio: 10,
                collapseOrder: 3,
                minWidth: 50,
                computeValue: (cartLine: ProxyEntities.CartLine): string => {
                    return ObjectExtensions.isNullOrUndefined(cartLine.Quantity) ?
StringExtensions.EMPTY : cartLine.Quantity.toString();
                }
            },
            {
                title: context.resources.getString("string_3"), // Discount
                ratio: 10,
                collapseOrder: 1,
                minWidth: 50,
                computeValue: (cartLine: ProxyEntities.CartLine): string => {
                    return ObjectExtensions.isNullOrUndefined(cartLine.DiscountAmount) ?
StringExtensions.EMPTY : cartLine.DiscountAmount.toString();
                }
            },
            {
                title: context.resources.getString("string_4"), // Cost
                ratio: 10.

```

```

        collapseOrder: 5,
        minWidth: 50,
        computeValue: (cartLine: ProxyEntities.CartLine): string => {
            return ObjectExtensions.isNullOrUndefined(cartLine.TotalAmount) ?
StringExtensions.EMPTY : cartLine.TotalAmount.toString();
        }
    }
}
];
};
this.cartLinesDataList = new DataList(cartLinesDataListOptions);

// Logs the completion of constructing the DualDisplayCustomControl.

this.context.logger.logInformational("DualDisplayCustomControl constructed",
this.context.logger.getNewCorrelationId());
}

/**
 * Binds the control to the specified element.
 * @param {HTMLElement} element The element to which the control should be bound.
 */

public onReady(element: HTMLElement): void {
    ko.applyBindingsToNode(element, {
        template: {
            name: DualDisplayCustomControl.TEMPLATE_ID,
            data: this
        }
    });
}

/**
 * Initializes the control.
 * @param {IDualDisplayCustomControlState} state The initial state of the page used to initialize
the control.
 */

public init(state: IDualDisplayCustomControlState): void {
    this._cart(state.cart);
    this._customer(state.customer);
    this._loggedOn(state.loggedOn);
    this._employee(state.employee)
}
}
}

```

18. In the **DualDisplayExtension** folder, create a JavaScript Object Notation (JSON) file (.json file) that is named **manifest.json**.
19. Copy the following code, and paste it into the **manifest.json** file. Delete the default generated code before you copy this code.

```

{
  "$schema": "../manifestSchema.json",
  "name": "Pos_Extensibility_DualDisplaySample",
  "publisher": "Microsoft",
  "version": "7.2.0",
  "minimumPosVersion": "7.2.0.0",
  "components": {
    "resources": {
      "supportedUICultures": [ "en-US" ],
      "fallbackUICulture": "en-US",
      "culturesDirectoryPath": "Resources/Strings",
      "stringResourcesFileName": "resources.resjson"
    },
    "dualDisplay": {
      "customControl": {
        "controlName": "DualDisplayCustomControl",
        "htmlPath": "CustomControl/DualDisplayCustomControl.html",
        "modulePath": "CustomControl/DualDisplayCustomControl"
      }
    }
  }
}

```

20. Open the **extensions.json** file under the **POS.Extensions** project, and update it with the **DualDisplayExtension** samples. In that way, the POS will include this extension during runtime.

```

{
  "extensionPackages": [
    {
      "baseUrl": "SampleExtensions"
    },
    {
      "baseUrl": " SampleExtensions2"
    },
    {
      "baseUrl": " DualDisplayExtension"
    }
  ]
}

```

21. Open the **tsconfig.json** file, and comment out the extension package folders in the exclude list. The POS will use this file to include or exclude the extension. By default, the list contains all the excluded extensions. If you want to include an extension as part of the POS, add the name of the extension folder, and comment out the extension in the extension list, as shown here.

```

"exclude": [
  "AuditEventExtensionSample",
  "B2BSample",
  "CustomerSearchWithAttributesSample",
  "FiscalRegisterSample",
  "PaymentSample",
  "PromotionsSample",
  "SalesTransactionSignatureSample",
  //"SampleExtensions2",
  "SampleExtensions",
  "StoreHoursSample",
  "SuspendTransactionReceiptSample"
  //"SampleExtensions",
  //"DualDisplayExtension"
],

```

22. Compile and rebuild the project.

## Validate the customization

1. Sign in to Retail Modern POS by using **000160** as the operator ID and **123** as the password.
2. On the welcome screen, select the **Current transaction** button.
3. Add any item to the transaction. For example, add item number **0005**.
4. Add any customer to transaction. For example, add **Karen Berg**.
5. The dual display should show the cart, total, employee, and customer details.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

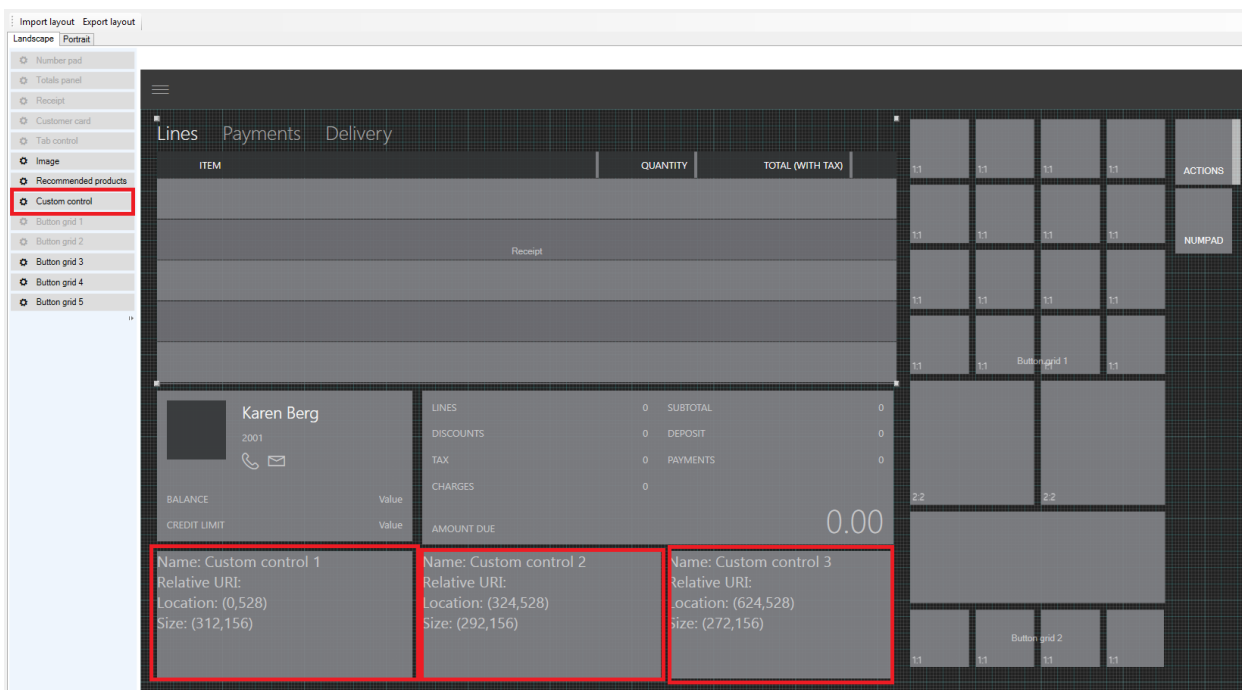

# Add custom controls to POS views

2/18/2021 • 5 minutes to read • [Edit Online](#)

To enhance the information that appears in the views in Microsoft Dynamics 365 Commerce POS, you can add custom controls. A custom control lets you add your own custom information to the existing POS views. Custom controls can be implemented by using the POS extension framework.

In Cart view, you can add custom controls by using the POS screen layout designer. In this case, you can drag a custom control to a location of your choice, and you can also set the height and width of the control. You then write the extension logic in the extension project.

For example, in the following illustration, three custom controls were added by using the screen layout designer.

Currently, only Cart view lets you use the screen layout designer to add custom controls. For all other screens, you should do the layout in the extension project. One advantage of using the screen layout designer is that you can drag the custom control wherever you want on the screen. On other screens, the position is fixed, but you can modify the position by specifying the height and width.

## Custom control matrix

The following table shows the views that support custom controls in POS.

POS VIEW	SUPPORTS CUSTOM CONTROLS	SUPPORTS SCREEN LAYOUT DESIGNER
Cart view/Transaction page	Yes	Yes
Customer details view	Yes	No
Product details view	Yes	No
Customer Add/Edit view	Yes	No

POS VIEW	SUPPORTS CUSTOM CONTROLS	SUPPORTS SCREEN LAYOUT DESIGNER
Address Add/Edit view	Yes	No

#### NOTE

Custom controls are supported only in the following product versions:

- **For views that aren't based on the screen layout designer:** Microsoft Dynamics 365 for Finance and Operations App update 3 and Microsoft Dynamics 365 Retail App update 3
- **For views that are based on the screen layout designer:** Microsoft Dynamics 365 for Finance and Operations App update 4 and Microsoft Dynamics 365 Retail App update 4

## Create a custom control

The following example shows how you can use extension to add custom controls to one of the existing POS views. For this example, we want information about product availability to appear in the product details view. To show this information, we will add a custom data list that has four columns: **Location**, **Inventory**, **Reserved**, and **Ordered**. You can use the same procedure to show other custom information in the POS views.

1. On the developer virtual machine (VM), start Microsoft Visual Studio 2015.
2. Open the **ModernPos.sln** file from RetailSDK\POS.
3. In the **POS.Extensions** project, add a new folder, and name it **SampleExtensions**.
4. In the new **SampleExtensions** folder, add another folder, and name it **ViewExtensions**.
5. In the **ViewExtensions** folder, add another folder, and name it **SimpleProductDetails**.

#### NOTE

If you're extending a view, you should give the folder the same name as the view, to make navigation and code maintenance easier.

6. In the **SimpleProductDetails** folder, add a new .html file, and name it **ProductAvailabilityPanel.html**. Also add a new .ts file, and name it **ProductAvailabilityPanel.ts**. In the .html file, you can add whatever information you want the custom control to show. In the .ts file, you add the corresponding logic.

A custom control is a simple HTML page that has your custom information.

7. Open the **ProductAvailabilityPanel.html** file, and paste the following code into it.

```

<!DOCTYPE html>
<html lang="en" xmlns="http://www.w3.org/1999/xhtml">
  <head>
    <meta charset="utf-8" />
    <title></title>
  </head>
  <body>
    <!-- Note: The element ID differs from the ID that is generated by the POS extensibility
    framework. This 'template' ID isn't used by the POS extensibility framework. -->
    <script id="Microsot_Pos_Extensibility_Samples_ProductAvailabilityPanel"
    type="text/html">
      <h2 class="marginTop8 marginBottom8" data-bind="text: title"></h2>
      <div class="width400 grow col">
        <div id="Microsot_Pos_Extensibility_Samples_ProductAvailabilityPanel_DataList"
        data-bind="msPosDataList: dataList"></div>
      </div>
    </script>
  </body>
</html>

```

In the file, you add the POS data list control to show the product availability information. You also specify the width of the control.

You can copy the full code from

RetailSDK\Code\POS\Extensions\SampleExtensions\ViewExtensions\SimpleProductDetails\ProductAvailabilityPanel.html.

8. Open the **ProductAvailabilityPanel.ts** file, and paste the following code into it.

```

import {
  SimpleProductDetailsCustomControlBase,
  ISimpleProductDetailsCustomControlState,
  ISimpleProductDetailsCustomControlContext
} from "PosApi/Extend/Views/SimpleProductDetailsView";
import { ProxyEntities } from "PosApi/Entities";
import { ArrayExtensions } from "PosApi/TypeExtensions";
import { DataList, SelectionMode } from "PosUISdk/Controls/DataList";

```

To write our custom logic, we imported the list of controls and other data objects from the POS application programming interface (API).

## Add constructor and initialize data list

Next, you must add the constructor and initialize the data list with the product availability information. In this way, when you navigate to the page, the product availability information is loaded.

### NOTE

We didn't copy the source code here, but you can copy the full code from RetailSDK\Code\POS\Extensions\SampleExtensions\ViewExtensions\SimpleProductDetails\ProductAvailabilityPanel.ts.

1. In your **SampleExtensions** folder, add a new .json file, name it **manifest.json**, and paste the following code into it.

```

{
  "$schema": "../manifestSchema.json",
  "name": "Pos_Extensibility_Samples",
  "publisher": "Microsoft",
  "version": "7.2.0",
  "minimumPosVersion": "7.2.0.0",
  "components": {
    "resources": {
      "supportedUICultures": [ "en-US" ],
      "fallbackUICulture": "en-US",
      "culturesDirectoryPath": "Resources/Strings",
      "stringResourcesFileName": "resources.resjson",
      "cultureInfoOverridesFilePath": "Resources/cultureInfoOverrides.json"
    },
    "extend": {
      "views": {
        "SimpleProductDetailsView": {
          "controlsConfig": {
            "customControls": [
              {
                "controlName": "productAvailabilityPanel",
                "htmlPath":
"ViewExtensions/SimpleProductDetails/ProductAvailabilityPanel.html",
                "modulePath":
"ViewExtensions/SimpleProductDetails/ProductAvailabilityPanel"
              }
            ]
          }
        }
      }
    }
  }
}

```

During runtime, the manifest informs the POS that a custom control has been added in **SimpleProductDetailsView**. In the preceding code example, we included all the required metadata that the POS requires in order to load the control.

- **Extend** – Inform the POS that there is an extension for an existing POS feature.
- **Views** – Specify that an existing POS view is being extended.
- **View Name** – Specify the view that is being extended.
- **Controls config** – Specify the control that you are adding, such as **Custom control**.
- **Control metadata** – Specify the name, the path of the .html file path, and the path of the typescript module (that is, the .ts file).

2. Open the **extensions.json** file, and paste the following code into it.

```

{
  "extensionPackages": [
    {
      "baseUrl": "SampleExtensions"
    }
  ]
}

```

In the **extensions.json** file, you specify the various extensions that you have. In this case, we added a new extension folder. Therefore, we must specify that folder.

## NOTE

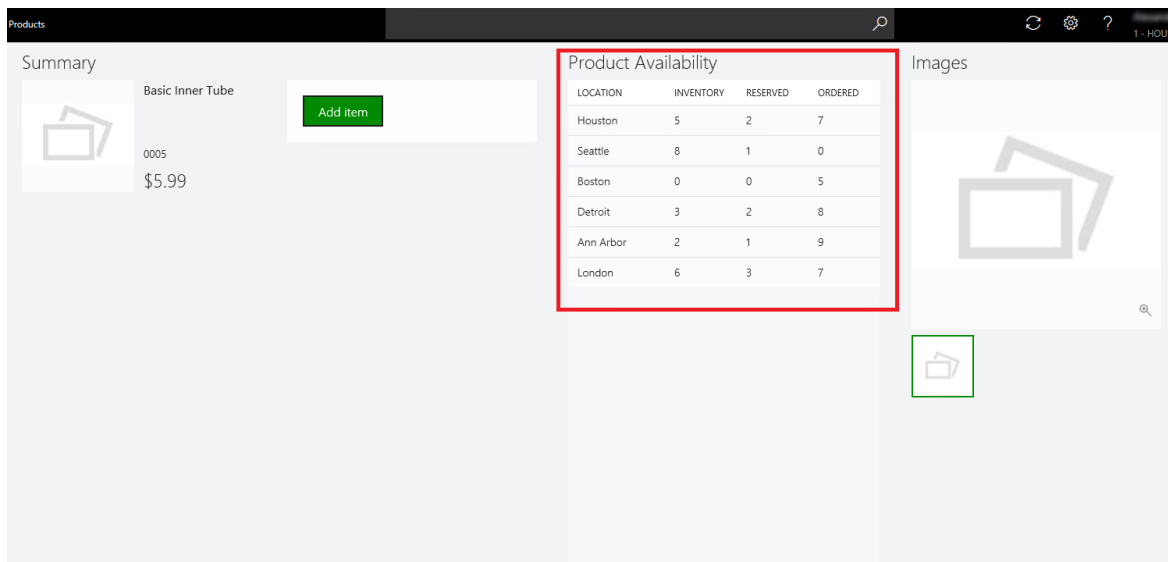

Each extension folder or package that you specify here should have a manifest.

3. Open the `tsconfig.json` file, and include your extension. Paste the following code into the file.

```
"extends": "../tsconfigs/tsmodulesconfig",  
"exclude": [  
  // "SampleExtensions"  
],
```

## Test the extension

1. Press F5, and deploy the POS to test your customization.
2. After the POS is started, sign in. Then search for any product, and open to product details view. You should now see the custom control that you added. Here is an example.

You can copy the full code for this sample from `RetailSDK\Code\POS\Extensions\SampleExtensions\ViewExtensions\SimpleProductDetails`.

# Add POS operations to POS layouts by using Button grid designer

2/18/2021 • 9 minutes to read • [Edit Online](#)

This topic explains how to create a new point of sale (POS) operation and add it to the POS layout by using Button grid designer. This topic applies to the following applications where Platform update 8 and the Application update 4 hotfix are installed:

- Finance
- Dynamics 365 Commerce

If you want your business logic to be run in the POS when users click a button, you should create POS operations. POS operations can run multiple activities or workflows. For example, they can open a new view, ask for user input, or run business logic. All standard and custom POS operations support pre-triggers and post-triggers.

## NOTE

If logic should be run as part of another workflow, or if no button click is required, create POS request/response application programming interfaces (APIs). POS operations aren't required in these scenarios.

Every operation should implement the following elements:

- **Operation request** – The operation request is extended from the **ExtensionOperationRequestBase** class. It contains all the input that is required in order to run the operation.
- **Operation response** – The operation response is extended from the **Response** class. It contains the whole response, based on execution of the operation.
- **Operation factory** – The operation factory links the button click for the operation with the operation handler.
- **Operation handler** – The operation handler is extended from the **ExtensionOperationRequestHandlerBase** class. It contains core logic for the operation. All the business logic should be written in the handler, and it should return the operation response after the operation is run.

## Create a POS operation

This section explains how to create a sample operation that does simplified end-of-day (EOD) processing. This operation calls the standard Tender removal, Safe drop, Tender declaration, and Close shift operations in a sequence. Therefore, this one operation combines multiples steps. It is run based on the conditions that you define.

## NOTE

You can create a new operation and run your own custom logic, you can call existing POS operations, such as Add item to cart and Apply line discount, or you can call existing APIs, such as Get current cart and Set extension properties.

1. Start Microsoft Visual Studio 2015 in administrator mode.
2. From ...\**RetailSDK\POSOpen**, open the **ModernPOS** solution.
3. Under the **POS.Extensions** project, create a folder that is named **EODSample**.

4. Under the **EODSample** folder, create a folder that is named **Operations**.

### Create the operation request class

1. In the **Operations** folder, create a typescript (.ts) file that is named **EndOfDayOperationRequest.ts**.
2. Open the **EndOfDayOperationRequest.ts** file, and add the following **import** statements to import the relevant entities and context.

```
import { ExtensionOperationRequestBase } from "PosApi/Create/Operations";
import EndOfDayOperationResponse from "../EndOfDayOperationResponse";
```

3. Add a class that is named **EndOfDayOperationRequest**, and extend it from the **ExtensionOperationRequestBase** class. In this example, the operation ID in the **super** method is initialized to **5001**. However, you can use any operation ID starting from 4001. Operation IDs 0 through 4000 are reserved for internal POS operations, and no two operations should have the same operation ID. Additionally, the custom parameters field appears in Button grid designer properties only if the operation ID is 4001 or higher. (You can use custom parameters field to pass parameters to the POS operation from Retail headquarters).

```
/**
 * (Sample) Operation request for executing end of day operations.
 */
export default class EndOfDayOperationRequest<TResponse> extends EndOfDayOperationResponse<TResponse> extends ExtensionOperationRequestBase<TResponse> {
  constructor(correlationId: string) {
    super(5001, correlationId);
  }
}
```

### Create the operation response class

1. In the **Operations** folder, create a typescript (.ts) file that is named **EndOfDayOperationResponse.ts**.
2. Open the **EndOfDayOperationResponse.ts** file, and add the following **import** statement to import the relevant entities and context.

```
import { Response } from "PosApi/Create/RequestHandlers";
```

3. Add a class that is named **EndOfDayOperationResponse**, and extend it from the **Response** class.

```
/**
 * (Sample) Operation response of executing end of day operations.
 */
export default class EndOfDayOperationResponse extends Response { }
```

### Create the operation handler class

1. In the **Operations** folder, create a typescript (.ts) file that is named **EndOfDayOperationRequestHandler.ts**.
2. Open the **EndOfDayOperationRequestHandler.ts** file, and add the following **import** statements to import the relevant entities and context.

```
import { ExtensionOperationRequestType, ExtensionOperationRequestHandlerBase } from
"PosApi/Create/Operations";
import { CloseShiftOperationRequest, CloseShiftOperationResponse } from "PosApi/Consume/Shifts";
import { SafeDropOperationRequest, SafeDropOperationResponse } from "PosApi/Consume/StoreOperations";
import { TenderDeclarationOperationRequest, TenderDeclarationOperationResponse } from
"PosApi/Consume/StoreOperations";
import { TenderRemovalOperationRequest, TenderRemovalOperationResponse } from
"PosApi/Consume/StoreOperations";
import EndOfDayOperationResponse from "./EndOfDayOperationResponse";
import EndOfDayOperationRequest from "./EndOfDayOperationRequest";
import { ClientEntities } from "PosApi/Entities";|
```

3. Add a class that is named **EndOfDayOperationRequestHandler**, and extend it from the **ExtensionOperationRequestHandlerBase** class.

Each handler should implement two methods:

- supportedRequestType
- executeAsync

```
export default class EndOfDayOperationRequestHandler<TResponse extends EndOfDayOperationResponse>
extends ExtensionOperationRequestHandlerBase<TResponse> {}
```

4. Add the supported request type in the class.

```
/**
 * Gets the supported request type.
 * @return {RequestType<TResponse>} The supported request type.
 */
public supportedRequestType(): ExtensionOperationRequestType<TResponse> {
    return EndOfDayOperationRequest;
}
```

5. Implement the **executeAsync** method.

```
/**
 * Executes the request handler asynchronously.
 * @param {EndOfDayOperationRequest<TResponse>} request The request.
 * @return {Promise<ICancelableDataResult<TResponse>>} The cancelable async result containing the
response.
 */
public executeAsync(printRequest: EndOfDayOperationRequest<TResponse>):
Promise<ClientEntities.ICancelableDataResult<TResponse>> {
    this.context.logger.logInformational("Log message from PrintOperationRequestHandler
executeAsync().", this.context.logger.getNewCorrelationId());
    // Tender Removal
    let tenderRemovalRequest: TenderRemovalOperationRequest<TenderRemovalOperationResponse> =
new TenderRemovalOperationRequest(this.context.logger.getNewCorrelationId());
    return this.context.runtime.executeAsync(tenderRemovalRequest).then((result:
ClientEntities.ICancelableDataResult<TenderRemovalOperationResponse>)
: Promise<Commerce.Client.Entities.ICancelableDataResult<SafeDropOperationResponse>> => {
        // Safe Drop
        if (!result.canceled) {
            let safeDropRequest: SafeDropOperationRequest<SafeDropOperationResponse> =
new SafeDropOperationRequest(this.context.logger.getNewCorrelationId());
            return this.context.runtime.executeAsync(safeDropRequest);
        } else {
            return Promise.resolve({
                canceled: true,
                data: null
            });
        }
    });
}
```

```

    }).then((result: Commerce.Client.Entities.ICancelableDataResult<SafeDropOperationResponse>)
    : Promise<ClientEntities.ICancelableDataResult<TenderDeclarationOperationResponse>> => {
        // Tender Declaration
        if (!result.canceled) {
            let tenderDeclarationRequest:
TenderDeclarationOperationRequest<TenderDeclarationOperationResponse> =
            new TenderDeclarationOperationRequest(this.context.logger.getNewCorrelationId());
            return this.context.runtime.executeAsync(tenderDeclarationRequest);
        } else {
            return Promise.resolve({
                canceled: true,
                data: null
            });
        }
    }).then((result: ClientEntities.ICancelableDataResult<TenderDeclarationOperationResponse>)
    : Promise<ClientEntities.ICancelableDataResult<CloseShiftOperationResponse>> => {
        // Close Shift
        if (!result.canceled) {
            return new Promise(
                (resolve: (value?: ClientEntities.ICancelableDataResult<CloseShiftOperationResponse>)
=> void, reject: (reason?: any) => void) => {
                    // A delay of ten seconds is added here as a work-around for issues with printing
a second receipt to the windows driver
                    // printer before the first dialog is closed. A ten second delay gives the user a
chance to close the first dialog before
                    // the issue occurs.
                    setTimeout(() => { resolve(null); }, 10000);
                }).then(() => {
                    let closeShiftOperationRequest:
CloseShiftOperationRequest<CloseShiftOperationResponse> =
                    new CloseShiftOperationRequest(this.context.logger.getNewCorrelationId());
                    return this.context.runtime.executeAsync(closeShiftOperationRequest);
                });
        } else {
            return Promise.resolve({
                canceled: true,
                data: null
            });
        }
    }).then((result: ClientEntities.ICancelableDataResult<CloseShiftOperationResponse>)
    : ClientEntities.ICancelableDataResult<EndOfDayOperationResponse> => {
        return <ClientEntities.ICancelableDataResult<EndOfDayOperationResponse>>{
            canceled: result.canceled,
            data: result.canceled ? null : new EndOfDayOperationResponse()
        };
    });
}
}
}
}

```

The overall code should look like this.

```

import { ExtensionOperationRequestType, ExtensionOperationRequestHandlerBase } from
"PosApi/Create/Operations";
import { CloseShiftOperationRequest, CloseShiftOperationResponse } from "PosApi/Consume/Shifts";
import { SafeDropOperationRequest, SafeDropOperationResponse } from "PosApi/Consume/StoreOperations";
import { TenderDeclarationOperationRequest, TenderDeclarationOperationResponse } from
"PosApi/Consume/StoreOperations";
import { TenderRemovalOperationRequest, TenderRemovalOperationResponse } from
"PosApi/Consume/StoreOperations";
import EndOfDayOperationResponse from "./EndOfDayOperationResponse";
import EndOfDayOperationRequest from "./EndOfDayOperationRequest";
import { ClientEntities } from "PosApi/Entities";
/**
 * (Sample) Request handler for the EndOfDayOperationRequest class.
 */
export default class EndOfDayOperationRequestHandler<TResponse extends EndOfDayOperationResponse>
extends ExtensionOperationRequestHandlerBase<TResponse> {

```

```

/**
 * Gets the supported request type.
 * @return {RequestType<TResponse>} The supported request type.
 */
public supportedRequestType(): ExtensionOperationRequestType<TResponse> {
    return EndOfDayOperationRequest;
}
/**
 * Executes the request handler asynchronously.
 * @param {EndOfDayOperationRequest<TResponse>} request The request.
 * @return {Promise<ICancelableDataResult<TResponse>>} The cancelable async result containing the
response.
 */
public executeAsync(printRequest: EndOfDayOperationRequest<TResponse>):
Promise<ClientEntities.ICancelableDataResult<TResponse>> {
    this.context.logger.logInformational("Log message from PrintOperationRequestHandler
executeAsync().", this.context.logger.getNewCorrelationId());
    // Tender Removal
    let tenderRemovalRequest: TenderRemovalOperationRequest<TenderRemovalOperationResponse> =
    new TenderRemovalOperationRequest(this.context.logger.getNewCorrelationId());
    return this.context.runtime.executeAsync(tenderRemovalRequest).then((result:
ClientEntities.ICancelableDataResult<TenderRemovalOperationResponse>)
: Promise<Commerce.Client.Entities.ICancelableDataResult<SafeDropOperationResponse>> => {
        // Safe Drop
        if (!result.canceled) {
            let safeDropRequest: SafeDropOperationRequest<SafeDropOperationResponse> =
            new SafeDropOperationRequest(this.context.logger.getNewCorrelationId());
            return this.context.runtime.executeAsync(safeDropRequest);
        } else {
            return Promise.resolve({
                canceled: true,
                data: null
            });
        }
    }).then((result: Commerce.Client.Entities.ICancelableDataResult<SafeDropOperationResponse>)
: Promise<ClientEntities.ICancelableDataResult<TenderDeclarationOperationResponse>> => {
        // Tender Declaration
        if (!result.canceled) {
            let tenderDeclarationRequest:
TenderDeclarationOperationRequest<TenderDeclarationOperationResponse> =
            new TenderDeclarationOperationRequest(this.context.logger.getNewCorrelationId());
            return this.context.runtime.executeAsync(tenderDeclarationRequest);
        } else {
            return Promise.resolve({
                canceled: true,
                data: null
            });
        }
    }).then((result: ClientEntities.ICancelableDataResult<TenderDeclarationOperationResponse>)
: Promise<ClientEntities.ICancelableDataResult<CloseShiftOperationResponse>> => {
        // Close Shift
        if (!result.canceled) {
            return new Promise(
                (resolve: (value?:
ClientEntities.ICancelableDataResult<CloseShiftOperationResponse>) => void, reject: (reason?: any) =>
void) => {
                    // A delay of ten seconds is added here as a work-around for issues with
printing a second receipt to the windows driver
                    // printer before the first dialog is closed. A ten second delay gives the
user a chance to close the first dialog before
                    // the issue occurs.
                    setTimeout(() => { resolve(null); }, 10000);
                }).then(() => {
                    let closeShiftOperationRequest:
CloseShiftOperationRequest<CloseShiftOperationResponse> =
                    new CloseShiftOperationRequest(this.context.logger.getNewCorrelationId());
                    return this.context.runtime.executeAsync(closeShiftOperationRequest);
                });
            } else {

```

```

        } else {
            return Promise.resolve({
                canceled: true,
                data: null
            });
        }
    }).then((result: ClientEntities.ICancelableDataResult<CloseShiftOperationResponse>)
: ClientEntities.ICancelableDataResult<EndOfDayOperationResponse> => {
        return <ClientEntities.ICancelableDataResult<EndOfDayOperationResponse>>{
            canceled: result.canceled,
            data: result.canceled ? null : new EndOfDayOperationResponse()
        };
    });
}
}
}

```

### Create the operation factory class

1. In the **Operations** folder, create a typescript (.ts) file that is named **EndOfDayOperationRequestFactory.ts**.
2. Open the **EndOfDayOperationRequestFactory.ts** file, and add the following **import** statements to import the relevant entities and context.

```

import EndOfDayOperationResponse from "../EndOfDayOperationResponse";
import EndOfDayOperationRequest from "../EndOfDayOperationRequest";
import { ExtensionOperationRequestFactoryFunctionType, IOperationContext } from
"PosApi/Create/Operations";
import { ClientEntities } from "PosApi/Entities";

```

3. Add a function to link the operation handler and the operation button.

```

let getOperationRequest: ExtensionOperationRequestFactoryFunctionType<EndOfDayOperationResponse> =
/**
 * Gets an instance of EndOfDayOperationRequest.
 * @param {number} operationId The operation Id.
 * @param {string[]} actionParameters The action parameters.
 * @param {string} correlationId A telemetry correlation ID, used to group events logged from this
request together with the calling context.
 * @return {EndOfDayOperationRequest<TResponse>} Instance of EndOfDayOperationRequest.
 */
function (
    context: IOperationContext,
    operationId: number,
    actionParameters: string [],
    correlationId: string
): Promise<ClientEntities.ICancelableDataResult<EndOfDayOperationRequest<EndOfDayOperationResponse>>>
{
    let operationRequest: EndOfDayOperationRequest<EndOfDayOperationResponse> = new
EndOfDayOperationRequest<EndOfDayOperationResponse>(correlationId);
    return
Promise.resolve(<ClientEntities.ICancelableDataResult<EndOfDayOperationRequest<EndOfDayOperationRespo
nse>>>{
        canceled: false,
        data: operationRequest
    });
};
export default getOperationRequest;

```

The overall code should look like this.

```

import EndOfDayOperationResponse from "../EndOfDayOperationResponse";
import EndOfDayOperationRequest from "../EndOfDayOperationRequest";
import { ExtensionOperationRequestFactoryFunctionType, IOperationContext } from
"PosApi/Create/Operations";
import { ClientEntities } from "PosApi/Entities";
let getOperationRequest: ExtensionOperationRequestFactoryFunctionType<EndOfDayOperationResponse> =
/**
 * Gets an instance of EndOfDayOperationRequest.
 * @param {number} operationId The operation Id.
 * @param {string[]} actionParameters The action parameters.
 * @param {string} correlationId A telemetry correlation ID, used to group events logged from this
request together with the calling context.
 * @return {EndOfDayOperationRequest<TResponse>} Instance of EndOfDayOperationRequest.
 */
function (
  context: IOperationContext,
  operationId: number,
  actionParameters: string[],
  correlationId: string
): Promise<ClientEntities.ICancelableDataResult<EndOfDayOperationRequest<EndOfDayOperationResponse>>>
{
  let operationRequest: EndOfDayOperationRequest<EndOfDayOperationResponse> = new
EndOfDayOperationRequest<EndOfDayOperationResponse>(correlationId);
  return
Promise.resolve(<<ClientEntities.ICancelableDataResult<EndOfDayOperationRequest<EndOfDayOperationRespo
nse>>>{
    canceled: false,
    data: operationRequest
  });
};
export default getOperationRequest;

```

4. Open the **manifest.json** file, and paste in the following code.

```

{
  "$schema": "../manifestSchema.json",
  "name": "Pos_Extensibility_EODSample",
  "publisher": "Microsoft",
  "version": "7.3.0",
  "minimumPosVersion": "7.3.0.0",
  "components": {
    "create": {
      "operations": [
        {
          "operationId": "5001",
          "operationRequestFactoryPath": "Operations/ EndOfDayOperationRequestFactory",
          "operationRequestHandlerPath": "Operations/ EndOfDayOperationRequestHandler"
        }
      ]
    }
  }
}

```

5. Open the **extensions.json** file under the **POS.Extensions** project, and update it with **EODSample**, so that the POS will include the extension at runtime.

```

{
  "extensionPackages": [
    {
      "baseUrl": "SampleExtensions"
    },
    {
      "baseUrl": "EODSample"
    }
  ]
}

```

6. Open the `tsconfig.json` file, and comment out the extension package folders in the exclude list. The POS will use this file to include or exclude the extension. By default, the list contains the whole excluded extensions list. To include an extension as part of the POS, you must add the name of the extension folder and comment out the extension in the extension list, as shown here.

```

"extends": "../tsconfigs/tsmodulesconfig",
"exclude": [
  "AuditEventExtensionSample",
  "B2BSample",
  "CustomerSearchWithAttributesSample",
  "FiscalRegisterSample",
  // "EODSample",
  "PromotionsSample",
  "SalesTransactionSignatureSample",
  "SampleExtensions2",
  // "SampleExtensions",
  "StoreHoursSample",
  "SuspendTransactionReceiptSample"
],

```

7. Compile and rebuild the project.

## Add a custom operation button to the POS layout in Retail headquarters

1. In Retail go to **Retail and commerce > Channel setup > POS setup > POS > Operations**.
2. Create an operation that is named **EOD** and that has an operation ID of **5001**.
3. Go to **Retail and commerce > Channel setup > POS setup > POS > Button grids**.
4. Filter for **'F2W2'**.
5. Select the **Designer** button, and then follow the instructions to install the designer. If you're prompted for credentials, enter the Retail user name and password.
6. Right-click in the designer area, and then select **Add new row**.
7. Right-click the new button, and then select **Button properties**.
8. Set the **Action** property to **EOD**. Then select **OK**, and close the designer.
9. Go to **Retail and commerce > Retail IT > Distribution schedule**.
10. Select **1090**, and then select **Run now**.

**NOTE**

The preceding steps assume that you're using demo data. If you aren't using demo data, create and add the button according to your custom configurations.

## Validate your extension

1. Press F5, and deploy the POS to test your customization.
2. On the transaction screen, select the new EOD operation button, and follow the steps.

**NOTE**

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Point of sale (POS) APIs

2/18/2021 • 7 minutes to read • [Edit Online](#)

Retail POS APIs help you to easily build extensions or new features to the POS app. For example, if you are extending the Retail POS application to add new features in which to want to get product details, change prices, or add items to a cart. you can consume APIs that will do the work for you. To do this, you need to call the APIs to do the work. The POS API simplifies the extension pattern and provides continuous support to build the extensions.

Extension patterns have been unified across commerce runtime (CRT), POS, and Hardware station (HWS) by following the request/response pattern. All the POS APIs are exposed as request/response like CRT and HWS.

POS APIs are categorized into three different scenarios:

- **Consume** – Consume public APIs in your extension.
- **Extend** – Override public APIs to do some additional logic.
- **Create** – Create new APIs using the exposed POS interface, which can be used across extensions.

Many APIs can be consumed in extensions. For example, if you want to change the price of the item based on an external web service call, you can call `PriceOverrideOperationRequest` to change the price of the item. Within the consume, the APIs are sub categorized by module like cart, peripherals, store operations, etc.

## NOTE

A list of the all of the APIs is available in `Pos.Api.d.ts`, which is part of the Retail SDK (...Retail SDK\POS\Extensions\Pos.Api.d.ts). Extensions must consume only the exposed request and response from the `Pos.Api.d.ts` and no modification is allowed to `Pos.Api.d.ts`. Extensions should not consume or update any POS APIs, properties, methods, or handlers directly from POS commerce or sessions objects.

## How to consume APIs in your extension

Use the following steps to consume Retail APIs in your extensions.

1. Import the API in your extension file.

For example, if you want to consume the save attribute on cart API in your extension, then you need to add the following import statements.

The pattern is `import { api name } from "PosApi/Consume/Module name";`

```
import { SaveAttributesOnCartClientRequest, SaveAttributesOnCartClientResponse } from
"PosApi/Consume/Cart";
```

2. Import the client entities and proxy entities if necessary.

```
import { ClientEntities } from "PosApi/Entities";

import { ProxyEntities } from "PosApi/Entities";
```

3. Declare the API variable and execute it using the POS runtime, which you can access the runtime by

using: this.context.runtime.executeAsync("api name")

```
executeAsync<TResponse extends Response>(request: Request<TResponse>):  
Promise<Client.Entities.ICancelableDataResult<TResponse>>;
```

For example, if you want to execute the tender removal, use `SaveAttributesOnCartClientRequest` api, and refer to the following steps.

```
let attributeValue: ProxyEntities.AttributeTextValue = new ProxyEntities.AttributeTextValueClass();  
  
attributeValue.Name = PreEndTransactionTrigger.B2B_CART_ATTRIBUTE_NAME;  
  
attributeValue.TextValue = "Yes";  
  
let attributeValues: ProxyEntities.AttributeValueBase[] = [attributeValue];  
  
let saveAttributesOnCartRequest:  
SaveAttributesOnCartClientRequest<SaveAttributesOnCartClientResponse> =  
  
new SaveAttributesOnCartClientRequest(attributeValues);  
  
result = this.context.runtime.executeAsync(saveAttributesOnCartRequest);
```

## Samples showing how to access APIs

### Get Current cart

```
// Gets the current cart.  
  
let currentCart: ProxyEntities.Cart;  
  
return this.context.runtime.executeAsync<GetCurrentCartClientResponse>(new GetCurrentCartClientRequest())  
.then((getCurrentCartClientResponse: ClientEntities.ICancelableDataResult<GetCurrentCartClientResponse>):  
  
Promise<ClientEntities.ICancelableDataResult<GetCustomerClientResponse>> => {  
  
currentCart = getCurrentCartClientResponse.data.result;
```

### Get Current customer added to cart

```
// Gets the current customer.  
  
let result: Promise<ClientEntities.ICancelableDataResult<GetCustomerClientResponse>>;  
  
if (!ObjectExtensions.isNullOrUndefined(currentCart) &&  
!ObjectExtensions.isNullOrUndefined(currentCart.CustomerId)) {  
  
let getCurrentCustomerClientRequest: GetCustomerClientRequest<GetCustomerClientResponse> =  
  
new GetCustomerClientRequest(currentCart.CustomerId);  
  
result = this.context.runtime.executeAsync<GetCustomerClientResponse>(getCurrentCustomerClientRequest);  
  
} else {  
  
result = Promise.resolve({ canceled: true, data: new GetCustomerClientResponse(null) });  
  
}
```

## Force void transaction

```
// Force void transaction.
let forceVoidTransactionRequest: VoidTransactionOperationRequest<VoidTransactionOperationResponse> =

    new VoidTransactionOperationRequest<VoidTransactionOperationResponse>(false,
this.context.logger.getNewCorrelationId());

    this.context.runtime.executeAsync(forceVoidTransactionRequest).then((value:
ICancelableDataResult<VoidTransactionOperationResponse>) => {

    this.currentCart(JSON.stringify(value.data.cart));

    }).catch((err: any) => {

    this.currentCart(JSON.stringify(err));

    });
```

## Cart

The following table lists APIs exposed to perform cart-related functionality.

POS API	DESCRIPTION	RELEASE
AddPreprocessedTenderLineToCartClientRequest	Adds the pre-processed tender line to the cart.	10.0.14
AddTenderLineToCartClientRequest	Adds the tender line to the cart.	10.0.14
ConcludeTransactionClientRequest	Concludes the transaction.	10.0.14
GetCurrentCartClientRequest	Gets the current cart.	10.0.14
GetKeyedInPriceClientRequest	Gets the keyed in price.	10.0.14
GetPickupDateClientRequest	Gets the pickup date.	10.0.14
GetReasonCodeLinesClientRequest	Gets the reason code.	10.0.14
GetReceiptEmailAddressClientRequest	Gets the receipt email address.	10.0.14
GetShippingDateClientRequest	Gets the shipping date.	10.0.14
RefreshCartClientRequest	Refresh the current cart with the cart data from the server.	10.0.14
ResumeSuspendedCartClientRequest	Resumes the suspended transaction based on the ID passed.	10.0.14
SaveAttributesOnCartClientRequest	Saves the attributes on the cart.	10.0.14
SaveAttributesOnCartLinesClientRequest	Saves the attributes on the cart line.	10.0.14
SaveExtensionPropertiesOnCartClientRequest	Saves the extension properties on the cart.	10.0.14

POS API	DESCRIPTION	RELEASE
SaveExtensionPropertiesOnCartLinesClientRequest	Saves the extension properties on the cart line.	10.0.14
SaveReasonCodeLinesOnCartClientRequest	Saves the reason code lines on the cart.	10.0.14
SaveReasonCodeLinesOnCartLinesClientRequest	Saves the reason code lines on the cart line.	10.0.14
SelectSalesLinesForPickUpClientRequest	Select the sales lines for pickup.	10.0.14
SetCartAttributesClientRequest	Sets the cart attribute.	10.0.14
ShowChangeDueClientRequest	Shows the change due dialog.	10.0.14
AddAffiliationOperationRequest	Adds affiliation to the cart.	10.0.14
AddItemToCartOperationRequest	Add items to the cart.	10.0.14
CalculateTotalOperationRequest	Calculate the total for the cart.	10.0.14
ChangeCartLineUnitOfMeasureOperationRequest	Changes the cart line unit of measure.	10.0.14
CreateCustomerOrderOperationRequest	Creates the customer order.	10.0.14
CreateCustomerQuoteOperationRequest	Creates the customer quote.	10.0.14
CustomerAccountDepositOperationRequest		10.0.14
DepositOverrideOperationRequest	Overrides the deposit amount.	10.0.14
EditCustomerOrderOperationRequest	Edit the customer order.	10.0.14
LineDiscountAmountOperationRequest	Add line discount amount to the cart line.	10.0.14
LineDiscountPercentOperationRequest	Add line discount percent to the cart line.	10.0.14
OverrideLineTaxFromListOperationRequest	Override the cart line tax from the list.	10.0.14
OverrideLineTaxOperationRequest	Override the cart line tax.	10.0.14
OverrideTransactionTaxOperationRequest	Override the transaction tax.	10.0.14

POS API	DESCRIPTION	RELEASE
PickupAllOperationRequest	Picks up the order.	10.0.14
PriceOverrideOperationRequest	Override the price for the cart line.	10.0.14
SetCartLineCommentOperationRequest	Sets the cart line comment.	10.0.14
SetCartLineQuantityOperationRequest	Sets the cart line quantity.	10.0.14
SetCustomerOnCartOperationRequest	Sets the customer on the cart.	10.0.14
SetTransactionCommentOperationRequest	Sets the transaction comment.	10.0.14
SuspendCurrentCartOperationRequest	Suspends the current transaction.	10.0.14
TotalDiscountAmountOperationRequest	Add total discount amount to the transaction.	10.0.14
TotalDiscountPercentOperationRequest	Add total discount percent to the transaction.	10.0.14
VoidCartLineOperationRequest	voids the cart line.	10.0.14
VoidTenderLineOperationRequest	voids the tender line.	10.0.14
VoidTransactionOperationRequest	voids the transaction.	10.0.14
CreateEmptyCartServiceRequest	Creates empty cart.	10.0.14
GetTaxOverridesServiceRequest	Gets the tax override list.	10.0.14
UpdateTenderLineSignatureServiceRequest	Updates the tender line signature data.	10.0.14
CarryoutSelectedProductsOperationRequest	Marks the selected line as carry out.	10.0.14
AddCouponsOperationRequest	Add coupon to the transaction.	10.0.14
CreateNonSalesTransactionServiceRequest	Create non sales transaction cart.	10.0.14
ReturnTransactionOperationRequest	Returns the transaction.	10.0.14
AddLoyaltyCardToCartOperationRequest	Adds loyalty card to the transaction.	10.0.14
ReturnCartLineOperationRequest	Returns the cart line.	10.0.14
ReturnItemOperationRequest	Returns the item.	10.0.14

POS API	DESCRIPTION	RELEASE
AddExpenseAccountLineToCartOperationRequest	Add expense account line to the cart.	10.0.14
ShipAllCartLinesOperationRequest	Ships all the cart lines.	10.0.14
ShipSelectedCartLinesOperationRequest	Ships the selected cart line.	10.0.14
PickupSelectedOperationRequest	Marks the included lines for pickup	10.0.16

## Payments

The following table lists APIs exposed to perform payment-related functionality.

POS API	DESCRIPTION	RELEASE
GetGiftCardByIdServiceRequest	Gets the gift card ID.	10.0.12
GetPaymentCardTypeByBinRangeClientRequest	Get the card type bin range.	10.0.12
GetSignatureClientRequest	Shows the signature capture dialog in POS or sends the message to the signature capture device based on the configuration.	10.0.15

## Peripherals

The following table lists APIs exposed to perform peripheral-related functionality.

POS API
CardPaymentAuthorizePaymentRequest
CardPaymentBeginTransactionRequest
CardPaymentCapturePaymentRequest
CardPaymentEndTransactionRequest
CardPaymentEnquireGiftCardBalancePeripheralRequest
CardPaymentExecuteTaskRequest
CardPaymentRefundPaymentRequest
CardPaymentVoidPaymentRequest
CardPaymentAuthorizeCardTokenPeripheralRequest
CashDrawerIsOpenRequest
HardwareStationDeviceActionRequest

POS API
HardwareStationStatusRequest
LineDisplayDisplayLinesRequest
PaymentTerminalAuthorizePaymentActivityRequest
PaymentTerminalAuthorizePaymentRequest
PaymentTerminalBeginTransactionRequest
PaymentTerminalCancelOperationRequest
PaymentTerminalCapturePaymentRequest
PaymentTerminalEndTransactionRequest
PaymentTerminalEnquireGiftCardBalancePeripheralRequest
PaymentTerminalExecuteTaskRequest
PaymentTerminalRefundPaymentActivityRequest
PaymentTerminalRefundPaymentRequest
PaymentTerminalUpdateLinesRequest
PaymentTerminalVoidPaymentRequest
PaymentTerminalFetchTokenPeripheralRequest
PrinterPrintRequest
ScaleReadRequest

### ScanResults

The following table lists APIs exposed to perform scan results-related functionality.

POS API
GetScanResultClientRequest

### Customer

The following table lists APIs exposed to perform customer-related functionality.

POS API
GetCustomerClientRequest
CreateCustomerServiceRequest

POS API
UpdateCustomerServiceRequest
SelectCustomerClientRequest

### Authentication

The following table lists APIs exposed to perform authentication-related functionality.

POS API
LogOffOperationRequest
LockRegisterOperationRequest

### DataService

The following table lists APIs exposed to perform data service-related functionality.

POS API
DataServiceRequest

### Device

The following table lists APIs exposed to perform device-related functionality.

POS API
GetDeviceConfigurationClientRequest
GetExtensionProfileClientRequest
GetHardwareProfileClientRequest
GetAuthenticationTokenClientRequest
GetConnectionStatusClientRequest
GetActiveHardwareStationClientRequest
GetApplicationVersionClientRequest
GetChannelConfigurationClientRequest

### Diagnostics

The following table lists APIs exposed to perform diagnostics-related functionality.

POS API
GetSessionInfoClientRequest

### Dialog

The following table lists APIs exposed to perform dialog-related functionality.

POS API
ShowMessageDialogClientRequest
IAlphanumericInputDialogResult
ShowAlphanumericInputDialogClientRequest
ShowNumericInputDialogClientRequest
ShowListInputDialogClientRequest
ShowTextInputDialogClientRequest

## Employee

The following table lists APIs exposed to perform employee-related functionality.

POS API	DESCRIPTION	RELEASE
GetLoggedInEmployeeClientRequest	Gets the current logged in POS employee details.	10.0.14
SelectStoreEmployeeClientRequest	Gets the current store employee list for selection.	10.0.16

## Formatters

The following table lists APIs exposed to perform formatter-related functionality.

POS API
IBooleanFormatter
ICurrencyFormatter
IDateFormatter
ITransactionTypeFormatter
IPurchaseTransferOrderTypeFormatter

## OrgUnits

The following table lists APIs exposed to perform org units-related functionality.

POS API
GetOrgUnitConfigurationClientRequest
GetOrgUnitTenderTypesClientRequest
InventoryLookupOperationRequest

## Products

The following table lists APIs exposed to perform products-related functionality.

POS API
GetProductsByIdsClientRequest
GetCurrentProductCatalogStoreClientRequest
SelectProductVariantClientRequest
GetSerialNumberClientRequest
GetRefinerValuesByTextServiceRequest
SelectProductClientRequest
SelectProductVariantClientRequest
GetActivePricesServiceRequest

### Categories

The following table lists APIs exposed to perform categories-related functionality.

POS API
GetCategoriesServiceRequest

### SalesOrders

The following table lists APIs exposed to perform sales orders-related functionality.

POS API
GetReceiptsClientRequest
RegisterPrintReceiptCopyEventRequest
GetSalesOrderDetailsByTransactionIdClientRequest
GetGiftReceiptsClientRequest
RegisterPrintReceiptCopyEventRequest
MarkAsPickedServiceRequest
PrintPackingSlipClientRequest
PickUpCustomerOrderLinesClientRequest

### Shifts

The following table lists APIs exposed to perform shifts-related functionality.

POS API
CloseShiftOperationRequest
CloseShiftOperationRequest

### StockCountJournals

The following table lists APIs exposed to perform stock count journals-related functionality.

POS API
SyncAllStockCountJournalsClientRequest

### StoreOperations

The following table lists APIs exposed to perform store operations-related functionality.

POS API	DESCRIPTION	RELEASE
DeclareStartingAmountClientRequest	Declare start amount using this request.	10.0.14
GetSalesOrdersWithNoFiscalTransactionsRequest	Gets sales order with no fiscal transaction request.	10.0.14
RegisterCustomAuditEventClientRequest	Register custom audit event request.	10.0.14
GetOfflinePendingTransactionCountClientRequest	Gets the offline pending transaction count.	10.0.14
SaveFiscalTransactionClientRequest	Save fiscal transaction request.	10.0.14
SafeDropOperationRequest	Safe drop operation request.	10.0.14
TenderDeclarationOperationRequest	Tender declaration operation request.	10.0.14
TenderRemovalOperationRequest	Tender removal operation request.	10.0.14
CreateBankDropTransactionClientRequest	Bank drop transaction request.	10.0.14
CreateFloatEntryTransactionClientRequest	Float entry transaction request.	10.0.14
CreateStartingAmountTransactionClientRequest	Create start amount transaction request.	10.0.14
CreateTenderDeclarationTransactionClientRequest	Create tender declaration transaction request.	10.0.14
CreateTenderRemovalTransactionClientRequest	Remove tender declaration transaction request.	10.0.14

POS API	DESCRIPTION	RELEASE
GetDenominationTotalsClientRequest	Gets the denomination total request.	10.0.14
SelectZipCodeInfoClientRequest	Selects the Zip code information request.	10.0.14
CreateSafeDropTransactionClientRequest	Create safe drop transaction request.	10.0.14
GetTenderDetailsClientRequest	Gets the tender details.	10.0.14
LoyaltyCardPointsBalanceOperationRequest	Gets the loyalty card balance.	10.0.14
GetCommissionSalesGroupsServiceRequest	Gets the commission sales group.	10.0.14
GetCurrenciesServiceRequest	Gets the store currencies.	10.0.14
GetSrsReportDataSetServiceRequest	Gets the Srs report data.	10.0.14
SearchCommissionSalesGroupsServiceRequest	Search commission sales groups request.	10.0.14
IssueLoyaltyCardOperationRequest	Issues loyalty card.	10.0.14
GetPickingAndReceivingOrdersClientRequest	Gets the picking and receiving orders list.	10.0.14
BankDropOperationRequest	Bank drop request.	10.0.14
DeclareStartAmountOperationRequest	Declare start amount request.	10.0.14
GetAllDiscountsServiceRequest	Gets the discount applicable for the current cart.	10.0.16

# Point of sale (POS) payment extension

2/18/2021 • 7 minutes to read • [Edit Online](#)

With the extension points in point of sale (POS) to support payment extensibility, you can implement the core payment logic in the payment device or payment connector using the Hardware station APIs. Some scenarios where you might want to do this are:

- You need to pass additional information such as extension properties to your connector/device.
- You want to show custom messages in between the payment flow.
- You need input from the cashier to complete the flow and send an intermediate response back to the payment device/connector. For example, you might need the customer ID validation status or voice authorization.
- You want to show processing dialog messages, such as waiting for the customer pin input. You can override POS payment requests to implement these scenarios.

You can override the following request handlers from the POS side to customize the payment flow:

- `PaymentTerminalAuthorizePaymentRequestHandler`
- `PaymentTerminalCapturePaymentRequestHandler`
- `PaymentTerminalExecuteTaskRequestHandler`
- `PaymentTerminalRefundPaymentRequestHandler`
- `PaymentTerminalVoidPaymentRequestHandler`

The POS runtime checks the extension manifest to see if there are any extensions for these request handlers. If there are extensions, then the runtime loads the extended requests and executes the overridden requests. In the extension project, you can override these requests, add your own implementation to call the custom payment providers, and then update the response based on the status that is returned by your providers. When you override a request, you are overriding only the core logic. After all your custom logic has run, you send the updated response that you received from Hardware station (payment device/connector) to POS. All the standard workflow is handled by the POS, so that you do not need to worry about how to add, void, or decline the payment line and conclude the transaction based on the response.

## PaymentTerminalAuthorizePaymentRequestHandler

`PaymentTerminalAuthorizePaymentRequestHandler`, the authorization request, is the core payment request from POS that initiates and authorizes a card payment request. You can override this request if you want to change the authorize workflow. To override the request, you need to extend the `PaymentTerminalAuthorizePaymentRequestHandler` in POS.

```

import { PaymentTerminalAuthorizePaymentRequestHandler } from
"PosApi/Extend/RequestHandlers/PeripheralsRequestHandlers";
import { PaymentTerminalAuthorizePaymentRequest, PaymentTerminalAuthorizePaymentResponse } from
"PosApi/Consume/Peripherals";
import { ClientEntities, ProxyEntities } from "PosApi/Entities";
import { GetCurrentCartClientRequest, GetCurrentCartClientResponse } from "PosApi/Consume/Cart";
import { PaymentHandlerHelper } from "../PaymentHandlerHelper";
import { ObjectExtensions } from "PosApi/TypeExtensions";

/**
 * Override request handler class for the payment terminal authorize payment request.
 */
export default class PaymentTerminalAuthorizePaymentRequestHandlerExt extends
PaymentTerminalAuthorizePaymentRequestHandler {

    /**
     * Executes the request handler asynchronously.
     * @param {PaymentTerminalAuthorizePaymentRequest<PaymentTerminalAuthorizePaymentResponse>} request The
request.
     * @return {Promise<ICancelableDataResult<PaymentTerminalAuthorizePaymentResponse>>} The cancelable
promise containing
     * the response.
     */
    public executeAsync(request:
PaymentTerminalAuthorizePaymentRequest<PaymentTerminalAuthorizePaymentResponse>):
    Promise<ClientEntities.ICancelableDataResult<PaymentTerminalAuthorizePaymentResponse>> {
        let cart: ProxyEntities.Cart = null;
        let cartRequest: GetCurrentCartClientRequest<GetCurrentCartClientResponse> = new
GetCurrentCartClientRequest();

        // Get cart first and then build extension properties based on cart info.
        return this.context.runtime.executeAsync(cartRequest)
            .then((result: ClientEntities.ICancelableDataResult<GetCurrentCartClientResponse>): void => {
                if (!(result.canceled || ObjectExtensions.isNullOrUndefined(result.data))) {
                    cart = result.data.result;
                }
            }).then(() :
Promise<ClientEntities.ICancelableDataResult<PaymentTerminalAuthorizePaymentResponse>> => {
                let newRequest:
PaymentTerminalAuthorizePaymentRequest<PaymentTerminalAuthorizePaymentResponse> =
                    new PaymentTerminalAuthorizePaymentRequest<PaymentTerminalAuthorizePaymentResponse>(
                        request.paymentConnectorId,
                        request.amount,
                        request.tenderInfo,
                        request.voiceAuthorization,
                        request.isManualEntry,
                        PaymentHandlerHelper.FillExtensionProperties(cart,
request.extensionTransactionProperties));

                return this.defaultExecuteAsync(newRequest);
            });
    }
}

```

You need to make these changes in PaymentHandlerHelper.ts.

```

import { ClientEntities, ProxyEntities } from "PosApi/Entities";
import { ObjectExtensions, StringExtensions } from "PosApi/TypeExtensions";

/**
 * Override request handler class for the payment terminal authorize payment request.
 */
export class PaymentHandlerHelper {
  // Get extra properties for payment terminal
  public static FillExtensionProperties(
    cart: ProxyEntities.Cart,
    extensionProperties: ClientEntities.IExtensionTransaction): ClientEntities.IExtensionTransaction {

    let extraProperties: ClientEntities.IExtensionTransaction = null;
    // Build extra extension properties.
    if (!ObjectExtensions.isNullOrUndefined(cart)) {
      extraProperties = {
        ExtensionProperties: [
          <ProxyEntities.CommerceProperty>{
            Key: "CartId",
            Value: <ProxyEntities.CommercePropertyValue>{
              StringValue: !ObjectExtensions.isNullOrUndefined(cart) ? cart.Id : ""
            }
          }, {
            Key: "ChannelId",
            Value: <ProxyEntities.CommercePropertyValue>{
              StringValue: (ObjectExtensions.isNullOrUndefined(cart.ChannelId)) ? ""
                : cart.ChannelId.toString()
            }
          }, {
            Key: "TerminalId",
            Value: <ProxyEntities.CommercePropertyValue>{
              StringValue: cart.TerminalId
            }
          }, {
            Key: "StaffId",
            Value: <ProxyEntities.CommercePropertyValue>{ StringValue: cart.StaffId }
          }, {
            Key: "CustomerId",
            Value: <ProxyEntities.CommercePropertyValue>{
              StringValue: (StringExtensions.isNullOrWhitespace(cart.CustomerId)) ? ""
                : cart.CustomerId
            }
          }, {
            Key: "ShippingZipCode",
            Value: <ProxyEntities.CommercePropertyValue>{
              StringValue: !ObjectExtensions.isNullOrUndefined(cart.ShippingAddress) ?
                (StringExtensions.isNullOrWhitespace(cart.ShippingAddress.ZipCode) ? "" :
                  cart.ShippingAddress.ZipCode) : ""
            }
          }
        ]
      };
    }

    if (ObjectExtensions.isNullOrUndefined(extensionProperties)) {
      extensionProperties = extraProperties;
    } else {
      for (let i: number = 0; i < extraProperties.ExtensionProperties.length; i++) {
        extensionProperties.ExtensionProperties.push(extraProperties.ExtensionProperties[i]);
      }
    }

    return extensionProperties;
  }
}

```

After implementing the request logic, you need to update manifest.json with the extension information so that POS loads the extension.

```
{
  "$schema": "../manifestSchema.json",
  "name": "Pos_Payment_Samples",
  "publisher": "Microsoft",
  "version": "7.2.0",
  "minimumPosVersion": "7.2.0.0",
  "components": {
    "extend": {
      "requestHandlers": [
        {
          "modulePath": "Peripherals/Handlers/PaymentTerminalAuthorizePaymentRequestHandlerExt"
        }
      ]
    }
  }
}
```

The full code sample, including how to pass extension properties, is available in Retail SDK app update 3 in the RetailSDK\Code\POS\Extensions\PaymentSample folder. If you check in the above code sample, only the calling portion has been overridden, and not the core logic on how to complete the payment or add payment line. The POS workflow manages that.

## PaymentTerminalCapturePaymentRequestHandler

**PaymentTerminalCapturePaymentRequestHandler**, the payment request, is a payment request from POS that initiates and captures the card payment request. Override this request if you want to change the capture workflow. To override the request, you need to extend the **PaymentTerminalCapturePaymentRequestHandler** in POS.

```

import { PaymentTerminalCapturePaymentRequestHandler } from
"PosApi/Extend/RequestHandlers/PeripheralsRequestHandlers";
import { PaymentTerminalCapturePaymentRequest, PaymentTerminalCapturePaymentResponse } from
"PosApi/Consume/Peripherals";
import { ClientEntities, ProxyEntities } from "PosApi/Entities";
import { GetCurrentCartClientRequest, GetCurrentCartClientResponse } from "PosApi/Consume/Cart";
import { PaymentHandlerHelper } from "./PaymentHandlerHelper";
import { ObjectExtensions } from "PosApi/TypeExtensions";

/**
 * Override request handler class for the payment terminal Capture payment request.
 */
export default class PaymentTerminalCapturePaymentRequestHandlerExt extends
PaymentTerminalCapturePaymentRequestHandler {
    /**
     * Executes the request handler asynchronously.
     * @param {PaymentTerminalCapturePaymentRequest<PaymentTerminalCapturePaymentResponse>} request The
request.
     * @return {Promise<ICancelableDataResult<PaymentTerminalCapturePaymentResponse>>}
     * The cancelable promise containing the response.
     */
    public executeAsync(request:
PaymentTerminalCapturePaymentRequest<PaymentTerminalCapturePaymentResponse>):
        Promise<ClientEntities.ICancelableDataResult<PaymentTerminalCapturePaymentResponse>> {
        let cart: ProxyEntities.Cart = null;
        let cartRequest: GetCurrentCartClientRequest<GetCurrentCartClientResponse> = new
GetCurrentCartClientRequest();

        // Get cart first and then build extension properties based on cart info.
        return this.context.runtime.executeAsync(cartRequest)
            .then((result: ClientEntities.ICancelableDataResult<GetCurrentCartClientResponse>): void => {
                if (!(result.canceled || ObjectExtensions.isNullOrUndefined(result.data))) {
                    cart = result.data.result;
                }
            }).then(() : Promise<ClientEntities.ICancelableDataResult<PaymentTerminalCapturePaymentResponse>>
=> {
                let newRequest: PaymentTerminalCapturePaymentRequest<PaymentTerminalCapturePaymentResponse>
=
                    new PaymentTerminalCapturePaymentRequest<PaymentTerminalCapturePaymentResponse>(
                        request.amount,
                        request.paymentProperties,
                        PaymentHandlerHelper.FillExtensionProperties(cart,
request.extensionTransactionProperties));

                return this.defaultExecuteAsync(newRequest);
            });
    }
}

```

After implementing the request logic, you need to update the manifest.json with the extension information so that POS loads the extension. Any requests that you override are specified in the manifest. If you didn't override any of the standard requests, then you do not need to specify anything in the manifest. The example of the manifest shows two overridden requests.

```

{
  "$schema": "../manifestSchema.json",
  "name": "Pos_Payment_Samples",
  "publisher": "Microsoft",
  "version": "7.2.0",
  "minimumPosVersion": "7.2.0.0",
  "components": {
    "extend": {
      "requestHandlers": [
        {
          "modulePath": "Peripherals/Handlers/PaymentTerminalAuthorizePaymentRequestHandlerExt"
        },
        {
          "modulePath": "Peripherals/Handlers/PaymentTerminalCapturePaymentRequestHandlerExt"
        }
      ]
    }
  }
}

```

The full code sample, with how to pass extension properties, is available in Retail SDK app update in the RetailSDK\Code\POS\Extensions\PaymentSample folder.

## PaymentTerminalExecuteTaskRequestHandler

**PaymentTerminalExecuteTaskRequestHandler**, the execution request, is used from POS to initiate any custom payment device/connector operation from POS. You might use this to do a health check of the payment device from POS, to do batch processing, or for an end-of-day request to the payment device. You can override this request if you want to do a custom operation other than the standard authorize, capture, void, and refund. To override the request, you need to extend the **PaymentTerminalExecuteTaskRequestHandler** in POS.

```

import { PaymentTerminalExecuteTaskRequestHandler } from
"PosApi/Extend/RequestHandlers/PeripheralsRequestHandlers";
import { PaymentTerminalExecuteTaskRequest, PaymentTerminalExecuteTaskResponse } from
"PosApi/Consume/Peripherals";
import { ClientEntities, ProxyEntities } from "PosApi/Entities";
import { GetCurrentCartClientRequest, GetCurrentCartClientResponse } from "PosApi/Consume/Cart";
import { PaymentHandlerHelper } from "./PaymentHandlerHelper";
import { ObjectExtensions } from "PosApi/TypeExtensions";

/**
 * Override request handler class for the payment terminal ExecuteTask request.
 */
export default class PaymentTerminalExecuteTaskRequestHandlerExt extends
PaymentTerminalExecuteTaskRequestHandler {
    /**
     * Executes the request handler asynchronously.
     * @param {PaymentTerminalExecuteTaskRequest<PaymentTerminalExecuteTaskResponse>} request The request.
     * @return {Promise<ICancelableDataResult<PaymentTerminalExecuteTaskResponse>>}
     * The cancelable promise containing the response.
     */
    public executeAsync(request: PaymentTerminalExecuteTaskRequest<PaymentTerminalExecuteTaskResponse>):
    Promise<ClientEntities.ICancelableDataResult<PaymentTerminalExecuteTaskResponse>> {
        let cart: ProxyEntities.Cart = null;
        let cartRequest: GetCurrentCartClientRequest<GetCurrentCartClientResponse> = new
GetCurrentCartClientRequest();

        // Get cart first and then build extension properties based on cart info.
        return this.context.runtime.executeAsync(cartRequest)
            .then((result: ClientEntities.ICancelableDataResult<GetCurrentCartClientResponse>): void => {
                if (!(result.canceled || ObjectExtensions.isNullOrUndefined(result.data))) {
                    cart = result.data.result;
                }
            }).then(() : Promise<ClientEntities.ICancelableDataResult<PaymentTerminalExecuteTaskResponse>> =>
{
            let newRequest: PaymentTerminalExecuteTaskRequest<PaymentTerminalExecuteTaskResponse> =
                new PaymentTerminalExecuteTaskRequest<PaymentTerminalExecuteTaskResponse>(
                    request.task,
                    PaymentHandlerHelper.FillExtensionProperties(cart,
request.extensionTransactionProperties));

            return this.defaultExecuteAsync(newRequest);
        });
    }
}

```

After implementing the request logic, you need to update the manifest.json with the extension information so that POS loads the extension.

```

{
  "$schema": "../manifestSchema.json",
  "name": "Pos_Payment_Samples",
  "publisher": "Microsoft",
  "version": "7.2.0",
  "minimumPosVersion": "7.2.0.0",
  "components": {
    "extend": {
      "requestHandlers": [
        {
          "modulePath": "Peripherals/Handlers/PaymentTerminalAuthorizePaymentRequestHandlerExt"
        },
        {
          "modulePath": "Peripherals/Handlers/PaymentTerminalCapturePaymentRequestHandlerExt"
        },
        {
          "modulePath": "Peripherals/Handlers/PaymentTerminalExecuteTaskRequestHandlerExt"
        }
      ]
    }
  }
}

```

The full code sample, with how to pass extension properties, is available in Retail SDK app update 3 in the RetailSDK\Code\POS\Extensions\PaymentSample folder

## PaymentTerminalRefundPaymentRequestHandler

**PaymentTerminalRefundPaymentRequestHandler**, the refund request, is a payment request from POS that initiates a refund or return of the card payment. You override this request if you want to change the refund workflow. To override the request, you need to extend the **PaymentTerminalRefundPaymentRequestHandler** in POS.

## PaymentTerminalVoidPaymentRequestHandler

**PaymentTerminalVoidPaymentRequestHandler**, the void request, is a payment request from POS that initiates the void card payment request. You override this request if you want to change the void workflow. To override the request, you need to extend the **PaymentTerminalVoidPaymentRequestHandler** in POS.

Extending the void and refund request code pattern is same as the authorize and capture request. The full code sample for the void and refund payment request, with how to pass extension properties, is available in Retail SDK app update 3 in the RetailSDK\Code\POS\Extensions\PaymentSample folder.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Support for tipping in the payments SDK

2/18/2021 • 3 minutes to read • [Edit Online](#)

This topic describes how the payments software development kit (SDK) for Microsoft Dynamics 365 Commerce supports tip amounts that are entered through a payment terminal. The purpose of this feature is to add first-class support to the payments SDK by including a separate field for the tip amount in authorization responses.

This feature doesn't add support for tipping or tip reporting at the point of sale (POS). Implementation of full tipping capabilities requires POS extensions.

## Key terms

TERM	DESCRIPTION
Tips	Tips, which are also known as gratuities, are common in the quick service and hospitality industries. They enable a payment to be given directly to the store or restaurant employee who provides services.
Header-level charge	A charge that can be applied to a purchase, but that isn't for a specific line item.

## Overview of the tipping feature

Tipping is common in some locales and industries. For example, in the quick service and hospitality industries, tipping is now done almost everywhere in the United States. For many businesses, the ability to support tipping through payment terminals is becoming an important factor that helps attract employees. This feature adds a separate **TipAmount** field to the payments SDK, so that tip amounts that are selected on the payment terminal can be sent back to the POS as part of the authorization response.

Although this feature adds support for tipping at the level of the payments SDK, it doesn't include support for other important aspects of tipping functionality. For example, the feature doesn't support reporting of tip payouts at the end of shifts, the ability to pool tips, or the ability to report tips for payroll. To enable full tipping support, you must implement those capabilities through extensions.

For more information about how to create the payment terminal integrations and SDK references that are mentioned in this topic, see [Create an end-to-end payment integration for a payment terminal](#).

### Prerequisites

PREREQUISITE	DESCRIPTION
Tip support on devices	Customers must be able to select a tip amount on the payment terminal.
<b>isTippingEnabled</b> support	Payment connectors must support the <b>isTippingEnabled</b> variable for payment initialization.
<b>TipAmount</b> field	The tip amount must be returned from the payment connector in the <b>TipAmount</b> field of the authorization response.

PREREQUISITE	DESCRIPTION
POS tip support through extension	The tip amount that is returned from the payment connector should be added to the sale as a header-level charge. Tip reporting and management aren't provided out of the box.

### Tippping support by payment processors

This feature adds a new `isTippingEnabled` variable to the `AuthorizePaymentTerminalDeviceRequest` request. When a payment is requested from the POS, this variable indicates whether the authorization request is eligible to have a tip added. Payment connectors that receive this request can then request a tip-eligible authorization from the connected payment service or terminal.

When the `isTippingEnabled` variable is set to `True`, if a customer selects a tip amount on the payment terminal, that amount should be returned in the `TipAmount` field of the `AuthorizePaymentCardPaymentResponse` response that is returned from the payment connector. The tip amount is also included in the `ApprovedAmount` field of the authorization response.

### Tippping support for the Adyen connector

The Adyen connector includes tip support. Customization is required to set the `isTippingEnabled` variable to `True` when the authorization response is passed to the connector. When the `isTippingEnabled` variable is set to `True`, if a customer selects a tip amount on the device, that amount should be returned in the `TipAmount` field of the authorization response.

Before a customer can be prompted to select a tip amount on the Adyen terminal, the terminal must be configured for tipping. This configuration is done through the Adyen customer area. To enable tipping, select the **Point of Sale** tab in the Adyen portal. Tipping can be enabled by terminal or through the fleet-wide **Terminal settings** option. In both the settings for individual terminals and the fleet-wide terminal settings, tipping is enabled on the **Payment features** tab. After tipping is enabled on your Adyen device, settings on the device must be updated. The change won't take effect until this update is done.

### Suggested implementation

We recommend that a header-level charge be used to add the tip amount to the transaction after the authorization response is returned from the payment connector. To support this functionality, an extension should be created for the `PaymentTerminalAuthorizePaymentRequestHandler` handler. That extension should include logic to add a header-level charge to the transaction if a `TipAmount` value is returned in the authorization response.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Support for external gift cards

2/18/2021 • 16 minutes to read • [Edit Online](#)

This topic explains how to set up external gift cards in Retail Modern point of sale (MPOS), the call center, and the storefront.

Microsoft Dynamics 365 Commerce supports both *internal* and *external* gift cards. Internal gift cards are managed entirely in Dynamics 365 Commerce, whereas external gift cards are administered by a third party. If a retailer's operations are run entirely in Microsoft Dynamics, internal gift cards are sometimes the best solution. For complex enterprises that span multiple countries or regions, and multiple point of sale (POS) systems, it's often best to use a third party to manage gift card balances and enable gift cards to be used across those systems.

Like support for other card payment types, support for external gift cards must be built into the payment connector that is used. The out-of-box payment connector for Adyen supports external gift cards through SVS and Givex in POS, the call center, and the e-commerce storefront.

## External gift card setup

### NOTE

Some setup steps assume that demo data is used. The steps might vary, depending on the dataset that is used. The test connector is for sandbox purposes only. The test connector is not supported for use in UAT or production environments.

### Card types

1. Search for **Card Types**.
2. Select **New**, add the following values, and then select **Save**.

FIELD NAME	VALUE
Card ID	EXTGC
Card type name	External Gift Card
Card types	Gift card
Card issuer	Enter any description.

### Card numbers

1. On the **Card types** page, select the newly created gift card, and then select **Card numbers**.
2. Specify the range of card numbers that should be used for external gift cards, and then select **Save**.

In the following example, if the first four digits of a card number are **6036**, the card will be mapped to the gift card that you set up in the "Card types" section of this topic.

FIELD NAME	VALUE
Card number from	6000

FIELD NAME	VALUE
Card number to	6999
Digits to identify	4

## Payment methods

1. Search for **Payment methods** to open the **Payment methods** page.
2. Select **New**, and then follow these steps:
  - a. In the **Payment method** field, enter **12**.
  - b. In the **Payment method name** field, enter **External Gift Card**.
  - c. In the **Default function** field, select **Card**.
  - d. Select **Save**.

## Store setup

1. Search for **All stores** to open the **All stores** page.
2. Select the **San Francisco** store in the list.
3. On the Action Pane, on the **Set up** tab, in the **Set up** group, select **Payment methods**.
4. Select **New**.
5. In the **Payment method** field, enter **12**. The **Payment method name** and **Function** fields should then be set automatically.
6. On the **General** FastTab, set the following fields:
  - Set the **Operation name** field to **Pay gift card**.
  - Set the **Connector name** field to **TestConnector**.
7. On the **Posting** FastTab, set the **Gift card item number** field to **0010**.

The screenshot shows the 'Payment methods' configuration page in Microsoft Dynamics 365. The left sidebar lists various payment methods, with '12 External Gift Card Card' selected. The main area displays the 'Posting' tab with the following fields and values:

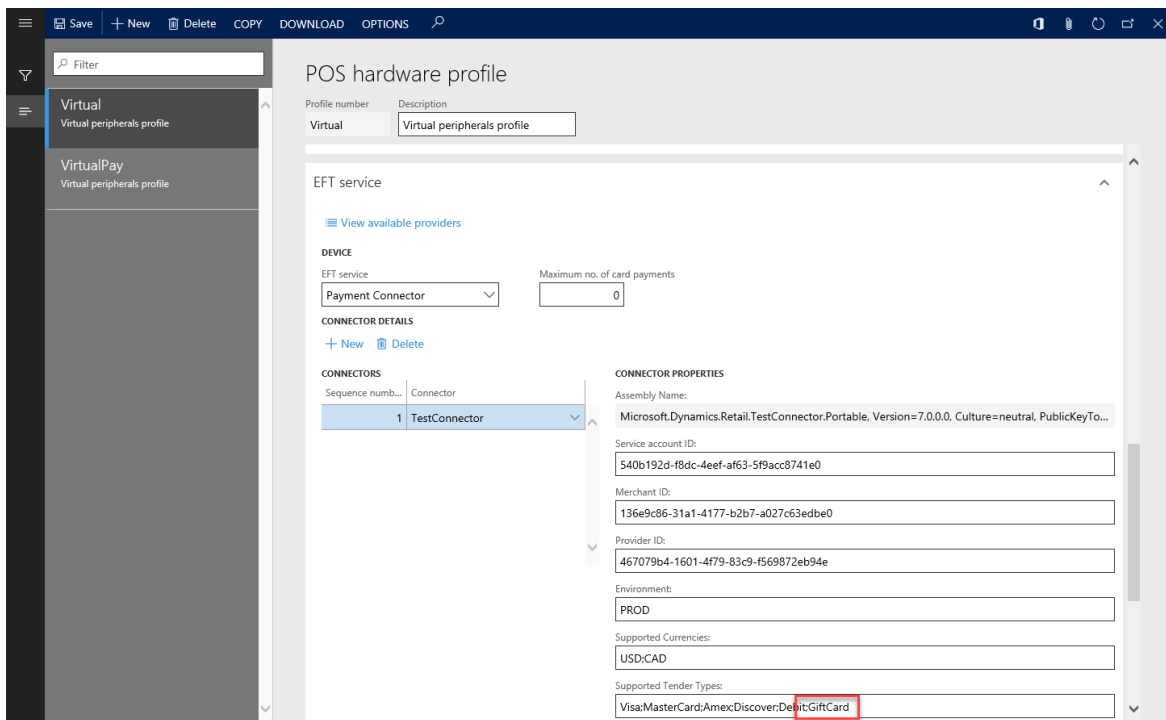

- Payment method:** 12
- Payment method name:** External Gift Card
- Function:** Card
- Posting:**
  - ACCOUNT:**
    - Account type: Ledger account
    - Account number: [empty]
  - GIFT CARD ACCOUNT:**
    - Company: USRT
    - Account type: Ledger account
    - Account number: [empty]
    - Gift card item number:** 0010 (highlighted with a red box)
  - DIFFERENCE ACCOUNT:**
    - Difference account: [empty]
    - Account name: [empty]
  - Maximum difference amount:** 0.00
  - Big difference account:** [empty]
  - Account name:** [empty]
  - TENDER DECLARATION OPTIONS:**
    - Compress payment entries: No
    - Counting required: No
    - Multiply in tender operations: No
    - Allow float: No
    - Taken to bank: No
    - Taken to safe: No
  - BANK TRANSACTION:**
    - Use bank account: No
    - Account type: Ledger account
    - Account number: [empty]
    - Bank transaction type: [empty]
  - SAFE TRANSACTION:**
    - Use safe account: No
    - Account type: Ledger account
    - Safe account: [empty]

8. Select **Save**.

9. Select **Card setup**, and then select **New** to map the gift card payment method to the newly created external gift card payment method for the San Francisco store.

## POS setup

1. In Dynamics 365 Commerce Headquarters, search for **Hardware profiles** to open the **POS hardware profile** page.
2. In the left pane, select **Virtual**.
3. Select **Edit**.
4. On the **EFT service** FastTab, in the **Connectors** grid, select the first entry, **TestConnector**.
5. In the **Supported Tender Types** field, add **GiftCard**.

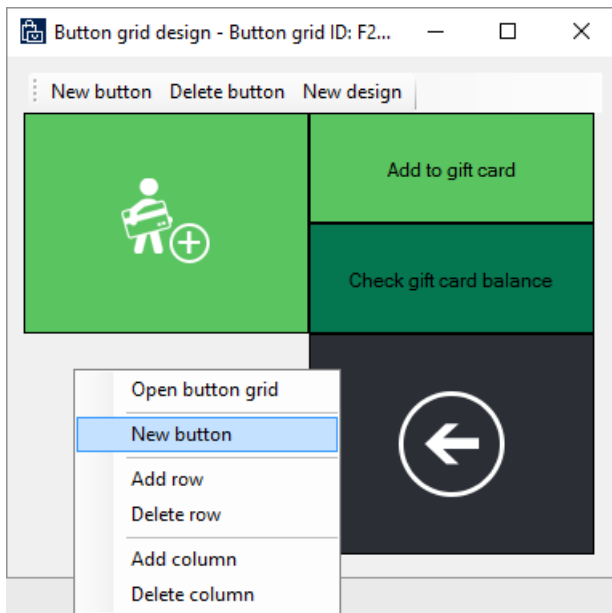

6. Select **Save**.

### NOTE

You can also use the **New** button to create multiple payment connectors. In this way, you can take advantage of the support for multiple connectors that has been added to the solution. You can then have different payment connectors for different payment methods. For example, all credit cards can be processed through one connector, but gift cards can be processed through a different connector.

## Update the button grid

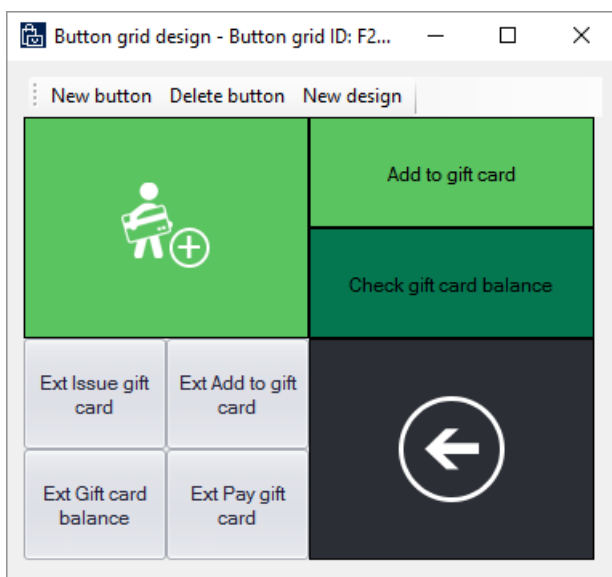

1. Go to the **Button grid** page.
2. In the navigation bar on the left side of the page, search for **F2S1M**, and select the filtered option.
3. On the Action Pane, select **Designer** to download the button designer application.
4. When the grid designer appears, right-click on an empty (gray) area, and then select **New button**.

5. Right-click the new button, and then select **Button properties**.
6. Set the **Action**, **Payment type**, and **Text on button** properties according to the following matrix.

ACTION	PAYMENT TYPE	TEXT ON BUTTON
Issue gift card	External Gift Card	Ext Issue gift card
Add to gift card	External Gift Card	Ext Add to gift card
Gift card balance	External Gift Card	Ext Gift card balance
Pay gift card	External Gift Card	Ext Pay gift card

When you've finished, your button layout should resemble the following illustration.

7. Close the designer.
8. Search for **Distribution Schedule**.
9. In the navigation bar on the left side of the page, search for 1090, 1115, and 1070.
10. On the Action Pane, select **Run now**.

11. Check the status of the job by searching for **Download sessions**.
12. Wait until **Applied** appears next to all the jobs, and then close the browser.

#### NOTE

If you are using Retail Commerce Scale Unit (RCSU) that is located in the store, you need to perform an IIS reset to clear the cache. You can either do this through the IIS application or open an admin Command Prompt window and enter `iisreset`. Otherwise, wait for the RCSU to be updated.

## Configure and test Modern POS

1. Start the Modern POS (MPOS) application.
2. Sign in by using the standard credentials.
3. When you're prompted, select **Perform a non-drawer operation**.
4. On the main screen, select **Select hardware station**.
5. On the bar on the right side of the page, select **Manage**.
6. Turn on **Virtual Peripherals**, and then select **OK**.
7. In the **Available paired stations** field, select **Virtual Peripherals**.
8. You're prompted to either open a new shift or perform non-drawer operations. You can now open a new shift.
9. On the main screen, select **Current transaction**.
10. Select **Gift cards**.
11. Select **Ext Issue gift card**.
12. Enter a number that starts with **9**, and then provide an amount.
13. After items are added to the cart, you can pay by using cash or a card.

When you use the test connector to demonstrate support for external gift cards, you should use card number **61234** to make payments. You won't be prompted for a personal identification number (PIN). The test connector should **never** be used in production.

## External gift cards for the call center and storefront

#### NOTE

External gift card support for call center and storefront is enabled in the **Feature management** workspace. Enable **Omni-channel payments**, then enable **Enable advanced external gift card**. For additional steps required to set up external gift cards in the storefront, please visit the docs article dedicated to [E-commerce digital gift cards](#).

### Tokenization

The out-of-box implementation and Payments software development kit (SDK) support for external gift cards in the call center and storefront requires tokenization. When external gift cards are processed, tokens are used to refer to the actual gift card number. This is important for 3rd party implementations because without tokens, external gift card processing may not function correctly. For example, if a gift card payment is captured when it's added to an order, but an issue occurs during order creation, the gift card payment will be reversed using references (tokens) to the transaction itself, not using the actual gift card number.

### Purchases and refunds

When an external gift card is used for a purchase, the tender line for the gift card is saved as a prepayment. Therefore, the funds for the purchase are captured when the order is created.

External gift cards aren't eligible for refunds. In part, this limitation is in place to prevent a refund from being

given for a gift card that the user has discarded. If an unprocessed order includes an external gift card as payment, and the customer wants to cancel the order, a new gift card or some other form of credit must be issued to the customer.

Gift cards lines that are issued as part of an order can be canceled before fulfillment.

### Issuing gift cards through fulfillment

Physical gift cards and virtual gift cards have distinct fulfillment methods.

Physical gift cards are gift cards that are mapped to a mode of delivery of the **Shipping** type. They must be issued directly through the gift card provider as part of order processing. The gift card number must then be mapped to the order line as part of the pick list registration process. Next, the masked gift card number is saved back to the order line. The gift card that is issued is then activated as part of order invoicing.

Virtual gift cards are issued as part of order invoicing. When a gift card line is marked as **Packed**, it becomes eligible to be issued. Virtual gift cards are issued as part of invoicing. When invoicing occurs, the gift card number is obtained from the provider through the payment connector. The number for the activated gift card is then sent to the gift card recipient via email. When invoicing occurs, the masked gift card number is then saved back to the order line.

### Using modes of delivery for gift card products in the call center and e-commerce

In the call center and storefront channels, unlike in POS, a dedication operation isn't used to issue gift cards. Instead, gift cards are issued by adding a line item to a transaction. Specifically, gift card products for e-commerce and the call center can be either mapped to product variants or modeled as standard products.

If product variants are used, the person who creates the gift card order is prompted to select the variant. The relevant mode of delivery will then be available for that product variant.

Modes of delivery must support the type of gift card. For example, a gift card product variant of the **Physical** style must be mapped to a mode of delivery that is related to shipping. A gift card product variant of the **Email** style must be mapped to an electronic mode of delivery. The electronic mode of delivery is defined on the **Customer orders** tab of the **Commerce parameters** page.

#### NOTE

Only virtual gift cards are currently supported in e-commerce. For more details about setting up virtual gift cards in e-commerce, see [E-commerce digital gift cards](#).

## Setup for the call center and storefront

### Payment services setup

In the back office, on the **Payment services** page, configure the payment services account for the call center. Each payment connector requires different setup steps. The payment service that the call center uses is marked as **Default**.

## Call center setup

1. Search for **All call centers** to open the call centers page.
2. Select the **Fashion call center** store in the list.
3. On the Action Pane, on the **Set up** tab, in the **Set up** group, select **Payment methods**.
4. Select **New**.
5. In the **Payment method** field, enter 12. The **Payment method name** and **Function** fields will then be

set automatically.

6. On the **General** FastTab, set the following fields:
  - In the **Operation name** field, select **Pay gift card**.
  - In the **Connector name** field, select **TestConnector**.
7. On the **Posting** FastTab, set the **Gift card item number** field to **0010**.
8. Select **Save**.
9. Select **Card setup**, and then select **New** to map the gift card payment method to the newly created external gift card payment method for the **Fashion call center**.

## Online store setup

1. Search for **Online stores** to open the online stores page.
2. Select the **Fabrikam extended online** store in the list.
3. On the Action Pane, on the **Set up** tab, in the **Set up** group, select **Payment methods**.
4. Select **New**.
5. In the **Payment method** field, enter **12**. The **Payment method name** and **Function** fields will then be set automatically.
6. On the **General** FastTab, set the following fields:
  - In the **Operation name** field, select **Pay gift card**.
  - In the **Connector name** field, select **TestConnector**.
7. On the **Posting** FastTab, set the **Gift card item number** field to **0010**.
8. Select **Save**.
9. Select **Card setup**, and then select **New** to map the gift card payment method to the newly created external gift card payment method for the **Fabrikam extended online store**.

## Online store payments setup

To configure the payment accounts for your online store to use Adyen for external gift card processing, please refer to the [e-Commerce setup section](#) of the documentation for the Adyen connector.

### Adyen external gift card setup

For an example that shows how to set up payment services, see the [documentation for the Adyen payment connector](#).

For the call center and storefront, the Adyen connector supports the following gift cards.

BRAND	GIFT CARD TYPE	SUPPORTED	ACTIVATION
SVS	Physical	Yes	Manually
SVS	Email	Yes	Programmatically
Givex	Physical	Yes	Manually

## NOTE

In the out-of-box Adyen connector, gift cards are not configured by default. To specify the gift card provider in the merchant properties of the payment connector, follow the instructions in the [documentation for the Adyen payment connector](#).

### Test connector external gift card setup

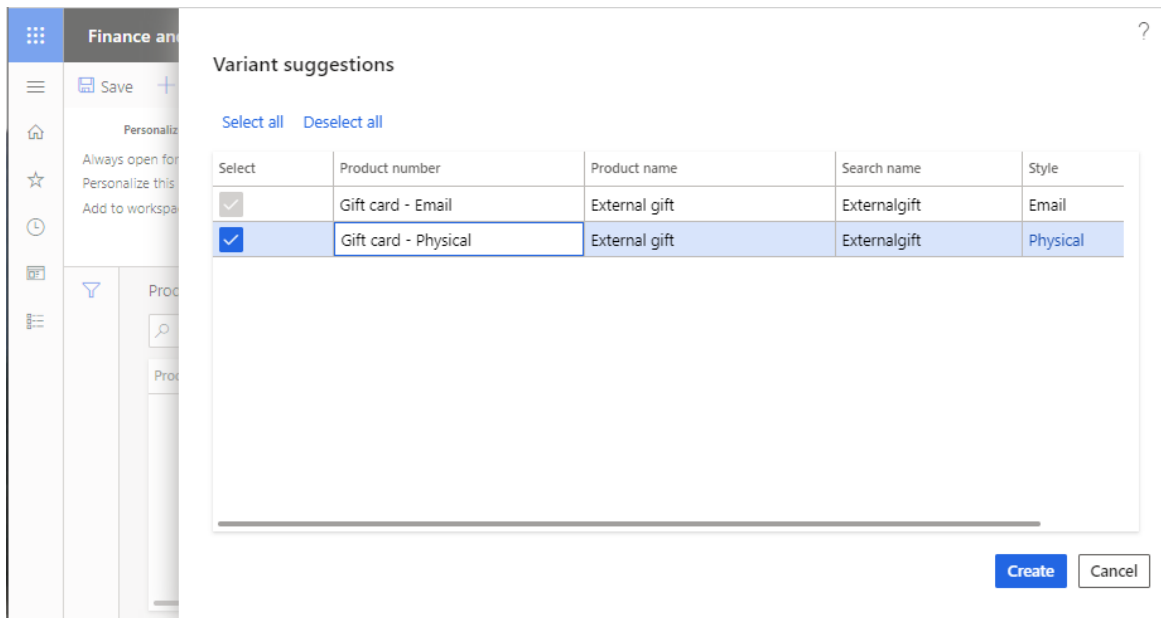

To set up external gift cards for the test connector, on the **Payment services** page, select **Dyn Online**, and then, in the **Supported Tender Types** field, add **;GiftCard** after **Debit**. Then select **Credit card types**, and assign a payment journal to the gift card payment method.

### Gift card product setup

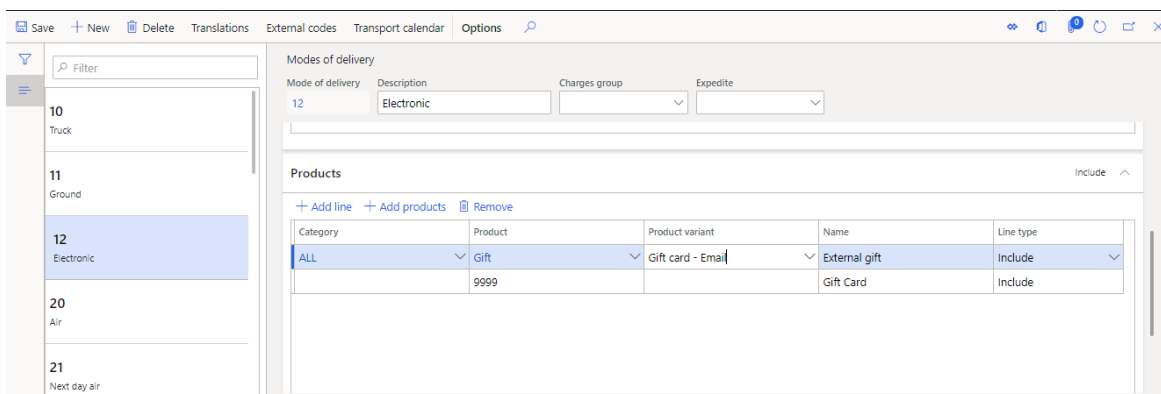

The following procedure shows how to set up an external gift card by using product masters. Product masters aren't required for external gift cards. However, they can be helpful when both physical and virtual gift cards are used.

1. Search for **Style groups** to open the **Style groups** page.
2. Select **New**.
3. Enter a name (for example, **Gift**) and a description (for example, **Gift card style group**).
4. Add styles to suit the types of gift cards that are available. For example, add **Physical** and **Email** styles.
5. Save your changes.
6. Search for **Product masters** to open the **Product masters** page.
7. Select **New**.
8. Enter a product number (for example, **Gift**), and assign a retail category.
9. In the **Product dimension group** field, select **Style**.
10. Select **OK**.
11. In the product master, select the style group that you created earlier (**Gift**).
12. On the Action Pane, on the **Product** tab, in the **Set up** group, select **Dimension groups**, and then assign a storage dimension group and a tracking dimension group.
13. Select **Save**.
14. Select **Product variants**, select **Variant suggestions**, and edit the gift card variant numbers as you require.
15. Select **Create**.

16. Select **Release products**, select **Next** two times, select a company (for example, **USRT**), and then select **Next**. Finally select **Next** to release the product master.
17. Search for **Modes of delivery** to open the **Modes of delivery** page.
18. Select the **Electronic** mode of delivery, and add the **Email** gift card variant. Make sure that applicable call centers and online channels are included.

19. Select a shipping mode of delivery, and add the **Physical** gift card variant.
20. Select **Save**.
21. Search for **Process delivery modes** to open the **Process delivery modes** dialog box.
22. Select **OK**.

**NOTE**  
Gift cards aren't currently supported for MPOS customer order creation or for in-store pickup.

23. Search for **Released products by category** to open the **Released product details** page.
24. Select the external gift card item.
25. Set the following values.

FASTTAB	FIELD	VALUE
General	Item model group	MA_Retail
Purchase	Purchase order unit	ea
Sell	Sales order unit	ea
Sell	Allow price adjust	Yes
Manage inventory	Inventory unit	ea
Manage costs	Posting item group	Any

26. Select **Save**.

For the storefront, the gift card must also be included in the storefront's assortment. For more information, see [Assortment management](#).

#### NOTE

The gift card product used for external gift card setup in POS should not use product masters with item variants. Gift cards based on item variants may still be used for payments, balance inquiries, and cash out in POS, but gift card products associated with the POS for issuance must be standard products.

#### Set up notification emails for virtual gift cards

For information about email setup, see [Configure email functionality](#).

For information about how to set up email notifications for Commerce, see [Set up an email notification profile](#).

For gift cards that are issued via email, the value of the **Retail email notification type** field is **Issue gift card**.

#### Call center setup

1. Search for **All call centers** to open the **Call center** page.
2. In the list, select a call center.
3. On the Action Pane, on the **Channel** tab, in the **Users** group, select **Channel users**.
4. Add a user, select **Save**, and then close the **Channel users** page.

#### IMPORTANT

Users must be call center users when they access the **Customer service** page and create orders. Otherwise, call center capabilities won't be available.

5. Back on the **Call center** page, on the Action Pane, on the **Set up** tab, in the **Set up** group, select **Payment methods**.
6. Select **New**.
7. In the **Payment method** field, enter **12**. The **Payment method name** and **Function** fields should then be set automatically.
8. On the **General** FastTab, select the connector that should be used for the external gift card.

9. Select **Card setup**, and then select **New** to map the gift card payment method to the external gift card payment method.
10. On the **Posting** FastTab, specify general ledger accounts for the external gift cards. In demo data, **112140** can be used as the general ledger account number.
11. Select **Save**.
12. Select **Card setup**.
13. Select **New**, select the external gift card that you created earlier, and then select **Save**.
14. Close the **Card setup** page, and refresh the **Payment methods** page.
15. Select the external gift card payment method, and then, on the **General** FastTab, in the **Gift card account** section, in the **Connector name** field, assign the **TestConnector** connector.
16. On the **Posting** FastTab, assign the gift card item number.
17. Select **Save**.
18. Select **Card setup**.
19. The **Card setup** page for the internal gift card now includes two additional configuration fields: **Check expiration date** and **PIN required**. Set these fields as required by the external gift card provider.

#### **Issue external gift cards in the call center**

1. As a call center user, search for **Customer service** to open the **Customer service** page.
2. Add a customer by using the **Search** function.
3. Select **New sales order**.
4. Select **Header**, and add a valid mode of delivery.
5. Select **Lines**.
6. In the **Item number** field, specify the gift card item number.
7. In the **Variant number** field, specify the variant number if you're using a product master.
8. In the **Unit price** field, specify the unit price for the gift card.

#### **NOTE**

If modes of delivery are mapped to variants, and if **Electronic** modes of delivery are specified for any gift cards, the gift card type should automatically be set to **Email** on the **Packing** tab.

9. On the **Line details** FastTab, on the **Packing** tab, follow one of these steps:
  - For virtual gift cards, set the **Buyer name**, **Buyer email**, **Recipient name**, **Recipient email**, and **Gift message** fields.
  - For physical gift cards, set the **Buyer name**, **Recipient name**, and **Gift message** fields.
10. On the **Price and discount** tab, in the **Reason code** field, specify the reason for the price override.
11. Select **Complete**, add a payment, and submit the order.

#### **Pay by using external gift cards in the call center**

1. As a call center user, create an order, and select **Complete**.
2. On the **Payments** FastTab, select **Add**.

3. Select the external gift card payment method, and enter the number and PIN, if applicable. For the test connector, 61234 can be used as the number, and the PIN isn't validated.
4. Use a percentage amount or a payment amount to define the payment amount.

The screenshot shows the Dynamics 365 Finance and Operations interface. On the left, a sidebar contains navigation options like 'New', 'Service order', 'Purchase order', and 'Direct delivery'. The main area displays a 'Sales order summary' with the following details:

- Order: Order (dropdown) / Hold (dropdown)
- Sales status: Open order
- Payment status: Not submitted
- Currency: USD
- TOTALS:
  - Sales total: 118.24
  - Payment total: 118.24
  - Balance: 0.00
- Payment method: 12
- Payment method name: External gift card

On the right, a dialog box titled 'Enter customer payment information' is open. It contains the following fields and options:

- Payment method: 12
- Payment method name: EXTERNAL (dropdown)
- Payment method name: External gift card
- Number: 61234
- Pin required: 222
- Check expiration date: [button]
- Available balance: 1,000.00 [refresh button]
- Percent amount: 100.00
- Payment amount: 118.24
- Prepay:  Yes

At the bottom right of the dialog box are 'OK' and 'Cancel' buttons.

5. Select OK.
6. Select Submit to complete the order.

## Troubleshooting

### Issue: An error occurs when you start the HardwareStationConfigurationUtility program

1. From an elevated command prompt, open the HardwareStationConfigurationUtility.exe.config file in Notepad.
2. In the file, follow these steps:
  - a. Replace the DataServiceUrl value with the correct Commerce Scale Unit URL.
  - b. Verify that the AADLogonUrl value is correct.
3. Save and close the file.
4. Restart the utility.

### Issue: A token error occurs when you try to pair virtual peripherals

1. Exit MPOS.
2. Go to C:\Program Files (x86)\Microsoft Dynamics 365\70\Retail Hardware Station\Package.
3. From an elevated command prompt, open the Web.config file in Notepad.
4. Replace the RetailServer value with the correct Commerce Scale Unit value.
5. Save and close the file.
6. Restart MPOS.

7. If the issue persists, exit MPOS, use Task Manager to end any instances of dllhost.exe that are running, and then do another reset of Internet Information Services (IIS).

**NOTE**

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Create and apply branding to the Retail Experience app

2/18/2021 • 10 minutes to read • [Edit Online](#)

You can apply your branding to the Retail Experience app, and release it to Google Play and the Apple App Store. This topic explains how to build the app, connect, and apply your branding.

## Development tools

The Retail Experience app supports the Android and iOS phone platforms. The app is built by using Xamarin.Forms, and you must install Xamarin on your development computer. To build the iOS app, you must have a Mac that has Xamarin installed. Although you can do development for both Android and iOS on a computer that runs Microsoft Windows, you must use a Mac to complete the build for the iOS platform. If your Mac is a shared team resource, you might want to use a Mac just for the build process. You must install the Retail software development kit (SDK) on all the computers you use for development.

### Install Xamarin

You can download Xamarin from [Visual Studio Tools for Xamarin](#).

For a tutorial that shows how to install Xamarin on Windows, see [Installing Xamarin](#).

### Update Xamarin

After you've installed Xamarin, you must update it to the latest stable version.

- **Windows:** In Microsoft Visual Studio, click **Tools > Options > Environment > Xamarin > Other**.
- **Mac:** In Xamarin Studio, click **Check for Updates > Update channel**. For more information, see [Change the Updates Channel](#).

### Connecting to a Mac

If you're developing on Windows and using the Mac just for building the iOS app then you must connect the computer that runs Windows and the Mac. For instructions, see [Connecting to the Mac](#).

## Connect to an online channel

Open the Retail Experience app solution in Visual Studio for the next steps. The Retail Experience app uses an online channel to show the products. You can use any online channel. Depending on your requirements, you can use a different online channel for each app, or you can use the same online channel for both apps. Any released product that is assorted to the online channel will appear in the app.

### NOTE

The app can't be used to issue gift cards. Therefore, gift cards must be excluded from the assortment for the online channel that the apps use. Information about the Commerce Scale Unit endpoint and the online channel is added to the config.xml file that is present in each app project. You must make the following changes in the config.xml file:

- In the `<DataServiceUrl>` tag, add the URL of the Commerce Scale Unit.
- In the `<MediaBaseUrl>` tag, add the URL of the media server. Make sure that this URL has a slash (/) at the end.
- In the `<OperatingUnitNumber>` tag, add the operating unit number of the online channel that you want

to use together with the app.

#### NOTE

Enter the complete operating unit number. For example, in the demo data, the operating unit number for Contoso online store is 068.

## Connect to a payment connector

To enable payments to be accepted from the app, you must set up a payment connector on the online channel that is used for the app. The payment connector loads the card-related controls on a host HTML page. We have added a host page that is named `CardPaymentHost.html` to the Retail SDK. We have also verified that this host page works with the MasterCard connector. However, you might have to edit this page to meet the requirements of the other payment providers. Different connectors might provide pages. The host page can be hosted on any website that you choose. However, we recommend that you host it on your eCommerce site, if you have an eCommerce site. After the page has been hosted, add the URL of the host page in the `<CardPaymentHostPageUrl>` tag.

## Update the About page

Add the following links to the about page:

- In the `<TermsOfUseUrl>` tag, add a link to the license terms.
- In the `<PrivacyPolicyUrl>` tag, add a link to the privacy policy.
- In the `<ThirdPartyNoticesUrl>` tag, add a link to the third-party notices.

#### NOTE

If these links are missing, and the user clicks them, the app might stop responding. Therefore, be sure to add the links to these tags. The About page has an `<EvaluationModeEnabled>` tag that is used to enable Evaluation Mode view. Evaluation Mode lets retailers easily change the Commerce Scale Unit endpoint without having to change any code. This feature helps retailers evaluate the app for various channels. **Evaluation Mode must be disabled in the production version of the app.** By default, Evaluation Mode is disabled in the Retail SDK.

## Apply branding

After you've successfully built the Retail Experience app by using the Microsoft sample branding, you can change icons, labels, and colors to make the app meet your own branding requirements. The following list shows some of the icons, labels, and colors that retailers might want to change. This list isn't exhaustive.

### Icons

- **App** – The icon that users see after the app is installed on their phones.
- **Retailer's brand** – The icon that appears on the menu flyout on Android.
- **Shop** – The icon that appears on the menu flyout on Android, and on the tab bar on Apple iPhone.
- **Information** – The icon that appears on the menu flyout on Android, and on the tab bar on iPhone.
- **Shopping Cart** – The icon that appears in the upper-right corner on Android, and on the tab bar on iPhone.
- **Search** – The icon that appears in the upper-right corner on Android and iPhone.
- **Splash screen** – The icon that appears as the loading image on Android and iPhone.

### Labels/texts

- App name (the name that appears below the app icon when the app is installed on the phone).

- Shop icon name and the corresponding page title.
- Information icon name and the corresponding page title.
- Confirmation messages that appear as toast notifications.
- "Add to cart" button text and the corresponding page title.
- "Checkout" button text and the corresponding page title.
- "Place order" button text.
- About page label and the corresponding page title.

## Colors

- App bar (The app bar is also known as the action bar or toolbar.)
- Status bar color
- Accent color
- Primary action button colors. For example, the **Add to Cart**, **Checkout**, **Place Order**, and **Continue** buttons all have the same color.

## Applying branding to the Android app

### Icons

To change the icons for the Android app, open the Resource folder, and update the icons in each drawable folder. These drawable folders contain images for Android at different resolutions. You can either preserve the sizes of the images in these folders or change them to meet your requirements. For information about how Android handles different screen sizes, see [Screen compatibility overview](#). The splash screen is put in the drawable folder and is a special type of image that Android requires. For more information about the splash screen, see [Create resizable bitmaps](#).

### Label/text

To change the text labels on the Android app, open the TextResources.resx file, and edit the values of the available resources. The following table shows the name of the label/text that appears on the Android device and the corresponding property/key that must be changed in TextResources.resx. The app name is specified in the strings.xml file.

LABEL/TEXT	PROPERTY NAME/KEY
App name	<b>App_name</b> . This property can be found in the strings.xml file at ../ShoppingAppDroidResources/values.
Shop icon name and the corresponding page title	<b>MenuPage_Products</b> and <b>Pages_CategoryListPage_Products</b> , respectively
Information icon name and the corresponding page title	<b>MainTabs_Account</b> and <b>Pages_AccountPage_AccountInformation</b> , respectively
Confirmation messages that appear as toast notifications	Multiple messages in TextResources.resx
"Add to cart" button text and the corresponding page title	<b>Pages_ProductDetail_AddToCart</b> and <b>Pages_CartPage_Title</b> , respectively
"Checkout" button text and the corresponding page title	<b>Pages_CartPage_Checkout</b> and <b>Pages_CheckoutPage_Title</b> , respectively
"Place order" button text	<b>Pages_CheckoutPage_PlaceOrder</b>
About page label and the corresponding page title	<b>Pages_AccountPage_About</b> and <b>Pages_AboutPage_Title</b> , respectively

#### NOTE

Some of the resources in the TextResources.resx file aren't used by the Android app, but they are used by the iOS app. Examples include **MainTabs\_Cart** and **MainTabs\_Products**. You can change those resources from the Android app without affecting the iOS app.

#### Colors

To change the colors that appear in the Android app, open the config.xml file and colors.xml files (colors.xml is under Resources->values folder). Now change the values for **Primary** (the app bar color), **PrimaryDark** (the status bar color), **Accent**, and **ActionButtonBackground** in both the files and keep them consistent.

#### NOTE

The product price is shown on two pages namely products list page and the product details page. The price shown on the product list page is set to green (#008A00) and cannot be altered. However, the price shown on the product details page is governed by the value set for the "PrimaryDark" property.

### Applying branding to the iOS app

#### Icons

To change the icons on the iOS app, open the Resource folder, and update the icons. You can either preserve the sizes of the images in the folders or change them to meet your requirements.

#### Label/text

To change the text for the iOS app, open the TextResources.resx file, and edit the values of the available resources. The following table shows the name of the label/text that appears on the iOS device and the corresponding property/key that must be changed in TextResources.resx. The app name is specified in the info.plist file.

LABEL/TEXT	PROPERTY NAME/KEY
App name	<b>CFBundleDisplayName</b> . This property can be found in the info.plist file in the app's iOS project.
Shop icon name and the corresponding page title	<b>MainTabs_Products</b> and <b>Pages_CategoryListPage_Products</b> , respectively
Information icon name and the corresponding page title	<b>MainTabs_Account</b> and <b>Pages_AccountPage_AccountInformation</b> , respectively
Confirmation messages that appear as toast notifications	Multiple messages in TextResources.resx
"Add to cart" button text and the corresponding page title	<b>Pages_ProductDetail_AddToCart</b> and <b>Pages_CartPage_Title</b> , respectively
"Checkout" button text and the corresponding page title	<b>Pages_CartPage_Checkout</b> and <b>Pages_CheckoutPage_Title</b> , respectively
"Place order" button text	<b>Pages_CheckoutPage_PlaceOrder</b>
About page label and the corresponding page title	<b>Pages_AccountPage_About</b> and <b>Pages_AboutPage_Title</b> , respectively

#### NOTE

Some of the resources in the info.plist file aren't used by the iOS app, but they are used by the Android app. An example is `MenuPage_Products`. You can change those resources from the iOS app without affecting the Android app.

#### Colors

To change the colors that appear in the iOS app, open the config.xml file, and change the values for **Primary** (the app bar color), **PrimaryDark** (the status bar color), **Accent**, and **ActionButtonBackground**.

#### NOTE

The product price is shown on two pages namely products list page and the product details page. The price shown on the product list page is set to green (#008A00) and cannot be altered. However, the price shown on the product details page is governed by the value set for the "PrimaryDark" property.

## Build, test, and distribute apps

The next step is to build the app and test on devices. Testing will be followed by publishing the app to the public app stores. We have added the standard external links from Xamarin and Apple which explain the basics of Android and iOS app distribution.

### Android

To test the Android app on an emulator follow the below steps on Visual Studio

1. Select Droid as startup project, Marshmallow as Android device.
2. Build Release | Any CPU.
3. Run in Marshmallow emulator.

To learn how to use the Archive manager on Visual Studio to **create an .apk file** that can be signed by a signing certificate, see [Preparing an Application for Release](#).

For details about how to create a signing certificate and **sign the .apk file** for ad hoc and Google Play store distribution, see [Signing the Android Application Package](#).

For more information about the steps involved with the **public distribution of an application** created with Xamarin.Android via channels such as email, a private web server, Google Play, or the Amazon App Store for Android, see [Publishing an Application](#).

### iOS

To test the iOS app on an emulator, use the following steps in Visual Studio.

1. Select iOS as startup project.
2. Connect to Mac as explained above.
3. Build Release | iPhone.
4. Run the app in Visual Studio.

For detailed information about the distribution techniques that are available for Xamarin.iOS applications, see [Xamarin.iOS App Distribution overview](#).

To learn how to maintain your signing identities and certificates, refer to [What is app signing](#).

**NOTE**

If you are using the certificates as a part of Apple Developer Enterprise Program and you install an app manually (such as for testing), then you must also manually establish trust. For more information, see [Install custom enterprise apps on iOS](#).

**NOTE**

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Set up POS hybrid app on Android and iOS

2/18/2021 • 5 minutes to read • [Edit Online](#)

This topic shows how to build and run the Retail POS hybrid app on Android and iOS devices.

## Overview

Retail hybrid app is shell built using [Xamarin](#). Inside the shell is a Web view controller that loads the cloud POS, which is based on the Commerce Scale Unit URL specified in the settings of this app. This is a Retail hybrid app shell for Android and iOS which will internally load the Cloud POS. For more information, see [Cloud POS](#).

## Development tools

The Retail hybrid app supports the Android and iOS phone platforms. The app is built by using Xamarin, which means that you must install Xamarin on your development computer. To build the iOS app, you must have a Mac that has Xamarin installed. Although you can do development for both Android and iOS on a computer that runs Microsoft Windows, you must use a Mac to complete the build for the iOS platform. If your Mac is a shared team resource, you might want to use a Mac just for the build process. You must copy the Retail software development kit (Retail SDK) on all the computers that you use for development. The Retail SDK is available in all developer VMs that are provisioned for using [Microsoft Dynamics Lifecycle Services \(LCS\)](#).

For more information about Xamarin, see the [Xamarin documentation](#).

## Set up and install Xamarin on Windows

To set up and install Xamarin on Windows, go to </xamarin/android/get-started/installation/windows>.

### Update Xamarin

#### NOTE

We recommend that you use Xamarin.Android SDK version < 10.0.

After you've installed Xamarin, you must update it to the latest stable version (Xamarin.Android SDK version must be < 10.0).

- **Windows** - In Microsoft Visual Studio, click **Tools > Options > Environment > Xamarin > Other**.
- **Mac** - In Xamarin Studio, click **Check for Updates > Update channel**. For more information about this step, see [Change the Updates Channel](#).

### Build the Android Retail hybrid app

1. When installation is complete, launch Visual Studio and sign in with your Microsoft account (this is the same account that you use with Windows). Check for Xamarin updates by clicking **Tools > Options > Xamarin** or **Tools > Options > Xamarin > Other**. Here you'll find a **Check Now** link. If you do not see an option for Xamarin in **Tools > Options**, review your installation, or try restarting Visual Studio. You can also search for Xamarin in the **Options** dialog box. If needed, download and install the latest version.
2. In the Retail SDK folder, open `SampleExtensions\HybridApp\Android\solution`. Build and deploy using the emulator and verify that everything appears as it should.

- Using the [Visual Studio Emulator for Android](#) or any emulator for Android, launch the POS hybrid app and enter the Commerce Scale Unit URL and save.
- You should be able to sign in and activate the device.

### Build the iOS Retail hybrid app

#### Connecting to a Mac

If you're developing on Windows and using the Mac just for building the iOS app then you must connect the computer that runs Windows and the Mac. For instructions, see [Connecting to the Mac](#).

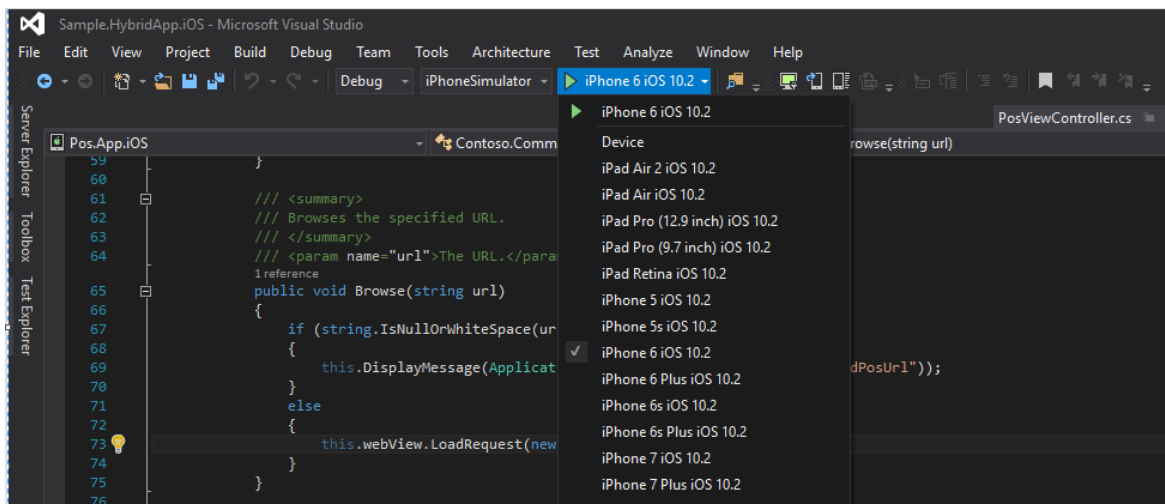

## Set up and install Xamarin on iOS

For more detailed steps on installing Xamarin on iOS, refer to [Xamarin.iOS installation](#).

- Download and install Xcode from <https://developer.apple.com/xcode/>. Add your Apple ID using the instructions described in [Adding your account to Xcode](#) (apple.com).
- Download and install Xamarin by following the instructions in [Installing and configuring Xamarin.iOS](#) (xamarin.com).
- When you have completed installing Xamarin on both the Windows and Mac computers, follow the instructions in [Connecting to the Mac](#) (xamarin.com). After you do this, you can work with iOS and Mac from Visual Studio on the Windows computer.

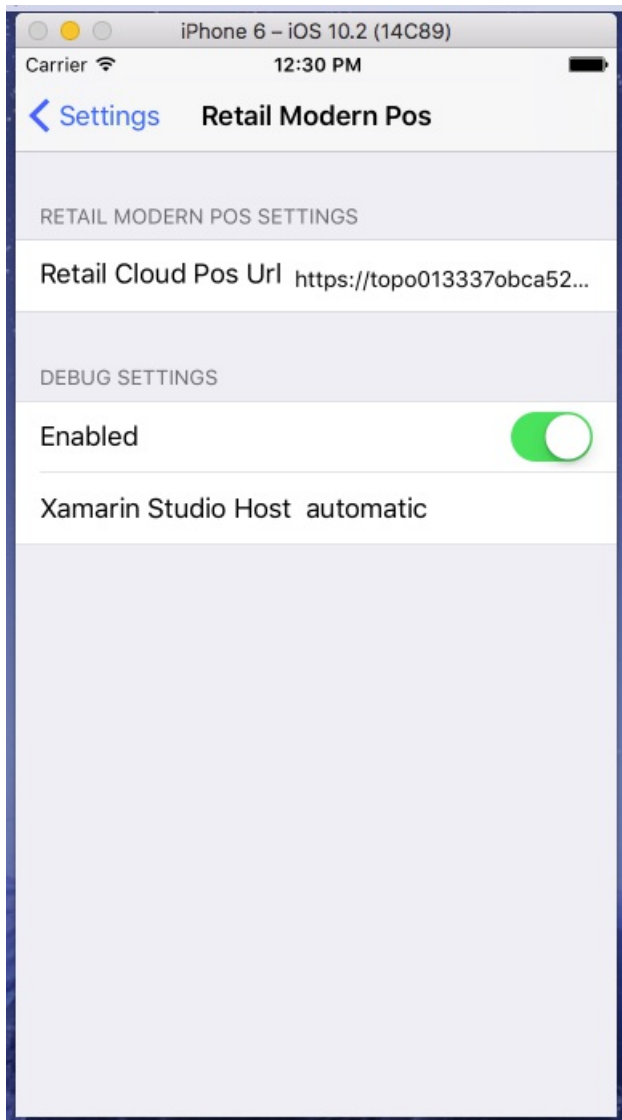

### Build the iOS Retail hybrid app

- In the Retail SDK folder, open SampleExtensions\HybridApp\iOS\solution. After connecting to the Mac and building the application in Visual Studio, select the iOS device type and deploy the app on the selected device.

- Using the Emulator, go to **Settings > RetailIMPOS**. Enter the Commerce Scale Unit URL.

3. Launch the MPOS app. You should be able to sign in and activate the device.

## Dedicated hardware station support for the hybrid Android app

Starting in release 8.1.3, dedicated hardware station support has been added to the hybrid Android app. In the same way that the Retail Modern POS has built-in support for peripheral devices, the Android app can also use the dedicated hardware station to connect to peripherals without needing to deploy an IIS-based hardware station. Out of the box, the hybrid Android app supports using payment terminals and receipt printers over network connections. Communicating with devices over a network typically requires adherence to a proprietary communication protocol specified by the manufacturer. For the hybrid Android app, out-of-the-box integrations are provided for the Dynamics 365 payment connector for Adyen and Epson receipt printers.

### Out-of-the-box supported devices

DEVICE	DESCRIPTION
Payment terminals	Any supported by the <a href="#">Adyen Payment Terminal API</a> through the Dynamics 365 Payment Connector for Adyen.
Receipt printer	Network-enabled Epson printers that support the Epson SOAP HTTP interface. Network-enabled Star Micronics printers.

DEVICE	DESCRIPTION
Cash drawer	Introduced in Dynamics 365 Commerce version 10.0.8: Cash drawers that are connected to network-enabled printers via the drawer kick (d/k) port.

Support for other payment processors and peripheral devices can be implemented by ISVs through the Payments and Hardware SDKs.

### Set up peripherals to work with the hybrid Android app

To enable direct hardware support for the hybrid Android app, set up a dedicated hardware station in the same way it would be set up for MPOS. Instructions for setting up the dedicated, or IPC, hardware station can be found in [Retail peripherals](#)

#### NOTE

The dedicated hardware station provided with demo data should not be used with the hybrid Android app. To test the hybrid Android app in an environment with demo data, delete the existing hardware stations and create a new dedicated hardware station.

To do this, go to **Retail and Commerce > Channels > Stores > All stores**. Select the store that will be used, typically "HOUSTON".

In the store details form, scroll down to the **Hardware stations** FastTab. Remove the existing dedicated hardware station, then select **Add** to add a new hardware station of type **Dedicated**. A description is optional. No other details are necessary for the hardware station.

To set up the payment connector, follow the standard setup steps noted in the [Dynamics 365 Payment Connector for Adyen](#). Skip the section labeled "Update the Modern POS or IIS Hardware Station configuration."

For details on setting up network connected peripherals the docs [Support for network peripherals](#).

## Additional resources

- [Payments FAQ](#)

#### NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Override POS request handler

2/18/2021 • 8 minutes to read • [Edit Online](#)

This topic explains how to override POS request handler. We've introduced an extension pattern for overriding the POS business logic. If you have a scenario where you want to modify/add some business logic to the core POS business flow, then you can follow this pattern.

For example, when you sell a serial item, POS will display a dialog box where you can enter the serial number for that item after the scan. If you want to automate the serial number process by entering the serial number through code, then you can override this serial number request handler and use custom business logic. Most of the business logic in POS is implemented in request handler, however, you can override the relevant request handler and return the response according to your business flow.

## NOTE

Not all request handler logic is exposed for customization. If you want to customize any business logic and if that request handler is not overridable, then create a support ticket or log a request in the LCS extensibility tool.

## POS request handler logic exposed for overriding

This list is based on [Microsoft Dynamics 365 for Finance and Operations - Version 7.3.5](#).

In each monthly update we will be adding additional extension points, so check the Pos.api.d.ts file in the Retail SDK for the full list.

## Cart extension handlers

REQUEST NAME	DESCRIPTION
AddTenderLineToCartClientRequestHandler	This handler is executed when you add tender (payment) line to cart.
GetKeyedInPriceClientRequestHandler	This handler is executed when you add an item that has a configuration key in price during sale.
GetPickupDateClientRequestHandler	Executed when you select a pickup date during a customer order.
GetShippingDateClientRequestHandler	Executed when you select a shipping date during a customer order.
ShowChangeDueClientRequestHandler	Executed when the change due dialog box is shown at the end of transaction.
GetReceiptEmailAddressClientRequestHandler	Executed when you get a receipt email address.
DepositOverrideOperationRequestHandler	Executed when you override a deposit.
GetShippingChargeClientRequestHandler	Executed when get shipping charge workflow initiated during customer order flow.

REQUEST NAME	DESCRIPTION
GetKeyedInPriceClientRequestHandler	Executed when the key in product price dialog box is shown.

### Payment extension handler

REQUEST NAME	DESCRIPTION
GetGiftCardByIdServiceRequestHandler	This handler is executed when you receive the gift card ID.
GetPaymentCardTypeByBinRangeClientRequestHandler	This handler is executed when POS gets the card type, such as Visa or Master Card. This is based on the HQ configuration during the card tender line processing.

### Peripherals request handler

REQUEST NAME	DESCRIPTION
CardPaymentAuthorizePaymentRequestHandler	Executed when a card payment is authorized.
CardPaymentCapturePaymentRequestHandler	Executed when a card payment is captured.
CardPaymentExecuteTaskRequestHandler	Used to execute any custom task. This handler is mainly for extensions for custom functionality with payment connector, which is not supported.
CardPaymentRefundPaymentRequestHandler	Executed when a card payment is refunded.
CardPaymentVoidPaymentRequestHandler	Executed when a card payment is voided.
CardPaymentBeginTransactionRequestHandler	Executed when a card payment is initiated.
CardPaymentEndTransactionRequestHandler	Executed when a card payment is ended.
CardPaymentEnquireGiftCardBalancePeripheralRequestHandler	Executed when a gift card balance inquiry is made.
PaymentTerminalAuthorizePaymentActivityRequestHandler	Executed when a card payment is authorized using a payment. terminal/device.
PaymentTerminalAuthorizePaymentRequestHandler	Executed when a card payment is authorized using a payment. terminal/device.
PaymentTerminalEnquireGiftCardBalancePeripheralRequestHandler	Executed when a gift card balance inquiry is made using a payment. terminal/device.
PaymentTerminalExecuteTaskRequestHandler	Used to execute any custom task. This handler is mainly for extensions for custom functionality with payment terminal/device, which is not supported.
PaymentTerminalRefundPaymentRequestHandler	Executed when a card payment is refunded using a payment terminal/device.
PaymentTerminalUpdateLinesRequestHandler	Executed when POS sends line item details to a payment device for display purposes.

REQUEST NAME	DESCRIPTION
PaymentTerminalVoidPaymentRequestHandler	Executed when a card payment is voided using a payment terminal/device.
PaymentTerminalBeginTransactionRequestHandler	Executed when a card payment is initiated using a payment terminal/device.
PaymentTerminalCancelOperationRequestHandler	Executed when a card payment is canceled using a payment terminal/device.
PaymentTerminalEndTransactionRequestHandler	Executed when a card payment is ended using a payment terminal/device.
CashDrawerOpenRequestHandler	Executed when a cash drawer open request is initiated by POS.
PaymentTerminalActivateGiftCardPeripheralRequestHandler	Executed when activate gift card request is initiated by POS.
PaymentTerminalAddBalanceToGiftCardPeripheralRequestHandler	Executed when add balance to gift card request is initiated by POS.

### Scan request handler

REQUEST NAME	DESCRIPTION
GetScanResultClientRequestHandler	Executed when you scan or key in a POS transaction screen Numpad.

### Store fulfillment request handler

REQUEST NAME	DESCRIPTION
PrintPackingSlipClientRequestHandler	Executed when you print a packing slip from the store fulfillment view.
MarkAsPickedServiceRequestHandler	Executed when you mark a sales line as picked from the store fulfillment view.

### Store operations request handler

REQUEST NAME	DESCRIPTION
CreateTenderRemovalTransactionClientRequestHandler	Executed when you do a tender removal operation in POS.
CreateFloatEntryTransactionClientRequestHandler	Executed when you do a float entry operation in POS.
SelectZipCodeInfoClientRequestHandler	Executed when you key in zip code in address add/edit view in POS.
CreateStartingAmountTransactionClientRequestHandler	Executed when you do a start amount declaration in POS.
LoyaltyCardPointsBalanceOperationRequestHandler	Executed when you do a loyalty card balance operation in POS.

REQUEST NAME	DESCRIPTION
GetReportParametersClientRequestHandler	Executed when you use a report parameter. If your POS report needs an input parameter this dialog will be executed to capture the parameters.
GetPickingAndReceivingOrdersClientRequestHandler	Executed when orders fetched for picking and receiving processing.
GetStartingAmountClientRequestHandler	Executed when you do a start amount declaration in POS (before navigating to the view).

### Tender counting request handler

REQUEST NAME	DESCRIPTION
CreateSafeDropTransactionClientRequestHandler	Executed when you do a safe drop operation in POS.
GetTenderDetailsClientRequestHandler	Executed when you get tender declaration details in POS.
CreateBankDropTransactionClientRequestHandler	Executed when you do a bank drop operation in POS.
CreateTenderDeclarationTransactionClientRequestHandler	Executed when you do a tender declaration operation in POS.
GetCountedTenderDetailAmountClientRequestHandler	Executed when you do a tendercount detail in POS.
CreateBankDropTransactionClientRequestHandler	Executed when you do a bank drop operation in POS.

### Sales orders request handlers

REQUEST NAME	DESCRIPTION
GetGiftReceiptsClientRequestHandler	Executed when you print a gift receipt in POS.
SelectCustomerOrderTypeClientRequestHandler	Executed when you get a dialog box with options to choose between customer order or quote.
GetCancellationChargeClientRequestHandler	Executed when you get a dialog box to enter the cancellation shipping charge during the customer order workflow.

## How to override a handler in POS

If you want to override any of the above POS request handler logic, you to need to use the following steps:

1. Create a new class and extend it from the corresponding handler class. For example, if you are overriding GetSerialNumberClientRequestHandler, then extend your class from GetSerialNumberClientRequestHandler.
2. Implement the executeAsync method.
3. Either call the default handler or do your custom logic inside the executeAsync method and return the response.

## Step by step instructions

The following example shows how to override the `GetSerialNumberClientRequestHandler` to automate the serial number entry in POS. By default, POS will display a dialog box to enter the serial number if the item is configured to ask for serial number. We want to avoid showing this dialog box and enter serial number through code.

1. Open Visual Studio 2015 in administrator mode.
2. Open ModernPOS solution from ...\RetailSDK\POS.
3. Under the POS.Extensions project, create a new folder called `POSRequestHandlerExtension`.
4. Under the `POSRequestHandlerExtension` folder, create new folder called `Handlers`.
5. In the `Handlers` folder, add a new `.ts` (typescript) file and name it `GetSerialNumberClientRequestHandlerExt.ts`.
6. Add the following import statement to import the relevant entities and context in the `GetSerialNumberClientRequestHandlerExt.ts` file.

```
import { GetSerialNumberClientRequestHandler } from
"PosApi/Extend/RequestHandlers/ProductsRequestHandlers";
import { GetSerialNumberClientRequest, GetSerialNumberClientResponse } from
"PosApi/Consume/Products";
import { ClientEntities } from "PosApi/Entities";
```

7. In the `GetSerialNumberClientRequestHandlerExt.ts` file, create a new class called `GetSerialNumberClientRequestHandlerExtend` and extend it from `GetSerialNumberClientRequestHandler`.

```
export default class GetSerialNumberClientRequestHandlerExt extends
GetSerialNumberClientRequestHandler { }
```

8. Implement the `executeAsync` method inside the `GetSerialNumberClientRequestHandlerExt` class. In the `executeAsync` method, you can write your custom logic and return the response or call the default handler. When POS sells the serial item, it will look for `executeAsync` to execute the logic for the serial number, however because we are overriding it, POS will now execute this overridden `executeAsync` method instead of the standard method.

### Sample implementation of how to override the `executeAsync` method

```

public executeAsync(request: GetSerialNumberClientRequest<GetSerialNumberClientResponse>):
    Promise<ClientEntities.ICancelableDataResult<GetSerialNumberClientResponse>> {

    // User could implement new business logic here to process the serial number.
    // The following example sets serial number "112233" for product 82001.

    if (request.product.ItemId === "82001") {
    let response: GetSerialNumberClientResponse = new GetSerialNumberClientResponse("112233");
    return Promise.resolve(<ClientEntities.ICancelableDataResult<GetSerialNumberClientResponse>>{

    canceled: false,
    data: response

    });
    }

    // If you don't want to execute custom logic on some conditions, and you just want to call the
    standard logic, you can call the default request, as shown below.

    return this.defaultExecuteAsync(request);

}

```

Full sample code:

```

import { GetSerialNumberClientRequestHandler } from
"PosApi/Extend/RequestHandlers/ProductsRequestHandlers";
import { GetSerialNumberClientRequest, GetSerialNumberClientResponse } from
"PosApi/Consume/Products";
import { ClientEntities } from "PosApi/Entities";

/**
 * Override request handler class for getting serial number request.
 */

export default class GetSerialNumberClientRequestHandlerExt extends
GetSerialNumberClientRequestHandler {

/**
 * Executes the request handler asynchronously.
 * @param {GetSerialNumberClientRequest<GetSerialNumberClientResponse>} request The request containing
the response.
 * @return {Promise<ICancelableDataResult<GetSerialNumberClientResponse>>} The cancelable promise
containing the response.
 */

public executeAsync(request: GetSerialNumberClientRequest<GetSerialNumberClientResponse>):
    Promise<ClientEntities.ICancelableDataResult<GetSerialNumberClientResponse>> {

    // User could implement new business logic here to process the serial number.
    // The following example sets serial number "112233" for product 82001.

    if (request.product.ItemId === "82001") {
    let response: GetSerialNumberClientResponse = new GetSerialNumberClientResponse("112233");
    return Promise.resolve(<ClientEntities.ICancelableDataResult<GetSerialNumberClientResponse>>{
    canceled: false,
    data: response
    });
    }

    return this.defaultExecuteAsync(request);
    }
}

```

9. Create a new json file under the POSRequestHandlerExtension folder. Name it manifest.json.
10. In the manifest.json file, copy and paste the following code. Be sure to delete the default generated code before copying this code.

```
{
  "$schema": "../manifestSchema.json",
  "name": "Pos_Extensibility_Samples",
  "publisher": "Microsoft",
  "version": "7.3.5.0",
  "minimumPosVersion": "7.3.5.0",
  "components": {
    "extend": {
      "requestHandlers": [
        {
          "modulePath": "Handlers/GetSerialNumberClientRequestHandlerExt"
        }
      ]
    }
  }
}
```

11. Open the extensions.json file under the POS.Extensions project. Update it with POSRequestHandlerExtension samples, so that POS during runtime will include this extension.

```
{
  "extensionPackages": [
    {
      "baseUrl": "SampleExtensions2"
    },
    {
      "baseUrl": " SampleExtensions"
    },
    {
      "baseUrl": "POSRequestHandlerExtension"
    }
  ]
}
```

#### NOTE

The extension.json file should always contain two extensions folder names, so be sure to keep the SampleExtensions folder name or your custom extension folder name. For production, don't use the sample extensions. You should add your own extension folders and remove all the samples.

12. Open the tsconfig.json file to comment out the extension package folders from the exclude list. POS will use this file to include or exclude the extension for compilation. By default, the list contains all the excluded extensions list. If you want to compile any extension part of the POS, then you need to add the extension folder name and comment the extension from the extension list, as shown below.

```
"exclude": [

  // "SampleExtensions",
  // "SampleExtensions2",
  // "POSRequestHandlerExtension"

],
```

13. Compile and rebuild the project.

# How to test your extension

1. Press F5 and deploy the POS to test your customization.
2. After POS launches, sign in to POS and add a serial item to a transaction.
3. Place a break point in the extension code. When you add the serial item you should be able to debug the extension code.

## **NOTE**

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# View POS extension package information

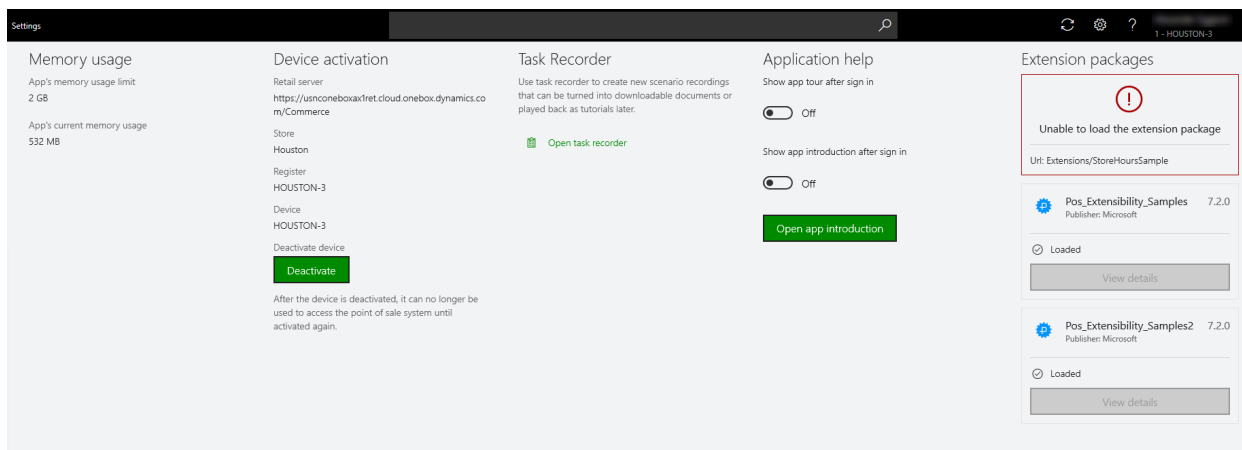

2/18/2021 • 2 minutes to read • [Edit Online](#)

In the **Settings** view in the point of sale (POS), the **Extension packages** section shows the list of POS extension packages that are included as part of the core POS. The tile for each package shows the status of that package. The package status indicates whether the extension was loaded, could not be loaded, or was skipped.

## Extension package status

This section describes what each package status means.

- **Loaded** – The extension package was successfully loaded.
- **Failed** – The extension package wasn't successfully loaded.
- **Skipped** – The package was skipped and wasn't loaded. In the extension manifest, you can specify that a package should be loaded for a specific locale, such as **en-fr**, but skipped for all the other locales.

### NOTE

Cloud POS will not display the extension version in the Customization.settings file under the **About** section on the **POS settings** page, it will only show the Microsoft app package version. Extension package versions can only be viewed from the **Extension details** section.

## Extension package details

If an issue occurs when an extension is loaded, or if there is a conflicting extension, you can use the details that are provided for each extension package to determine which extension file is causing the issue. In this way, you can troubleshoot the issue.

To view the details of an extension package, select **View details** on the tile for that package. The POS opens a new view, where you can see the details of all the individual extensions in the package. If any extensions weren't successfully loaded or were skipped, the details appear in the right pane.

The **Status** column shows the status of each extension in the package, the **Name** column shows the name of the extension type, and the **Path** column shows the path of the implementation file in the package. When you select a specific line item, the right pane also shows a description of the extension.

The information in this view is based on the manifest file that is included in the extension package. The POS extension loader loads all the extension packages and updates the status. The status information includes any

errors that have been logged.

**NOTE**

Dual display custom control and other extension details information related to dual display will not be shown in the extension details view.

**NOTE**

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Test recorder and Regression suite automation tool for Cloud POS

2/18/2021 • 21 minutes to read • [Edit Online](#)

This topic explains how to use the new test recorder tool in Cloud POS to record business scenarios for user acceptance testing (UAT) and user interface (UI) testing. It also explains how to automate test validation by using the Regression suite automation tool (RSAT). RSAT uses the Microsoft Azure DevOps test suite to download test cases. It then reports the results, together with the test execution status, back to Azure DevOps. The test cases can be manually created in Azure DevOps, or they can be synced from the Business process modeler (BPM) tool in Microsoft Dynamics Lifecycle Services (LCS) to Azure DevOps and then to RSAT.

This topic applies to Dynamics 365 Retail and Dynamics 365 Finance version 10.0.5 (October 2019) and later.

## NOTE

The test recorder is supported in Cloud POS only when the Google Chrome web browser is used. Support for other web browsers and device types will be added later.

## Test recorder

The test recorder in POS helps significantly reduce the time and cost of UAT. UAT is typically required before a Microsoft application update is applied, or before custom code and configurations are applied to your POS production environments.

The test recorder can record user actions in the client, and it provides exact fidelity for all controls and for all elements in the Document Object Model (DOM). In POS, the test recorder captures an event that has occurred and stores it, together with all relevant information about the corresponding user action, in real time. From this information, the test recorder can capture the type of user action (such as a button click, value entry, or navigation) and any data that is related to that user action (such as the value and type of input data, the view context, or the record context). However, password information isn't captured. During a recording session, the test recorder persists all the recorded information in memory. Then, at the end of the recording session, it generates an output file that includes enough detail so that RSAT can be used later to play back the actions just as the user performed them.

## IMPORTANT

The test recorder captures all the data that is entered during a recording session except POS user passwords. Don't record any personally identifiable information (PII), secrets, sensitive data, or user-specific data. All data that is entered during a recording session is stored in the Recording.xml file, and other users can see it in LCS and Azure DevOps, in the variables.xlsx and Recording.xml files, and during playback.

## Regression suite automation tool

RSAT lets functional power users run test cases in POS. It then updates the test execution results in Azure DevOps for reporting and investigation purposes.

RSAT provides options for investigating test failures. It also decouples the test parameters from test steps and stores the parameters in Microsoft Excel files. In that way, the values of test parameters can easily be edited.

# Prerequisites

- You must have a POS environment.
- Your test environment must be running binary update 10.0.5 or later.
- RSAT must have access to your test environment via a web browser.
- You must have Excel installed to generate and edit test parameters.
- You must have an Azure DevOps project to store and manage your test cases, test plans, and test case results.

# Enable test recording in the POS application

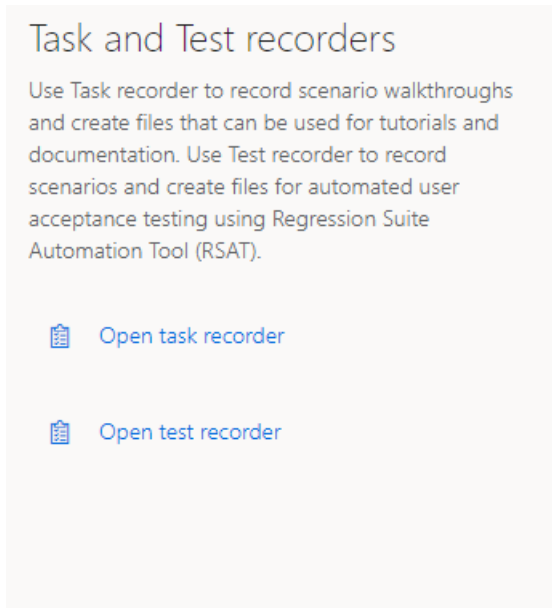

To turn on the test recording functionality in POS, follow these steps in Headquarters.

1. Go to **Retail and Commerce > Channel Setup > POS Setup > Registers**.
2. Select the register where the test recording functionality should be turned on.
3. On the **Register** tab, on the **General** FastTab, set the **Enable task and test recorder** option to **Yes**.
4. Select **Save**.
5. Go to **Retail and Commerce > Retail and Commerce IT > Distribution schedule**.
6. Select the **Registers (1090)** job, and then select **Run now**.

# Controlling the test recorder

## Open the test recorder

To open the test recorder, sign in to Cloud POS, and then, on the **Settings** page, in the **Task and Test recorders** section, select **Open test recorder**.

## Stop a recording session

To end a recording session, select **Stop**. Note that you can't restart a recording session after you end it. Therefore, make sure that the recording session is completed before you end it.

## Pause a recording session

To temporarily stop (pause) a recording session, select **Pause**. Steps that you perform after you select **Pause** aren't recorded.

### Continue a recording session

To resume a recording session after you've paused it, select **Recording**.

### Start and end a task

To help organize your procedures, you can group steps together into tasks. To specify the beginning and end of a set of grouped steps, use the **Start task** and **End task** buttons. Select **Start task** to add a "Start Task" step, and then perform the steps that should be included in the group. After you've finished performing the steps for the group, select **End task**.

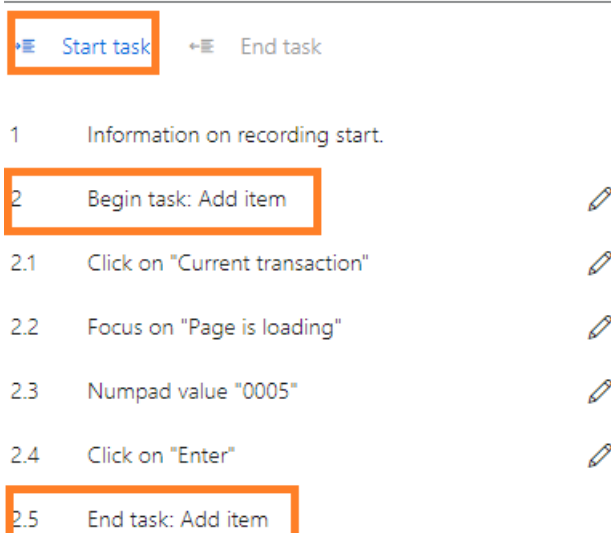

Tasks can be nested inside other tasks. In this way, you can better organize very long and complex business processes.

Enable validation mode

### Steps

### Add a new task

## New task

Name

Comment

### **Add an annotation**

An annotation is additional text that you add to a step in a recording. For example, you can use annotations to give the user more context or instructions. You can add an annotation to any step by selecting the **Edit** button (pencil symbol) to the right of the step.

Enable validation mode

## Steps

---

→ Start task   ← End task

- 1 Information on recording start.
- 2 Click on "Lines"

### Add text and notes

You can use the **Text** and **Notes** fields in the annotation dialog box to add text that should be associated with a step in a task guide.

- **Text** – Text that you enter in this field appears *above* the step text in the test steps.
- **Notes** – Text that you enter in this field appears *below* the step text.

### Change input values

You can change user input values that are entered during a recording session. For example, if you added product 0005 during the recording session, the product ID is stored by default in the Recording.xml file. If you want to specify a different product ID, you can change the value here. The value will be shown only if there is user input.

## Current step

Numpad value "0005"

Text

Numpad value "0005"

Notes

Value

0005

Save

Cancel

### Hide the test recorder pane

To hide and show the test recorder pane during a recording session, select the collapse button.

Enable validation mode

No

### Test recorder floating control

The test recorder floating control is useful when the test recorder pane is hidden during a recording session. The test recorder pane overrides non-error dialog boxes and/or part of the POS view. Therefore, you must sometimes hide the pane to add validation in the dialog boxes or select controls. If the test recorder pane is hidden, but you must still be able to access test recording functionality (for example, you must turn on validation mode, or pause or continue the recording session), you can use this floating control.

Test Recorder

The following sections describe the controls on the floating control.

#### **Move control**

The move control lets you move the floating control within the POS app.

#### **Validation mode**

When you turn on validation mode, the recording session is paused. To continue the recording session, you must turn off validation mode.

#### **Pause**

To temporarily stop (pause) the recording session and continue the operation, select the **Pause** button. Steps that you perform after you select **Pause** aren't recorded.

#### **Recording**

To resume the recording session after you've paused it, select **Recording**.

## Record a test case in POS

### **Create a recording**

#### **IMPORTANT**

Before creating the recording or test execution/playback, turn off the Show app tour and Show app introduction after sign in. To do this, go to the **CPOS Settings > Application help** section (applicable only if Dynamics 365 Commerce demo data is used). Turn this off in the demo data by running the following script in your channel database: Update [ax]. [SYSSERVICECONFIGURATIONSETTING] SET VALUE = '0' WHERE NAME = 'APPTOUR'.

Follow these steps to create a new recording by using the test recorder:

1. Launch Cloud POS.
2. Select the hamburger icon on the left pane and select **Settings**. Don't sign in to Cloud POS. The sign in step must be recorded as part of the test recording flow, so you need to launch the recorder before sign in.)
3. On the **Settings** page, in the **Task and Test recorders** section, select **Open test recorder**.

## Task and Test recorders

Use Task recorder to record scenario walkthroughs and create files that can be used for tutorials and documentation. Use Test recorder to record scenarios and create files for automated user acceptance testing using Regression Suite Automation Tool (RSAT).

 [Open task recorder](#)

 [Open test recorder](#)

4. Select **Create a new recording**.

## What would you like to do?

Create a new recording

Privacy statement: Any information that you enter into the application while you are recording will be captured and included in the recording file, Training document and BPM package. If you decide to share the recording file, training document or BPM package others may be able to see the information that was captured.

Cancel

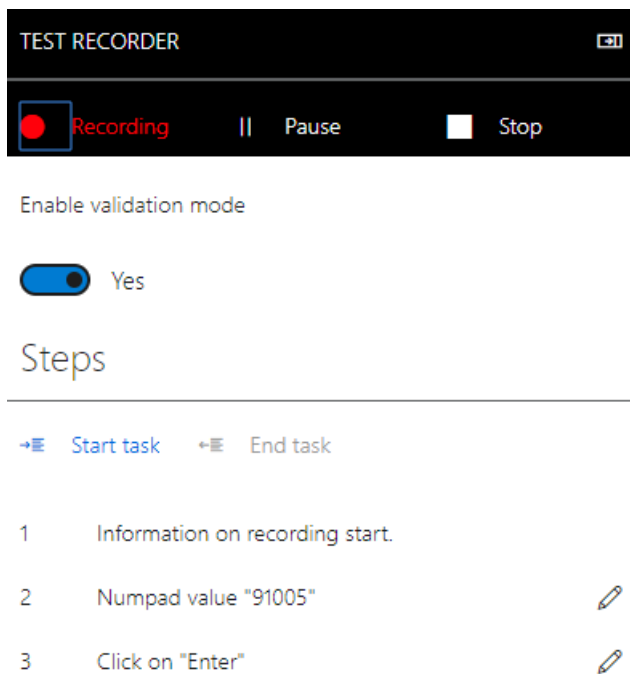

5. Enter a name and description for the recording, and then select **Start**.

The test recorder enters recording mode, and the recording session begins. The test recorder pane shows information and controls that are related to the recording session.

### NOTE

All test recording must begin from the Cloud POS sign in page. If the recording is started from the home page, any transaction or other page playback will fail and you will need to start the recording again from the sign in page.

6. Perform the needed actions in the POS user interface.

### Validation mode

When you use validation mode during a recording session, users can then validate values during test execution. For example, you can use the validation mode feature if you want to validate label text or an error message, or if you want to validate that the item price or tax is calculated correctly. To turn on validation mode during a recording session, use the **Enable validation mode** option.

1. Set the **Enable validation mode** option to **Yes**.
2. Select values or text in the POS to add a validation step. No validation is done for passwords, sensitive data, or fields where the test recorder can't get the field values. During test execution, the playback engine determines whether the value is same. The test case then either passes or fails, depending on the result of the validation.

#### NOTE

While validation mode is turned on, the test recorder will be in a paused state. It will just add validations steps, and POS won't respond to any user actions except the addition of validation steps. For example, in validation mode, you can't open a different POS view or use any POS functionality. To continue the recording session, you must turn off validation mode by setting the **Enable validation mode** option to **No**.

Enable validation mode

## Steps

→ Start task   ← End task

- 1 Information on recording start.
- 2 Numpad value "91005" 
- 3 Click on "Enter" 

3. To end the recording session, select **Stop**.

### Download options

After you end a recording session, you can download the recording by selecting **Save to this PC**.

## Value

Name

Sale transaction

Save to this PC

Privacy statement: Any information that you enter into the application while you are recording will be captured and included in the recording file, Training document and BPM package. If you decide to share the recording file, training document or BPM package others may be able to see the information that was captured.

The .axtr file is saved to the local file system. You must manually upload this file to LCS or Azure DevOps and then either delete it from the file system or secure it.

To upload to Azure DevOps directly:

1. Change the .axtr file extension to .zip.
2. Open the .zip package.
3. Inside the package there will be file with name Recording.xml. Upload the Recording.xml to the test case in Azure DevOps. Don't upload the entire .zip or .axtr package.

## Install RSAT

Download the Microsoft Windows Installer (MSI) package file for RSAT from [Regression Suite Automation Tool](#).

Double-click the MSI file to run it. After you install RSAT, you must install drivers for Selenium and the web browser.

#### NOTE

Before you run the test, you must set up Azure DevOps, and you must complete the required general settings and other required settings in RSAT. For detailed steps, see [Regression suite automation tool installation and configuration](#).

The following procedure describes the configuration that is required to run the POS test cases.

### Configure the POS settings

1. Open RSAT from your desktop.
2. Select the **Settings** button in the upper right to configure RSAT.
3. In the **Settings** dialog box, click the **Optional** tab and select the **Configure Retail POS** option to enable the Retail POS automation.
4. In the **Settings** dialog box, on the **Retail POS** tab, on the **Playback environment** tab, set the following fields:
  - **Cloud POS URL** – Enter the URL of the Cloud POS environment where you want to run the test.
  - **Commerce Scale Unit URL** – Enter the Commerce Scale Unit URL that should be used for device activation, if the device hasn't already been activated.

#### NOTE

The Cloud POS and Commerce Scale Unit URL can be obtained from Finance and Operations environment. Navigate to **Retail and Commerce > Channel setup > Channel profiles**. You can also obtain the URLs from the LCS environment page.

- **AAD user email** – Enter the email address of the Azure Active Directory (Azure AD) user that should be used for device activation. The Azure AD user must have permission to activate the device.
- **AAD password** – Enter the password of the Azure AD user that should be used for device activation.
- **Register number** – Enter the ID of the register number (channel) where the test should be run.
- **Device** – Enter the ID of the device where the test should be run.
- **Default wait time** – Enter the wait time, in seconds, before the test case fails if any element isn't found. During test execution, the playback engine keeps trying to find element until this default wait time has passed. It then fails the test case and notifies you that the element that was recorded wasn't found or loaded for playback.

Settings ×

General Optional Retail POS Preview Process

Playback environment POS login credentials

Cloud POS URL:

Commerce Scale Unit URL:

AAD user email:

AAD password:

Register Number:

Device:

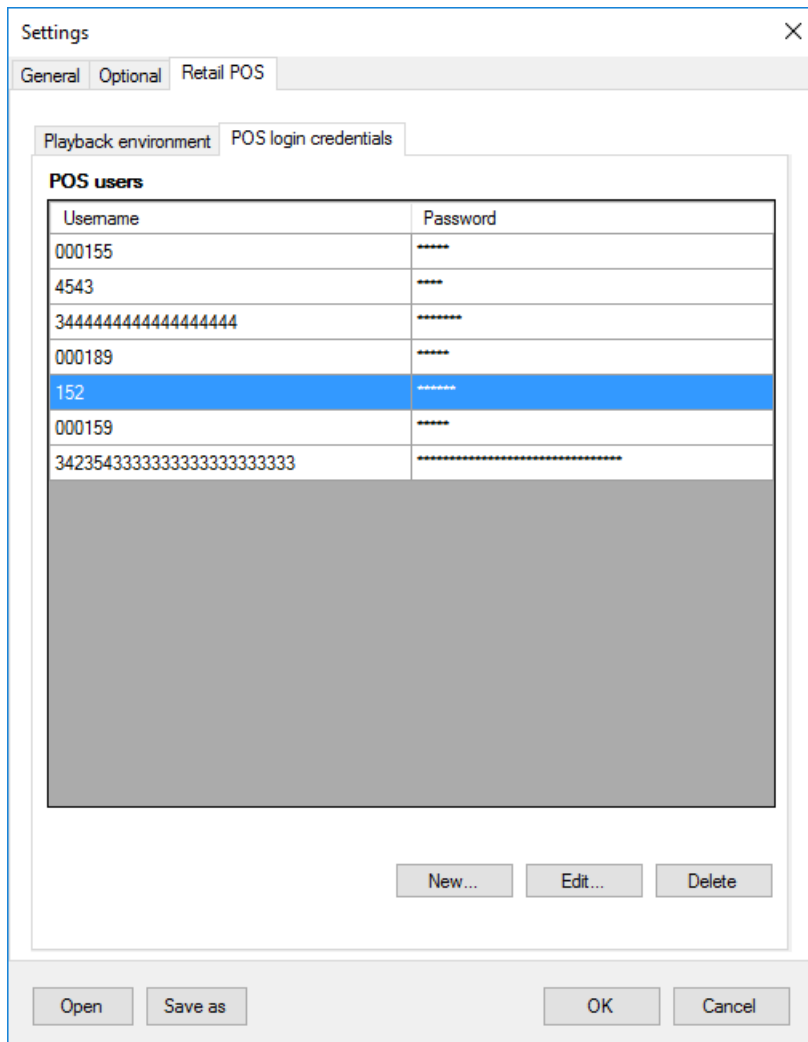

Default wait time (seconds):

Open Save as OK Cancel

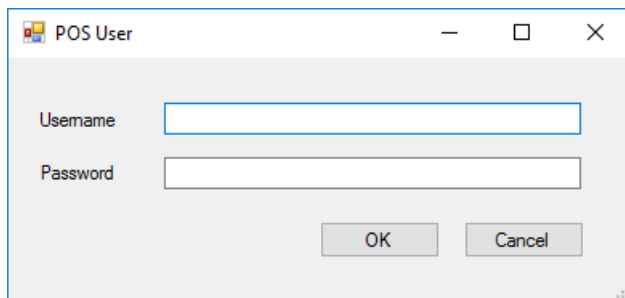

5. Select the **POS login credentials** tab.

During a recording session, the test recorder captures only the user name from the POS. It doesn't store any password. However, to run the test, you must have both the user name and the password that are used to sign in to POS. This tab captures the POS user name and password, so that the password information is securely stored outside the recording file. During test execution, the user ID is then mapped to the same user ID that is entered in RSAT, and the password is retrieved.

Therefore, on the **POS login credentials** tab, you must enter all the user name and password information that was used during the recording session, so that the password can be retrieved during test execution. Otherwise, test execution will fail, and you will be notified that sign-in details weren't found.

6. Select **New**.

7. In the **Username** field, enter the user name for sign in to POS.

8. In the **Password** field, enter the password for sign in to POS.

9. Repeat steps 6 through 8 to enter other user names and passwords.

10. To edit a set of POS sign-in credentials, select **Edit**.

11. To delete a set of POS sign-in credentials, select **Delete**.

## Run tests

This section explains how to load test cases from Azure DevOps, generate automation files, modify test parameters, run tests, investigate results, and save your work back to Azure DevOps.

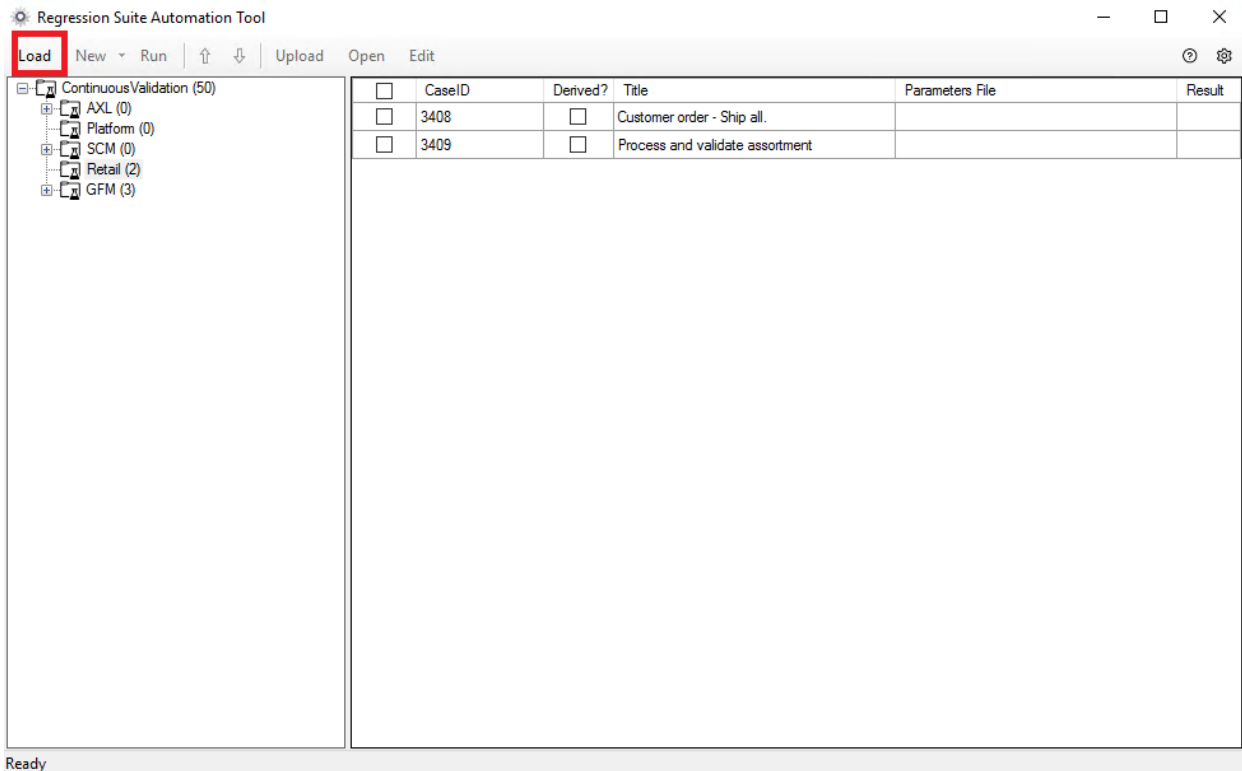

## NOTE

For detailed information about how to set up Azure DevOps and test cases, see [Regression suite automation tool installation and configuration](#). You must complete that setup before you start to run tests. Before test execution/playback, turn off the Show app tour and Show app introduction after sign in. Turn this off in the demo data by running the following script in your channel database: Update [ax].[SYSSERVICECONFIGURATIONSETTING] SET VALUE = '0' WHERE NAME = 'APPTOUR'.

## Load test cases and create parameter files

In RSAT, select **Load** to download test cases and test case automation files from Azure DevOps. All test cases that belong to the test plan that is specified in the **Settings** dialog box are downloaded.

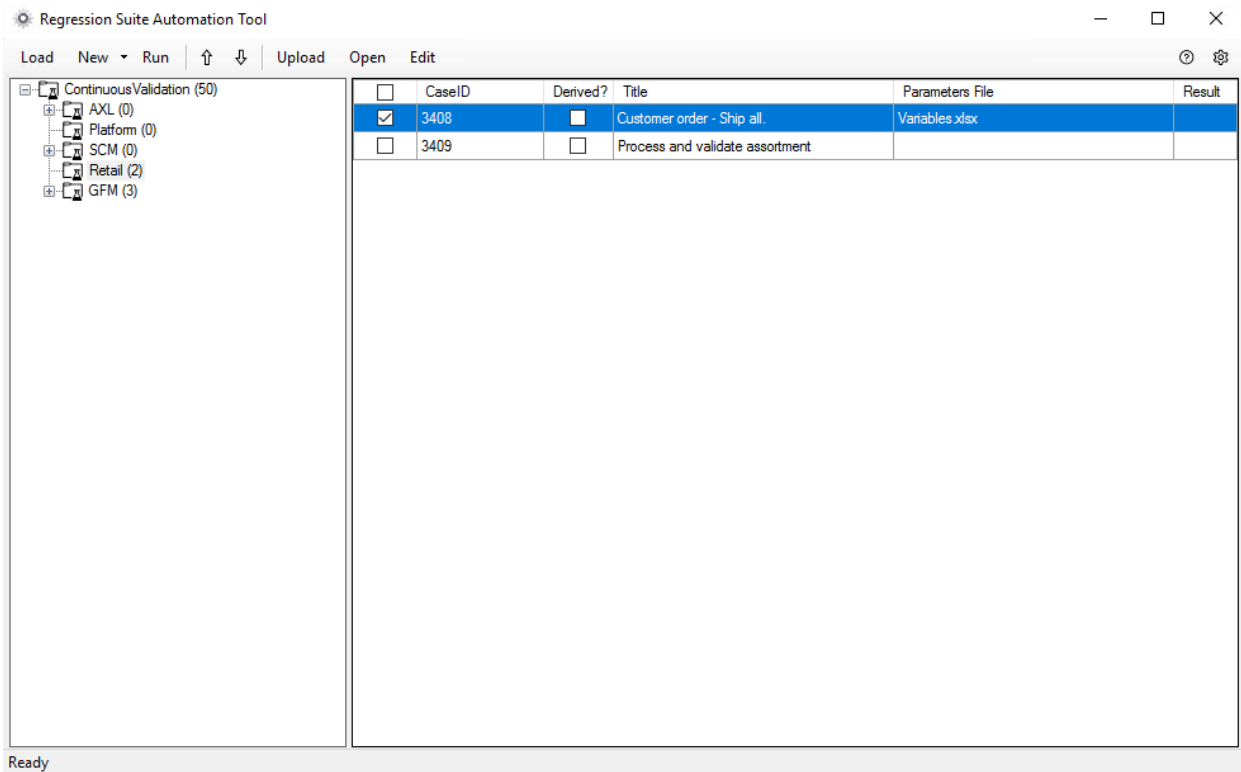

Test cases are organized by test suite under a common test plan. The test suites are the test suites that you created in your Azure DevOps project. By using RSAT, you can work with one test suite at a time. If RSAT can't load any test case, verify that your test plan was correctly created in Azure DevOps, and that it contains the required test suites and test cases.

If you're loading the test plan for the first time, the **Parameters File** column in the grid is blank, and you must generate test automation parameter files for your test cases.

To run the tests, generate the following test automation files:

- Test parameter files (Excel files that contain test case parameters)
- XML files that are required to run the tests

When you select **New**, test automation files are generated in your working directory. The Excel test parameter files appear in the **Parameters File** column in the grid.

For the test recording files, the **Generate Test Execution files only** option is unavailable. Because Cloud POS uses Selenium WebDriver directly to do the playback, no additional script file must be generated.

### Modify test parameters and validation values

This section explains how to modify Excel files by specifying input and validation parameters for your test run.

In RSAT, select one or more test cases to modify, and then select **Edit**. An Excel window is opened for each test case that you selected. Alternatively, you can open the Excel files directly from the working directory.

In addition to a **Summary** tab, the Excel file includes a **Variables** tab that has the details of all the variables that were generated. POS automatically generates variables for all the input values that are entered during a recording session. You don't have to generate the variables separately. Each variable has a unique variable ID that you can pass, in order, to different test cases in a single instance of test execution. All the variables on the **Variables** tab appear in the order that they were entered in during the recording session.

To pass variables or values between POS test cases, select the test cases in the RSAT tool and open the Variables.xlsx file by selecting the Excel icon in the tool. Copy the Variable ID (Column C) value and paste it in the Variable value field (Column D). For example, to pass the Receipt ID from **Test case 1 - variable.xlsx** to **Test case 2 - variable.xlsx**, copy the variable ID value from column C: c8cc0571-9a27-b3c5-0749-c26c3cca6afe. Paste the value in the Variable value column D in to the test case 2 - variable.xlsx file, in braces: `{{ c8cc0571-9a27-b3c5-0749-c26c3cca6afe}}`

#### Test case 1 – Variable.xlsx

A (DESCRIPTION)	B (VIEW NAME)	C (VARIABLE ID)	D (VARIABLE VALUE)
Receipt Id "HOU123R456"	ShowJournalView	c8cc0571-9a27-b3c5-0749-c26c3cca6afe	HOU123R456

#### Test case 2 – Variable.xlsx

A (DESCRIPTION)	B (VIEW NAME)	C (VARIABLE ID)	D (VARIABLE VALUE)
Receipt Id "HOU123R456"	ShowJournalView	80f23afa-5b76-5442-d16a-6cc9b8b245cb	{{c8cc0571-9a27-b3c5-0749-c26c3cca6afe}}

### Validate expected values

Validation of expected values is an important component of a test case. When you create your test cases, you can define validation parameters by using the test recorder in validation mode.

During the recording session, turn on validation mode. Then, while the test recorder is recording, select all the fields that must be validated. This action becomes a validation step that you can use with RSAT. The validation values will appear, in the order that they were entered in, on the **Variables** tab in the Excel file. You can then modify the values in the Excel file before test execution, and the new values will be used for data entry and validation during test execution.

	A	B	C	D
1	Description	View Name	Variable ID	Variable Value
2	In "Operator ID" set v	LoginView	68ff7367-0df0-37ab	
3	In "Password" set val	LoginView	c15c9013-e586-2ad	
4	Numpad value "9100"	CartView	262d3277-81db-ed19	9100
5	Numpad value "91005"	CartView	66af3a4a-4cce-87ac	91005
6	Numpad value "2001"	CartView	c4e5b0ab-4181-2a7	2001
7	Validation on "AMOU"	CartView	61bd5f98-d6ec-a25	\$141.31
8	Validation on "\$8.31"	CartView	de1e5cb8-eead-92	\$8.31
9				

### Run

In RSAT, select **Run** to run the selected test cases. You can run only test cases that automation files have been generated for. RSAT opens POS and runs the tests by using the data that is entered in Excel. After the test run, the results are updated in the **Result** column in RSAT, and also in Azure DevOps.

To change the order that test cases are run in, use the up arrow and down arrow buttons.

### Investigate results

After test cases have finished running, the pass or fail status appears in the **Result** column in RSAT. More details are available in Azure DevOps, and you can use them to investigate the results. From your Azure DevOps project page, go to **Test > Runs**.

All error messages are also available locally at

C:\Users\%YourUserName%\AppData\Roaming\regressionTool\errormsg<TestCaselD>.txt.

## System and metadata files

The following table shows the files that are generated during recording sessions, test execution, and playback.

FILE NAME	DESCRIPTION	FILE GENERATION FLOW	FILE SAVE FLOW
Recording.xml	This file contains all the steps that are required to play back a recording. It includes all user-specific values for each step in the recording.	The file is generated by the user when that user records a test case and uploads it to Azure DevOps so that it can be used by RSAT.	The file is saved to disk when the test case is loaded into RSAT.

FILE NAME	DESCRIPTION	FILE GENERATION FLOW	FILE SAVE FLOW
Variables.xml	This file contains the values for all the variables that are used in the recording file. It's used by the playback tool.	The file is generated when the user selects <b>New &gt; Generate Test Execution and Parameter files</b> in RSAT.	The file is saved when the user selects <b>New &gt; Generate Test Execution and Parameter files</b> .
Variables.xlsx	This file contains the values for all the variables that are used in the recording file. It can be modified by the user and is used by the playback tool.	The file is generated when the user selects <b>New &gt; Generate Test Execution and Parameter files</b> in RSAT.	The file is saved when the user selects <b>New &gt; Generate Test Execution and Parameter files</b> .
OutputLog.txt	This file contains a log of execution of the playback process. It includes a description of each step that was run. It might also include an exception. Depending on the exception, it might contain data that is available in the Recording.xml file.	The file is generated after the playback tool in RSAT has finished running, regardless of whether the test case was successfully played back.	The file is saved when a test case is played back.
Time.xml	This file contains the list of steps, the user-edited description of each step, and the amount of time that the execution of each step required.	The file is generated after the playback tool in RSAT has finished running, but only if the test case was successfully played back.	The file is saved when a test case is successfully played back.
Out.xml	This file contains the values for all the variables that are used in the recording file. For each variable, this file uses the updated value from the Variables.xlsx file. The playback tool uses this file to support test cases that depend on variables from other test cases.	The file is generated after the playback tool in RSAT has finished running, regardless of whether the test case was successfully played back.	The file is saved when a test case is played back.
In.xml	This file contains the values for all the variables that are used in the recording file of every test case that was run before the current test case. It uses the updated values from each Variables.xlsx file. The playback tool uses this file to support test cases that depend on variables from other test cases.	The file is generated before the playback tool in RSAT is run, when multiple test cases are run.	The file is saved when the previous test case has finished running and before a new test case is run.

You must manually delete these files and secure them as you require. All these files are stored in the RSAT working directory.

## Best practices

## Creating test cases by using the test recorder

- Before creating the recording or test execution/playback, turn off the Show app tour and Show app introduction after sign in. To do this, go to the **CPOS Settings > Application help** section (applicable only if Dynamics 365 Commerce demo data is used). Turn this off in the demo data by running the following script in your channel database: Update [ax].[SYSSERVICECONFIGURATIONSETTING] SET VALUE = '0' WHERE NAME = 'APPTOUR'.
- Disable Chrome extension - If possible, disable the Chrome extension in the Chrome browser that used to record and play back. The Chrome extension may change the DOM element xpath, which can result in test case failure because the element is not found during the execution of steps (xpath is different from the recording).
- Keep individual recordings short, and focus on a business task that is performed by one user, such as the creation a sale transaction. This approach makes it easier to maintain and reuse test cases.
- Don't record any scenario that includes secrets.
- Recording and playback must be done in the same screen layout and at the same resolution. If recording and playback are done in different layouts and at different resolutions, playback will fail.
- You can't change the POS user name during playback of a recording. When you make a recording, always use the same user name that will be used later for playback.
- Recording the POS activation flow is not supported.
- Keystroke recording performance may be slow, so type slowly while recording so that all the events are captured property.
- Peripheral emulation is currently not supported, use a keyboard wedge-based device.
- Don't hold a key down during recording, as this could record multiple key press events.
- Extension controls should follow the best practice of proper XPath and if possible have a unique ID for each HTML element.

## Troubleshooting guides

### Chrome driver

If playback fails by flickering (opens and closes browser multiple times without starting playback), this could be related to the Chrome driver version. Check the error log in the RSAT tool. If the error states that the Chrome driver version is not supported, then download the supported chromedriver.exe version mentioned in the error message and paste it in the ...\\Regression Suite Automation Tool\\Common\\External\\Selenium folder. You can download the Chrome driver from [ChromeDriver](#).

### Disable Chrome extension

If possible, disable the Chrome extension in the Chrome browser that used to record and play back. The Chrome extension may change the DOM element xpath, which can result in test case failure because the element is not found during the execution of steps (xpath is different from the recording).

### .NET standard error

If you get the following 'netstandard' error, install .NET Framework 4.8 runtime. You can download the .NET Runtime from [Download SDKs](#).

Unhandled Exception: System.IO.FileNotFoundException: Could not load file or assembly 'netstandard, Version=2.0.0.0, Culture=neutral, PublicKeyToken=cc7b13ffcd2ddd51' or one of its dependencies. The system cannot find the file specified at Microsoft.Dynamics.Commerce.PosPlayback.RecordingsRunner.Program.Main(String[] args).Multifactor authentication:

### Multifactor authentication

If multifactor authentication is enabled for the device activation user, then playback may fail. If possible, disable the multifactor authentication for the activation user temporarily. After the activation is completed, then re-

enable the multifactor authentication. Activation will be required only for the first-time playback. We recommend that you discuss this approach with your security experts before making this change.

**NOTE**

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Add custom fields to the point of sale (POS) Totals panel

2/18/2021 • 6 minutes to read • [Edit Online](#)

This topic explains how to add a new custom field to the **Totals** panel on the POS transaction screen by using the screen layout designer. This topic is applicable to Microsoft Dynamics 365 for Finance and Operations 7.3 and later, and to Microsoft Dynamics 365 Retail 7.3 and later.

Custom fields that you add for the **Totals** panel on the **Custom fields** page will appear in the designer. You can then select which custom fields should be in the left and right columns. The logic for the custom fields should be coded in the point of sale (POS) extensions.

## Scenario/business problem

You will add a custom field to the **Totals** panel on the POS transaction screen by using the screen layout designer. You will also code the business logic for the custom field in the POS extensions.

## Overview of the required steps

First, you must complete these steps to configure Headquarters.

1. On the **Language text** page, add the language text for the custom field.
2. On the **Custom fields** page, add the new custom field.
3. In the screen layout designer, add the new custom field to the **Totals** panel.
4. Run the **Registers (1090)** job.

You must then complete this step in the POS extension project.

- Add the business logic for the custom field.

## Configure Headquarters

1. Sign in to Commerce.
2. Go to **Retail and Commerce > Channel setup > POS setup > POS profiles > Language text**.
3. On the **POS** tab, select **Add** to add a new POS language text.

The text that appears in the **Totals** panel can be localized. Therefore, you can create multiple texts in different languages for the same text ID. Here is an example.

LANGUAGE ID	TEXT ID	TEXT
en-US	1	Sample
en-UK	1	Demo

4. On the Action Pane, select **Save** to save your changes.
5. Go to **Retail and Commerce > Channel setup > POS setup > POS profiles > Custom fields**.
6. On the Action Pane, select **New** to add a new custom field, and specify the following information:

- a. In the **Name** field, enter the name of the custom field.
- b. In the **Type** field, select **Totals area**.
- c. In the **Caption text ID** field, specify the text ID that you used in step 3.

Here is an example.

NAME	TYPE	CAPTION TEXT ID
Sample	Totals area	1

7. On the Action Pane, select **Save** to save your changes.
8. Go to **Retail and Commerce > Channel setup > POS setup > POS > Screen layouts**.
9. Select the **F3MGR** screen layout ID, and then, on the Action Pane, select **Designer**.

#### NOTE

You can select any existing layout or create a new layout. The **F3MGR** screen layout ID is available only if you're using demo data.

10. Select the **1440x960 – Full** layout size, and then select **Layout designer**.
11. If you're prompted to confirm that you want to open the application, select **Open**, and then follow the installation instructions.
12. After the designer is installed, you're asked for Azure Active Directory (Azure AD) credentials. Enter the information to start the designer.
13. In the designer, drag the **Totals panel** control from the left pane to the screen layout. If the layout already includes a **Totals** panel, the control appears dimmed in the left pane.
14. In the screen layout, right-click the **Totals panel**, and then select **Customize**.
15. In the **Customization - Totals panel** dialog box, the **SAMPLE** custom field should appear in the **Available fields** list. Move it to either the left column or the right column by using the arrow buttons.
16. To move the custom field up or down, use the **Up** and **Down** buttons.
17. Select **OK** to save your changes and close the **Customization - Totals panel** dialog box.
18. Select the **Close** button (X) in the upper-right corner to close the designer.
19. When you're prompted to save your changes, select **Yes**. If you select **No**, your changes aren't saved.
20. Go to **Retail and Commerce > Retail and Commerce IT > Distribution schedule**.
21. Select the **Registers (1090)** job, and then select **Run now**.

## Add business logic to the custom field

You can find similar sample code in the Retail software development kit (SDK), at ...  
 \RetailSDK\POS\Extensions\SampleExtensions\ViewExtensions\Cart\TipsCustomField.ts.

1. Start Microsoft Visual Studio 2015 in administrator mode.
2. Open the **ModernPOS** solution from ... \RetailSDK\POS.
3. Under the **POS.Extensions** project, create a folder that is named **CustomFieldExtensions**.

4. Under the **CustomFieldExtensions** folder, create a folder that is named **Cart**.
5. In the **Cart** folder, create a **.ts** (typescript) file that is named **SampleCustomField.ts**.
6. In the **SampleCustomField.ts** file, add the following **import** statement to import the relevant entities and context.

```
import { CartViewTotalsPanelCustomFieldBase } from "PosApi/Extend/Views/CartView";
import { ProxyEntities } from "PosApi/Entities";
```

7. Create a class that is named **SampleCustomField**, and extend it from the **CartViewTotalsPanelCustomFieldBase** class. In this way, the **computeValue** method from the base class will do any custom logic for the custom field.

```
export default class SampleCustomField extends CartViewTotalsPanelCustomFieldBase {
}
```

8. Inside the **SampleCustomField** class, implement the abstract **computeValue** method to set the logic for the custom field.

```
public computeValue(cart: ProxyEntities.Cart): string {
    // Let's show 10% of total amount in the custom field.
    if (isNaN(cart.TotalAmount) || cart.TotalAmount <= 0) {
        return "$0.00";
    }
    return "$" + (cart.TotalAmount * 0.1).toFixed(2).toString();
}
```

The overall class should look like this.

```
import { CartViewTotalsPanelCustomFieldBase } from "PosApi/Extend/Views/CartView";
import { ProxyEntities } from "PosApi/Entities";

export default class SampleCustomField extends CartViewTotalsPanelCustomFieldBase {
    public computeValue(cart: ProxyEntities.Cart): string {
        // Let's show 10% of total amount in the custom field.
        if (isNaN(cart.TotalAmount) || cart.TotalAmount <= 0) {
            return "$0.00";
        }
        return "$" + (cart.TotalAmount * 0.1).toFixed(2).toString();
    }
}
```

9. In the **CustomFieldExtensions** folder, create a **.json** file that is named **manifest.json**.
10. In the **manifest.json** file, paste the below code.

```

{
  "$schema": "../manifestSchema.json",
  "name": "Pos_Extensibility_Samples",
  "publisher": "Contoso",
  "version": "7.3.0",
  "minimumPosVersion": "7.3.0.0",
  "components": {
    "extend": {
      "views": {
        "CartView": {
          "totalsPanel": {
            "customFields": [
              {
                "fieldName": "Sample",
                "modulePath": "Cart/SampleCustomField"
              }
            ]
          }
        }
      }
    }
  }
}

```

In the manifest, note that the **fieldName** value in the **customFields** section should match the name of the custom field added in the Headquarters, the name you specified for the custom field in step 6 of the "Configure Headquarters" procedure. **modulePath** is the name of the implementation file, the implementation file name is the name of the file that you created in step 5 of "Add business logic to the custom field" procedure.

If you add multiple custom fields, you should add multiple implementation files and update the information under the customFields section.

For example, if you add two custom fields, **Sample1** and **Sample2**, you should have two implementation files that extend from the same base class, **CartViewTotalsPanelCustomFieldBase**.

In this case, the manifest should look like this.

```

"customFields": [
  {
    "fieldName": "Sample1",
    "modulePath": "Cart/SampleCustomField1"
  },
  {
    "fieldName": "Sample2",
    "modulePath": "Cart/SampleCustomField2"
  }
]

```

In this example, **SampleCustomField1** and **SampleCustomField2** are the names of the typescript files where you will do the business logic.

11. Open the **extensions.json** file under the **POS.Extensions** project, and update it with the **CustomFieldExtensions** samples, so that POS will load this extension at runtime.

```
{
  "extensionPackages": [
    {
      "baseUrl": "SampleExtensions2"
    },
    {
      "baseUrl": "CustomFieldExtensions"
    }
  ]
}
```

12. Open the `tsconfig.json` file, and add the extension folder name `CustomFieldExtensions` and comment out the extension folder in the `exclude` list. POS will use this file to include or exclude the extension. By default, the `exclude` list contains all the excluded extensions. To include an extension as part of the POS, you must add the extension folder name and comment out the extension in the `extension` list, as shown here.

```
"exclude": [
  "SampleExtensions",
  //"SampleExtensions2",
  //"CustomFieldExtensions"
],
```

13. Compile and rebuild the project.
14. Deploy the customized version of Retail Modern POS (MPOS) by selecting the **Local Machine** button. Make sure that the solution platform is x86. Alternatively, you can create a deployable package and install MPOS from it.

#### NOTE

Although MPOS is used in this topic, you can use either MPOS or Cloud POS.

## Validate the customization

1. Sign in to MPOS by using **000160** as the operator ID and **123** as the password.
2. On the welcome screen, select the **Current transaction** button.
3. Add any item to the transaction.

The custom field should appear in the **Totals** panel.

#### NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Show custom notifications in the POS

2/18/2021 • 8 minutes to read • [Edit Online](#)

This topic explains how to add custom notifications in the point of sale (POS). This topic applies to Microsoft Dynamics 365 for Finance and Operations, Enterprise edition 7.3 and Dynamics 365 for Retail 7.3, and later versions that have the latest binary fix.

You can extend the POS notification framework for these scenarios:

- Show a custom notification so that a store associate can either perform a required action, based on that notification, or perform custom logic.
- Periodically perform some operation in the background. However, this scenario isn't recommended, because it might cause performance issues.

## How custom notifications work

The notification framework in the POS periodically runs for the configured operation in Retail headquarters. (The frequency of the periodic runs can be configured.) It calls the notification service in the Commerce runtime (CRT) and Real time service in Retail headquarters. When the POS makes the call to the notification service in CRT, CRT runs the business logic and determines whether any notification must be sent to the POS for the operation. The operation ID is passed to the request as a parameter. The CRT notification service checks the operation ID and returns the notification details.

If the notification exists, CRT returns the response to the POS and reports that a notification is available. POS parses this notification and shows it in the user interface (UI). When the POS user selects the notification, the relevant operation in POS is run. Notifications are linked to an operation. Inside the operation handler, you write the business logic that must be performed.

When CRT returns the response for the notification, it returns the number of notifications, messages, and action parameters. The POS framework has built-in logic to parse the response to get the POS operation ID and call it when the user selects the notification.

Inside the operation, you can write custom logic to specify what should happen when the POS user selects the notification. Additional parameters can be sent from CRT to the POS by using the action property. Those parameters will then be available inside the operation request in the POS.

### Example

To notify the POS user to prepare orders for pickup, inside CRT, check whether there is an order for pickup. If there is, update the notification response with the relevant parameters. The POS parses the response and shows the notification. When the POS user selects the notification, the POS calls the operation by using the parameter from the notification. (The extension logic determines whether parameters should be sent.) Inside the operation, the POS reads all the pending orders for pickup and shows the orders in the UI so that the POS user can take further action.

## Required steps to make notifications available for a custom operation

1. In Retail headquarters, go to **Retail and Commerce > Channel Setup > POS Setup > POS > POS operations**, and create an operation.

#### NOTE

For custom operations, use an operation ID that is above 5000.

2. Extend the notification service. When the scheduler for the notification service runs, it calls the extension code for both CRT and the Real time transaction service to get the notification message.
3. Extend the POS. In the POS, write logic inside the POS operation to specify what should happen when the POS user selects the notification. For information about how to create a POS operation, see [Add POS operations to POS layouts by using Button grid designer](#).
4. In Retail headquarters, configure the notification service with the custom operation. Then, when the scheduler runs the notification service, it includes the custom operation. For information about how to configure notifications in the POS, see [Add POS operations to POS layouts by using Button grid designer](#).

When the POS user selects the notification, the framework calls the correct operation, based on the response that is returned from CRT. The notification service runs for all the notifications that are configured in Retail headquarters, and it returns the response that includes the operation ID and notification details. Therefore, the POS will have the context of the operation ID, and the framework will use this context to call the operation implementation.

#### NOTE

The notification scheduler checks both CRT and Retail headquarters for new notifications. Depending on the scenario, you can extend the Real time transaction service in Retail headquarters or only in CRT. In scenarios where real-time processing is required for notifications, extend the Real-time transaction service method in Retail headquarters. If real-time processing isn't required, extend only CRT.

## Extend the notification service in CRT

To extend the notification service in CRT, override `GetNotificationsExtensionServiceRequest`, and return `GetNotificationsExtensionServiceResponse`.

The Retail software development kit (SDK) includes a sample that shows how to extend the notification service (`RetailSDK\SampleExtensions\CommerceRuntime\Extensions.NotificationSample`).

- `GetNotificationsExtensionServiceRequest` – This class contains the operation ID, staff, and channel. Based on the configuration of Retail headquarters, the POS runs the notification scheduler for each configured operation.
- `GetNotificationsExtensionServiceResponse` – In the response, return the notification detail entity (`NotificationDetailCollection`), update `GetNotificationsExtensionServiceResponse`, and return all the notifications. Because the response is a collection, multiple notifications can be returned.

## Properties of the notification detail entity

The notification detail entity has the following properties.

PROPERTY	DATA TYPE	DESCRIPTION
ActionProperty	string	A custom property to send to the POS operation.
DisplayText	string	The display text of the notification.

PROPERTY	DATA TYPE	DESCRIPTION
IsLiveContentOnly	bool	A value that indicates whether the notification is only for live content.
IsNew	bool	A value that indicates whether the notification is new.
IsSuccess	bool	A value that indicates whether the notification was successful.
ItemCount	long	The number of notifications.
LastUpdatedDateTime	DateTimeOffset	The date/time when the item in the action property was last updated.
LastUpdatedDateTimeStr	string	The date/time when the item in the action property was last updated, in string format.

## Detailed steps

1. Open `Runtime.Extensions.NotificationSample.proj` from the Retail SDK (`RetailSDK\SampleExtensions\CommerceRuntime\Extensions.NotificationSample`).
2. Rename the project according to the standard naming convention.
3. Inside the project, there is a class file that is named `NotificationExtensionService.cs`. Open this file.
4. The `GetNotificationsExtensionServiceRequest` class is overridden to add a custom notification. Override `GetNotificationsExtensionServiceRequest`, and return `GetNotificationsExtensionServiceResponse`.
5. Either create a new class and override `GetNotificationsExtensionServiceRequest`, or use the sample template.
6. In the `NotificationExtensionService` class, there is a method that is named `Process`. The code inside that method checks the operation ID and then, based on the operation ID, creates a notification details object and adds any notifications. Check whether the operation ID is custom operation ID, and then write logic to check whether there are any notifications. If there are, create a notification object that contains the details, and return it together with the response. The POS will then parse the response and show the notification. The following code example is based on the template.

### NOTE

Remove the sample implementation inside the process method. Keep only the custom logic.

```

namespace Contoso
{
    namespace Commerce.Runtime.NotificationSample
    {
        using System;
        using Microsoft.Dynamics.Commerce.Runtime;
        using Microsoft.Dynamics.Commerce.Runtime.DataModel;
        using Microsoft.Dynamics.Commerce.Runtime.Services.Messages;
        /// <summary>
        /// Service class responsible executing the service requests.
        /// </summary>
        public class NotificationExtensionService :
        SingleRequestHandler<GetNotificationsExtensionServiceRequest,
        GetNotificationsExtensionServiceResponse>
        {
            /// <summary>
            /// The handler for the <c>GetNotificationsExtensionServiceRequest</c> request.
            /// </summary>
            /// <param name="request">The request with the operation.</param>
            /// <returns>The notification details for the operation.</returns>
            protected override GetNotificationsExtensionServiceResponse
            Process(GetNotificationsExtensionServiceRequest request)
            {
                ThrowIf.Null(request, "request");
                NotificationDetailCollection details = new NotificationDetailCollection();
                DateTimeOffset lastNotificationDateTime = DateTimeOffset.Now;
                string myOperationId = "5000";
                // do the actual work here
                if ((request.SubscribedOperation).ToString() == myOperationId)
                {
                    NotificationDetail detail = new NotificationDetail()
                    {
                        // Text which will display for the notification detail in the POS notification
                        center
                        DisplayText = "Custom notification",
                        // Number of notifications found
                        ItemCount = 1,
                        // Timestamp of creation of latest notification item (Used to determine whether
                        notification is new)
                        LastUpdatedDateTime = lastNotificationDateTime,
                        // Boolean value representing whether the attempt to get notifications for the
                        given operation was successful
                        IsSuccess = true,
                        // If you would like POS to navigate to a specific action property for the given
                        operation
                        // when the notification tile is selected, define the action property as well.
                        ActionProperty = "1"
                    };
                    details.Add(detail);
                }
                var serviceResponse = new GetNotificationsExtensionServiceResponse(details);
                return serviceResponse;
            }
        }
    }
}

```

7. After you've completed your changes, build the project, and drop the output library into `\RetailServer\webroot\bin\Ext`.
8. Register the output library in the `CommerceRuntime.Ext.config` file.
9. In the POS, create a new operation that has the same operation ID that is used in the CRT extension. In this example, the operation ID is **5000**. You can use any operation ID that is above 5000.
10. When the POS user selects the notification tile, the POS framework calls the operation handler for the

operation ID that is used. Inside the handler, add the required logic to specify what should happen when the POS user selects the notification. For information about how to create a POS operation request, response, and handler, see [Show order notifications in the point of sale \(POS\)](#).

#### **NOTE**

The action property in the Notification detail entity will be sent to the POS operation request. Use that action property to pass any custom information from the notification service to the POS.

11. Configure the notification scheduler according to the instructions in [Show order notifications in the point of sale \(POS\)](#).

## Validate the customization

1. Open the extended Cloud POS or Modern POS application.

The POS triggers the notification service, based on your notification scheduler configuration.

2. Debug the CRT code by attaching the CRT project to w3wp.exe. The breakpoint should be hit whenever the notification service is called from the POS.
3. When the notification is received in the POS, select it. The notification should call the POS operation handler and run the custom logic that is written inside it.

#### **NOTE**

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Sign MPOS appx with a code signing certificate

2/18/2021 • 6 minutes to read • [Edit Online](#)

To install Modern POS (MPOS) you must sign the MPOS app with a code signing certificate from a trusted provider and install the same certificate on all the machines where MPOS is installed under the trusted root folder for the current user.

To sign the MPOS app with a certificate, use one of these options in the **Retail SDK\Build tool\Customization.settings** file:

- Add the Secure file task part of Azure DevOps build steps and upload the certificate to secure the file task. Use the secure file task output path variable as a parameter in the Customization.settings file.

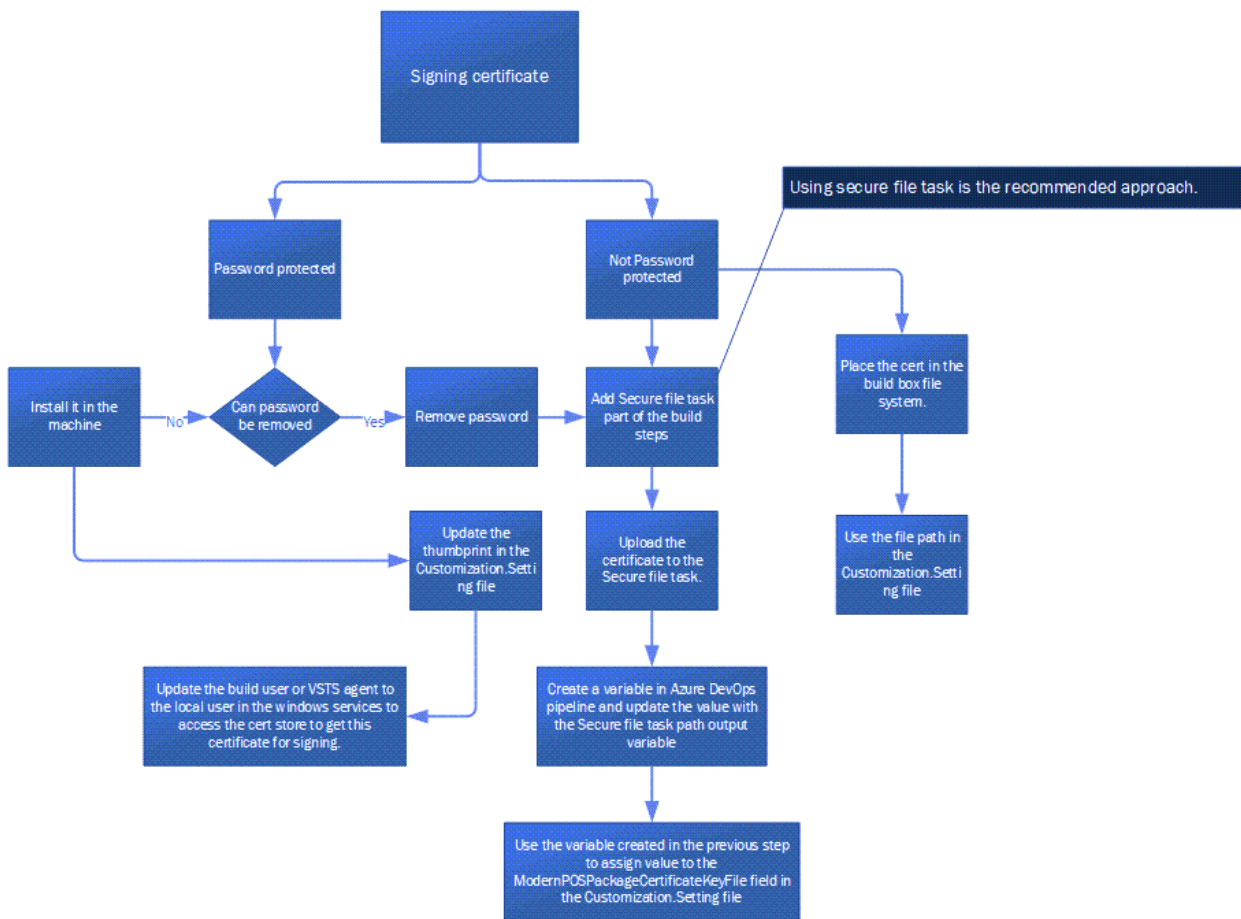

## NOTE

The Secure File task doesn't support a password protected certificate. You must remove the password before uploading this task. Because the certificate is uploaded to the secure file system task in Azure, you can remove the password only for this step. However, you should discuss removing the password with your security experts to determine if this is the correct action for your project. Don't remove the certificate password for other scenarios.

- Use a certificate that is in the file system. To do this, download or generate a certificate and place it in the file system where the build is running. The Microsoft-hosted agent or build user should have access to this path and file.
- Use thumbprint to look up in the certificate in the store and sign in with that certificate.

## Use a Secure File task for Universal Windows Platform app signing

Using a Secure File task is the recommended approach for Universal Windows Platform (UWP) app signing. For more information about package signing, see [Configure package signing](#). This process is shown in the following image.

#### NOTE

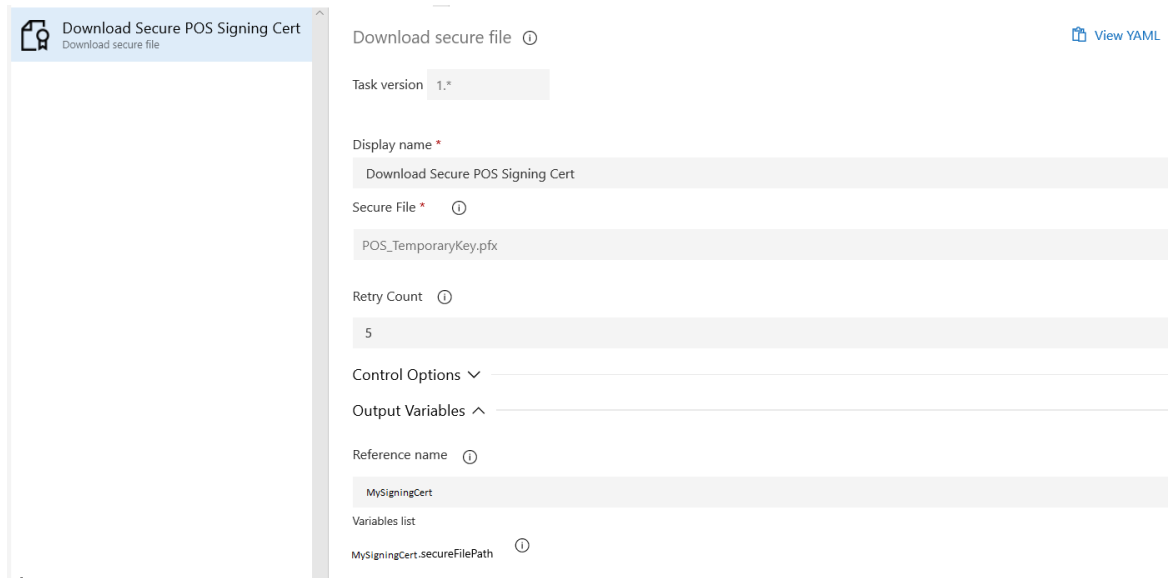

Currently the OOB packaging supports signing only the appx file, the different self-service installers like MPOIS, RSSU, and HWS are not signed by this process. You need to manually sign it using SignTool or other signing tools. The certificate used for signing the appx file must be installed in the machine where Modern POS is installed.

## Steps to configure the certificate for signing

### Certificate in the file system/secure location

Download the [DownloadFile task](#) and add it as the first step in the build process. The advantage of using the Secure File task is that the file is encrypted and placed in the disk during build no matter if the build pipeline succeeds, fails, or is canceled. The file is deleted from the download location after the build process is completed.

1. Download and add the Secure File task as the first step in the Azure DevOps build pipeline. You can download the Secure File task from [DownloadFile](#).
2. Upload the certificate to the Secure File task and set the Reference name under Output Variables, as shown in the following image.

3. Create a new variable in the Azure DevOps pipeline by clicking **New Variable** under the **Variables** tab.
4. Provide a name for the variable in the value field `$(MySigningCert.secureFilePath)`, for example, **CertFile**.
5. Save the variable.
6. Open the `Customization.settings` file from `RetailSDK\BuildTools` and update the `ModernPOSPackageCertificateKeyFile` with the variable name created in the Azure DevOps pipeline (step 3). For example:

```
<ModernPOSPackageCertificateKeyFile Condition="'$(ModernPOSPackageCertificateKeyFile)'
== ''">$(CertFile)</ModernPOSPackageCertificateKeyFile>
```

## Download or generate a certificate to sign the MPOS app

If a downloaded or generated certificate is used to sign the MPOS app, then the update the `ModernPOSPackageCertificateKeyFile` node in the `BuildTools\Customization.settings` file to point to the pfx file location (`$(SdkReferencesPath)\appxsignkey.pfx`). For example:

```
<ModernPOSPackageCertificateKeyFile Condition="'$(ModernPOSPackageCertificateKeyFile)'
== ''">$(SdkReferencesPath)\appxsignkey.pfx</ModernPOSPackageCertificateKeyFile>
```

In this case, the certificate file name is `appxsignkey.pfx`, located in the `Retail SDK\Reference` folder.

## Use thumbprint to sign the MPOS app

If you use thumbprint to sign the MPOS app, then install the certificate locally. Update the thumbprint value in the `ModernPOSPackageCertificateThumbprint` node in the `BuildTools\Customization.settings` file.

This option will work if the build user is a local user. However if you are using the Azure DevOps agents to generate the build, then the agent may not have permission to access the cert store to use the certificate for signing or the build machine will not have the certificate installed. In this case, the workaround is to change the build user to local user and install the certificate in the box. However, this option will not work if you don't have admin access to the box.

## NOTE

If the .pfx file or Secure File task option is used to sign the app, then leave the **ModernPOSPackageCertificateThumbprint** node in **Customization.settings** empty. If the thumbprint option is used, then leave **ModernPOSPackageCertificateKeyFile** empty. If both the values are updated, then the build will fail.

## Certification renewal

### Renew a certificate from trusted CA

Contact your certifying authority (CA) for the certificate renewal process. For a trusted certificate, no action is required on the MPOS side.

### Renew a self-signed certificate

Don't use the sample certificate available in the Retail SDK for production. It can be used only for development purposes. The sample Contoso certificate can't be renewed and the sample certificate included in Retail SDK version 10.0.16 or earlier will expire on December 31, 2020. If this certificate, or a self-signed certificate, has been used to sign a customized Modern POS, there is a strong possibility that Modern POS will not function properly after this date.

### Impact

If the above is true for you, the issue you will be encountering is that the installer will not be able to run after December 31, 2020. Depending on the corporate IT policies used, Modern POS may not be able to function. It is critical that you test this by changing the date temporarily to a future date, to determine the impact to your organization.

### Steps to determine the issue

1. Use Windows settings to change the computer clock to a date and time in the year 2021.
2. Verify that Modern POS can be opened, sign in can occur, and a transaction can be completed.
3. Verify that Modern POS Self-service installer is able to be run, and if so, that installation will complete successfully.
4. Return the Windows clock settings to the correct date and time.

If you can complete all of these steps without issues, then you will be able to operate on the current certificate past December 31, 2020.

### Steps going forward

It is highly recommended that you renew the previously used certificate. We strongly recommend that you obtain a new certificate. To do this, you must perform one of the following actions:

- **Preferred** - Obtain a code signing certificate from a trusted certificate authority.
- **Preferred** - Generate a self-signed code signing certificate to use. This is typically used when within a domain.
- **Available as a temporary Solution** - Use the renewed Contoso code signing certificate. This is typically used for testing purposes, so it's not recommended that it be deployed in production.

Next, generate a new customized Modern POS package that is signed using this certificate obtained from one of the actions above. Depending on the certificate, one of the following steps must be followed:

- If using a new, trusted certificate (or a new, self-signed certificate), you will be required to install a new certificate on every device. After that, you need to take the newly created Modern POS Package (installer), uninstall the existing application, and then reinstall the new Modern POS package. You will need to perform a device activation of Modern POS on every device.

- If using the renewed Contoso certificate, you will be required to install the new certificate on every device and install the Modern POS Package (installer). You are not required to uninstall, however you must reinstall on the device. Note that device activation of Modern POS will not be required. This option is a temporary solution. Only use this option to avoid reactivation and resolve the issue before obtaining a new trusted certificate.

**NOTE**

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Extend POS views to add custom columns and app bar buttons

2/18/2021 • 8 minutes to read • [Edit Online](#)

This topic explains how you can extend existing point of sale (POS) views. To extend the **Transaction** screen and **Welcome** screen, you can use the screen layout designer. To extend all other POS views, such as the **Customer Add/Edit** screen, you use the Retail software development kit (SDK). This topic focuses on the extension of existing POS views via the Retail SDK.

POS views support the following extension points and patterns:

- **Custom app bar buttons** – Add custom buttons to the app bar on selected pages.
- **Custom column sets** – Replace the grid columns with custom columns on selected pages.
- **Custom controls** – Add new controls to selected pages.

## POS views that currently support extensions

The following table shows the POS views that currently support extensions. It also indicates the types of extension points that each POS view supports.

### NOTE

The upcoming releases and hotfix will add support for more extension points in other views.

POS VIEW (RELEASE)	CUSTOM CONTROLS ARE SUPPORTED	CUSTOM COLUMNS ARE SUPPORTED	CUSTOM APP BAR BUTTONS ARE SUPPORTED
Cart view (Screen layout based)	Yes	Yes	No
CustomerAddEditView	Yes	No	Yes
CustomerDetailsView	Yes	No	Yes
SearchView	No	Yes	Yes
InventoryLookupView	No	Yes	Yes
ShowJournalView	No	Yes	Yes
SimpleProductDetailsView	Yes	No	Yes
AddressAddEditView	Yes	No	Yes
PaymentView	No	No	Yes
PriceCheckView	Yes	No	Yes

POS VIEW (RELEASE)	CUSTOM CONTROLS ARE SUPPORTED	CUSTOM COLUMNS ARE SUPPORTED	CUSTOM APP BAR BUTTONS ARE SUPPORTED
PriceCheckViewPhone	No	No	Yes
SearchOrdersView	No	Yes	No
SearchPickingAndReceivingView	No	Yes	Yes
CustomerOrderHistoryView	No	Yes	No
SearchStockCountView	No	Yes	No
StockCountDetailsView	No	Yes	Yes
ResumeCartView	No	Yes	Yes
InventoryLookupMatrixView	No	No	Yes

InventoryDocumentShippingAndReceivingView (10.0.13)	No	No	Yes
InventoryDocumentListView	No	Yes (10.0.15)	Yes (10.0.13)

#### NOTE

The table shown above is updated based on the latest released version and hotfix. In earlier versions, some of these extension points will not be available.

#### NOTE

In Show journal (lines grid) and Return transaction view custom columns are supported using the row sub fields. These sub fields will be displayed as rows instead of columns, like the info code messages or serial number or discounts values.

Filter extensions are also supported in **Show journal view** and **Search order views** to add custom filters. **Search order views** also supports setting default parameters for search in the user interface (UI) using extension. For example, if you want to add default store search parameter you can do that by using extension and showing that in the UI.

## Add a custom column and an app bar button

1. Start Microsoft Visual Studio 2015 as an administrator.
2. Open the **ModernPOS** solution from ...\**RetailSDK\POS**.
3. In the **POS.Extensions** project, create a folder that is named **SearchExtension**.
4. In the **SearchExtension** folder, create a folder that is named **ViewExtensions**.
5. In the **ViewExtensions** folder, create a folder that is named **Search**.
6. In the **Search** folder, create a Typescript file that is named **CustomCustomerSearchColumns.ts**.
7. In the **CustomCustomerSearchColumns.ts** file, add the following **import** statements to import the relevant entities and context.

```
import { ICustomerSearchColumn } from "PosApi/Extend/Views/SearchView";  
import { ICustomColumnsContext } from "PosApi/Extend/Views/CustomListColumns";  
import { ProxyEntities } from "PosApi/Entities";
```

8. Add the existing column and the custom column to the file.

```

export default (context: ICustomColumnsContext): ICustomerSearchColumn[] => {
  return [
    {
      title: context.resources.getString("string_2"),
      computeValue: (row: ProxyEntities.GlobalCustomer): string => { return row.AccountNumber;
    },
    ratio: 15,
    collapseOrder: 5,
    minWidth: 120
  }, {
    title: context.resources.getString("string_3"),
    computeValue: (row: ProxyEntities.GlobalCustomer): string => { return row.FullName; },
    ratio: 20,
    collapseOrder: 4,
    minWidth: 200
  }, {
    title: context.resources.getString("string_4"),
    computeValue: (row: ProxyEntities.GlobalCustomer): string => { return row.FullAddress; },
    ratio: 25,
    collapseOrder: 1,
    minWidth: 200
  }, {
    title: context.resources.getString("string_5"),
    computeValue: (row: ProxyEntities.GlobalCustomer): string => { return row.Email; },
    ratio: 20,
    collapseOrder: 2,
    minWidth: 200
  }, {
    title: context.resources.getString("string_7"),
    computeValue: (row: ProxyEntities.GlobalCustomer): string => { return row.Phone; },
    ratio: 20,
    collapseOrder: 3,
    minWidth: 120
  }
  ];
};

```

9. You will now add the resource file for localization of the column name. In the **SearchExtension** folder, create a folder that is named **Resources**.
10. In the **Resources** folder, create a folder that is named **Strings**.
11. In the **Strings** folder, create a folder that is named **en-US**.
12. In the **en-us** folder, create a file that is named **resources.resjson**.
13. In the **resources.resjson** file, add the following code.

```

{
  //===== Sample View extensions strings. =====
  "string_0" : "Quick compare products",
  "_string_0.comment" : "Product search page app bar command label.",
  "string_1" : "View customer summary",
  "_string_1.comment" : "Customer search page app bar command label.",
  //===== Column names. =====
  "string_2" : "ACCOUNT NUMBER_CUSTOMIZED",
  "_string_2.comment" : "Customer search column name.",
  "string_3" : "NAME",
  "_string_3.comment" : "Customer search column name.",
  "string_4" : "ADDRESS",
  "_string_4.comment" : "Customer search column name.",
  "string_5" : "CONTACT EMAIL",
  "_string_5.comment" : "Customer search column name.",
  "string_7" : "PHONE NUMBER",
  "_string_7.comment" : "Customer search column name."
}

```

14. In the **SearchExtension** folder, create a folder that is named **DialogSample**.
15. In the **DialogSample** folder, create a TypeScript file that is named **MessageDialog.ts**.
16. In the **MessageDialog.ts** file, add the following **import** statements to import the relevant entities and context.

```

import { ShowMessageDialogClientRequest, ShowMessageDialogClientResponse, IMessageDialogOptions }
from "PosApi/Consume/Dialogs";
import { IExtensionContext } from "PosApi/Framework/ExtensionContext";
import { ClientEntities } from "PosApi/Entities";

```

17. Create a class that is named **MessageDialog**.

```

export default class MessageDialog {}

```

18. In the **MessageDialog** class, add the following **show** method.

```

public static show(context: IExtensionContext, message: string): Promise<void> {
    let promise: Promise<void> = new Promise<void>((resolve: () => void, reject: (reason?: any) =>
void) =>
    {
        let messageDialogOptions: IMessageDialogOptions = {
            title: "Extension Message Dialog",
            message: message,
            showCloseX: true, // this property will return "Close" as result when "X" is clicked to
close dialog.
            button1: {
                id: "Button1Close",
                label: "OK",
                result: "OKResult"
            },
            button2: {
                id: "Button2Cancel",
                label: "Cancel",
                result: "CancelResult"
            }
        };
        let dialogRequest: ShowMessageDialogClientRequest<ShowMessageDialogClientResponse> =
new ShowMessageDialogClientRequest<ShowMessageDialogClientResponse>
(messageDialogOptions);
        context.runtime.executeAsync(dialogRequest).then((
            result: ClientEntities.ICancelableDataResult<ShowMessageDialogClientResponse>) => {
            if (!result.canceled) {
                context.logger.logInformational("MessageDialog result: " +
result.data.result.dialogResult);
                resolve();
            }
        }).catch((reason: any) => {
            context.logger.logError(JSON.stringify(reason));
            reject(reason);
        });
    });
    return promise;
}

```

19. You will now add a custom app bar button in the search view to open a dialog box that contains details about the selected customer. In the **ViewExtensions** folder, create a Typescript file that is named **ViewCustomerSummaryCommand.ts**.
20. In the **ViewCustomerSummaryCommand.ts** file, add the following **import** statements to import the relevant entities and context.

```

import { ProxyEntities } from "PosApi/Entities";
import { ArrayExtensions, ObjectExtensions } from "PosApi/TypeExtensions";
import { IExtensionCommandContext } from "PosApi/Extend/Views/AppBarCommands";
import * as SearchView from "PosApi/Extend/Views/SearchView";
import MessageDialog from "../../Controls/DialogSample/MessageDialog";

```

21. Create a class that is named **ViewCustomerSummaryCommand**, and extend it from **CustomerSearchExtensionCommandBase**.

```

export default class ViewCustomerSummaryCommand extends SearchView.CustomerSearchExtensionCommandBase
{}

```

22. In the **ViewCustomerSummaryCommand** class, declare a private variable to capture the results when searching for the selected customer.

```
private _customerSearchResults: ProxyEntities.GlobalCustomer[];
```

23. Add the class **constructor** method to initialize and clear the search handler.

```
constructor(context:
IExtensionCommandContext<SearchView.ICustomerSearchToExtensionCommandMessageTypeMap>) {
    super(context);
    this.id = "viewCustomerSummaryCommand";
    this.label = context.resources.getString("string_1");
    this.extraClass = "iconLightningBolt";
    this._customerSearchResults = [];
    this.searchResultsSelectedHandler = (data: SearchView.CustomerSearchSearchResultSelectedData):
void => {
    this._customerSearchResults = data.customers;
    this.canExecute = true;
};
this.searchResultSelectionClearedHandler = (): void => {
    this._customerSearchResults = [];
    this.canExecute = false;
};
}
```

24. Add the **init** method to initialize the **visible** property.

```
protected init(state: SearchView.ICustomerSearchExtensionCommandState): void {
    this.isVisible = true;
}
```

25. Add the **execute** method to handle the app button click handler. The **execute** method reads the data for the selected customer from the handler and shows it in a simple dialog box.

```
protected execute(): void {
    let customer: ProxyEntities.GlobalCustomer =
ArrayExtensions.firstOrUndefined(this._customerSearchResults);
    if (!ObjectExtensions.isNullOrUndefined(customer)) {
        let message: string = "Customer Account: " + (customer.AccountNumber || "") + " | ";
        message += "Name: " + customer.FullName + " | ";
        message += "Phone Number: " + customer.Phone + " | ";
        message += "Email Address: " + customer.Email;
        MessageDialog.show(this.context, message);
    }
}
```

The whole code sample should look like this.

```

import { ProxyEntities } from "PosApi/Entities";
import { ArrayExtensions, ObjectExtensions } from "PosApi/TypeExtensions";
import { IExtensionCommandContext } from "PosApi/Extend/Views/AppBarCommands";
import * as SearchView from "PosApi/Extend/Views/SearchView";
import MessageDialog from "../../DialogSample/MessageDialog";
export default class ViewCustomerSummaryCommand extends SearchView.CustomerSearchExtensionCommandBase
{
    private _customerSearchResults: ProxyEntities.GlobalCustomer[];

    /**
     * Creates a new instance of the ViewCustomerSummaryCommand class.
     * @param
     {IExtensionCommandContext<CustomerDetailsView.ICustomerSearchToExtensionCommandMessageTypeMap>}
    context The command context.
     * @remarks The command context contains APIs through which a command can communicate with POS.
     */
    constructor(context:
    IExtensionCommandContext<SearchView.ICustomerSearchToExtensionCommandMessageTypeMap>) {
        super(context);
        this.id = "viewCustomerSummaryCommand";
        this.label = context.resources.getString("string_1");
        this.extraClass = "iconLightningBolt";
        this._customerSearchResults = [];

        this.searchResultsSelectedHandler = (data:
    SearchView.CustomerSearchSearchResultSelectedData): void => {
            this._customerSearchResults = data.customers;
            this.canExecute = true;
        };

        this.searchResultSelectionClearedHandler = (): void => {
            this._customerSearchResults = [];
            this.canExecute = false;
        };
    }

    /**
     * Initializes the command.
     * @param {CustomerDetailsView.ICustomerDetailsExtensionCommandState} state The state used to
    initialize the command.
     */
    protected init(state: SearchView.ICustomerSearchExtensionCommandState): void {
        this.isVisible = true;
    }

    /**
     * Executes the command.
     */
    protected execute(): void {
        let customer: ProxyEntities.GlobalCustomer =
    ArrayExtensions.firstOrUndefined(this._customerSearchResults);
        if (!ObjectExtensions.isNullOrUndefined(customer)) {
            let message: string = "Customer Account: " + (customer.AccountNumber || "") + " | ";
            message += "Name: " + customer.FullName + " | ";
            message += "Phone Number: " + customer.Phone + " | ";
            message += "Email Address: " + customer.Email;
            MessageDialog.show(this.context, message);
        }
    }
}

```

26. In the **SearchExtension** folder, create a JSON file that is named **manifest.json**.

27. In the **manifest.json** file, add the following code.

```

{
  "$schema": "../manifestSchema.json",
  "name": "Pos_Extensibility_Samples",
  "publisher": "Microsoft",
  "version": "7.2.0",
  "minimumPosVersion": "7.2.0.0",
  "components": {
    "resources": {
      "supportedUICultures": [ "en-US" ],
      "fallbackUICulture": "en-US",
      "culturesDirectoryPath": "Resources/Strings ",
      "stringResourcesFileName": "resources.resjson",
      "cultureInfoOverridesFilePath": "Resources/cultureInfoOverrides.json"
    },
    "extend": {
      "views": {
        "SearchView": {
          "customerAppBarCommands": [ { "modulePath":
"ViewExtensions/Search/ViewCustomerSummaryCommand" } ],
          "customerListConfiguration": { "modulePath":
"ViewExtensions/Search/CustomCustomerSearchColumns" }
        }
      }
    }
  }
}

```

28. In the **POS.Extensions** project, open the **extensions.json** file, and update it with **SearchExtension** samples, so that the POS includes this extension at runtime.

```

{
  "extensionPackages": [
    {
      "baseUrl": "SampleExtensions2"
    },
    {
      "baseUrl": "SearchExtension"
    }
  ]
}

```

29. In the **tsconfig.json** file, comment out the extension package folders in the exclude list. The POS uses this file to include or exclude the extension. By default, the list contains the whole excluded extensions list. To include an extension as part of the POS, add the name of the extension folder, and comment out the extension in the exclude list, as shown here.

```

"exclude": [
  "SampleExtensions"
  //"SampleExtensions2",
  //"SearchExtension"
],

```

30. Compile and rebuild the project.

## Validate the customization

Follow these steps to validate the customization.

1. Sign in to Modern POS by using **000160** as the operator ID and **123** as the password.

2. Search for customer **2001** by using the search bar on the top.

You should see the custom columns that you added.

3. Select a customer, and then select the new app bar button. A dialog box should appear that contains details about the selected customer.

**NOTE**

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Add custom controls to Modern POS (MPOS) transaction pages

2/18/2021 • 7 minutes to read • [Edit Online](#)

You can add more information to a transaction page by using custom controls. You can add a custom control to a transaction page by using the screen layout designer. In the designer, you can use a drag-and-drop operation to add the custom control, and then set the location, height, and width of the control. You can implement business logic for the custom control in your own extensions by using the POS extension framework. This topic explains how to add a new custom control that shows the details for the selected line item, the item ID, and the description.

## NOTE

This topic applies to Dynamics 365 for Finance and Operations, and to Microsoft Dynamics 365 Retail with platform update 8 and Retail App update 4 hotfix.

## Add a new custom control

1. Sign in to Dynamics 365 Commerce.
2. Select **Retail > Channel setup > POS setup > POS > Screen layouts**.
3. Select the **F3MGR** screen layout ID, and then, on the Action Pane, select **Designer**.
4. Select **1440x960 – Full layout** as the layout size, and then select **Layout designer**.
5. If you're prompted to install the designer tool, select **Open**, and follow the installation instructions.
6. When you're prompted for your Microsoft Azure Active Directory (Azure AD) credentials, enter the information to start the designer.
7. In the designer, drag the custom control from the left pane to the page, and then adjust, resize, or reposition the custom control as you require.
8. On the page, right-click the custom control, and then select **Customize**.
9. In the dialog box, set these properties:
  - **Control Name:** lineDetails
  - **Package Name:** Pos\_Extensibility\_Samples
  - **Publisher Name:** Contoso

## NOTE

These names should match the names in the extension manifest.

10. Close the designer by selecting the **Close** button (X).
11. When you're prompted to save your changes, select **Yes**. If you select **No**, your changes won't be saved.
12. Select **Retail > Retail IT > Distribution schedule**.

13. Select the **Registers (1090)** job, and then select **Run now**.

## Add business logic to the custom control

1. Start Microsoft Visual Studio 2015 as an administrator.
2. Open the **ModernPOS** solution from ...\**RetailSDK\POS**.
3. In the **POS.Extensions** project, create a folder that is named **CustomControlExtensions**.
4. In the **CustomControlExtensions** folder, create a folder that is named **Cart**.
5. In the **Cart** folder, create a Typescript file that is named **CartViewController.ts**.
6. In the **CartViewController.ts** file, add the following **import** statement to import the relevant entities and context.

```
import { ProxyEntities } from "PosApi/Entities";
import { IExtensionCartViewControllerContext } from "PosApi/Extend/Views/CartView";
import * as CartView from "PosApi/Extend/Views/CartView";
```

7. Create a class that is named **CartViewController**, and extend it from **CartExtensionViewControllerBase**. The **CartExtensionViewControllerBase** class contains the cart and tender lines, the cart line selected handler, and the cart line cleared handler. These elements will be used to show the selected line in the custom control.

```
export default class CartViewController extends CartView.CartExtensionViewControllerBase {
}
```

8. In the **CartViewController** class, add two private variables to get the selected cart lines and tender lines.

```
private _selectedCartLines: ProxyEntities.CartLine[];

private _selectedTenderLines: ProxyEntities.TenderLine[];
```

9. Create a class **constructor** method to set the cart and tender selection information.

```
constructor(context: IExtensionCartViewControllerContext) {
  super(context);
  this.cartLineSelectedHandler = (data: CartView.CartLineSelectedData): void => {
    this._selectedCartLines = data.cartLines;
  };

  this.cartLineSelectionClearedHandler = (): void => {
    this._selectedCartLines = undefined;
  };

  this.tenderLineSelectedHandler = (data: CartView.TenderLineSelectedData): void => {
    this._selectedTenderLines = data.tenderLines;
  };

  this.tenderLineSelectionClearedHandler = (): void => {
    this._selectedCartLines = undefined;
  };
}
```

The overall class should look like this.

```

import { ProxyEntities } from "PosApi/Entities";
import { IExtensionCartViewControllerContext } from "PosApi/Extend/Views/CartView";
import * as CartView from "PosApi/Extend/Views/CartView";

export default class CartViewController extends CartView.CartExtensionViewControllerBase {
  private _selectedCartLines: ProxyEntities.CartLine[];
  private _selectedTenderLines: ProxyEntities.TenderLine[];

  /**
   * Creates a new instance of the CartViewController class.
   * @param {IExtensionCartViewControllerContext} context The events Handler context.
   * @remarks The events handler context contains APIs through which a handler can communicate with
   POS.
   */
  constructor(context: IExtensionCartViewControllerContext) {
    super(context);
    this.cartLineSelectedHandler = (data: CartView.CartLineSelectedData): void => {
      this._selectedCartLines = data.cartLines;
    };

    this.cartLineSelectionClearedHandler = (): void => {
      this._selectedCartLines = undefined;
    };

    this.tenderLineSelectedHandler = (data: CartView.TenderLineSelectedData): void => {
      this._selectedTenderLines = data.tenderLines;
    };

    this.tenderLineSelectionClearedHandler = (): void => {
      this._selectedCartLines = undefined;
    };
  }
}

```

10. In the **Cart** folder, create an HTML file that is named **LineDetailsCustomControl.html**.

11. In the **LineDetailsCustomControl.html** file, add two text fields to show the ID and description for the selected line item. Delete the default code, and add the following code.

```

<!DOCTYPE html>
<html lang="en" xmlns="http://www.w3.org/1999/xhtml">
  <head>
    <meta charset="utf-8" />
    <title></title>
  </head>
  <body>
    <!-- Note: The element ID differs from the ID generated by the POS extensibility
framework. This 'template' ID is not used by the POS extensibility framework. -->
    <script id="Microsoft_Pos_Extensibility_Samples_LineDetails" type="text/html">
      <!-- ko ifnot: isCartLineSelected -->
      <h4>No cart lines selected</h4>
      <!-- /ko -->
      <!-- ko if: isCartLineSelected -->
      <h4 data-bind="text: cartLineItemId">Item ID</h4>
      <h4 data-bind="text: cartLineDescription">Item ID</h4>
      <!-- /ko -->;
    </script>
  </body>
</html>
...

```

12. In the **Cart** folder, create a Typescript file that is named **LineDetailsCustomControl.ts**.

13. In the `LineDetailsCustomControl.ts` file, add the logic to bind the line details information.
14. Import the POS entities and type extensions to use the reference type in the constructor and other events.

```
import {
  ObjectExtensions,
  StringExtensions,
  ArrayExtensions
} from "PosApi/TypeExtensions";
import { ProxyEntities } from "PosApi/Entities";
```

15. Create a class, and extend it from `CartViewCustomControlBase`.

```
export default class LineDetailsCustomControl extends CartViewCustomControlBase {}
```

16. Declare the following private variables to set the cart item ID and description.

```
private static readonly TEMPLATE_ID: string = "Microsoft_Pos_Extensibility_Samples_LineDetails";
public readonly cartLineItemId: Computed<string>;
public readonly cartLineDescription: Computed<string>;
public readonly isCartLineSelected: Computed<boolean>;
private readonly _cartLine: Observable<ProxyEntities.CartLine>;
private _state: ICartViewCustomControlState;
```

17. Create the **constructor** method to initialize and get the selected handler.

```
constructor(id: string, context: ICartViewCustomControlContext) {
  super(id, context);
  this._cartLine = ko.observable(null);
  this.cartLineItemId = ko.computed(() => {
    let cartLine: ProxyEntities.CartLine = this._cartLine();
    if (!ObjectExtensions.isNullOrUndefined(cartLine)) {
      return cartLine.ItemId;
    }
    return StringExtensions.EMPTY;
  });

  this.cartLineDescription = ko.computed(() => {
    let cartLine: ProxyEntities.CartLine = this._cartLine();
    if (!ObjectExtensions.isNullOrUndefined(cartLine)) {
      return cartLine.Description;
    }
    return StringExtensions.EMPTY;
  });

  this.isCartLineSelected = ko.computed(() =>
!ObjectExtensions.isNullOrUndefined(this._cartLine()));
  this.cartLineSelectedHandler = (data: CartLineSelectedData) => {
    if (ArrayExtensions.hasElements(data.cartLines)) {
      this._cartLine(data.cartLines[0]);
    }
  };

  this.cartLineSelectionClearedHandler = () => {
    this._cartLine(null);
  };
}
```

18. Add the **onReady** method to bind the control to the specified HTML element.

```

public onReady(element: HTMLElement): void {
    ko.applyBindingsToNode(element, {
        template: {
            name: LineDetailsCustomControl.TEMPLATE_ID,
            data: this
        }
    });
}

```

19. Add the `init` method to set the state.

```

public init(state: ICartViewCustomControlState): void {
    this._state = state;
}

```

The overall class should look like this.

```

import {
    CartViewCustomControlBase,
    ICartViewCustomControlState,
    ICartViewCustomControlContext,
    CartLineSelectedData
} from "PosApi/Extend/Views/CartView";

import {
    ObjectExtensions,
    StringExtensions,
    ArrayExtensions
} from "PosApi/TypeExtensions";

import { ProxyEntities } from "PosApi/Entities";

export default class LineDetailsCustomControl extends CartViewCustomControlBase {
    private static readonly TEMPLATE_ID: string = "Microsoft_Pos_Extensibility_Samples_LineDetails";
    public readonly cartLineItemId: Computed<string>;
    public readonly cartLineDescription: Computed<string>;
    public readonly isCartLineSelected: Computed<boolean>;
    private readonly _cartLine: Observable<ProxyEntities.CartLine>;
    private _state: ICartViewCustomControlState;

    constructor(id: string, context: ICartViewCustomControlContext) {
        super(id, context);
        this._cartLine = ko.observable(null);

        this.cartLineItemId = ko.computed(() => {
            let cartLine: ProxyEntities.CartLine = this._cartLine();
            if (!ObjectExtensions.isNullOrUndefined(cartLine)) {
                return cartLine.ItemId;
            }
            return StringExtensions.EMPTY;
        });

        this.cartLineDescription = ko.computed(() => {
            let cartLine: ProxyEntities.CartLine = this._cartLine();
            if (!ObjectExtensions.isNullOrUndefined(cartLine)) {
                return cartLine.Description;
            }
            return StringExtensions.EMPTY;
        });

        this.isCartLineSelected = ko.computed(() =>
!ObjectExtensions.isNullOrUndefined(this._cartLine()));
        this.cartLineSelectedHandler = (data: CartLineSelectedData) => {
            if (ArrayExtensions.hasElements(data.cartLines)) {

```

```

        this._cartLine(data.cartLines[0]);
    }
};

this.cartLineSelectionClearedHandler = () => {
    this._cartLine(null);
};
}

/**
 * Binds the control to the specified element.
 * @param {HTMLElement} element The element to which the control should be bound.
 */
public onReady(element: HTMLElement): void {
    ko.applyBindingsToNode(element, {
        template: {
            name: LineDetailsCustomControl.TEMPLATE_ID,
            data: this
        }
    });
}

/**
 * Initializes the control.
 * @param {ICartViewCustomControlState} state The initial state of the page used to initialize the control.
 */
public init(state: ICartViewCustomControlState): void {
    this._state = state;
}
}
}

```

20. In the **CustomControlExtensions** folder, create a JSON file that is named **manifest.json**.

21. In the **manifest.json** file, add the following code.

```

{
  "$schema": "../manifestSchema.json",
  "name": "Pos_Extensibility_Samples",
  "publisher": "Contoso",
  "version": "7.2.0",
  "minimumPosVersion": "7.2.0.0",
  "components": {
    "extend": {
      "views": {
        "CartView": {
          "viewController": { "modulePath": "Cart/CartViewController" },
          "controlsConfig": {
            "customControls": [
              {
                "controlName": "lineDetails",
                "htmlPath": "Cart/LineDetailsCustomControl.html",
                "modulePath": "Cart/LineDetailsCustomControl"
              }
            ]
          }
        }
      }
    }
  }
}

```

22. In the **POS.Extensions** project, open the **extensions.json** file, and update it with the following **CustomControlExtensions** samples, so that the POS includes this extension at runtime.

```
{
  "extensionPackages": [
    {
      "baseUrl": "SampleExtensions2"
    },
    {
      "baseUrl": "CustomControlExtensions"
    }
  ]
}
```

23. In the `tsconfig.json` file, comment out the extension package folders in the exclude list. The POS uses this file to include or exclude the extension. By default, the list contains the whole excluded extensions list. To include an extension as part of the POS, add the name of the extension folder, and comment out the extension in the exclude list, as shown here.

```
"exclude": [
  "SampleExtensions"
  // "SampleExtensions2",
  // "CustomControlExtensions"
],
```

24. Compile and rebuild the project.

## Validate the customization

1. Sign in to Modern POS by using **000160** as the operator ID and **123** as the password.
2. On the **Welcome** screen, select the **Current transaction** button.
3. Add any item to the transaction, and then select the line item that you added.

The custom control should show the ID and description for the selected line item.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Add custom columns to a point of sale (POS) transaction grid

2/18/2021 • 4 minutes to read • [Edit Online](#)

This topic explains how to add a new custom column to a POS transaction page using the screen layout designer. You can add more information to a transaction page by using the custom column feature. A custom column can be added to the transaction page receipt grid by using the screen layout designer. You can adjust the width and position of the columns by using the designer. There are 10 custom columns in the layout for extensions scenarios. You can use all 10 in one layout. The custom columns are already added to the designer metadata. After adding the column to the layout, you run the distribution job so that the column shows up on the transaction page.

## NOTE

This topic applies to Dynamics 365 for Finance and Operations, and to Microsoft Dynamics 365 Retail with platform update 8 and Retail App update 4 hotfix.

## Add a custom column to the page

1. Sign in to Dynamics 365 Commerce.
2. Navigate to **Retail and Commerce > Channel setup > POS setup > POS > Screen layouts**. Or, search for **Screen layout** in the search bar.
3. Select the **F3MGR** screen layout ID and click the **Designer** button in the action bar.
4. Follow the instructions if prompted to install and enter the Azure Active Directory (AAD) credentials to launch the designer.
5. Select **1440x960 – Full layout** from the layout sizes and click the **Layout designer** button.
6. If prompted, click **Open** and follow the instruction to install the designer tool.
7. After installing, enter your AAD credentials to launch the designer.
8. In the designer, right-click the transaction grid (receipt grid) and select **Customize**.
9. In the **Customization – Receipt** window, select the **lines** in the pivot panel drop-down menu.

## NOTE

Similarly, you can add a custom column to the **Payment and Delivery** tab.

10. In the **Available columns** window, select **Custom column 1**, and then click the **> (arrow)** button to move the column to the **Selected** columns.
11. Click **OK** to save and close the window.
12. Adjust the column width in the transaction grid using the **Screen layout** designer. Make sure the column is visible.
13. Click the **X** button in the designer to close the designer.

14. When prompted to **Save changes**, click **Yes**. If you click **No** the changes will not be saved.
15. Go to **Retail and Commerce > Retail and Commerce IT > Distribution schedule**.
16. Select the **Registers (1090)** job and click **Run now**.

## Add business logic to a custom column

1. Open Visual Studio 2015 in administrator mode.
2. Open the **ModernPOS** solution from `...\RetailSDK\POS`.
3. Under the **POS.Extensions** project create a new folder named **CustomColumnExtensions**.
4. Under **CustomColumnExtensions**, create a new folder named **Cart**.
5. Under **Cart**, create a new folder named **LinesGrid**.
6. In the **LinesGrid** folder, add a new Typescript file and name it **CustomColumn1Configuration.ts**.
7. Add the following **import** statements to import the relevant entities and context.

```
import {  
  
    ICustomLinesGridColumnContext,  
    CustomLinesGridColumnBase  
  
} from "PosApi/Extend/Views/CartView";  
  
import { CustomGridColumnAlignment } from "PosApi/Extend/Views/CustomGridColumnns";  
import { ProxyEntities } from "PosApi/Entities";
```

8. Create a new class named **LinesCustomGridColumn1** and extend it from **CustomLinesGridColumnBase**.

```
export default class LinesCustomGridColumn1 extends CustomLinesGridColumnBase {}
```

9. Inside the class declare a private variable to capture the selected tender lines.

```
private _selectedTenderLines: ProxyEntities.TenderLine[ ];
```

10. Create a class constructor method to initialize the context.

```
constructor(context: ICustomLinesGridColumnContext) {  
    super(context);  
}
```

11. Add the following methods for the columns title and alignment.

```
public title(): string {  
    return "Line number";  
}  
  
public alignment(): CustomGridColumnAlignment {  
    return CustomGridColumnAlignment.Right;  
}
```

12. Add the column compute value method, which returns the line number.

```
public computeValue(cartLine: ProxyEntities.CartLine): string {
    return cartLine.LineNumber.toString();
}
```

The code for the entire class is:

```
import {
    ICustomLinesGridColumnContext,
    CustomLinesGridColumnBase
} from "PosApi/Extend/Views/CartView";
import { CustomGridColumnAlignment } from "PosApi/Extend/Views/CustomGridColumns";
import { ProxyEntities } from "PosApi/Entities";

export default class LinesCustomGridColumn1 extends CustomLinesGridColumnBase {
    constructor(context: ICustomLinesGridColumnContext) {
        super(context);
    }

    public title(): string {
        return "Line number";
    }

    public computeValue(cartLine: ProxyEntities.CartLine): string {
        return cartLine.LineNumber.toString();
    }

    public alignment(): CustomGridColumnAlignment {
        return CustomGridColumnAlignment.Right;
    }
}
```

13. Create a new .json file under the **CustomColumnExtensions** folder and name it **manifest.json**.

14. In the **manifest.json** file, replace the generated code with the following code.

```

{
  "$schema": "../manifestSchema.json",
  "name": "Pos_Extensibility_Samples",
  "publisher": "Microsoft",
  "version": "7.2.0",
  "minimumPosVersion": "7.2.0.0",
  "components": {
    "extend": {
      "views": {
        "CartView": {
          "linesGrid": {
            "customColumn1": { "modulePath": "Cart/LinesGrid/CustomColumn1Configuration"
          }
        }
      }
    }
  }
}

> [!NOTE]
> If you are adding a custom column to payment or delivery grid, you need to update the manifest with
the following code.
"paymentsGrid": {
  "customColumn1": { "modulePath": "Cart/PaymentsGrid/CustomColumn1Configuration" }
},
"deliveryGrid": {
  "customColumn1": { "modulePath": "Cart/DeliveryGrid/CustomColumn1Configuration" }
}

```

- Open the **extensions.json** file under the **POS.Extensions** project and update it with the **CustomColumnExtensions** sample, so that POS during runtime will include this extension.

```

{
  "extensionPackages": [
    {
      "baseUrl": "SampleExtensions2"
    },
    {
      "baseUrl": "CustomColumnExtensions"
    }
  ]
}

```

- Open the **tsconfig.json** file and comment out the extension package folders from the exclude list. POS will use this file to include or exclude the extension. By default, the list contains all the excluded extensions. If you want to include any extension part of the POS, then you need add the extension folder name and comment the extension from the extension list as shown.

```
"exclude": [  
  "AuditEventExtensionSample",  
  "B2BSample",  
  "CustomerSearchWithAttributesSample",  
  "FiscalRegisterSample",  
  "PaymentSample",  
  "PromotionsSample",  
  "SalesTransactionSignatureSample",  
  //"SampleExtensions2",  
  "SampleExtensions",  
  "StoreHoursSample",  
  "SuspendTransactionReceiptSample"  
  //"CustomColumnExtensions"  
],
```

17. Compile and rebuild the project.

#### NOTE

You can find the sample for the custom column in the [Retail software development kit \(SDK\) architecture](#).

## Validate the customization

1. Sign in to MPOS using **000160** as the operator ID and **123** as the password.
2. Click the **Current transaction** button on the **Welcome** screen.
3. Add item (**0005**) to the transaction.
4. The custom column should display the line number.

#### NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Call point of sale (POS) APIs or operations from POS extensions

2/18/2021 • 6 minutes to read • [Edit Online](#)

The Retail POS APIs help you to build extensions or add new features to POS. For example, if you wanted to add new features that would retrieve product details, change a price, or add an item to a cart, you would call the POS APIs to do that work. The POS APIs simplify the extension pattern and provide continuous support to build the extensions. The extension patterns for Commerce Runtime (RT), POS, and Hardware Station now all use the request/response pattern.

This topic applies to Dynamics 365 for Finance and Operations and Dynamics 365 Retail with Platform update 8 and Retail Application update 4 hotfix.

## Scenarios

The POS APIs are categorized into three different scenarios.

- **Consume** - Consume the public APIs in your extension.
- **Extend** - Extend the public APIs to do some additional logic.
- **Create** - Create new APIs using the POS interface, which can then be used across your extensions.

## Consume POS APIs in extensions

Because the APIs are exposed using a request/response pattern, you can make an external web service call to implement your business logic. For example, if you wanted to change the price of an item, you would call **PriceOverrideOperationRequest**. The APIs are subcategorized by modules such as CRT, peripherals, and store operations.

Many new APIs have been added. You can find a list of all the APIs in the file ...**Retail** SDK\POS\Extensions\Pos.Api.d.ts.

### How to consume an API in an extension

To consume APIs in an extension, follow these steps:

1. Open Visual Studio 2015 in administrator mode.
2. Open the **ModernPOS** solution from ...\**RetailSDK\POS**.
3. Under the **POS.Extensions** project create a new folder named **POSAPIExtension**.
4. Under **POSAPIExtension**, create a new folder named **TriggersHandlers**.
5. In the **TriggersHandlers** folder, add a new Typescript file and name it **PreEndTransactionTrigger.ts**.
6. Add the following **import** statements to import the relevant entities and context.

```

import * as Triggers from "PosApi/Extend/Triggers/TransactionTriggers";
import { ClientEntities, ProxyEntities } from "PosApi/Entities";
import { ObjectExtensions, StringExtensions } from "PosApi/TypeExtensions";
import {
  GetCurrentCartClientRequest, GetCurrentCartClientResponse,
  SaveAttributesOnCartClientRequest, SaveAttributesOnCartClientResponse
} from "PosApi/Consume/Cart";

import {
  GetCustomerClientRequest, GetCustomerClientResponse,
} from "PosApi/Consume/Customer";

import { ShowMessageDialogClientRequest, ShowMessageDialogClientResponse } from
"PosApi/Consume/Dialogs";

```

7. Create a new class called **PreEndTransactionTrigger** and extend it from **PreEndTransactionTrigger**.

```

export default class PreEndTransactionTrigger extends Triggers.PreEndTransactionTrigger { }

```

8. Inside the class declare the following variables for the attributes names and sample values.

```

private static CART_ATTRIBUTE_NAME: string = "ATT SAMPLE";
private static CART_ATTRIBUTE_VALUE_TRUE: string = "True";
private static CART_ATTRIBUTE_VALUE_FALSE: string = "False";
private static DIALOG_RESULT_YES: string = "yes";
private static DIALOG_RESULT_NO: string = "no";
private static DIALOG_YES_BUTTON_ID: string = "CART_PreEndTransactionTrigger_MessageDialog_Yes";
private static DIALOG_NO_BUTTON_ID: string = "CART_PreEndTransactionTrigger_MessageDialog_No";

```

9. Implement the trigger **execute** method and call the existing POS APIs. The **execute** method calls APIs to get the current cart and customer, and then saves the attributes on the cart.

```

public execute(options: Triggers.IPreEndTransactionTriggerOptions):
Promise<ClientEntities.ICancelable> {
  console.log("Executing PreEndTransactionTrigger with options " + JSON.stringify(options) +
  ".");

  let currentCart: ProxyEntities.Cart;
  return this.context.runtime.executeAsync<GetCurrentCartClientResponse>(new
GetCurrentCartClientRequest())
  .then((getCurrentCartClientResponse:
ClientEntities.ICancelableDataResult<GetCurrentCartClientResponse>):
  Promise<ClientEntities.ICancelableDataResult<GetCustomerClientResponse>> => {
    currentCart = getCurrentCartClientResponse.data.result;

    // Gets the current customer.

    let result: Promise<ClientEntities.ICancelableDataResult<GetCustomerClientResponse>>;
    if (!ObjectExtensions.isNullOrUndefined(currentCart) &&
!ObjectExtensions.isNullOrUndefined(currentCart.CustomerId)) {
      let getCurrentCustomerClientRequest:
GetCustomerClientRequest<GetCustomerClientResponse> =
        new GetCustomerClientRequest(currentCart.CustomerId);
      result = this.context.runtime.executeAsync<GetCustomerClientResponse>
(getCurrentCustomerClientRequest);
    } else {
      result = Promise.resolve({ canceled: false, data: new
GetCustomerClientResponse(null) });
    }

    return result;
  })
}

```

```

        .then((getCurrentCustomerClientResponse:
ClientEntities.ICancelableDataResult<GetCustomerClientResponse>):
        Promise<ClientEntities.ICancelableDataResult<ShowMessageDialogClientResponse>> => {
            let currentCustomer: ProxyEntities.Customer =
getCurrentCustomerClientResponse.data.result;
            let result:
Promise<ClientEntities.ICancelableDataResult<ShowMessageDialogClientResponse>>;

            if (!ObjectExtensions.isNullOrUndefined(currentCart)

                && !ObjectExtensions.isNullOrUndefined(currentCustomer)) {

                let yesButton: ClientEntities.Dialogs.IDialogResultButton = {

                    id: PreEndTransactionTrigger.DIALOG_YES_BUTTON_ID,
                    label: "Yes", // "Yes"

                    result: PreEndTransactionTrigger.DIALOG_RESULT_YES
                };

                let noButton: ClientEntities.Dialogs.IDialogResultButton = {
                    id: PreEndTransactionTrigger.DIALOG_NO_BUTTON_ID,
                    label: "No", // "No"
                    result: PreEndTransactionTrigger.DIALOG_RESULT_NO
                };

                let showMessageDialogClientRequestOptions:
ClientEntities.Dialogs.IMessageDialogOptions = {
                    title: "Save attribute - Sample",
                    subTitle: StringExtensions.EMPTY,
                    message: "Save attribute ?",
                    button1: yesButton,
                    button2: noButton

                };

                let showMessageDialogClientRequest:
ShowMessageDialogClientRequest<ShowMessageDialogClientResponse> =
                    new ShowMessageDialogClientRequest(showMessageDialogClientRequestOptions);
                result = this.context.runtime.executeAsync<ShowMessageDialogClientResponse>
(showMessageDialogClientRequest);
            } else {
                result = Promise.resolve({ canceled: false, data: new
ShowMessageDialogClientResponse(null) });
            }
            return result;
        })

        .then((showMessageDialogClientResponse:
ClientEntities.ICancelableDataResult<ShowMessageDialogClientResponse>):
        Promise<ClientEntities.ICancelableDataResult<SaveAttributesOnCartClientResponse>> =>
{

            // Save the attribute value depending on the dialog result.
            let messageDialogResult: ClientEntities.Dialogs.IMessageDialogResult =
showMessageDialogClientResponse.data.result;
            let result:
Promise<ClientEntities.ICancelableDataResult<SaveAttributesOnCartClientResponse>>;

            if (!ObjectExtensions.isNullOrUndefined(messageDialogResult)) {
                let attributeValue: ProxyEntities.AttributeTextValue = new
ProxyEntities.AttributeTextValueClass();
                attributeValue.Name = PreEndTransactionTrigger.CART_ATTRIBUTE_NAME;
                attributeValue.TextValue = messageDialogResult.dialogResult ===
PreEndTransactionTrigger.DIALOG_RESULT_YES ?
                    PreEndTransactionTrigger.CART_ATTRIBUTE_VALUE_TRUE :
                    PreEndTransactionTrigger.CART_ATTRIBUTE_VALUE_FALSE;

                let attributeValues: ProxyEntities.AttributeValueBase[] = [attributeValue];

```

```

        let saveAttributesOnCartRequest:
SaveAttributesOnCartClientRequest<SaveAttributesOnCartClientResponse> =
            new SaveAttributesOnCartClientRequest(attributeValues);
            result = this.context.runtime.executeAsync(saveAttributesOnCartRequest);
        } else {
            result = Promise.resolve({ canceled: false, data: new
SaveAttributesOnCartClientResponse(null) });
        }
        return result;
    });
}

```

The overall code should look like the following example.

```

import * as Triggers from "PosApi/Extend/Triggers/TransactionTriggers";
import { ClientEntities, ProxyEntities } from "PosApi/Entities";
import { ObjectExtensions, StringExtensions } from "PosApi/TypeExtensions";
import {

    GetCurrentCartClientRequest, GetCurrentCartClientResponse,
    SaveAttributesOnCartClientRequest, SaveAttributesOnCartClientResponse

} from "PosApi/Consume/Cart";

import {

    GetCustomerClientRequest, GetCustomerClientResponse,
} from "PosApi/Consume/Customer";

import { ShowMessageDialogClientRequest, ShowMessageDialogClientResponse } from
"PosApi/Consume/Dialogs";

/**
 * Example implementation of an PreEndTransactionTrigger trigger that logs to the console.
 */

export default class PreEndTransactionTrigger extends Triggers.PreEndTransactionTrigger {
    private static CART_ATTRIBUTE_NAME: string = "ATT SAMPLE";
    private static CART_ATTRIBUTE_VALUE_TRUE: string = "True";
    private static CART_ATTRIBUTE_VALUE_FALSE: string = "False";
    private static DIALOG_RESULT_YES: string = "yes";
    private static DIALOG_RESULT_NO: string = "no";
    private static DIALOG_YES_BUTTON_ID: string = "CART_PreEndTransactionTrigger_MessageDialog_Yes";
    private static DIALOG_NO_BUTTON_ID: string = " CART_PreEndTransactionTrigger_MessageDialog_No";

    /**
     * Executes the trigger functionality.
     * @param {Triggers.IPreEndTransactionTriggerOptions} options The options provided to the trigger.
     */

    public execute(options: Triggers.IPreEndTransactionTriggerOptions):
Promise<ClientEntities.ICancelable> {
        console.log("Executing PreEndTransactionTrigger with options " + JSON.stringify(options) +
".".");

        let currentCart: ProxyEntities.Cart;
        return this.context.runtime.executeAsync<GetCurrentCartClientResponse>(new
GetCurrentCartClientRequest())
            .then((getCurrentCartClientResponse:
ClientEntities.ICancelableDataResult<GetCurrentCartClientResponse>):
Promise<ClientEntities.ICancelableDataResult<GetCustomerClientResponse>> => {
                currentCart = getCurrentCartClientResponse.data.result;

                // Gets the current customer.

                let result: Promise<ClientEntities.ICancelableDataResult<GetCustomerClientResponse>>;
                if (!ObjectExtensions.IsNullOrEmpty(currentCart) &&

```

```

!ObjectExtensions.isNullOrUndefined(currentCart.CustomerId)) {

            result: PreEndTransactionTrigger.DIALOG_RESULT_NO
        };

        let showMessageDialogClientRequestOptions:
ClientEntities.Dialogs.IMessageDialogOptions = {
            title: "Save attribute - Sample",
            subTitle: StringExtensions.EMPTY,
            message: "Save attribute ?",
            button1: yesButton,
            button2: noButton

        };

        let showMessageDialogClientRequest:
ShowMessageDialogClientRequest<ShowMessageDialogClientResponse> =
            new ShowMessageDialogClientRequest(showMessageDialogClientRequestOptions);
            result = this.context.runtime.executeAsync<ShowMessageDialogClientResponse>
(showMessageDialogClientRequest);
        } else {
            result = Promise.resolve({ canceled: false, data: new
ShowMessageDialogClientResponse(null) });
        }
        return result;
    })

    .then((showMessageDialogClientResponse:
ClientEntities.ICancelableDataResult<ShowMessageDialogClientResponse>):
Promise<ClientEntities.ICancelableDataResult<SaveAttributesOnCartClientResponse>> =>
{

        // Save the attribute value depending on the dialog result.
        let messageDialogResult: ClientEntities.Dialogs.IMessageDialogResult =
showMessageDialogClientResponse.data.result;

```

```

        let result:
Promise<ClientEntities.ICancelableDataResult<SaveAttributesOnCartClientResponse>>;

        if (!ObjectExtensions.IsNullOrEmpty(messageDialogResult)) {
            let attributeValue: ProxyEntities.AttributeTextValue = new
ProxyEntities.AttributeTextValueClass();
            attributeValue.Name = PreEndTransactionTrigger.CART_ATTRIBUTE_NAME;
            attributeValue.TextValue = messageDialogResult.dialogResult ===
PreEndTransactionTrigger.DIALOG_RESULT_YES ?
                PreEndTransactionTrigger.CART_ATTRIBUTE_VALUE_TRUE :
PreEndTransactionTrigger.CART_ATTRIBUTE_VALUE_FALSE;

            let attributeValues: ProxyEntities.AttributeValueBase[] = [attributeValue];
            let saveAttributesOnCartRequest:
SaveAttributesOnCartClientRequest<SaveAttributesOnCartClientResponse> =
                new SaveAttributesOnCartClientRequest(attributeValues);
            result = this.context.runtime.executeAsync(saveAttributesOnCartRequest);
        } else {
            result = Promise.resolve({ canceled: false, data: new
SaveAttributesOnCartClientResponse(null) });
        }
        return result;
    });
}
}

```

10. Create a new json file under the POSAPIExtension folder and name it manifest.json.
11. In the manifest.json file, copy and paste the following code. Delete the default generated code before copying this code.

```

{
  "$schema": "../manifestSchema.json",
  "name": "Pos_Extensibility_APISample",
  "publisher": "Microsoft",
  "version": "7.2.0",
  "minimumPosVersion": "7.2.0.0",
  "components": {
    "extend": {
      "triggers": [
        {
          "triggerType": "PreEndTransaction",
          "modulePath": "TriggersHandlers/PreEndTransactionTrigger"
        }
      ]
    }
  }
}

```

12. Open the extensions.json file under the POS.Extensions project and update it with the POSAPIExtension samples, so that POS during runtime will include this extension.

```

{
  "extensionPackages": [
    {
      "baseUrl": "SampleExtensions2"
    },
    {
      "baseUrl": "POSAPIExtension"
    }
  ]
}

```

#### NOTE

The extension.json file must contain at least two extensions folder names so don't remove the **SampleExtensions** folder name.

13. Open **tsconfig.json** and comment out the extension package folders from the exclude list. POS will use this file to include or exclude the extension. By default, the list contains all the excluded extensions, if you want to include any extensions that are part of the POS, then you need add the extension folder name and comment out the extension from the extension list as shown.

#### NOTE

Comment out both **SampleExtensions2** and **POSAPIExtension**.

```
"exclude": [  
  
    "AuditEventExtensionSample",  
    "B2BSample",  
    "CustomerSearchWithAttributesSample",  
    "FiscalRegisterSample",  
    "PaymentSample",  
    "PromotionsSample",  
    "SalesTransactionSignatureSample",  
    //"SampleExtensions2",  
    "SampleExtensions",  
    "StoreHoursSample",  
    "SuspendTransactionReceiptSample",  
    "CustomControlExtensions"  
    //"POSAPIExtension"  
  
],
```

14. Select the **POS.Extensions** project and click **Show all Files** in Solution Explorer.
15. Right-click and include the **SampleExtensions2** folder in the project.
16. Compile and rebuild the project.

## Test the extension

1. Press F5 and deploy the POS to test your customization.
2. Sign in to POS and add any item to a transaction.
3. Add any customer to a transaction.
4. Click the **Pay** button and commit the transaction. A dialog box should display asking if you want to save the attribute.

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# POS triggers

2/18/2021 • 18 minutes to read • [Edit Online](#)

You can use triggers to capture events that occur before or after Retail Modern POS operations. Using triggers supports several business logic scenarios that enable you to do the following:

- Insert custom logic before the operation runs or after it has completed. This includes operation-specific triggers and generic triggers called the PreOperationTrigger and PostOperationTrigger, which run at the beginning and end of all POS operations.
- Continue or cancel an operation. For example, if your validation fails or returns an error, then you can cancel the operation in pre-trigger. Post-triggers are not cancelable.
- Use the post-trigger for scenarios where you want to show custom messages or insert custom fields after the standard logic is performed.

The following table lists the available triggers and denotes whether they can be canceled.

## Application triggers

TRIGGER	TYPE	DESCRIPTION
ApplicationStartTrigger	Non-cancelable	Executed after the POS application is started. You can revert or cancel whatever executed previously.
ApplicationSuspendTrigger	Non-cancelable	Executed after the POS application is suspended.
PreLogOnTriggerTrigger	Cancelable	Executed before the POS log on.
PostLogOnTriggerTrigger	Non-cancelable	Executed after the POS log on.
PostLogOffTrigger	Non-cancelable	Executed after the POS log off.
PreLockTerminalTrigger	Cancelable	Executed before the POS register lock.
PostLockTerminalTrigger	Non-Cancelable	Executed after the POS register lock.
PreUnlockTerminalTrigger	Cancelable	Executed before the POS register is unlocked.
PostDeviceActivationTrigger	Non-Cancelable	Executed after the POS activation.
PreElevateUserTrigger	Cancelable	Executed before the manager override.
PreRegisterAuditEventTrigger	Cancelable	Executed before the audit event.
PostRegisterAuditEventTrigger	Non-Cancelable	Executed after the audit event.
PreOpenUrlTrigger	Cancelable	Executed before the open URL operation.

## Cash management triggers

TRIGGER	TYPE	DESCRIPTION
PreTenderDeclarationTrigger	Cancelable	Executed before the POS tender declaration.
PostTenderDeclarationTrigger	Non-cancelable	Executed after the POS tender declaration.
PreFloatEntryTrigger	Cancelable	Executed before the POS float entry.
PostFloatEntryTrigger	Non-cancelable	Executed after the POS float entry.

## Customer triggers

TRIGGER	TYPE	DESCRIPTION
PreCustomerAddTrigger	Cancelable	Executed before adding a customer to the transaction.
PostCustomerAddTrigger	Non-cancelable	Executed after adding a customer to the transaction.
PreCustomerClearTrigger	Cancelable	Executed before the customer cleared from the cart.
PostCustomerClearTrigger	Non-cancelable	Executed after the customer cleared from the cart.
PreCustomerSetTrigger	Cancelable	Executed before the customer is added to the cart.
PreCustomerSearchTrigger	Cancelable	Executed before customer search is performed.
PostCustomerSearchTrigger	Non-cancelable	Executed after customer search is performed.
PostIssueLoyaltyCardTrigger	Non-cancelable	Executed after the loyalty card is issued.
PreCustomerSaveTrigger	Cancelable	Executed before the customer is created.
PostCustomerSaveTrigger	Non-cancelable	Executed after the customer is created.
PreSaveCustomerAddressTrigger	Cancelable	Executed before the customer address is saved.
PreGetLoyaltyCardBalanceTrigger	Cancelable	Executed before getting the loyalty card balance.

TRIGGER	TYPE	DESCRIPTION
PostGetLoyaltyCardBalanceTrigger	Non-cancelable	Executed after getting the loyalty card balance.
PreDisplayLoyaltyCardBalanceTrigger	Cancelable	Executed before displaying the loyalty card balance.

## Discount triggers

TRIGGER	TYPE	DESCRIPTION
PreLineDiscountAmountTrigger	Cancelable	Executed before line discount amount is added to the cart line.
PostLineDiscountAmountTrigger	Non-cancelable	Executed after line discount amount added to the cart line.
PreLineDiscountPercentTrigger	Cancelable	Executed before line discount percent added to the cart line.
PostLineDiscountPercentTrigger	Non-cancelable	Executed after line discount percent added to the cart line.
PreTotalDiscountAmountTrigger	Cancelable	Executed before total discount percent added to the cart.
PostTotalDiscountAmountTrigger	Non-cancelable	Executed after total amount percent added to the cart.
PreTotalDiscountPercentTrigger	Cancelable	Executed before total discount percent added to the cart.
PostTotalDiscountPercentTrigger	Non-cancelable	Executed after total discount percent added to the cart.
PreAddCouponTrigger	Cancelable	Executed before adding discount coupon to the cart.
PostAddCouponTrigger	Non-cancelable	Executed after adding discount coupon to the cart.

## Operation triggers

TRIGGER	TYPE	DESCRIPTION
PreOperationTrigger	Cancelable	Generic trigger executed before all POS operations. You can use this trigger if there is no specific trigger available for a POS operation.
PreOperationValidationTrigger	Cancelable	Generic trigger executed before the operation validation begins.

TRIGGER	TYPE	DESCRIPTION
OperationFailureTrigger	Non-cancelable	Generic trigger executed after any POS operation failed.
PostOperationTrigger	Non-cancelable	Generic trigger executed after all POS operations. You can use this trigger if there is no specific trigger available for a POS operation.

## Payment triggers

TRIGGER	TYPE	DESCRIPTION
PreAddTenderLineTrigger	Cancelable	Executed before the payment line is added to the cart.
PrePaymentTrigger	Cancelable	Executed after you click the pay button in POS.
PostPaymentTrigger	Non-cancelable	Executed after all the payment processing is done.
PreVoidPaymentTrigger	Cancelable	Executed before the payment line is voided in POS.
PostVoidPaymentTrigger	Non-cancelable	Executed after the payment line is voided in POS.

## Printing Triggers

TRIGGER	TYPE	DESCRIPTION
PrePrintReceiptCopyTrigger	Cancelable	Executed before the receipt copy is printed from the show journal screen or receipt view screen.
PostReceiptPromptTrigger	Non-cancelable	Executed after the receipt prompt - Do you want to print or not print receipt.

## Product triggers

TRIGGER	TYPE	DESCRIPTION
PostGetSerialNumberTrigger	Non-cancelable	Executed after the serial number is added to the cart line.
PreProductSaleTrigger	Cancelable	Executed before the product is added to the cart.
PostProductSaleTrigger	Non-cancelable	Executed after the product is added to the cart.

TRIGGER	TYPE	DESCRIPTION
PreReturnProductTrigger	Cancelable	Executed before the return product is added to the cart.
PostReturnProductTrigger	Non-cancelable	Executed after the return product is added to the cart.
PreSetQuantityTrigger	Cancelable	Executed before the quantity information is updated in the cart line.
PostSetQuantityTrigger	Non-cancelable	Executed after the quantity information is updated in the cart line.
PrePriceOverrideTrigger	Cancelable	Executed before the price is overridden for a cart line.
PostPriceOverrideTrigger	Non-cancelable	Executed after the price is overridden for a cart line.
PreClearQuantityTrigger	Cancelable	Executed before the quantity information is cleared from the cart line.
PostClearQuantityTrigger	Non-cancelable	Executed after the quantity information is cleared from the cart line.
PreVoidProductsTrigger	Cancelable	Executed before the product is voided from the cart.
PostVoidProductsTrigger	Non-cancelable	Executed after the product is voided from the cart.
PostPriceCheckTrigger	Non-cancelable	Executed after the price check for the product is executed.

## Sales order triggers

TRIGGER	TYPE	DESCRIPTION
PreRecallCustomerOrderTrigger	Cancelable	Executed before the customer order is recalled.
PostRecallCustomerOrderTrigger	Non-cancelable	Executed after the customer order is recalled.
PrePickUpCustomerOrderLinesTrigger	Cancelable	Executed before the customer order lines are picked.
PreChangeShippingOriginTrigger	Cancelable	Executed before the shipping origin is changed during a customer order.

TRIGGER	TYPE	DESCRIPTION
PreGetFulfillmentLinesTrigger	Cancelable	Executed before the Order fulfillment lines are loaded in the Order fulfillment view.
PreShipFulfillmentLinesTrigger	Cancelable	Executed before the shipping is done from the Order fulfillment view by selecting the <b>Ship</b> button.
PostShipFulfillmentLinesTrigger	Non-Cancelable	Executed after the shipping is done from the Order fulfillment view by selecting the <b>Ship</b> button.
PreMarkFulfillmentLinesAsPackedTrigger	Cancelable	Executed before the mark as packed option is triggered from the order fulfillment view by selecting the <b>Pack</b> button.
PostMarkFulfillmentLinesAsPackedTrigger	Non-Cancelable	Executed after the mark as packed option is triggered from the order fulfillment view by selecting the <b>Pack</b> button.
PreCreatePackingSlipTrigger	Cancelable	Executed before the create packing slip option is triggered from the order fulfillment view by selecting the <b>Pack</b> button.
PostCreatePackingSlipTrigger	Non-Cancelable	Executed after the create packing slip option is triggered from the order fulfillment view by selecting the <b>Pack</b> button.
PostReturnInvoicedSalesLinesTrigger	Non-Cancelable	Executed after one or more invoices selected for return.
PreResendEmailReceiptTrigger (10.0.13)	Cancelable	Executed before sending the email from the Show journal view.
PreRecallCustomerQuoteTrigger (10.0.18)	Cancelable	Executed before the customer quote is recalled from the recall order view.
PostRecallCustomerQuoteTrigger (10.0.18)	Non-Cancelable	Executed after the customer quote is recalled from the recall order view.

## Shift triggers

TRIGGER	TYPE	DESCRIPTION	RELEASE
PostOpenShiftTrigger	Non-cancelable	This trigger is executed after the new shift is opened.	
PreCloseShiftTrigger	Cancelable	This trigger is executed before the shift is closed.	

TRIGGER	TYPE	DESCRIPTION	RELEASE
PreResumeShiftTrigger	Cancelable	This trigger is executed before the shift is resumed.	10.0.16
PostResumeShiftTrigger	Non-cancelable	This trigger is executed after the shift is resumed.	10.0.16

## Tax override triggers

TRIGGER	TYPE	DESCRIPTION
PreOverrideLineProductTaxTrigger	Cancelable	Executed before the tax amount or code is overridden for a cart line.
PostOverrideLineProductTaxTrigger	Non-cancelable	Executed after the tax amount or code is overridden for a cart line.
PreOverrideTransactionTaxTrigger	Cancelable	Executed before the tax amount or code is overridden for a cart or transaction.
PostOverrideTransactionTaxTrigger	Non-cancelable	Executed before the tax amount or code is overridden for a cart or transaction.

## Transaction triggers

TRIGGER	TYPE	DESCRIPTION
BeginTransactionTrigger	Non-cancelable	Executed before the transaction is initialized.
PreConfirmReturnTransactionTrigger	Cancelable	Executed before the return transaction is confirmed.
PreReturnTransactionTrigger	Cancelable	Executed before the return transaction is processed.
PostReturnTransactionTrigger	Non-cancelable	Executed after the return transaction is processed.
PreEndTransactionTrigger	Cancelable	Executed before the end transaction request is called to commit the changes to DB and close the transaction.
PostEndTransactionTrigger	Non-cancelable	Executed after the end transaction request is called to commit the changes to DB and close the transaction.
PreVoidTransactionTrigger	Cancelable	Executed before the transaction is voided.

TRIGGER	TYPE	DESCRIPTION
PostVoidTransactionTrigger	Non-cancelable	Executed after the transaction is voided.
PreSuspendTransactionTrigger	Cancelable	Executed before the transaction is suspended.
PostSuspendTransactionTrigger	Non-cancelable	Executed after the transaction is suspended.
PreRecallTransactionTrigger	Cancelable	Executed before the transaction or order is recalled.
PostRecallTransactionTrigger	Non-cancelable	Executed after the transaction or order is recalled.
PostCartCheckoutTrigger	Non-cancelable	Executed after the checkout process is completed.
PreRecallTransactionTrigger	Cancelable	Executed before the customer order is recalled.
PostRecallTransactionTrigger	Non-Cancelable	Executed after the customer order is recalled.
PreSelectTransactionPaymentMethodTrigger	Cancelable	When the user selects the <b>Totals</b> button in the <b>Cart view - totals</b> panel, the available payment methods are shown and this trigger will get executed before this dialog is shown. You can use extension code to modify the available payment methods from this trigger.
PreShipSelectedCartLinesTrigger	Cancelable	Executed when the product is selected for shipping.

## Reason code triggers

TRIGGER	TYPE	DESCRIPTION
PostGetReasonCodeLine	Cancelable	This trigger is executed after the reason code line value is entered (before the reason code is added to the cart).

## Transfer Order triggers

TRIGGER	TYPE	DESCRIPTION
PreCreateTransferOrderTrigger	Cancelable	This trigger is executed before the transfer order is created (executed after the order input).

TRIGGER	TYPE	DESCRIPTION
PreUpdateTransferOrderTrigger	Cancelable	This trigger is executed before the transfer order is updated.

## Inventory triggers

TRIGGER	TYPE	DESCRIPTION	RELEASE
PreCreateInventoryDocumentTrigger	Cancelable	This trigger is executed before the inbound/outbound document is created (executed after the order input).	10.0.15
PreUpdateInventoryDocumentTrigger	Cancelable	This trigger is executed before the inbound/outbound document is updated.	10.0.15

## Stock count triggers

TRIGGER	TYPE	DESCRIPTION	RELEASE
PreAdjustStockCountLineQuantityTrigger	Cancelable	This trigger is executed before the stock count for a line is adjusted.	10.0.16
PreSaveStockCountJournalTrigger	Cancelable	This trigger is executed before the stock count journal is saved.	10.0.16

## Business scenario

In this example, a custom receipt is printed when the user suspends a transaction. This example implements the **PostSuspendTransactionTrigger** trigger and prints the custom receipt using the existing print peripheral API.

To implement this scenario, you must complete these steps.

1. **POS extension:** Implement the **PostSuspendTransactionTrigger** trigger to get the receipt data from CRT and send it to the printer for printing.
2. **CRT extension:** Generate the receipt data for printing.

## Implement a trigger

1. Open Visual Studio 2015 in administrator mode.
2. Open the **ModernPOS** solution from `...\RetailSDK\POS`.
3. Under the **POS.Extensions** project, create a new folder named **SuspendReceiptSample**.
4. Under **SuspendReceiptSample**, create new folder named **TriggersHandlers**.
5. In the **TriggersHandlers** folder, add a new Typescript file named **PostSuspendTransactionTrigger.ts**.

6. Add the following **import** statements to import the relevant entities and context.

```
import * as Triggers from "PosApi/Extend/Triggers/TransactionTriggers";
import { ObjectExtensions } from "PosApi/TypeExtensions";
import { ClientEntities, ProxyEntities } from "PosApi/Entities";
import { PrinterPrintRequest, PrinterPrintResponse } from "PosApi/Consume/Peripherals";
import { GetHardwareProfileClientRequest, GetHardwareProfileClientResponse } from
"PosApi/Consume/Device";
import { GetReceiptsClientRequest, GetReceiptsClientResponse } from "PosApi/Consume/SalesOrders";
```

7. Create a new class named **PostSuspendTransactionTrigger** and extend it from **PostSuspendTransactionTrigger**.

```
export default class PostSuspendTransactionTrigger extends Triggers.PostSuspendTransactionTrigger { }
```

8. Implement the trigger's **execute** method to get the receipt profile and print the custom receipt:

```

public execute(options: Triggers.IPostSuspendTransactionTriggerOptions): Promise < void> {
    this.context.logger.logVerbose("Executing PostSuspendTransactionTrigger with options " +
JSON.stringify(options) + ".");
    if(ObjectExtensions.isNullOrUndefined(options) ||
ObjectExtensions.isNullOrUndefined(options.cart)) {

        // This will never happen, but is included to demonstrate how to return a rejected promise
when validation fails.

        let error: ClientEntities.ExtensionError
            = new ClientEntities.ExtensionError("The options provided to the
PostSuspendTransactionTrigger were invalid.");
        return Promise.reject(error);
    } else {
        return this.context.runtime.executeAsync(new GetHardwareProfileClientRequest())
            .then((response: ClientEntities.ICancelableDataResult<GetHardwareProfileClientResponse>
                : Promise<ClientEntities.ICancelableDataResult<GetReceiptsClientResponse>> => {
                    let hardwareProfile: ProxyEntities.HardwareProfile = response.data.result;
                    // Gets the receipts.
                    let salesOrderId: string = options.cart.Id;
                    let receiptRetrievalCriteria: ProxyEntities.ReceiptRetrievalCriteria = {
                        IsCopy: false,
                        IsRemoteTransaction: false,
                        IsPreview: false,
                        QueryBySalesId: true,
                        ReceiptTypeValue: ProxyEntities.ReceiptType.CustomReceipt7,
                        HardwareProfileId: hardwareProfile.ProfileId
                    };
                    let getReceiptsClientRequest: GetReceiptsClientRequest<GetReceiptsClientResponse> =
                        new GetReceiptsClientRequest(salesOrderId, receiptRetrievalCriteria);
                    return this.context.runtime.executeAsync(getReceiptsClientRequest);
                })
            .then((response: ClientEntities.ICancelableDataResult<GetReceiptsClientResponse>
                : Promise<ClientEntities.ICancelableDataResult<PrinterPrintResponse>> => {
                    let receipts: ProxyEntities.Receipt[] = response.data.result;
                    // Prints the receipts.
                    let printerPrintRequest: PrinterPrintRequest<PrinterPrintResponse> = new
PrinterPrintRequest(receipts);
                    return this.context.runtime.executeAsync(printerPrintRequest);
                }).then(): Promise<void> => {
                    // Resolves to a void result when fulfilled.
                    return Promise.resolve();
                }).catch((reason: any): Promise<void> => {
                    // Resolves to a void result when rejected. This matches existing POS printing
behavior.
                    this.context.logger.logError("PostSuspendTransactionTrigger execute error: " +
JSON.stringify(reason));
                    return Promise.resolve();
                });
    }
}

```

The entire example should look like the following.

```

import * as Triggers from "PosApi/Extend/Triggers/TransactionTriggers";
import { ObjectExtensions } from "PosApi/TypeExtensions";
import { ClientEntities, ProxyEntities } from "PosApi/Entities";
import { PrinterPrintRequest, PrinterPrintResponse } from "PosApi/Consume/Peripherals";
import { GetHardwareProfileClientRequest, GetHardwareProfileClientResponse } from
"PosApi/Consume/Device";
import { GetReceiptsClientRequest, GetReceiptsClientResponse } from "PosApi/Consume/SalesOrders";

export default class PostSuspendTransactionTrigger extends Triggers.PostSuspendTransactionTrigger {

/**
 * Executes the trigger functionality.

```

```

    * @param {Triggers.IPostSuspendTransactionTriggerOptions} options The options provided to the
    trigger.
    */
    public execute(options: Triggers.IPostSuspendTransactionTriggerOptions): Promise<void> {
        this.context.logger.logVerbose("Executing PostSuspendTransactionTrigger with options " +
JSON.stringify(options) + ".");
        if (ObjectExtensions.IsNullOrEmpty(options) ||
ObjectExtensions.IsNullOrEmpty(options.cart)) {
            // This will never happen, but is included to demonstrate how to return a rejected
            promise when validation fails.
            let error: ClientEntities.ExtensionError
                = new ClientEntities.ExtensionError("The options provided to the
PostSuspendTransactionTrigger were invalid.");
            return Promise.reject(error);
        } else {
            return this.context.runtime.executeAsync(new GetHardwareProfileClientRequest())
                .then((response:
ClientEntities.ICancelableDataResult<GetHardwareProfileClientResponse>
                : Promise<ClientEntities.ICancelableDataResult<GetReceiptsClientResponse>> => {
                    let hardwareProfile: ProxyEntities.HardwareProfile = response.data.result;
                    // Gets the receipts.
                    let salesOrderId: string = options.cart.Id;
                    let receiptRetrievalCriteria: ProxyEntities.ReceiptRetrievalCriteria = {
                        IsCopy: false,
                        IsRemoteTransaction: false,
                        IsPreview: false,
                        QueryBySalesId: true,
                        ReceiptTypeValue: ProxyEntities.ReceiptType.CustomReceipt7,
                        HardwareProfileId: hardwareProfile.ProfileId
                    };
                    let getReceiptsClientRequest: GetReceiptsClientRequest<GetReceiptsClientResponse>
                    =
                        new GetReceiptsClientRequest(salesOrderId, receiptRetrievalCriteria);
                    return this.context.runtime.executeAsync(getReceiptsClientRequest);
                })
                .then((response: ClientEntities.ICancelableDataResult<GetReceiptsClientResponse>
                : Promise<ClientEntities.ICancelableDataResult<PrinterPrintResponse>> => {
                    let receipts: ProxyEntities.Receipt[] = response.data.result;
                    // Prints the receipts.
                    let printerPrintRequest: PrinterPrintRequest<PrinterPrintResponse> = new
PrinterPrintRequest(receipts);
                    return this.context.runtime.executeAsync(printerPrintRequest);
                }).then(): Promise<void> => {
                    // Resolves to a void result when fulfilled.
                    return Promise.resolve();
                }).catch((reason: any): Promise<void> => {
                    // Resolves to a void result when rejected. This matches existing POS printing
                    behavior.
                    this.context.logger.logError("PostSuspendTransactionTrigger execute error: " +
JSON.stringify(reason));
                    return Promise.resolve();
                });
        }
    }
}
}
}

```

9. Create a new json file under the **SuspendReceiptSample** folder and name it **manifest.json**.
10. Replace the autogenerated code in **manifest.json** with the following code.

```

{
  "$schema": "../manifestSchema.json",
  "name": "Pos_Extensibility_SuspendTransactionReceiptSample",
  "publisher": "Microsoft",
  "version": "7.2.0",
  "minimumPosVersion": "7.2.0.0",
  "components": {
    "extend": {
      "triggers": [
        {
          "triggerType": "PostSuspendTransaction",
          "modulePath": "TriggersHandlers/PostSuspendTransactionTrigger"
        }
      ]
    }
  }
}

```

11. Open the **extensions.json** file in the **POS.Extensions** project and update it with the **SuspendReceiptSample** samples, so that during runtime POS will include this extension.

```

{
  "extensionPackages": [
    {
      "baseUrl": "SampleExtensions2"
    },
    {
      "baseUrl": "SuspendReceiptSample"
    }
  ]
}

```

12. Open the **tsconfig.json** file and comment out the extension package folders from the exclude list. POS will use this file to include or exclude the extension. By default, the list contains all the excluded extensions list. If you want to include an extension that is part of the POS, then add the extension folder name and comment out the extension from the extension, as shown.

```

"exclude": [
  "AuditEventExtensionSample",
  "B2BSample",
  "CustomerSearchWithAttributesSample",
  "FiscalRegisterSample",
  "PaymentSample",
  "PromotionsSample",
  "SalesTransactionSignatureSample",
  "SampleExtensions",
  //"SampleExtensions2",
  "StoreHoursSample",
  "SuspendTransactionReceiptSample"
  //"POSAPIExtension",
  //"CustomColumnExtensions",
  //"EODSample",
  //"ProdDetailsCustomColumnExtensions",
  //"SerachExtension",
  //"SuspendReceiptSample"
],

```

13. Compile and rebuild the project.

## Override the CRT receipt request to generate the receipt data

This section explains how to override the existing CRT request to print a receipt for suspended transactions.

1. Start Visual Studio 2015.
2. On the **File** menu, select **Open > Project/Solution**. Find the template project (**SampleCRTExtension.csproj**).
3. Rename the template project **Runtime.Extensions.SuspendReceiptSample**.
4. Optional: Change the default namespace.
5. Rename the output assembly **Contoso.Commerce.Runtime.SuspendReceiptSample**.
6. Inside the project, add a new request class file, and name it **GetCustomReceiptsRequestHandler.cs**.
7. Copy the following code, and paste it inside the class. Before you copy it, delete the automatically generated code.

```
namespace Contoso
{
    namespace Commerce.Runtime.ReceiptsSample
    {
        using System.Collections.Generic;
        using System.Collections.ObjectModel;
        using Microsoft.Dynamics.Commerce.Runtime;
        using Microsoft.Dynamics.Commerce.Runtime.DataModel;
        using Microsoft.Dynamics.Commerce.Runtime.Messages;
        using Microsoft.Dynamics.Commerce.Runtime.Services.Messages;
        using Microsoft.Dynamics.Commerce.Runtime.Workflow;

        /// <summary>
        /// The request handler for GetCustomReceiptsRequestHandler class.
        /// </summary>

        /// <remarks>
        /// This is an example of how to print custom types of receipts. In this example the receipt
        is for a transaction as opposed to
        /// a sales order. The implementation converts the transaction to a sales order so that
        existing receipt fields can be used.
        /// </remarks>

        public class GetCustomReceiptsRequestHandler : SingleRequestHandler<GetCustomReceiptsRequest,
        GetReceiptResponse>
        {
            {
            }
        }
    }
}
```

8. Copy the following code, and paste it inside the class to add a new method to read the transaction from the cart table, because suspended transactions aren't yet created in the commerce transaction table. You must then convert the cart transaction to sales transaction. This conversion is required because the receipt object can understand only sales transactions.

#### **NOTE**

If you're printing a custom receipt for a completed transaction, you don't have to get the cart transaction and convert it to a sales transaction. It has already been converted to a sales transaction, because the transaction is completed.

```

private SalesOrder GetSalesOrderForTransactionWithId(RequestContext requestContext, string
transactionId)
{
    SalesOrder salesOrder = new SalesOrder();
    var getCartRequest = new GetCartRequest(new CartSearchCriteria(transactionId),
QueryResultSettings.SingleRecord);
    var getCartResponse = requestContext.Execute<GetCartResponse>(getCartRequest);
    SalesTransaction salesTransaction = getCartResponse.Transactions.SingleOrDefault(); ;
    if (salesTransaction != null)
    {
        // The sales transaction is converted into a sales order so that existing receipt fields can
be used.
        salesOrder.CopyFrom<SalesTransaction>(salesTransaction);
    }
    else
    {
        throw new DataValidationException(
            DataValidationErrors.Microsoft_Dynamics_Commerce_Runtime_ObjectNotFound,
            string.Format("Unable to get the sales transaction. ID: {0}", transactionId));
    }
    return salesOrder;
}

```

9. Copy the following code, and paste it into the class to add a new method to construct the receipt format by using the sales transaction information, based on the custom receipt format that is defined in HQ.

```

private Collection<Receipt> GetCustomReceipts(SalesOrder salesOrder, ReceiptRetrievalCriteria
criteria)
{
    Collection<Receipt> result = new Collection<Receipt>();
    var getReceiptServiceRequest = new GetReceiptServiceRequest(
        salesOrder,
        new Collection<ReceiptType> { criteria.ReceiptType },
        salesOrder.TenderLines,
        criteria.IsCopy,
        criteria.IsPreview,
        criteria.HardwareProfileId);
    ReadOnlyCollection<Receipt> customReceipts = this.Context.Execute<GetReceiptServiceResponse>
(getReceiptServiceRequest).Receipts;
    result.AddRange(customReceipts);
    return result;
}

```

10. Copy the following code, and paste it into the class to add a new method to override the get receipt response. This method processes the request and returns the response.

```

protected override GetReceiptResponse Process(GetCustomReceiptsRequest request)
{
    ThrowIf.Null(request, "request");
    ThrowIf.Null(request.ReceiptRetrievalCriteria, "request.ReceiptRetrievalCriteria");

    // The sales order that we are printing receipts for is retrieved.
    SalesOrder salesOrder = this.GetSalesOrderForTransactionWithId(request.RequestContext,
request.TransactionId);

    // Custom receipts are printed.
    Collection<Receipt> result = new Collection<Receipt>();
    switch (request.ReceiptRetrievalCriteria.ReceiptType)
    {
        // An example of getting custom receipts.
        case ReceiptType.CustomReceipt7:
        {
            IEnumerable<Receipt> customReceipts = this.GetCustomReceipts(salesOrder,
request.ReceiptRetrievalCriteria);
            result.AddRange(customReceipts);
        }
        break;
        default:

            // Add more logic to handle more types of custom receipt types.

            break;
    }
    return new GetReceiptResponse(new ReadOnlyCollection<Receipt>(result));
}

```

The overall code should look like this.

```

namespace Contoso
{
    namespace Commerce.Runtime.ReceiptsSample
    {
        using System.Collections.Generic;
        using System.Collections.ObjectModel;
        using Microsoft.Dynamics.Commerce.Runtime;
        using Microsoft.Dynamics.Commerce.Runtime.DataModel;
        using Microsoft.Dynamics.Commerce.Runtime.Messages;
        using Microsoft.Dynamics.Commerce.Runtime.Services.Messages;
        using Microsoft.Dynamics.Commerce.Runtime.Workflow;

        /// <summary>
        /// The request handler for GetCustomReceiptsRequestHandler class.
        /// </summary>

        /// <remarks>
        /// This is an example of how to print custom types of receipts. In this example the receipt
is for a transaction as opposed to
        /// a sales order. The implementation converts the transaction to a sales order so that
existing receipt fields can be used.
        /// </remarks>

        public class GetCustomReceiptsRequestHandler : SingleRequestHandler<GetCustomReceiptsRequest,
GetReceiptResponse>
        {
            /// <summary>
            /// Processes the GetCustomReceiptsRequest to return the set of receipts. The request
should not be null.
            /// </summary>

            /// <param name="request">The request parameter.</param>

```

```

/// <returns>The GetReceiptResponse.</returns>

protected override GetReceiptResponse Process(GetCustomReceiptsRequest request)
{
    ThrowIf.Null(request, "request");
    ThrowIf.Null(request.ReceiptRetrievalCriteria, "request.ReceiptRetrievalCriteria");

    // The sales order that we are printing receipts for is retrieved.
    SalesOrder salesOrder =
this.GetSalesOrderForTransactionWithId(request.RequestContext, request.TransactionId);

    // Custom receipts are printed.
    Collection<Receipt> result = new Collection<Receipt>();
    switch (request.ReceiptRetrievalCriteria.ReceiptType)
    {
        // An example of getting custom receipts.
        case ReceiptType.CustomReceipt7:
        {
            IEnumerable<Receipt> customReceipts = this.GetCustomReceipts(salesOrder,
request.ReceiptRetrievalCriteria);
            result.AddRange(customReceipts);
        }
        break;
        default:

            // Add more logic to handle more types of custom receipt types.

            break;
    }
    return new GetReceiptResponse(new ReadOnlyCollection<Receipt>(result));
}

/// <summary>
/// Gets a sales order for the transaction with the given identifier.
/// </summary>

/// <param name="requestContext">The request context.</param>
/// <param name="transactionId">The transaction identifier.</param>

/// <returns>The sales order.</returns>

private SalesOrder GetSalesOrderForTransactionWithId(RequestContext requestContext,
string transactionId)
{
    SalesOrder salesOrder = new SalesOrder();
    var getCartRequest = new GetCartRequest(new CartSearchCriteria(transactionId),
QueryResultSettings.SingleRecord);
    var getCartResponse = requestContext.Execute<GetCartResponse>(getCartRequest);
    SalesTransaction salesTransaction = getCartResponse.Transactions.SingleOrDefault(); ;
    if (salesTransaction != null)
    {
        // The sales transaction is converted into a sales order so that existing receipt
fields can be used.
        salesOrder.CopyFrom<SalesTransaction>(salesTransaction);
    }
    else
    {
        throw new DataValidationException(
DataValidationErrors.Microsoft_Dynamics_Commerce_Runtime_ObjectNotFound,
string.Format("Unable to get the sales transaction. ID: {0}", transactionId));
    }
    return salesOrder;
}

/// <summary>
/// An example to get a custom receipt.
/// </summary>

/// <param name="salesOrder">The sales order that we are printing receipts for.</param>

```

```

    /// <param name="criteria">The receipt retrieval criteria.</param>

    /// <returns>A collection of receipts.</returns>

    private Collection<Receipt> GetCustomReceipts(SalesOrder salesOrder,
ReceiptRetrievalCriteria criteria)
    {
        Collection<Receipt> result = new Collection<Receipt>();
        var getReceiptServiceRequest = new GetReceiptServiceRequest(
            salesOrder,
            new Collection<ReceiptType> { criteria.ReceiptType },
            salesOrder.TenderLines,
            criteria.IsCopy,
            criteria.IsPreview,
            criteria.HardwareProfileId);
        ReadOnlyCollection<Receipt> customReceipts =
this.Context.Execute<GetReceiptServiceResponse>(getReceiptServiceRequest).Receipts;
        result.AddRange(customReceipts);
        return result;
    }
}
}
}
}

```

11. Compile and build the project.
12. Go to the output directory, and copy the output assembly.
13. Navigate to the ...\**RetailServer\webroot\bin\ext** folder, and paste the assembly.
14. Also paste the assembly in the ...\**RetailSDK\References** folder.
15. Open the **commercerruntime.ext.config** file, and add the custom assembly information under the <composition> section.

```
<add source="assembly" value="Contoso.Commerce.Runtime.SuspendReceiptSample" />
```

16. Save and close the file.
17. Restart the Commerce Scale Unit to load the new assembly.

## Add the custom receipt layout

1. Open Dynamics 365 Commerce.
2. Go to **Retail and Commerce > Channel setup > POS setup > POS > Receipts formats**.
3. Click **New** in **Receipts formats**.
4. In the **Receipt format filed** field, enter the format name **Suspend**. In the **Receipt type** field, select **CustomReceiptType7**.
5. Click **Designer** to open the receipt designer.
6. Follow the instructions if prompted to install. Enter the Azure Active Directory (AAD) credentials to launch the designer.
7. Drag and drop the required field into the header, lines, or footer. Or, copy the from existing receipt format by using the copy feature and then edit it.
8. Click **Save**.
9. Go to **Retail and Commerce > Channel setup > POS setup > POS profiles > Receipt profiles**.
10. Select the **Email receipt** profile or the that profile you store. Click the **Add** button in the **General** tab.
11. In the **Receipt type**, select **CustomReceiptType7** and in the **Receipt format** select **Suspend**.
12. Go to **Retail and Commerce > Retail and Commerce IT > Distribution schedule**.

13. Select **Registers (1090)** and click **Run now** in the action bar. When prompted, click **Yes** to run the job.

## Configure the XPS printer for quick testing

1. Go to **Retail and Commerce > Channel setup > POS setup > POS profiles > Hardware profiles**.
2. Select the hardware profile that your device is using. For example, in the demo data all the Houston devices uses **HW002**.
3. Click **Edit** in the action bar.
4. Expand the **Printer** FastTab. In the **Printer** drop-down list, select **Windows driver** and in the device name field enter **Microsoft XPS Document Writer**.
5. Click **Save**.
6. Go to **Retail and Commerce > Retail and Commerce IT > Distribution schedule**.
7. Select **Registers (1090)** and click **Run now** in the action bar. When prompted, click **Yes** to run the job.

## Validate the extension

1. Press **F5** and deploy the POS to test your customization.
2. After the POS starts, sign in to POS and add an item to a transaction.
3. Suspend the transaction.
4. The custom receipt should print.

# Add custom controls to non-screen designer-based POS views

2/18/2021 • 6 minutes to read • [Edit Online](#)

You can enhance the information displayed on a Dynamics 365 Commerce POS view by adding custom controls. A custom control allows you to add your own custom information to the existing POS views. Custom controls can be implemented by using the POS extension framework. Currently, you cannot place the custom control in the desired location, at runtime, POS will load it in a fixed position.

This topic applies to Dynamics 365 for Finance and Operations, and Dynamics 365 Retail with Platform update 8, and Retail Application update 4 hotfix.

The following table lists the non-screen layout designer-based views that support custom controls.

POS VIEWS	SUPPORT CUSTOM CONTROL	NUMBER OF CUSTOM CONTROLS
Customer Add/Edit view	Yes	Multiple
Address Add/Edit view	Yes	Multiple
Customer details view	Yes	Multiple
Product details view	Yes	Multiple
Price check view	Yes	Multiple

The following table lists the screen layout designer based-views that support custom controls.

POS VIEWS	SUPPORT CUSTOM CONTROL	NUMBER OF CUSTOM CONTROLS
Cart view	Yes	10

## Create the custom control

The following example demonstrates how to add a custom control to one of the existing POS views using extensions. For example, suppose you want to show the product availability information in the product details view by adding custom data list that has four columns - Location, Inventory, Reserved, and Ordered.

A custom control is an HTML page with the custom information to be displayed. A corresponding Typescript file contains the logic for the control.

1. Open Visual Studio 2015 in administrator mode.
2. Open Modern POS from `\RetailSDK\POS`.
3. Under the `POS.Extensions` project, create a new folder named `ProdDetailsCustomColumnExtensions`.
4. Under `ProdDetailsCustomColumnExtensions`, create a new folder named `ViewExtensions`.
5. Under `ViewExtensions`, create new folder named `SimpleProductDetails`.

6. Add a new HTML file inside the **SimpleProductDetails** folder and name it **ProductAvailabilityPanel.html**.
7. Open **ProductAvailabilityPanel.html** and add the following code. The code adds a POS data list control to show the product availability information and the width of the control.

```
<!DOCTYPE html>
<html lang="en" xmlns="http://www.w3.org/1999/xhtml">
<head>
  <meta charset="utf-8" />
  <title></title>
</head>
<body>
  <!-- Note: The element ID is different than the ID generated by the POS extensibility framework.
  This 'template' ID is not used by the POS extensibility framework. -->
  <script id="Microsoft_Pos_Extensibility_Samples_ProductAvailabilityPanel" type="text/html">
    <h2 class="marginTop8 marginBottom8" data-bind="text: title"></h2>
    <div class="width400 grow col">
      <div id="Microsot_Pos_Extensibility_Samples_ProductAvailabilityPanel_DataList" data-
bind="msPosDataList: dataList"></div>
    </div>
  </script>
</body>
</html>
```

8. In the **SimpleProductDetails** folder, add a new typescript file and name it **ProductAvailabilityPanel.ts**.
9. Add the following **import** statements to import the relevant entities and context.

```
import {

  SimpleProductDetailsCustomControlBase,
  ISimpleProductDetailsCustomControlState,
  ISimpleProductDetailsCustomControlContext

} from "PosApi/Extend/Views/SimpleProductDetailsView";

import { InventoryLookupOperationRequest, InventoryLookupOperationResponse } from
"PosApi/Consume/OrgUnits";
import { ClientEntities, ProxyEntities } from "PosApi/Entities";
import { ArrayExtensions } from "PosApi/TypeExtensions";
import { DataList, SelectionMode } from "PosUISdk/Controls/DataList";
```

10. Create a new class named **ProductAvailabilityPanel** and extend it from **SimpleProductDetailsCustomControlBase**.

```
export default class ProductAvailabilityPanel extends SimpleProductDetailsCustomControlBase { }
```

11. Inside the class, declare the following variables for state and data list information.

```
private static readonly TEMPLATE_ID: string =
"Microsot_Pos_Extensibility_Samples_ProductAvailabilityPanel";
public readonly orgUnitAvailabilities: ObservableArray<ProxyEntities.OrgUnitAvailability>;
public readonly dataList: DataList<ProxyEntities.OrgUnitAvailability>;
public readonly title: Observable<string>;
private _state: ISimpleProductDetailsCustomControlState;
```

12. Add a class constructor method to initialize the data list columns.

```

constructor(id: string, context: ISimpleProductDetailsCustomControlContext) {

    super(id, context);
    this.orgUnitAvailabilities = ko.observableArray([]);
    this.title = ko.observable("Product Availability");
    this.dataList = new DataList<ProxyEntities.OrgUnitAvailability>({
        columns: [

            {
                title: "Location",
                ratio: 31,
                collapseOrder: 4,
                minWidth: 100,
                computeValue: (value: ProxyEntities.OrgUnitAvailability): string => {
                    return value.OrgUnitLocation.OrgUnitName;
                }
            },

            {
                title: "Inventory",
                ratio: 23,
                collapseOrder: 3,
                minWidth: 60,
                computeValue: (value: ProxyEntities.OrgUnitAvailability): string => {
                    return ArrayExtensions.hasElements(value.ItemAvailabilities) ?
value.ItemAvailabilities[0].AvailableQuantity.toString() : "0";
                }
            },

            {
                title: "Reserved",
                ratio: 23,
                collapseOrder: 1,
                minWidth: 60,
                computeValue: (value: ProxyEntities.OrgUnitAvailability): string => {
                    return ArrayExtensions.hasElements(value.ItemAvailabilities) ?
value.ItemAvailabilities[0].PhysicalReserved.toString() : "0";
                }
            },

            {
                title: "Ordered",
                ratio: 23,
                collapseOrder: 2,
                minWidth: 60,
                computeValue: (value: ProxyEntities.OrgUnitAvailability): string => {
                    return ArrayExtensions.hasElements(value.ItemAvailabilities) ?
value.ItemAvailabilities[0].OrderedSum.toString() : "0";
                }
            }
        ],

        itemDataSource: this.orgUnitAvailabilities,
        selectionMode: SelectionMode.None
    });
}

```

13. Add the **OnReady** method to bind the HTML control.

```

public onReady(element: HTMLElement): void {

    ko.applyBindingsToNode(element, {
        template: {
            name: ProductAvailabilityPanel.TEMPLATE_ID,
            data: this
        }
    });
}

```

14. Add the **init** method to get the product availability details so when the page loads, the data is fetched and updated in the data list.

```

public init(state: ISimpleProductDetailsCustomControlState): void {

    this._state = state;
    let correlationId: string = this.context.logger.getNewCorrelationId();
    if(!this._state.isSelectionMode) {
        this.isVisible = true;

        let request: InventoryLookupOperationRequest<InventoryLookupOperationResponse> =
            new InventoryLookupOperationRequest<InventoryLookupOperationResponse>
                (this._state.product.RecordId, correlationId);
        this.context.runtime.executeAsync(request)
            .then((result: ClientEntities.ICancelableDataResult<InventoryLookupOperationResponse>) => {

                if (!result.canceled) {
                    this.orgUnitAvailabilities(result.data.orgUnitAvailability);
                }

            }).catch((reason: any) => {
                this.context.logger.logError(JSON.stringify(reason), correlationId);
            });
    }
}

```

The entire code example is shown below.

```

import {
    SimpleProductDetailsCustomControlBase,
    ISimpleProductDetailsCustomControlState,
    ISimpleProductDetailsCustomControlContext
} from "PosApi/Extend/Views/SimpleProductDetailsView";

import { InventoryLookupOperationRequest, InventoryLookupOperationResponse } from
"PosApi/Consume/OrgUnits";
import { ClientEntities, ProxyEntities } from "PosApi/Entities";
import { ArrayExtensions } from "PosApi/TypeExtensions";
import { DataList, SelectionMode } from "PosUISdk/Controls/DataList";
export default class ProductAvailabilityPanel extends SimpleProductDetailsCustomControlBase {

    private static readonly TEMPLATE_ID: string =
"Microsot_Pos_Extensibility_Samples_ProductAvailabilityPanel";
    public readonly orgUnitAvailabilities: ObservableArray<ProxyEntities.OrgUnitAvailability>;
    public readonly dataList: DataList<ProxyEntities.OrgUnitAvailability>;
    public readonly title: Observable<string>;
    private _state: ISimpleProductDetailsCustomControlState;

    constructor(id: string, context: ISimpleProductDetailsCustomControlContext) {
        super(id, context);
    }
}

```

```

this.orgUnitAvailabilities = ko.observableArray([]);
this.title = ko.observable("Product Availability");
this.dataList = new DataList<ProxyEntities.OrgUnitAvailability>({

    columns: [
        {
            title: "Location",
            ratio: 31,
            collapseOrder: 4,
            minWidth: 100,
            computeValue: (value: ProxyEntities.OrgUnitAvailability): string => {
                return value.OrgUnitLocation.OrgUnitName;
            }
        },
        {
            title: "Inventory",
            ratio: 23,
            collapseOrder: 3,
            minWidth: 60,
            computeValue: (value: ProxyEntities.OrgUnitAvailability): string => {
                return ArrayExtensions.hasElements(value.ItemAvailabilities) ?
                    value.ItemAvailabilities[0].AvailableQuantity.toString() : "0";
            }
        },
        {
            title: "Reserved",
            ratio: 23,
            collapseOrder: 1,
            minWidth: 60,
            computeValue: (value: ProxyEntities.OrgUnitAvailability): string => {
                return ArrayExtensions.hasElements(value.ItemAvailabilities) ?
                    value.ItemAvailabilities[0].PhysicalReserved.toString() : "0";
            }
        },
        {
            title: "Ordered",
            ratio: 23,
            collapseOrder: 2,
            minWidth: 60,
            computeValue: (value: ProxyEntities.OrgUnitAvailability): string => {
                return ArrayExtensions.hasElements(value.ItemAvailabilities) ?
                    value.ItemAvailabilities[0].OrderedSum.toString() : "0";
            }
        }
    ],

    itemDataSource: this.orgUnitAvailabilities,
    selectionMode: SelectionMode.None
});

}

/**
 * Binds the control to the specified element.
 * @param {HTMLElement} element The element to which the control should be bound.
 */

public onReady(element: HTMLElement): void {
    ko.applyBindingsToNode(element, {
        template: {
            name: ProductAvailabilityPanel.TEMPLATE_ID,
            data: this
        }
    }
}

```

```

    });

}

/**
 * Initializes the control.
 * @param {ISimpleProductDetailsCustomControlState} state The initial state of the page used to
initialize the control.
 */

public init(state: ISimpleProductDetailsCustomControlState): void {
    this._state = state;
    let correlationId: string = this.context.logger.getNewCorrelationId();
    if (!this._state.isSelectionMode) {
        this.isVisible = true;
        let request: InventoryLookupOperationRequest<InventoryLookupOperationResponse> =
            new InventoryLookupOperationRequest<InventoryLookupOperationResponse>
                (this._state.product.RecordId, correlationId);
        this.context.runtime.executeAsync(request)
            .then((result:
ClientEntities.ICancelableDataResult<InventoryLookupOperationResponse>) => {
                if (!result.canceled) {
                    this.orgUnitAvailabilities(result.data.orgUnitAvailability);
                }
            })
            .catch((reason: any) => {
                this.context.logger.logError(JSON.stringify(reason), correlationId);
            });
    }
}
}
}

```

15. Create a new .json file and under the **ProdDetailsCustomColumnExtensions** folder and name it **manifest.json**.

16. In the **manifest.json** file, add the following code.

```

{
  "$schema": "../manifestSchema.json",
  "name": "Pos_Extensibility_Samples",
  "publisher": "Microsoft",
  "version": "7.2.0",
  "minimumPosVersion": "7.2.0.0",
  "components": {
  "extend": {
    "views": {
      "SimpleProductDetailsView": {
        "controlsConfig": {
          "customControls": [
            {
              "controlName": "productAvailabilityPanel",
              "htmlPath":
"ViewExtensions/SimpleProductDetails/ProductAvailabilityPanel.html",
              "modulePath":
"ViewExtensions/SimpleProductDetails/ProductAvailabilityPanel"
            }
          ]
        }
      }
    }
  }
}

```

17. Open the **extensions.json** file under the **POS.Extensions** project and add the **ProdDetailsCustomColumnExtensions** samples, so during runtime POS will include the extension.

```

{
  "extensionPackages": [
    {
      "baseUrl": "SampleExtensions2"
    },
    {
      "baseUrl": "ProdDetailsCustomColumnExtensions"
    }
  ]
}

```

18. Open the **tsconfig.json** and comment out the extension package folders from the exclude list. POS uses this file to include or exclude extensions. By default, the list contains the excluded extensions list. If you want to include any extension part of the POS, then you need add the extension folder name and comment out the extension from the extension list as shown.

```

"exclude": [
  "AuditEventExtensionSample",
  "B2BSample",
  "CustomerSearchWithAttributesSample",
  "FiscalRegisterSample",
  "PaymentSample",
  "PromotionsSample",
  "SalesTransactionSignatureSample",
  "SampleExtensions",
  //"SampleExtensions2",
  //"ProdDetailsCustomColumnExtensions"
],

```

19. Compile and rebuild the project.

## Validate the customization

1. Press F5 and deploy the POS to test your customization.
2. After POS launches, login to POS. Search for any product and navigate to the product details view. You should see the custom control that you added.

### **NOTE**

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Run the point of sale (POS) samples

2/18/2021 • 2 minutes to read • [Edit Online](#)

There are several samples in the Retail SDK that demonstrate extensions. This topic explains how to run these samples.

## Run the SampleExtensions in POS

1. Open **ModernPos.Sln** or **CloudPos.sln** from the **Retail SDK\POS** folder.
2. Select the **POS.Extensions** project in the solution and click **Show All Files**.
3. Right-click the **SampleExtensions** folder and select **Include in Project**.
4. Right-click the **SampleExtensions2** folder and select **Include in Project**.
5. Open the **extensions.json** file and add the extension folder for **SampleExtensions** and **SampleExtensions2**. This means that during runtime POS will include this extension. The **baseUrl** value must exactly match the relative path and extension folder name.

```
{
  "extensionPackages": [
    {
      "baseUrl": "SampleExtensions"
    },
    {
      "baseUrl": "SampleExtensions2"
    }
  ]
}
```

### NOTE

In the extension.json file you must include at least two extension folders. If you add only one extension folder, then POS will not load the extension.

6. Open the **tsconfig.json** file and comment out the extension package folders from the exclude list. POS will use this file to determine whether to compile the extension. By default, the list contains the sample extensions list. If you want to compile any extension to the POS, then you need add the extension folder name and comment out the extension from the extension as shown below.

```

{
  "extends": "../tsconfigs/tsmodulesconfig",
  "exclude": [
    "AuditEventExtensionSample"
    , "B2BSample"
    ,"CustomerSearchWithAttributesSample"
    ,"FiscalRegisterSample"
    ,"PaymentSample"
    ,"PromotionsSample"
    ,"SalesTransactionSignatureSample"
    // ,"SampleExtensions"
    // ,"SampleExtensions2"
    ,"StoreHoursSample"
    ,"SuspendTransactionReceiptSample"
  ],
  "compilerOptions": {
    // There is an unexpected behavior for TypeScript 2.2.2 in map and source roots generated in
    compiled JS and map files.
    // The following may change in future TypeScript versions.
    // In case there is only one top level extensions folder with .ts files included, the
    following two root
    // directories need to be changed to include the extensions folder.
    // For example, change both roots to "./SampleExtensions" if "SampleExtensions" folder is the
    only top level
    // folder that has .ts files included in the project.
    // That is, either "SampleExtensions" folder is the only top level folder, or all other top
    level folders
    // have .js files only, no .ts files.
    "mapRoot": "./", /* Cannot be specified in base file. Adds full path to ".map" in the js file
    to enable debug in VS. */
    "sourceRoot": "./" /* Cannot be specified in base file. Adds full path to ".ts" in the map
    file to enable debug in VS. */
  }
}

```

If you want to enable other extensions, comment them out from the exclude list. For example, if you want to include **B2BSample**, the code would be as follows.

```

"exclude": [
  "AuditEventExtensionSample"
  // ,"B2BSample"
  ,"CustomerSearchWithAttributesSample"
  ,"FiscalRegisterSample"
  ,"PaymentSample"
  ,"PromotionsSample"
  ,"SalesTransactionSignatureSample"
  // ,"SampleExtensions"
  // ,"SampleExtensions2"
  ,"StoreHoursSample"
  ,"SuspendTransactionReceiptSample"
],

```

#### NOTE

Other extension package folders, even though not included in the Visual Studio project, should be kept in the exclude list if they are not meant to be included.

7. Set **Solution platform** to **x86** and **Deploy option** to **Local Machine** or **Simulator** if you are using Modern POS for validation.
8. Click **Save all** and press the **F5** key to validate the extensions.

**NOTE**

For cloud POS, use a clean solution in Visual Studio, and then rebuild the solution.

9. Go to the product search screen or use the top search bar to search for a product. You should see custom columns in the grid and new app bar buttons.

**NOTE**

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Device management implementation guidance

2/18/2021 • 13 minutes to read • [Edit Online](#)

This topic is intended for people who implement functionality that is related to device management in a commerce environment. It gives implementation tips and guidance that you should consider as you plan your implementation.

## Overview

A *device* is an instrument on which a point of sale (POS) application can be installed, configured, and used to perform operations that are required in order to run or help run the business that owns that instrument. In other words, a device is a piece of technology that runs a POS application to help run a business. This business doesn't have to be exclusively a commerce operation. For example, a hospital has a gift shop, a warehouse manages inventory, and a law firm generates invoices. What is important is that the application that the device runs makes business operations simpler, more efficient, or just better managed and recorded. Regardless of the scenario that they are used in, devices are critical elements. As the number of devices that are used increases, it becomes more valuable to put processes in place to track and manage those devices. Together, these processes are known as *device management*.

The POS application that this topic discusses is Modern POS (MPOS) in Microsoft Dynamics 365 Commerce. MPOS lets users complete business operations quickly, efficiently, and simply. It also helps the organization manage the many devices that run MPOS across the business. Although this topic discusses many aspects of an MPOS device, the two critical aspects are the business-oriented *register* and the physical concept of a *device*.

The **Registers** page is the virtual tracking mechanism for the business-oriented details of an instance of the MPOS application. These details include the visual profile that is used, the automatic sign-out time, and the store that the register is a part of. All these details are stored in the virtual register. When the register is correctly set up and configured, it's linked to a virtual device.

The **Devices** page is the virtual tracking mechanism for the physical concept of a device. The business-oriented register is linked here to complete the configuration and prepare for installation. The virtual device stores details such as the validation status, when the POS application was activated, and the version that will be installed or the version that is currently installed.

As more registers are generated and then linked to the appropriate devices, both physical and virtual management become critically important. For example, a business has one physical device, a Microsoft Surface that will run MPOS. The Surface must be configured for the business, because it might be on a domain or require additional software that is specific to that business. MPOS must also be installed and activated on the Surface. Over time, the device might require servicing or replacement, or it might even be stolen. If the business doesn't have just one device, but dozens, hundreds, or even thousands, processes must be put in place to appropriately watch, manage, and verify the status of all the devices. These devices include both devices that are currently used and devices that aren't currently used.

Commerce already provides the basic requirements for device management. As you plan your implementation, you must make sure that you take all the appropriate considerations, to help minimize pain and maximize benefit.

## Implementation considerations

This section describes some things that you should consider as you plan to implement features that are related to device management in your retail store and distribution locations.

## Generate the physical topology

Planning is the most critical requirement for successful implementation of an enterprise resource planning (ERP) solution. One of the main deliverables of this planning should be a *physical topology*. The physical topology is a visualization of many details about a company, from the lowest POS device to the highest network connections at the headquarters. At a minimum, the following deliverables should be completed:

- **Store templates** – A store template consists of one or more diagrams that show the layout of a physical location, such as a brick-and-mortar store. In the long term, these diagrams help you easily implement future locations and quickly assess how you can fix or improve any issues that are found. The store template should include the following details:
  - **Location** – The physical layout of a location. Details should include the position of all devices that exist in the location.
  - **Network** – The internal layout of the network infrastructure and details about internet connectivity (for example, bandwidth up and down, thread count, and latency to the headquarters or other important internet locations).
  - **Device** – The details of all devices that exist in a location. These details include the device specifications or some type of associable tag that lets you quickly find the details about a device.
  - **Peripheral** – A list of all peripherals that are attached to a device, a count of peripherals, and physical location of all peripherals. Often, there should also be an associable tag that lets you quickly find details.
- **Naming methodology** – For any implementation, it's important that you maintain naming conventions across all devices. Generate the rules that govern the naming conventions, and follow those rules.

### NOTE

When you generate the naming methodology, we recommend that the name of a register be the same as, or very similar to, the name of the device. The name of the device, in turn, should be the same as, or very similar to, the friendly name of the physical computer that the register works on.

- **Procedures plan** – The more a business grows, the more important it becomes that procedures remain in place to help maintain enough order so that the business can run efficiently. You should consider your plan a living document that you must be maintained and appended often. This plan should explain how to perform almost every action that will be repeated in the stores that make up a company.
- **Servicing plan** – As business continues, servicing becomes more critical. You must decide when you will replace devices, when you will update devices and peripherals (both the applications and the operating systems), and how you will perform these tasks. The answers will vary from business to business, but these tasks should be planned for.
- **Disaster plan** – If something can go wrong, it should be planned for. As planning proceeds, make a note of risks and potential mitigations. Generate a plan that explains how to fix a problematic situation.

After planning is completed and all potential details are known, you will eventually have a list of stores and, for each store, a list of associated registers and devices. The next question that you must answer is how you will deploy all the various devices that are listed.

## Distributed deployment

As the number of devices increases into the hundreds or even thousands, manual configuration, installation, and activation of the POS application quickly becomes impractical. There are several concepts that you can use to alleviate this issue and to manage or help manage devices on a large scale:

- **Devices page** – When you use MPOS, the page that shows the details of a device includes information about the POS client that should be used on the device. Under the **Register package** subheading, there are

four fields. The first three fields (**Package name**, **Package description**, and **Version number**) provide information about the version of the MPOS package that should be installed on the device either now or later. The fourth field shows the version of MPOS that is currently installed. Therefore, you can easily find this information for any device.

- **Channel deployment workspace** – This workspace lets you quickly view a large, filterable set of stores, registers, devices, and more. This workspace also provides options for mass deployment. (For more information, see [Customer orders in Modern POS \(MPOS\)](#)). This workspace gives you quick access to important pages, can help decrease validation times when you do status checks after a deployment, and helps you efficiently manage device statuses.
- **Mass deployment** – Dynamics 365 customers who use MPOS and other client-side components can silently perform various actions to help with installation, configuration, and servicing. By running basic commands at a command prompt, you might be able to deploy and service (that is, update) commerce components. This basic method of skipping the installer's manual user interface can reduce the time that is required for installation and servicing. The log files remain the same and can be viewed for installation details.
- **Scripting** – Based on the mass deployment functionality, scripts can be generated and set up to run automatically to install or update commerce components such as MPOS. These basic scripts can be entered as a scheduled task on a device. The task then runs at a predetermined time and return the logs and results to a predetermined location, where they can be viewed as time permits.
- **Systems management solution** – A systems management solution can help increase the amount of known data about the devices that are used. It can also decrease the time that is required in order to get that data. Examples of systems management solutions include Microsoft System Center and Microsoft Intune. By using a systems management solution together with mass deployment and scripting, you can configure and install components much more quickly. In addition, you can more efficiently validate status after deployment or servicing. Microsoft has published a document specifically about device management via System Center Configuration Manager, [Choose a device management solution for System Center Configuration Manager](#).

For more information that will help you better understand distributed deployment, see [Configure, install, and activate Modern POS \(MPOS\)](#) and [Customer orders in Modern POS \(MPOS\)](#).

## Servicing devices

Although deployment is an important topic that has many nuances, the ongoing nature of business requires that you consider servicing early, and that you plan for it. In that way, you can maximize efficiency and speed of completion every time that servicing is required. Servicing becomes even more important when you understand that, not only do applications have to be serviced, but the operating system and peripherals might also require updates. As we mentioned earlier, this process can be even more difficult when it's time to replace devices. In general, you should consider all the following factors:

- **Devices** – The process of servicing a device involves more than just determining whether servicing has been completed. Instead, many aspects of the device must be reviewed and updated, either individually or as part of a group of devices at the same time:
  - The information on the **Devices** page, or in the **Channel deployment** workspace, in Dynamics 365 headquarters can help you validate the current status and version of MPOS or other self-service components, such as hardware station or Commerce Scale Unit.
  - It's very useful if you know the version of Microsoft Windows. In scenarios where a systems management solution isn't used, you can use the **winver** command in a Command Prompt window to quickly learn the specific version of Windows that is currently installed. By comparing the version number against the [Windows version list](#), you can easily learn what updates a computer is missing at a service pack level.
  - Internal and peripheral drivers must be checked for version updates too. You should include and monitor this information in the device and peripheral lists that you created as part of the store templates during the planning phase, as explained earlier in this topic.

- Always track when a computer goes out of service (warranty or service plan). In this way, you can quickly determine when a computer should be replaced instead of being sent out for servicing (warranty or service plan).
- **Peripherals** – The peripherals that are attached to a device or to the network must be monitored. As part of this process, you must also monitor the network devices themselves. (Routers, switches, firewalls, and all other network devices also have firmware that requires occasional updates to maintain security and compatibility, and to comply with servicing terms.) If appropriate planning has occurred, the process of watching for service dates and correctly updating peripherals should become a simplified task within the larger servicing flow for device management.
- **Replacements** – Eventually, devices and peripherals either fail or reach a point where servicing just isn't enough. In general, we highly recommended that you have a replacement system that is ready before this situation arises. Based on the procedures and servicing plans that you created during the planning phase, this process can be very fast and efficient. For a device that runs MPOS, you can generically prepare the replacement device and install MPOS on it long before you either send the unit on-site or store it on-site, depending on the approach that works best for the business. At the time of replacement, MPOS can "reactivate" a device that is already active. Therefore, you can handle special cases where a system stops responding and must be replaced, because it can't be repaired. However, you must make sure that the replacement is correctly up to date, and that it has recently been serviced.
- **Systems management solution** – A systems management solution can dramatically improve how servicing works and when servicing is done. These solutions include telemetry tools that monitor all the systems that are being used. Because of these telemetry tools and the device information data that is constantly stored and available, servicing should become proactive instead of reactive. In this best-case scenario, appropriate plans exist for procedures and servicing, and the alerts and the known data about a system can let you know about impending servicing or an impending replacement before an issue occurs and becomes a critical task.

### **Worst-case scenarios**

Unfortunately, things sometimes go wrong. It's important that you consider worst-case scenarios and put mitigation plans in place (per the disaster plan that you created during the planning phase) to help resolve issues that arise. In Commerce, the **Devices** page can at least help with device management.

- **Lost/stolen device** – When a device is lost or stolen, it becomes a critical issue, because private data can end up in the hands of a malicious person. The first step is to deactivate any lost or stolen device on the **Devices** page in Headquarters, to immediately prevent sign-on to that device. If you created a disaster plan, follow the rest of the guidelines to complete all tasks that are required in order to tag the device as gone, file all important documents (which might include documents for insurance and the police), and work to replace the device and continue business. If appropriate procedures have been created, a replacement device should already be ready.
- **Infrastructure issues** – Network equipment might go bad, the store layout might have to be altered, or, as a part of a store update, the devices might be changed from desktops to tablets. When issues arise that can affect the management of devices, it can be difficult to react appropriately and fix the issues. In the best-case scenario, you've already discussed these issues and listed them in the procedures, servicing, and disaster plans. At a minimum, before something is done that affects the layout of a business location, you should update the store layout documents to reflect the new layout, so that fewer surprises are met. As we mentioned earlier, for issues that affect MPOS specifically, the ability to reactivate should help mitigate downtime and should help with change management. If you're concerned about outages of network equipment, or if outages occur, the MPOS client can support offline databases. This functionality can help mitigate the impact that outages have on business.
- **Disaster** – When a disaster occurs, everything is affected. If the disaster is environmental, the employees should always be the highest priority. However, eventually, you must handle the management of the internal systems, and those systems must be repaired. Unfortunately, no simple advice or specific considerations can

be listed. Instead, you should plan early in a more general way. What sorts of disasters could affect the business? Utilities such as water and power can have devastating effects on equipment. How can you mitigate the effects on employees, locations, and equipment in various disasters? Keep in mind concepts such as the data that is stored in the location, and when and how it's backed up and secured.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# POS Cart view events and handlers

2/18/2021 • 4 minutes to read • [Edit Online](#)

This topic explains how extensions can consume the point of sale (POS) view events and handlers for custom scenarios. For example, the Cart view in POS exposes multiple events and handlers so that your extensions can perform custom business flows, based on events. The extensions can subscribe to an event and receive a notification when that event occurs.

## Cart view event handlers

The base class that is used to consume the Cart view handlers is **CartExtensionViewControllerBase**.

```
export default class CartViewController extends CartView.CartExtensionViewControllerBase {  
}
```

BASE CLASS	EVENT/HANDLER	DESCRIPTION
CartExtensionViewControllerBase	cartLineSelectedHandler: (data: CartLineSelectedData) => void;	The handler for the message that appears when a cart line is selected.
	cartLineSelectionClearedHandler: () => void;	The handler for the message that appears when the selection of a cart line is cleared.
	tenderLineSelectedHandler: (data: TenderLineSelectedData) => void;	The handler for the message that appears when a tender line is selected.
	protected tenderLineSelectionClearedHandler: () => void;	The handler for the message that appears when the selection of a tender line is cleared.
	protected cartChangedHandler: (data: CartChangedData) => void;	The handler for the message that appears when the cart is changed.
	protected processingAddItemOrCustomerChangedHandler: (processing: boolean) => void;	The handler that adds the message about the item or customer processing state.
	protected setSelectedCartLines(setSelectedCartLinesData: SetSelectedCartLinesData): void;	The handler that selects the cart lines that are shown on the page.

The following example shows how to consume Cart view events.

```

import { ProxyEntities } from "PosApi/Entities";
import { IExtensionCartViewControllerContext } from "PosApi/Extend/Views/CartView";
import * as CartView from "PosApi/Extend/Views/CartView";
import { ArrayExtensions, StringExtensions } from "PosApi/TypeExtensions";

export default class CartViewController extends CartView.CartExtensionViewControllerBase {

    public static selectedCartLineId: string = StringExtensions.EMPTY;

    private _selectedCartLines: ProxyEntities.CartLine[];
    private _selectedTenderLines: ProxyEntities.TenderLine[];
    private _isProcessingAddItemOrCustomer: boolean;

    /**
     * Creates a new instance of the CartViewController class.
     * @param {IExtensionCartViewControllerContext} context The events Handler context.
     * @remarks The events handler context contains APIs through which a handler can communicate with POS.
     */
    constructor(context: IExtensionCartViewControllerContext) {
        super(context);

        this.cartLineSelectedHandler = (data: CartView.CartLineSelectedData): void => {
            this._selectedCartLines = data.cartLines;

            if (ArrayExtensions.hasElements(this._selectedCartLines)) {
                CartViewController.selectedCartLineId = this._selectedCartLines[0].LineId;
            }
        };

        this.cartLineSelectionClearedHandler = (): void => {
            this._selectedCartLines = undefined;
            CartViewController.selectedCartLineId = null;
        };

        this.tenderLineSelectedHandler = (data: CartView.TenderLineSelectedData): void => {
            this._selectedTenderLines = data.tenderLines;
        };

        this.tenderLineSelectionClearedHandler = (): void => {
            this._selectedCartLines = undefined;
        };

        this.processingAddItemOrCustomerChangedHandler = (processing: boolean): void => {
            this._isProcessingAddItemOrCustomer = processing;
        };
    }
}

```

## Base classes for consuming Cart view events in Cart view UI extensions

There are several base classes for consuming events in the user interface (UI):

- Custom controls
- Custom fields in the **Totals** pane
- Custom columns in the **Lines** grid
- Custom columns in the **Payment** grid
- Custom columns in the **Delivery** grid

### Custom controls

BASE CLASS	EVENT	DESCRIPTION
CartViewCustomControlBase	cartLineSelectedHandler: (data: CartLineSelectedData) => void;	The handler for the message that appears when a cart line is selected.
	cartLineSelectionClearedHandler: () => void;	The handler for the message that appears when the selection of a cart line is cleared.
	tenderLineSelectedHandler: (data: TenderLineSelectedData) => void;	The handler for the message that appears when a tender line is selected.
	protected tenderLineSelectionClearedHandler: () => void;	The handler for the message that appears when the selection of a tender line is cleared.
	protected cartChangedHandler: (data: CartChangedData) => void;	The handler for the message that appears when the cart is changed.
	protected processingAddItemOrCustomerChangedHandler: (processing: boolean) => void;	The handler that adds the message about the item or customer processing state.
	protected setSelectedCartLines(setSelectedCartLinesData: SetSelectedCartLinesData): void;	The handler that selects the cart lines that are shown on the page.

### Custom fields in the Totals pane

BASE CLASS	EVENT	DESCRIPTION
CartViewTotalsPanelCustomFieldBase	public computeValue(cart: ProxyEntities.Cart): string { }	Compute the value for the custom field.

### Custom columns in the Lines grid

BASE CLASS	EVENT	DESCRIPTION
CustomLinesGridColumnBase	public title(): string { }	Set the title for the custom column.
	public computeValue(cartLine: ProxyEntities.CartLine): string { }	Compute the value for the custom column.
	public alignment(): CustomGridColumnAlignment { } <b>Supported values:</b> enum CustomGridColumnAlignment { Left = 0, Right = 1 }	Set left or right alignment for the custom column.

### Custom columns in the Payment grid

BASE CLASS	EVENT	DESCRIPTION
CustomPaymentsGridColumnBase	public title(): string { }	Set the title for the custom column.

BASE CLASS	EVENT	DESCRIPTION
	<pre>public computeValue(cartLine: ProxyEntities.CartLine): string { }</pre>	Compute the value for the custom column.
	<pre>public alignment(): CustomGridColumnAlignment { } <b>Supported values:</b> enum CustomGridColumnAlignment { Left = 0, Right = 1 }</pre>	Set left or right alignment for the custom column.

### Custom columns in the Delivery grid

BASE CLASS	EVENT	DESCRIPTION
CustomDeliveryGridColumnBase	<pre>public title(): string { }</pre>	Set the title for the custom column.
	<pre>public computeValue(cartLine: ProxyEntities.CartLine): string { }</pre>	Compute the value for the custom column.
	<pre>public alignment(): CustomGridColumnAlignment { } <b>Supported values:</b> enum CustomGridColumnAlignment { Left = 0, Right = 1 }</pre>	Set left or right alignment for the custom column.

#### NOTE

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Add custom buttons to the POS header bar

2/18/2021 • 4 minutes to read • [Edit Online](#)

This topic explains how to add a new custom button to the header bar in the point of sale (POS). The POS header bar extension is supported by Microsoft Dynamics 365 Commerce version 10.0.14 and later.

The custom header button must contain an HTML file that includes Cascading Style Sheets (CSS) code that describes the control user interface (UI), styles, and themes. It must also contain a TypeScript view model file that specifies the logic. The class inside the file view model file must extend the **CustomPackingItem** class, so that it inherits the header button properties and events. The **cartChangedHandler** event is exposed on the header button to provide notification if something changes in the cart. Your extension code can do custom logic that is based on cart events, or it can do custom business logic.

## CustomPackingItem class

### Properties

PROPERTY	DESCRIPTION
CustomPackingItemPosition	The item's position relative to the POS header items.
ICustomPackingItemContext	The context of the custom header packing item.

### Events and methods

EVENT OR METHOD	DESCRIPTION
cartChangedHandler	The handler for the <b>CartUpdated</b> event.
constructor(id: string, context: ICustomPackingItemContext)	This method creates a new instance of the <b>CustomHeaderPackingItem</b> class.
id()	This method gets the identifier of the custom header packing item.
get visible(): boolean	This method gets the visible value.
set visible(isVisible: boolean)	This method sets the visible value.
abstract onReady(packedElement: HTMLElement, unpackedElement: HTMLElement): void	This method is called when the control element is ready.
dispose(): void	This method disposes of the control and releases its resources.
protected abstract init(state: ICustomPackingItemState): void	This method initializes the control.

You must add nodes for the header button extension in the **manifest.json** file, as shown in the following example.

```

"header": {
  "customPackingItems": [
    {
      "name": " name of the control",
      "description": "Description.",
      "modulePath": " view model file name with path",
      "htmlPath": " html file name with path"
    }
  ]
}

```

## Add a custom button to the POS header bar

Follow these steps to add a custom button to the header bar and show the amount due by reading it from the cart.

1. Open Visual Studio 2017.
2. Open the **ModernPOS/CloudPOS** solution from **\RetailSDK\POS**.
3. In the **POS.Extensions** project, create a folder that is named **HeaderExtensionSample**.
4. In the **HeaderExtensionSample** folder, create an HTML file that is named **CartAmountDuePackingItem.html**.
5. Copy the following code, and paste it into the file.

```

<!DOCTYPE html>
<html lang="en" xmlns="http://www.w3.org/1999/xhtml">
<head>
  <meta charset="utf-8" />
  <title>Cart Amount Due Item Templates</title>
</head>
<body>
  <script id="Microsoft_Pos_Extensibility_Samples_UnpackedCartAmountDueItem" type="text/html">
    <button class="pad0 center row"
      data-bind="click: onItemClickHandler">
      <div class="iconShop buttonIcon height20"></div>
      <div class="h4 padRight8" data-bind="text: amountDueLabel"></div>
    </button>
  </script>
  <script id="Microsoft_Pos_Extensibility_Samples_PackedCartAmountDueItem" type="text/html">
    <button class="row pad0"
      data-bind="click: onItemClickHandler">
      <div class="iconShop buttonIcon height20 margin12">
      </div>
      <div class="grow row marginLeft8 padTop12">
        <div class="h4 padRight4">Amount due: </div>
        <div class="h4 padRight8" data-bind="text: amountDueLabel"></div>
      </div>
    </button>
  </script>
</body>
</html>

```

6. In the **HeaderExtensionSample** folder, create a TypeScript file that is named **CartAmountDuePackingItem.ts**.
7. Copy the following code, and paste it into the file.

```

import {
  CustomPackingItem, ICustomPackingItemContext, CustomPackingItemPosition, ICustomPackingItemState,

```

```

CartChangedData
} from "PosApi/Extend/Header";
import { CurrencyFormatter } from "PosApi/Consume/Formatters";
import { ClientEntities } from "PosApi/Entities";
import { StringExtensions } from "PosApi/TypeExtensions";

/**
 * (Sample) Custom packing item that shows the cart's amount due and navigates to the cart on click.
 */
export default class CartAmountDuePackingItem extends CustomPackingItem {
    /**
     * The position of the custom packing item relative to the out-of-the-box items.
     */
    public readonly position: CustomPackingItemPosition = CustomPackingItemPosition.After;

    /**
     * Label displayed in the custom packing item with the current amount due.
     */
    public amountDueLabel: Observable<string>;

    private _currentAmountDue: Observable<number>;
    private _amountDueSubscription: IDisposable;

    /**
     * Initializes a new instance of the CartAmountDuePackingItem class.
     * @param {string} id The item identifier.
     * @param {ICustomPackingItemContext} context The custom packing item context.
     */
    constructor(id: string, context: ICustomPackingItemContext) {
        super(id, context);

        this.amountDueLabel = ko.observable(StringExtensions.EMPTY);

        this._currentAmountDue = ko.observable(0);
        this._amountDueSubscription = this._currentAmountDue.subscribe((newValue: number) => {
            if (newValue > 0) {
                this.amountDueLabel(CurrencyFormatter.toCurrency(newValue));
                this.visible = true;
            } else {
                this.visible = false;
            }
        });

        this.cartChangedHandler = this._cartChangedHandler.bind(this);
    }

    /**
     * Called when the control element is ready.
     * @param {HTMLElement} packedElement The DOM element of the packed element.
     * @param {HTMLElement} unpackedElement The DOM element of the unpacked element.
     */
    public onReady(packedElement: HTMLElement, unpackedElement: HTMLElement): void {
        this.context.logger.logInformational("Executing onReady!");
        ko.applyBindingsToNode(unpackedElement, {
            template: {
                name: "Microsoft_Pos_Extensibility_Samples_UnpackedCartAmountDueItem",
                data: this
            }
        });

        ko.applyBindingsToNode(packedElement, {
            template: {
                name: "Microsoft_Pos_Extensibility_Samples_PackedCartAmountDueItem",
                data: this
            }
        });
    }
}

/**

```

```

    * Initializes the control.
    * @param {ICustomPackingItemState} state The custom control state.
    */
    public init(state: ICustomPackingItemState): void {
        return;
    }

    /**
     * Disposes the control releasing its resources.
     */
    public dispose(): void {
        this._amountDueSubscription.dispose();
        super.dispose();
    }

    /**
     * Method used to handle the onClick of the custom packing item.
     */
    public onItemClickClickedHandler(): void {
        const correlationId: string = this.context.logger.getNewCorrelationId();
        let cartViewOptions: ClientEntities.CartViewNavigationParameters = new
        ClientEntities.CartViewNavigationParameters(correlationId);

        this.context.logger.logInformational("Cart amount due packing item clicked.", correlationId);

        this.context.navigator.navigateToPOSVIEW("CartView", cartViewOptions);
    }

    /**
     * Handler for the cart changed event.
     * @param {CartChangedData} data The data sent with the event.
     */
    private _cartChangedHandler(data: CartChangedData): void {
        this.context.logger.logInformational("CartChanged received.");
        this._currentAmountDue(data.cart.AmountDue);
    }
}

```

8. In the **HeaderExtensionSample** folder, create a JavaScript Object Notation (JSON) file that is named **manifest.json**.

9. Copy the following code, and paste it into the file.

```

{
  "$schema": "../schemas/manifestSchema.json",
  "name": "HeaderExtensionSample ",
  "publisher": "Microsoft",
  "version": "10.0.14",
  "minimumPosVersion": "9.24.0.0",
  "components": {
    "extend": {
      "header": {
        "customPackingItems": [
          {
            "name": " CartAmountDuePackingItem",
            "description": "An item showing amount due.",
            "modulePath": " CartAmountDuePackingItem",
            "htmlPath": " CartAmountDuePackingItem.html"
          }
        ]
      }
    }
  }
}

```

10. In the `POS.Extensions` project, open the `extensions.json` file.
11. Update the details of the `HeaderExtensionSample` package, so that the POS can include this extension package during the initial load.

```
{
  "extensionPackages": [
    {
      "baseUri": "HeaderExtensionSample"
    }
  ]
}
```

12. Build the project.

### Validate the customization

Follow these steps to validate the customization.

1. Sign in to the POS by entering the operator ID and password.
2. Look at the header bar. The custom button that you added should be visible.

You can view the status of the extension package on the [POS settings page](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Hardware Station extensibility

2/18/2021 • 3 minutes to read • [Edit Online](#)

## NOTE

This topic is applicable for Dynamics 365 for Finance and Operations version 7.1 and earlier. This implementation is not supported for versions 7.2 and higher. For those versions, follow the extension model without overlayering.

This topic explains how to extend Hardware Station to add support for new devices and new device types for existing devices.

## Hardware Station overview

Hardware Station is used by Modern POS and Cloud POS to connect to hardware peripherals, such as printers, cash drawers, scanners, and payment terminals.

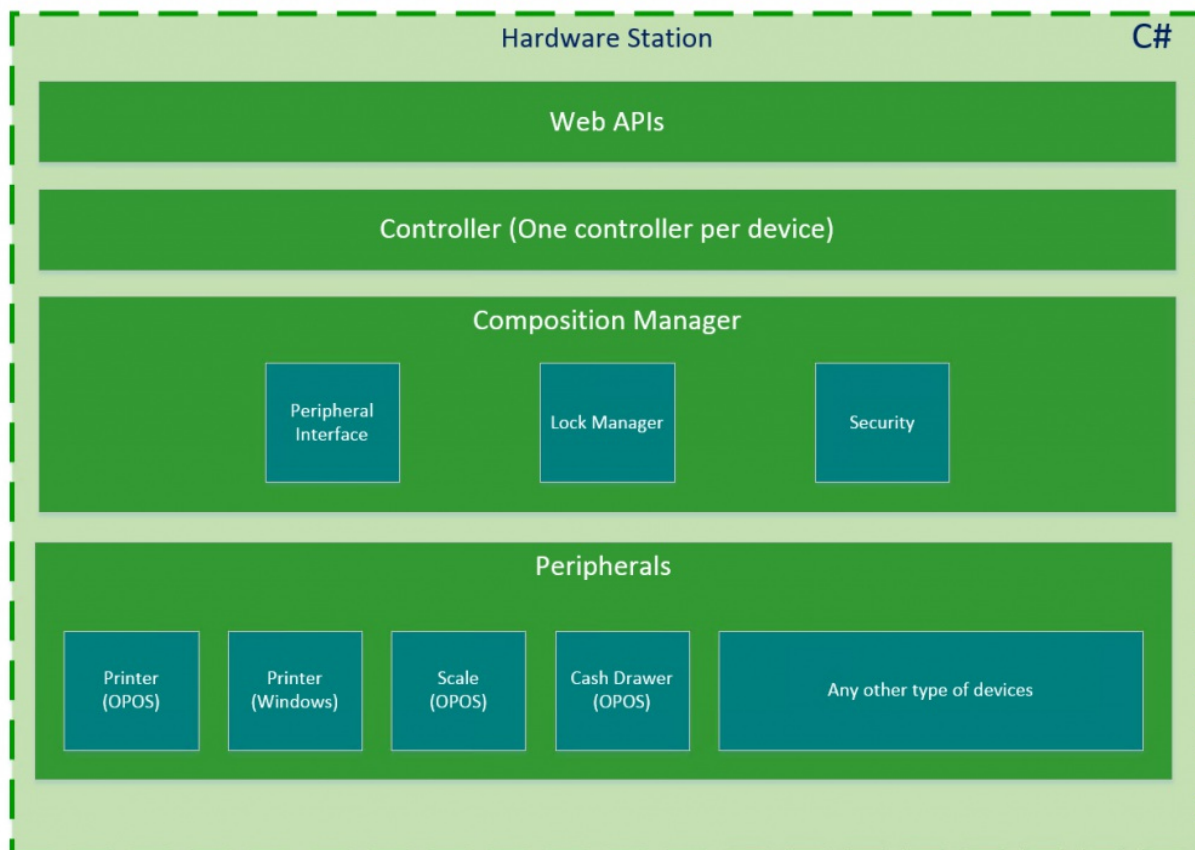

## Hardware Station setup

Before you start, use the information in [Configure and install Retail hardware station](#) to install Hardware Station, and to get a feel of what hardware is and how it's installed.

## Hardware Station architecture

Hardware Station exposes Web API for Hardware Station application programming interfaces (APIs). Hardware Station can be extended either by implementing a new controller for a new device (for example, a cash dispenser) or by overriding an existing controller for an existing device type (for example, a new Audio Jack magnetic stripe reader (MSR) implementation).

# Hardware Station Architecture

## Hardware Station extensibility scenarios

Extensibility in Hardware Station is achieved by using [Managed Extensibility Framework \(MEF\)](#), which is supported by .NET. **Extensibility guideline:** Always write your extension in your own extension assembly. That way, you're writing a true extension, and upgrades will be much easier. There are two basic scenarios for extension:

- **Adding a new device** – The out-of-box Hardware Station doesn't already support the device (for example, a cash dispenser). Therefore, you must add support for the new device in Hardware Station.
- **Adding a new device type for an existing device** – The out-of-box Hardware Station implementation already supports the device (for example, an MSR), but you must add support for a specific device type (for example, an Audio Jack MSR implementation).

### Scenario 1: Adding a new device

For this scenario, we will add support for a cash dispenser device in Hardware Station. In our example, we will create a fake cash dispenser that dispenses cash in the Notepad file. However, this example will help you understand the end-to-end extensibility of Hardware Station.

- The Retail software development kit (SDK) has a cash dispenser sample. See `RetailSdk\SampleExtensions\HardwareStation`.
- In this case, we must add a new Web API controller and helper properties/methods.
- The new `CashDispenser` controller must extend `ApiController` and `IHardwareStationController`.
- The `Export` attribute string here specifies the device that this controller is used for:  
`[Export("CASHDISPENSER", typeof(IHardwareStationController))]`

```

namespace Contoso
{
    namespace Commerce.HardwareStation.CashDispenserSample
    {
        using System;
        using System.Composition;
        using System.Web.Http;
        using Microsoft.Dynamics.Commerce.HardwareStation;
        using Microsoft.Dynamics.Retail.Diagnostics;
        /// <summary>
        /// Cash dispenser web API controller class.
        /// </summary>
        [Export("CASHDISPENSER", typeof(IHardwareStationController))]
        public class CashDispenserController : ApiController, IHardwareStationController
        {
            // Add your controller code here
        }
    }
}

```

## Scenario 2: Adding a new device type for an existing device

For this scenario, we will add support for a new device type for an existing device (an Audio Jack MSR implementation).

- The **Export** attribute string specifies the device that this controller is used for: [Export("MSR", typeof(IHardwareStationController))]
- Because there will be multiple controllers for MSRs, Hardware Station uses the configuration file to determine which implementation to use at run time. For more information, see the "Hardware Station extensibility configuration" section later in this article.

```

namespace Contoso
{
    namespace Commerce.HardwareStation.RamblerService
    {
        using System;
        using System.Composition;
        using System.Threading.Tasks;
        using System.Web.Http;
        using System.Web.Http.Controllers;
        using Microsoft.Dynamics.Commerce.HardwareStation;
        using Microsoft.Dynamics.Commerce.HardwareStation.DataEntity;
        using Microsoft.Dynamics.Commerce.HardwareStation.Models;
        using Microsoft.Dynamics.Retail.Diagnostics;
        /// <summary>
        /// MSR device web API controller class.
        /// </summary>
        [Export("MSR", typeof(IHardwareStationController))]
        [Authorize]
        public class AudioJackMSRController : ApiController, IHardwareStationController
        {
            // Add controller implementation here
        }
    }
}

```

## Hardware Station extensibility configuration

### Configuration for IIS-hosted Hardware Station

Before Hardware Station can consume your extension, the **composition** section in the Hardware Station Web.config file must be updated so that it includes an entry for your extension. The order of the composition targets in the configuration file determines precedence.

```

<?xml version="1.0" encoding="utf-8"?>
<configuration>
  <configSections>
    <section name="diagnosticsSection" type="Microsoft.Dynamics.Retail.Diagnostics.Core.Desktop.DiagnosticsConfigSection, Mi
    <section name="hardwareStation" type="Microsoft.Dynamics.Commerce.HardwareStation.Configuration.HardwareStationSection,
  </configSections>
  <hardwareStation>
    <secureStore cipherProvider="DPAPI" />
    <!-- Pairing key expiration period in days -->
    <pairingKeyExpirationPeriod="100" />
    <composition>
      <add source="assembly" value="Contoso.Commerce.HardwareStation.CashDispenserSample" />
      <add source="assembly" value="Microsoft.Dynamics.Commerce.HardwareStation.Security" />
      <add source="assembly" value="Microsoft.Dynamics.Commerce.HardwareStation.Peripherals.Desktop" />
      <add source="assembly" value="Microsoft.Dynamics.Commerce.HardwareStation.Peripherals.Network" />
      <add source="assembly" value="Microsoft.Dynamics.Commerce.HardwareStation.Peripherals.Opos" />
      <add source="assembly" value="Microsoft.Dynamics.Commerce.HardwareStation.Peripherals.SampleMx925Library" />
    </composition>
  </hardwareStation>

```

## Configuration for local IPC-based Hardware Station

Before local Hardware Station can consume your extension, the **composition** section in the Modern POS DLLHost.exe.config file (C:\Program Files (x86)\Microsoft Dynamics AX\70\Retail Modern POS\ClientBroker) must be updated so that it includes an entry for your extension. The order of the composition targets in the configuration file determines precedence.

```

<!-- Set to "true" to enable event tunneling. -->
<add key="IsNativeLoggingEnabled" value="true" />
<!-- Default download and upload interval for offline data sync are 1 minute -->
<add key="DefaultOfflineDownloadInterval" value="1" />
<add key="DefaultOfflineUploadInterval" value="1" />
<!-- AAD settings -->
<add key="AADLoginUrl" value="https://login.windows.net/common" />
<add key="AADClientId" value="d6b5a0bd-bf3f-4a8c-b370-619fb3d0e1cc" />
<add key="AADRetailServerResourceId" value="https://commerce.dynamics.com" />
<add key="LocatorServiceUrl" value="" />
<add key="CommerceAuthenticationAudience" value="Modern POS" />
</appSettings>
<commerceRuntime configSource="commerceRuntime.RealtimeServiceNotSupported.config" />
<commerceRuntime.HardwareStation configSource="commerceRuntime.HardwareStation.config" />
<hardwareStation>
  <secureStore cipherProvider="DPAPI" />
  <composition>
    <add source="assembly" value="Contoso.Commerce.HardwareStation.CashDispenserSample" />
    <add source="assembly" value="Microsoft.Dynamics.Commerce.HardwareStation.Security" />
    <add source="assembly" value="Microsoft.Dynamics.Commerce.HardwareStation.Peripherals.Desktop" />
    <add source="assembly" value="Microsoft.Dynamics.Commerce.HardwareStation.Peripherals.Opos" />
    <add source="assembly" value="Microsoft.Dynamics.Commerce.HardwareStation.Peripherals.SampleMx925Lib
  </composition>
</hardwareStation>
<diagnosticsSection>
  <application name="Modern POS" id="BF3114C0-8302-46EF-872A-8A479A04EDC5" />
  <emergencySink assembly="Microsoft.Dynamics.Retail.Diagnostics.Sinks" class="Microsoft.Dynamics.Retail
  <properties>
    <property name="LocatorServiceName" value="Microsoft.Dynamics.Modern POS" />

```

### NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Integrate the POS with a new hardware device

2/18/2021 • 5 minutes to read • [Edit Online](#)

This topic explains how to integrate the point of sale (POS) with a new hardware device.

To call Hardware station from the POS, you must use a request and a response:

- **HardwareStationDeviceActionRequest** – The request that is sent from the POS to Hardware station.
- **HardwareStationDeviceActionResponse** – The response that the POS receives from Hardware station.

The class that you extend depends on the version of the Retail software development kit (SDK) that you're using.

- For Retail SDK version 10.0.11 or later, you extend the **IController** interface.
- For Retail SDK versions that are earlier than version 10.0.11, you extend the **HardwareStationController** and **IHardwareStationController** classes.

## HardwareStationDeviceActionRequest

The following code example shows the definition of **HardwareStationDeviceActionRequest**.

```
class HardwareStationDeviceActionRequest<TResponse extends HardwareStationDeviceActionResponse> extends Request<TResponse> {
    readonly device: string;
    readonly action: string;
    readonly actionData: any;
    constructor(device: string, action: string, actionData: any, correlationId?: string);
}
```

The following table describes the parameters.

PARAMETER	DATA TYPE	DESCRIPTION
device	String	The device name that is passed to the Hardware station request should match the <b>Export</b> attribute that is added in the Hardware station Device extension controller class.
action	String	The method that should be called in the Hardware station extension. The method name should be passed as a string value. The core POS Hardware station layer will then call the corresponding method from your Hardware station extension code. The method should exactly match the method name in your Hardware station extension. The Hardware station extension should be passed as a parameter.
actionData	any	A custom parameter for the extension to pass.

### Sample code

The following code example creates a **HardwareStationDeviceActionRequest** object.

```
let hardwareStationDeviceActionRequest:
HardwareStationDeviceActionRequest<HardwareStationDeviceActionResponse> =
    new HardwareStationDeviceActionRequest("Export attribute in Hardware station controller class",
        "extension method name in Hardware station", "Custom parameters/you can also pass custom object");
return this.extensionContextRuntime.executeAsync(hardwareStationDeviceActionRequest);
```

## HardwareStationDeviceActionResponse

The following code example shows the definition of **HardwareStationDeviceActionResponse**.

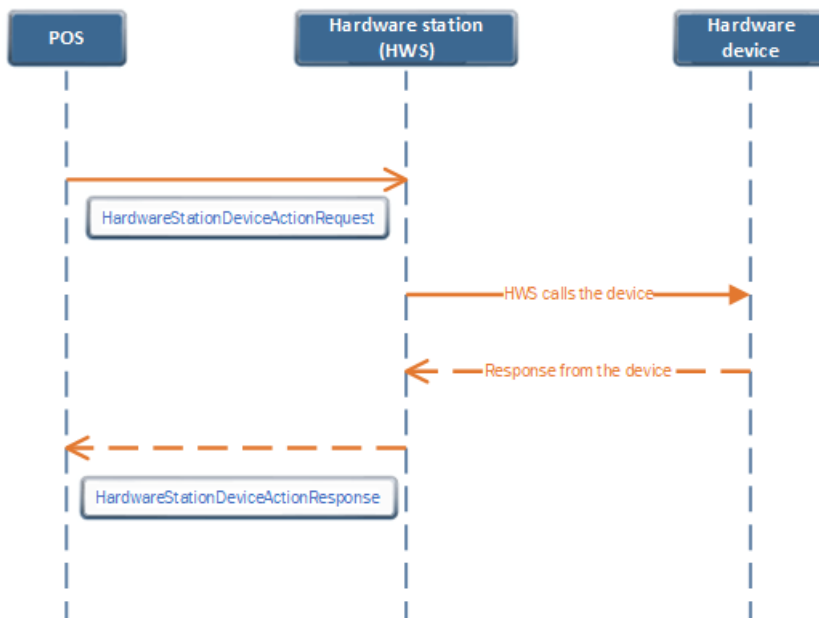

```
class HardwareStationDeviceActionResponse extends Response {
    readonly response: any;
    constructor(response: any);
}
```

The following table describes the parameters.

PARAMETER	DATA TYPE	DESCRIPTION
response	any	The response that is sent from the Hardware station extension code to the POS.

## End-to-end flow

The follow diagram shows the flow between the POS, Hardware station, and the hardware device.

## Hardware station extension

To call your new hardware device, you must implement the Hardware station code. You call your hardware device from that code.

To implement the Hardware station extension for Retail SDK version 10.0.11 or later, follow these steps.

1. Create a new C# class library project by using the Microsoft .NET Framework version 4.6.1. Alternatively, use one of the samples in the Retail SDK as a template. (You can find the samples at

...\RetailSDK\SampleExtensions\HardwareStation\.) We recommend that you use a sample as a template.

2. In the extension project, use the NuGet package manager to add the **Microsoft.Dynamics.Commerce.Hosting.Contracts** package. You can find the NuGet packages in the **RetailSDK\pkgs** folder.
3. Add a new controller class that extends the **IController** interface.
4. Add the **RoutePrefix** attribute to the controller class to expose the controller class to clients.

```
[RoutePrefix("ISVEXTENSIONDEVICE")]
```

5. To implement your custom logic to call the hardware device, in the controller class, add a method that has the **HttpPost** attribute. This method will be passed as the second parameter (action parameter) to the POS **HardwareStationDeviceActionRequest**. From the extension method, the extension can call other requests, such as printing and cash drawer requests. Just include the relevant NuGet packages from the Retail SDK.

```
[HttpPost]
public async Task<bool> IsReady(IEndpointContext context)
{
}
```

6. Build the project.

To implement the Hardware station extension for Retail SDK versions that are earlier than version 10.0.11, follow these steps.

1. Create a new C# class library project.
2. Add a new controller class that extends **HardwareStationController** and **IHardwareStationController**.
3. Add the **Export** attribute to the controller class. The **Export** attribute must be in all uppercase letters, and you must pass the value as a parameter from the POS extension. The device parameter that is passed from the POS **HardwareStationDeviceActionRequest** must match this value.
4. To implement your custom logic to call the hardware device, add your method in the controller class. This method will be passed as the second parameter (action parameter) to the POS **HardwareStationDeviceActionRequest**.
5. Build the project.

To deploy the Hardware station extension in Modern POS and test it by using the local Hardware station, follow these steps.

1. Copy the output library to the **C:\Program Files (x86)\Microsoft Dynamics 365\70\Retail Modern POS\ClientBroker\ext** folder.
2. Open the **HardwareStation.Extension.config** file.
3. In the **composition** section, add the extension library details.

```
<add source="assembly" value="your extension library name" />
```

4. Save the file.
5. Close Modern POS if it's running.
6. Open Task Manager, and end the **dllhost.exe** task.

7. Open Modern POS, and configure it to use the local Hardware station.

8. Validate your scenario.

To test by using Cloud POS, deploy the dynamics-link library (DLL) of the Hardware station extension to the shared Hardware station **ext** folder. Then update the **HardwareStation.Extension.config** file with the custom library in the shared Hardware station folder.

## Retail SDK samples

The Retail SDK includes some samples that you can use for reference.

- **POS:** \RetailSDK\POS\Extensions\FiscalRegisterSample
- **Hardware station:** \RetailSDK\SampleExtensions\HardwareStation\Extension.FiscalRegisterSample

## Sample code for Retail SDK version 10.0.11 or later

```

namespace Contoso
{
    namespace Commerce.HardwareStation.ISVExtensionDevice
    {
        using Microsoft.Dynamics.Commerce.Runtime.Hosting.Contracts;
        using System;
        using System.Threading.Tasks;

        /// <summary>
        /// Sample hardware station extension
        /// </summary>

        [RoutePrefix("ISVEXTENSIONDEVICE")]
        public class ISVExtensionDeviceController : IController
        {
            /// <summary>
            /// Sample.
            /// </summary>

            /// <param name="request">Custom request.</param>
            /// <returns>Result of Custom response.</returns>

            [HttpPost]
            public async Task<CustomResponse> Sample(CustomRequest request, IEndpointContext context)
            {
                CustomResponse response;
                try
                {
                    response = new CustomResponse();
                }
                catch (Exception ex)
                {
                    throw ex;
                }
                return await Task.FromResult(response);
            }
        }
        public class CustomResponse
        {
            public string sampleProp { get; set; }
            public CustomResponse()
            {
                this.sampleProp = "sampleValue";
            }
        }
    }
}

```

Sample code for Retail SDK versions before version 10.0.11

```

namespace Contoso
{
    namespace Commerce.HardwareStation.ISVExtensionDevice
    {
        using System;
        using System.Composition;
        using System.Web.Http;
        using Microsoft.Dynamics.Commerce.HardwareStation;

        /// <summary>
        /// Fiscal register peripheral web API controller class.
        /// </summary>

        [Export("ISVEXTENSIONDEVICE", typeof(IHardwareStationController))]
        [Authorize]
        public class ISVExtensionDeviceController : HardwareStationController, IHardwareStationController
        {
            /// <summary>
            /// Sample.
            /// </summary>
            /// <param name="request">Custom request.</param>
            /// <returns>Result of Custom response.</returns>

            [HttpPost]
            public CustomResponse Sample(CustomRequest request)
            {
                ThrowIf.Null(request, "request");
                try
                {
                    return null;
                }
                catch (Exception ex)
                {
                    throw ex;
                }
            }
        }
    }
}

```

## Sample POS code to call the Hardware station extension

From your POS extension, call the Hardware station by using the following pattern.

```

let hardwareStationDeviceActionRequest:
HardwareStationDeviceActionRequest<HardwareStationDeviceActionResponse> =
    new HardwareStationDeviceActionRequest("ISVEXTENSIONDEVICE",
        "Sample", "Custom parameters or custom object");
return this.extensionContextRuntime.executeAsync(hardwareStationDeviceActionRequest);

```

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Commerce Scale Unit customer and consumer APIs

2/18/2021 • 29 minutes to read • [Edit Online](#)

This topic provides an overview of the APIs that are available across various roles, and that can be used by various clients. The focus is on customer-facing application clients and eCommerce clients.

## Overview

- Commerce Scale Unit business data and operations are available to any connected device through the OData Web API, across both employee (point of sale) scenarios and customer (online store) scenarios.
- The embedded commerce runtime (CRT) enables a unified omni-channel platform.
- The application programming interfaces (APIs) are stateless and can process requests from many channels.
- The APIs have a linear scale-out model ("brick" scale-out).
- You use a composition pattern for plug-and-play customizations.
- The APIs are built on the .NET stack by using C#.

## Roles

Every request to Commerce Scale Unit (via commerce proxy) operates under these main roles:

- CommerceRole.Employee
- CommerceRole.Anonymous
- CommerceRole.Customer
- CommerceRole.Application

The Anonymous and Customer roles apply to eCommerce (customer/consumer) scenarios. The Anonymous role is used for requests that represent an eCommerce customer who hasn't signed in. The Customer role is used for requests that represent an eCommerce customer who has been authenticated and has signed in. A role filter is applied to every API that is exposed in Commerce Scale Unit. For eCommerce scenarios, you can use only APIs that have either CommerceRole.Anonymous or CommerceRole.Customer associated with them.

### NOTE

By default, Anonymous access is not enabled. To enable Anonymous access for your environment, contact [Support](#).

## Customer controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetOrderShipmentsHistory	string accountNumber, QueryResultSettings queryResultSettings	PageResult<OrderShipments>	Employee, Customer, Application	Gets order shipments history for the customers
CreateEntity	Customer	Customer	Employee, Anonymous, Application	Creates customer.

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
UpdateEntity	string key, Customer update	Customer	Employee, Customer, Application	Updates customer.
GetOrderHistory	string accountNumber, QueryResultSettings queryResultSettings	PageResult<SalesOrder>	Employee, Customer, Application	Returns the collection of sales orders.
Search	CustomerSearchCriteria customerSearchCriteria, QueryResultSettings queryResultSettings	PageResult<GlobalCustomer>	Employee, Application	Searches for the customers
GetPurchaseHistory	string accountNumber, QueryResultSettings queryResultSettings	PageResult<PurchaseHistory>	Employee, Customer, Application	Gets purchase history for the customers
GetByAccountNumbers	IEnumerable<string> accountNumbers, int searchLocationValue, QueryResultSettings queryResultSettings	IEnumerable<Customer>	Employee, Customer, Application	Gets customers list from the list of customer account numbers
GetCustomerSearchFields	queryResultSettings	IEnumerable<CustomerSearchField>	Employee, Customer, Application	Gets the customer search fields for the store set in headquarters
SearchByFields	Customer entity	PageResult<GlobalCustomer>	Employee, Customer, Application	Searches for customers by specified fields
PostNonTransactionalActivityLoyaltyPoints	string loyaltyCardNumber, long channelId, long affiliationId, string activityTypeId	void	Employee, Customer, Application	Post non-transactional activity loyalty points

## Sales order controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetReceipts	string id, ReceiptRetrievalCriteria receiptRetrievalCriteria, QueryResultSettings queryResultSettings	PageResult<Receipt>	Employee	Gets a set of receipts based on the formTypes for Printing.

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetGiftReceipts	string id, IEnumerable<decimal> salesLineNumbers, ReceiptRetrievalCriteria receiptRetrievalCriteria, QueryResultSettings queryResultSettings	PageResult<Receipt>	Employee	Gets the gift receipts
GetByReceiptId	string receiptId, string orderStoreNumber, string orderTerminalId, QueryResultSettings queryResultSettings	PageResult<SalesOrder>	Employee	Gets sales orders by the receipt identifier
SearchSalesTransactionsBy- ReceiptId	string receiptId, QueryResultSettings queryResultSettings	PageResult<SalesOrder>	Employee	Search sales transaction by the receipt identifier
Search	SalesOrderSearchCriteria salesOrderSearchCriteria, QueryResultSettings queryResultSettings	PageResult<SalesOrder>	Employee, Customer	Searches for any orders matching the given search criteria
SearchOrders	OrderSearchCriteria orderSearchCriteria, QueryResultSettings queryResultSettings	PageResult<SalesOrder>	Employee, Customer	Searches for orders matching the given search criteria.
GetInvoicesBySalesId	string salesId, QueryResultSettings queryResultSettings	PageResult<SalesInvoice>	Employee	Gets the sales invoice associated with the passed sales identifier
GetOrderInvoices	string customerAccount, QueryResultSettings queryResultSettings	PageResult<OrderInvoice>	Employee	Gets the open order invoices associated with the customer associated with the given customer identifier
GetInvoices	InvoiceSearchCriteria invoiceSearchCriteria, QueryResultSettings queryResultSettings	PageResult<OrderInvoice>	Employee	Gets the open invoices associated with the search criteria
GetInvoicedSalesLinesBy- SalesIds	IEnumerable<string> salesIds, QueryResultSettings queryResultSettings	PageResult<SalesLine>	Employee	Gets the list of invoiced sales lines by sales order identifiers

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
CreatePickingList [Obsolete("Use CreatePickingListForItems instead.")]	string salesId	void	Employee	Creates a picking list for a sales order
CreatePickingListForItems	string salesId, IEnumerable<PickAndPackSalesLineParameter> pickAndPackSalesLineParameters	string	Employee	Creates a picking list for selected lines on sales order.
GetPickingLists	string salesId, QueryResultSettings queryResultSettings	PageResult<PickingList>	Employee	Gets the picking lists for an order from Headquarters.
CreatePackingSlip		void	Employee	Creates a packing slip
GetSalesOrderDetails By- TransactionId	string transactionId, int searchLocationValue	SalesOrder	Employee, Customer	Gets the sales order details by transaction id.
GetSalesOrderDetails By- SalesId	string salesId	SalesOrder	Employee, Customer	Gets the sales order details by sales id.
GetSalesOrderDetails By- QuotationId	string quotationId	SalesOrder	Employee, Customer	Gets the sales order details by Quotation id.

## Cart controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
Checkout	string id, string receiptEmail, TokenizedPaymentCard tokenizedPaymentCard, string receiptNumberSequence, IEnumerable<CartTenderLine> cartTenderLines, long? cartVersion	SalesOrder	Employee, Customer, Anonymous, Application	Checkout the cart.
AddCartLines	string id, System.Collections.Generic.IEnumerable<CartLine> cartLines, long? cartVersion	Cart	Employee, Customer, Anonymous, Application	Adds the cart lines into Cart.

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
VoidCartLines	string id, System.Collections.Generic.IEnumerable<CartLine> cartLines	Cart	Employee	voids the cart lines in the cart.
UpdateCartLines	string id, System.Collections.Generic.IEnumerable<CartLine> cartLines	Cart	Employee, Customer, Anonymous, Application	Updates the cart lines in the cart.
RefillGiftCard	string id, string giftCardId, decimal amount, string currencyCode, string lineDescription)	Cart	Employee	Adds balance to gift card
IssueGiftCard	string id, string giftCardId, decimal amount, string currencyCode, string lineDescription, string tenderTypeId	Cart	Employee	Issues gift card.
CashOutGiftCard	string id, string giftCardId, decimal amount, string currencyCode, string lineDescription	Cart	Employee	Cash out a gift card.
AddTenderLine	string id, CartTenderLine cartTenderLine, long? cartVersion	Cart	Employee	Adds the cart tender line.
AddPreprocessed-TenderLine	string id, TenderLine preprocessedTenderLine, long? cartVersion	Cart	Employee	Adds the pre-processed tender line.
ValidateTender-LineForAdd	string id, TenderLine tenderLine	void	Employee	Validates the tender line.
UpdateTenderLine-Signature	string id, string tenderLineId, string signatureData	Cart	Employee	Updates the cart tender line signature.

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
VoidTenderLine	string id, string tenderLineId, System.Collections.Generic.IEnumerable<ReasonCodeLine> reasonCodeLines, bool? isPreprocessed = false, bool? forceVoid = false	Cart	Employee.	voids the cart tender line.
SuspendWithJournal	string id, string journalCartId, string receiptNumberSequence	Cart	Employee	Suspends a cart and makes journal entry.
Resume	string id	Cart	Employee	Resumes a suspended cart.
ResumeFromReceiptId	string receiptId	Cart	Employee	Resumes a suspended cart based on receipt id.
RecallOrder	string transactionId, string salesId	Cart	Employee	Recalls a customer order.
AddInvoicedSalesLinesToCart	string transactionId, IEnumerable<long> invoicedLineIds	Cart	Employee.	Add invoiced sales lines to cart.
RecallQuote	string transactionId, string quoteId	Cart	Employee	Recalls a quote.
RecallSalesInvoice	string transactionId, string invoiceId	Cart	Employee	Gets the cart that represents the invoice associated with the passed invoice identifier.
AddOrderInvoice	string id, string invoiceId, string lineDescription	Cart	Employee	Adds the invoice associated with the passed invoice identifier to the cart.
AddInvoices	string key, IEnumerable<string> invoiceIds	Cart	Employee	Add invoices to cart.
RecalculateOrder	string id	Cart	Employee	Recalculates a customer order.

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
UpdateCommission-SalesGroup	string transactionId, string cartLineId, string commissionSalesGroup, bool isUserInitiated	Cart	Employee	Updates a commission sales group on a line or transaction.
CartDeliveryPreferences	string id	CartDeliveryPreferences	Customer, Anonymous, Application	Gets the applicable delivery preference types based on the items in the cart.
GetLineDeliveryOptions	string id, IEnumerable<LineShippingAddresses> lineShippingAddresses, QueryResultSettings queryResultSettings	PageResult<SalesLineDeliveryOption>	Employee, Customer, Anonymous, Application	Gets the delivery line option of the cart.
GetLineDeliveryOptionsBy-ChannelId	string id, IEnumerable<LineShippingAddresses> lineShippingAddresses, long channelId, QueryResultSettings queryResultSettings	PageResult<SalesLineDeliveryOption>	Employee, Customer, Anonymous, Application	Gets the delivery line option of the cart by the channel identifier.
GetPaymentsHistory	string id, QueryResultSettings queryResultSettings	PageResult<TenderLine>	Employee	Gets the payments history given the cart identifier.
GetDeliveryOptions	string id, Address shippingAddress, QueryResultSettings queryResultSettings	PageResult<DeliveryOption>	Employee, Customer, Anonymous, Application	Gets the delivery options for the cart.
UpdateLineDelivery-Specifications	string id, System.Collections.Generic.IEnumerable<LineDeliverySpecification> lineDeliverySpecifications	Cart	Customer, Anonymous, Application	Updates the delivery specifications per cart line.
AddCharge	string cartId, int moduleTypeValue, string chargeCode, decimal calculatedAmount	Cart	Employee, Application	Add a charge to the cart.

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
OverrideCharge	string cartId, string chargeLineId, decimal amount, IEnumerable<ReasonCodeLine> reasonCodeLines	Cart	Employee, Application	Override the amount of a charge in the cart.
AddCartLineCharge	string cartId, string cartLineId, int moduleTypeValue, string chargeCode, decimal calculatedAmount	Cart	Employee, Application	Add a charge to the cart line.
OverrideCartLineCharge	string cartId, string cartLineId, string chargeLineId, decimal amount, IEnumerable<ReasonCodeLine> reasonCodeLines	Cart	Employee, Application	Override the amount of a cart line charge.
UpdateDelivery-Specification	string id, DeliverySpecification deliverySpecification	Cart	Customer, Anonymous, Application	Updates the delivery specification for cart header.
OverrideCartLinePrice	string id, string cartLineId, decimal price	Cart	Employee	Processes the barcode workflow by sending the cart identifier and barcode scanned information.
GetPromotions	string id	CartPromotions	Customer, Anonymous, Application	Gets the promotions for cart.
AddDiscountCode	string id, string discountCode	Cart	Employee, Customer, Anonymous, Application	Add discount code to cart.
RemoveDiscountCodes	string id, IEnumerable<string> discountCodes	Cart	Customer, Anonymous, Application	Remove discount code from cart.
RemoveCartLines	string id, System.Collections.Generic.IEnumerable<string> cartLineIds	Cart	Customer, Anonymous, Application	Deletes the cart lines.
Search	CartSearchCriteria cartSearchCriteria, QueryResultSettings queryResultSettings	PageResult<Cart>	Customer	Gets the carts by customer.

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetCardPayment-AcceptPoint	string id, CardPaymentAcceptSettings cardPaymentAcceptSettings	CardPaymentAcceptPoint	Employee, Customer, Anonymous, Application	Gets the accepting point of card payment, e.g. a web page.
RetrieveCardPayment - AcceptResult	string resultAccessCode	CardPayment-AcceptResult	Employee, Customer, Anonymous, Application	Retrieves the accepting result of card payment, e.g. payment authorization, card token.
AddCoupons	string id, IEnumerable<string> couponCodes, bool? isLegacyDiscountCode = false	Cart	Employee, Customer, Anonymous, Application	Add coupons to the cart.
RemoveCoupons	string id, IEnumerable<string> couponCodes	Cart	Employee, Customer, Anonymous, Application	Remove coupon codes from the cart.
GetChargeCodes	QueryResultSettings settings	PageResult<ChargeCode>	Employee, Application	Gets all the charge codes.
GetMaxLoyaltyPointsTo- RedeemFor- TransactionBalance	string cartId, string loyaltyCardNumber, string redeemCurrency	LoyaltyPoint-RedemptionEstimate	Employee, Customer	Get a LoyaltyPoint-RedemptionEstimate object, which contains the max currency amount a loyalty card can apply to a transaction's balance, and the reward point quantities used to generate that max currency amount.
GetDeclinedOrVoided - CardReceipts	string cartId, TenderLine preprocessedTenderLine, ReceiptRetrievalCriteria criteria, QueryResultSettings queryResultSettings	PageResult<Receipt>	Employee	Gets a collection of gift receipts for a declined or terminated card tender line.
ResetAllCharges	string id	Cart	Employee, Application	Recalculates charges (including deleting all manually added and overridden charges) for the cart.

## Address controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetAddressPurposes	QueryResultSettings queryResultSettings	PageResult<AddressPurpose>	Employee, Customer, Anonymous, Application	Gets the address purposes

## Barcode controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetBarcodeById	string barcodeId	Barcode	Employee	Gets barcode by identifier.

## Cash declaration controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetCashDeclarations	QueryResultSettings queryResultSettings	PageResult<CashDeclaration>	Employee	Gets barcode by identifier.

## Cities controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetCities	string countryRegionId, string stateProvinceId, string countyId, QueryResultSettings queryResultSettings	PageResult<CityInfo>	Employee	Get all the cities filtered by Country/Region, State Province and County.

## Counties controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetCounties	string countryRegionId, string stateProvinceId, QueryResultSettings queryResultSettings	PageResult<CountyInfo>	Employee	Get all the counties filtered by country/region and state province.

## Country region controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetCountryRegionsFor- Shipping	QueryResultSettings queryResultSettings PageResult<CountryRegionInfo>		Employee, Customer, Anonymous, Application	Gets the translated countries/regions with delivery modes configured for the current channel.
GetCountryRegionsBy- LanguageId	string languageId, QueryResultSettings queryResultSettings	PageResult<CountryRegionInfo>	Employee, Customer, Anonymous, Application	Get all the countries/regions filter by Language Id.
GetCountryRegions	QueryResultSettings queryResultSettings	PageResult<CountryRegionInfo>	Employee	Get all the countries/regions.

## Credit memo controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetCreditMemoById	string creditMemoid	CreditMemo	Employee	Get credit memo by identifier.

## Delivery options controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetDeliveryOptions	string id, Address shippingAddress, QueryResultSettings queryResultSettings	PageResult<DeliveryOption>	Employee, Customer, Anonymous, Application	Get the delivery options for the channel.

## Customer group controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetCustomerGroups	QueryResultSettings queryResultSettings	PageResult<CustomerGroup>	Employee, Customer, Anonymous, Application	Gets collection of customer group.

## Currency controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetCurrenciesAmount	string currencyCode, decimal amount, QueryResultSettings queryResultSettings	PageResult<CurrencyAmount>	Employee	Gets the currencies amount.

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
CalculateTotalCurrencyAmount	System.Collections.Generic.IEnumerable<CurrencyRequest> currenciesAmount	CurrencyAmount	Employee	Calculates the total currency amount.

## Customer balance controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetCustomerBalance	string accountNumber, string invoiceAccountNumber	CustomerBalances	Employee	Gets the customer balance.

## Device configuration controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetDeviceConfiguration		DeviceConfiguration	Employee	Gets a single device configuration.

## District controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetDistricts	string countryRegionId, string stateProvinceId, string countyId, string cityName, QueryResultSettings queryResultSettings	PageResult<DistrictInfo>	Employee	Get all the district info filtered by country/region, state province, county, city.

## State province controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetStateProvinces	string countryRegionId, QueryResultSettings queryResultSettings	PageResult<StateProvinceInfo>	Employee, Customer, Anonymous, Application	Get all the states or provinces filtered by country/region.

## Discount controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetDiscountCodes	QueryResultSettings queryResultSettings	PageResult<Discount Code>	Employee	Gets collection of discount codes.
GetDiscountCodesBy OfferId	string offerId, QueryResultSettings queryResultSettings	PageResult<Discount Code>	Employee	Gets collection of discount codes filtered by offer identifier.
GetDiscountCodesBy Keyword	string keyword, DateTimeOffset activeDate, QueryResultSettings queryResultSettings	PageResult<Discount Code>	Employee	Searches the discount codes.
GetDiscountCode	string discountCode	DiscountCode	Employee	Gets the discount code.

## Zipcodes controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetZipCodes	string countryRegionId, string stateProvinceId, string countyId, string cityName, string district, QueryResultSettings queryResultSettings	PageResult<ZipCodeInfo>	Employee	Get all the zip codes filtered by country/region, state province, county, city and district.
GetAddressFromZipCode	string countryRegionId, string zipPostalCode, QueryResultSettings queryResultSettings	PageResult<ZipCodeInfo>	Employee, Customer, Anonymous, Application	Get details of addresses associated with zip code filtered by country/region.

## Suspended cart controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetAllSuspendedCarts	QueryResultSettings queryResultSettings	PageResult<SuspendedCart>	Employee	Gets all suspended carts.

## Tender types controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
-----	-----------	--------------	--------------------------	-------------

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetTenderTypes	QueryResultSettings queryResultSettings	PageResult<TenderType>	Employee, Customer, Anonymous, Application	Gets tender types.
RoundAmountByTenderType	decimal amount, string tenderType	decimal	Employee	Round amount by tender type.

## Publishing controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
SetOnlineChannelPublishStatus	int publishingStatus, string publishingStatusMessage	void	Application	Updates Online Channel publishing status.

## Language controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetLanguages	QueryResultSettings queryResultSettings	PageResult<SupportedLanguage>	Employee	Gets collection of supported languages.

## Localized string controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetLocalizedStrings	string languageId, int? textId, QueryResultSettings queryResultSettings	PageResult<LocalizedString>	Employee	Gets all localized strings filtered by language identifier, text identifier.

## Notification controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetNotifications	IEnumerable<int> subscribedOperations, QueryResultSettings queryResultSettings	ICollection<NotificationItem>	Employee	Gets the notifications.
AcknowledgeNotifications	DateTimeOffset lastPullDateTime	void	Employee	Acknowledge notifications.

## Number sequence controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetLatestNumberSequence	QueryResultSettings queryResultSettings	PageResult<Localized String>	Employee	Gets the next number sequence for the current terminal.

## ReasonCodes controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetReasonCodes	QueryResultSettings queryResultSettings	PageResult<ReasonCode>	Employee	Gets the reason codes.
GetReturnOrderReasonCodes	QueryResultSettings queryResultSettings	PageResult<ReasonCode>	Employee	Gets return order reason codes.
GetReasonCodesById	string reasonCodeGroupId, QueryResultSettings queryResultSettings	PageResult<ReasonCode>	Employee	Gets the reason codes by group or single identifier.

## Receipt controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetReceiptMasks	int? receiptTransactionType, QueryResultSettings queryResultSettings	PageResult<ReceiptMask>	Employee	Gets the receipts masks.
ValidatePrintReceiptCopyAllowed	SalesOrder salesOrderToPrint	void	Employee	Performs validation, whether receipt copy printing operation is allowed or not.

## Report datasets controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
SearchReportDataSet	int? receiptTransactionType, QueryResultSettings queryResultSettings	ReportDataSet	Employee	Searches all the report dataset filtered by Report Identifier, Parameters and Locale.
GetReportDataSetById	SalesOrder salesOrderToPrint	ReportDataSet	Employee	Gets report data set by id.
GetSrsReportDataSet		ReportDataSet	Employee	Gets SSRS report data set.

## Search controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetSearchSuggestions	SearchSuggestionCriteria suggestionCriteria, QueryResultSettings settings	PageResult<SearchSuggestion>	Employee, Customer, Anonymous, Application	Gets Search suggestions.
GetSearchConfiguration		SearchConfiguration	Employee, Customer, Anonymous, Application	Gets Channel Search Configuration from Azure Search

## Tax controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetTaxOverrides	SearchSuggestionCriteria suggestionCriteria, QueryResultSettings settings	PageResult<TaxOverride>	Employee	Searches for any tax overrides matching the given search criteria.
GetSalesTaxGroups		PageResult<SalesTaxGroup>	Employee	Gets the sales tax groups.

## Tender drop and declare operation controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
CreateDropAndDeclareTransaction	DropAndDeclareTransaction dropAndDeclareTransaction	DropAndDeclareTransaction	Employee	Performs saving tender drop and declare store operations.

## Unit of measure controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetUnitsOfMeasure	QueryResultSettings queryResultSettings	PageResult<UnitOfMeasure>	Employee	Get all the units of measure supported by the store.

## Income expense accounts controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
-----	-----------	--------------	--------------------------	-------------

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetIncomeExpenseAccounts	int incomeExpenseAccountType, QueryResultSettings queryResultSettings	PageResult<IncomeExpenseAccount>	Employee	Gets the income or expense accounts.

## Products controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
Search	ProductSearchCriteria productSearchCriteria, QueryResultSettings queryResultSettings	IEnumerable<Product>	Employee, Customer, Anonymous, Application	Searches for the product using OData query.
GetById	long recordId, long channelId	SimpleProduct	Employee, Customer, Anonymous, Application	Gets a SimpleProduct by its record identifier.
Get		PageResult<Product>	Employee, Customer, Storefront	Searches for the product.
GetByIds	long channelId, IEnumerable<long> productIds, QueryResultSettings queryResultSettings	PageResult<SimpleProduct>	Employee, Customer, Anonymous, Application	Gets a collection of products based on channel identifier and record identifier.
GetRecommendedProducts	IEnumerable<long> productIds, string customerAccountNumber, QueryResultSettings queryResultSettings	PageResult<ProductSearchResult>	Employee, Customer, Anonymous, Application	Retrieves a collection of SimpleProduct recommendations given a collection of product identifiers.
Compare	long channelId, long catalogId, IEnumerable<long> productIds, QueryResultSettings queryResultSettings	PageResult<ProductComparisonLine>	Employee, Customer, Anonymous, Application	Compares products.
SearchByCategory	long channelId, long catalogId, long categoryId, QueryResultSettings queryResultSettings	PageResult<ProductSearchResult>	Employee, Customer, Anonymous, Application	Searches for products that belong to a category directly or via its child categories.
SearchByText	long channelId, long catalogId, string searchText, QueryResultSettings queryResultSettings	PageResult<ProductSearchResult>	Employee, Customer, Anonymous, Application	Searches for products that are associated to the given search text.

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetSearchSuggestions	long channelId, long catalogId, string searchText, string hitPrefix, string hitSuffix, QueryResultSettings queryResultSettings	PageResult-<SearchSuggestion>	Employee, Customer, Anonymous, Application	Gets recommended search phrases based on a (partial) search text.
GetRefinersByCategory	long catalogId, long categoryId, QueryResultSettings queryResultSettings	PageResult-<ProductRefiner>	Employee, Customer, Anonymous, Application	Gets the product refiner(s) available for the given category product(s).
GetRefinersByText	long catalogId, string searchText, QueryResultSettings queryResultSettings	PageResult-<ProductRefiner>	Employee, Customer, Anonymous, Application	Gets the product refiner(s) available for product(s) resulting from searching the given text.
GetProductSearchRefiners	ProductSearchCriteria searchCriteria, QueryResultSettings queryResultSettings	PageResult-<ProductRefiner>	Employee, Customer, Anonymous, Application	Gets the product refiner(s) available for product(s) resulting from the combination of refiners and search text/ category ids being used.
GetRefinerValuesByCategory	long catalogId, long categoryId, long refinerId, int refinerSourceValue, QueryResultSettings queryResultSettings	PageResult-<ProductRefinerValue>	Employee, Customer, Anonymous, Application	Gets the product refiner value(s) available for the given category product(s).
GetRefinerValuesByText	long catalogId, string searchText, long refinerId, int refinerSourceValue, QueryResultSettings queryResultSettings	PageResult-<ProductRefinerValue>	Employee, Customer, Anonymous, Application	Gets the product refiner value(s) available for product(s) resulting from searching the given text.
RefineSearchByCategory	long channelId, long catalogId, long categoryId, IEnumerable-<ProductRefinerValue> refinementCriteria, QueryResultSettings queryResultSettings	PageResult-<ProductSearchResult>	Employee, Customer, Anonymous, Application	Refines searches performed on products that belong to a category directly or via its child categories.

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
RefineSearchByText	long channelId, long catalogId, string searchText, IEnumerable<ProductRefinerValue> refinementCriteria, QueryResultSettings queryResultSettings	PageResult<ProductSearchResult>	Employee, Customer, Anonymous, Application	Refines searches performed on products that are associated to the given search text.
GetDimensionValues	long recordId, long channelId, int dimension, IEnumerable<ProductDimension> matchingDimensionValues, QueryResultSettings queryResultSettings	PageResult<ProductDimensionValue>	Employee, Customer, Anonymous, Application	Gets the dimension values for a product based on the specified requirements.
GetVariantsBy-DimensionValues	long recordId, long channelId, IEnumerable<ProductDimension> matchingDimensionValues, QueryResultSettings queryResultSettings	PageResult<SimpleProduct>	Employee, Customer, Anonymous, Application	Gets the variations of a product based on the specified requirements.
GetVariantsBy-ComponentsInSlots	long recordId, long channelId, IEnumerable<ComponentInSlotRelation> matchingSlotTo-ComponentRelation, QueryResultSettings queryResultSettings	PageResult<SimpleProduct>	Employee, Customer, Anonymous, Application	Gets the variations of a product based on the component in slot combination specified.
GetDefaultComponents	long recordId, long channelId, QueryResultSettings queryResultSettings	PageResult<ProductComponent>	Employee, Customer, Anonymous, Application	Gets the default individual parts that constitute the specified product.
GetComponentByProduct-SlotRelation	long channelId, ComponentInSlotRelation componentRelation	ProductComponent	Employee, Customer, Anonymous, Application	Gets a specific product component based on the provided ComponentInSlotRelation.
GetSlotComponents	long recordId, long channelId, long slotId, QueryResultSettings queryResultSettings	PageResult<ProductComponent>	Employee, Customer, Anonymous, Application	Gets the default individual parts that can fit into a slot of a product to complete its constitution.

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetFiltered-SlotComponents	long recordId, long channelId, long slotId, IEnumerable<ComponentInSlotRelation> selectedComponents, QueryResultSettings queryResultSettings	PageResult-<ProductComponent >	Employee, Customer, Anonymous, Application	Gets the Product components that may be selected given a set of previously selected components.
GetAttributeValues	long recordId, long channelId, long catalogId, QueryResultSettings queryResultSettings	PageResult<Attribute Value>	Employee, Customer, Anonymous, Application	Gets the attribute values of the specified product.
GetRelationTypes	long recordId, long channelId, long catalogId, QueryResultSettings queryResultSettings	PageResult-<ProductRelationType>	Employee, Customer, Anonymous, Application	Gets the types of relationships the specified product has with other products.
GetRelatedProducts	long recordId, long channelId, long catalogId, long relationTypeId, QueryResultSettings queryResultSettings	PageResult-<ProductSearchResult>	Employee, Customer, Anonymous, Application	Searches for products that are associated to the specified product by the specified relationship.
GetRefiners	ProductSearchCriteria productSearchCriteria, QueryResultSettings queryResultSettings	PageResult<ProductRefiner>	Employee, Customer, Anonymous, Application	Searches for product refiners using OData query.
Changes	ChangedProductsSearchCriteria productSearchCriteria, QueryResultSettings queryResultSettings	IEnumerable<Product>	Employee, Storefront	Searches and retrieves changed products given the specified query criteria.
ReadChangedProducts	ChangedProductsSearchCriteria productSearchCriteria, QueryResultSettings queryResultSettings	PageResult<Product >	Application	Searches and retrieves changed products given the specified query criteria.
GetDeletedListings	long catalogId, long skip, long top	DeletedListingsResult	Application	Searches and retrieves changed products given the specified query criteria.
GetDeletedCatalogs	QueryResultSettings queryResultSettings	IEnumerable<long>	Application	Gets deleted catalogs.
GetDeletedLanguages	QueryResultSettings queryResultSettings	IEnumerable<string>	Application	Gets deleted languages.

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
DeleteListingsBy-Catalogs	IEnumerable<long> catalogIds	void	Application	Deletes listings by catalogs.
DeleteListingsBy-Languages	IEnumerable<string> languages	void	Application	Deletes listings by languages.
BeginRead-ChangedProducts	ChangedProductsSearchCriteria changedProductSearchCriteria	ReadChanged-ProductsSession	Application	Begins session to read changed products.
EndReadChangedProducts	ReadChangedProductsSession session	void	Application	Ends session to read changed products.
UpdateListing-PublishingStatus	IEnumerable<ListingPublishStatus> publishingStatuses	void	Application	Searches and retrieves changed products given the specified query criteria.
GetProductAvailabilities	IEnumerable<long> itemIds, long channelId, QueryResultSettings queryResultSettings	PageResult<ProductAvailableQuantity>	Employee, Customer, Anonymous, Application	Get available inventory for given list of items for given channel and customer.
GetPrices	string itemId, string inventoryDimensionId, string barcode, string customerAccountNumber, string unitOfMeasureSymbol, decimal quantity, QueryResultSettings queryResultSettings	PageResult<ProductPrice>	Employee	Gets the price of an item in context of the current customer.
GetPrice	long recordId, string customerAccountNumber, string unitOfMeasureSymbol	ProductPrice	Employee, Customer, Anonymous, Application	Gets the price of a product in context of the current customer.
CalculateProductPrice	long recordId, string customerAccountNumber, string unitOfMeasureSymbol, string loyaltyCardId, IEnumerable<AffiliationLoyaltyTier> affiliationLoyaltyTiers	ProductPrice	Employee, Customer, Anonymous, Application	Gets the price.

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetActivePrices	ProjectionDomain projectDomain, IEnumerable<long> productIds, DateTimeOffset activeDate, string customerId, IEnumerable<Affiliati onLoyaltyTier> affiliationLoyaltyTiers, bool? includeSimpleDiscoun tsIn- ContextualPrice, QueryResultSettings queryResultSettings	PageResult<ProductP rice>	Employee, Customer, Anonymous, Application	Gets the price.
GetMediaLocations	long recordId, long channelId, long catalogId, QueryResultSettings queryResultSettings	PageResult<MediaLo cation>	Employee, Customer, Anonymous, Application	Gets the media locations for the specified product.
GetMediaBlobs	long recordId, long channelId, long catalogId, QueryResultSettings queryResultSettings	PageResult<MediaBlo b>	Employee, Customer, Anonymous, Application	Gets the media blobs for the specified product.
GetUnitsOfMeasure	long recordId, QueryResultSettings queryResultSettings	PageResult<UnitOfM easure>	Employee, Customer, Anonymous, Application	Gets the unit(s) of measure for the specified product.
GetChannel- ProductAttributes	QueryResultSettings queryResultSettings	PageResult<Attribute Product>	Employee, Customer, Anonymous, Application	Gets the channel product attributes.
GetProductRatings	IEnumerable<long> productIds, QueryResultSettings settings	PageResult<ProductR ating>	Employee, Customer, Anonymous, Application	Gets a collection of product ratings based on product identifiers.
GetEstimatedAvailabil ity	InventoryAvailabilityS earchCriteria searchCriteria	ProductWarehouseIn ventoryInformation	Employee, Customer, Anonymous, Application	Get estimated product availability based on search criteria.
GetEstimatedProduct WarehouseAvailabilit y	InventoryAvailabilityS earchCriteria searchCriteria	IEnumerable<Produc tWarehouse>	Employee, Customer, Anonymous, Application	Get estimated product availability for specific product warehouse pairs.

## Sales orders fulfillment controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
ShipFulfillmentLines	IEnumerable<ShipFulfillmentLine> fulfillmentLines	void	Employee	Ship the fulfillment lines. Invoices in AX.
AcceptFulfillmentLines	IEnumerable<FulfillmentLineParameter> fulfillmentLines	void	Employee	Updates the status of the fulfillment lines to Accepted.
PickFulfillmentLines	IEnumerable<FulfillmentLineParameter> fulfillmentLines, IEnumerable<FulfillmentLineParameter> fulfillmentLines	void	Employee	Updates the status of the fulfillment lines to Picking.
MarkAsPicked	IEnumerable<FulfillmentLineParameter> fulfillmentLines	void	Employee	Updates the status of the fulfillment lines to Picked.
PackFulfillmentLines	IEnumerable<FulfillmentLineParameter> fulfillmentLines	void	Employee	Updates the status of the fulfillment lines to Packed or Partially Packed.
MarkFulfillmentLinesAsPacked	IEnumerable<FulfillmentLineParameter> fulfillmentLines	String	Employee	Updates the status of the fulfillment lines to Packed or Partially Packed.
GetFulfillmentLines	FulfillmentLineSearchCriteria criteria, QueryResultSettings settings	IEnumerable<FulfillmentLine>	Employee	Gets the fulfillment lines.
GetFulfillmentPackingSlips		IEnumerable<Receipt>	Employee	Gets the packing slips.
GetFulfillmentPackingSlipsById	string salesId, string packingSlipId, string hardwareProfileId	IEnumerable<Receipt>	Employee	Gets the packing slips by packing slip Id and sales Id.
GetFulfillmentPickingLists	IEnumerable<FulfillmentLineParameter> pickingListFulfillmentLines, string hardwareProfileId, QueryResultSettings queryResultSettings	IEnumerable<Receipt>	Employee	Gets the picking lists.
RejectFulfillmentLines	IEnumerable<RejectFulfillmentLine> fulfillmentLines	void	Employee	Updates the status of the fulfillment lines to Rejected.

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetPackingSlipsData	string salesId	IEnumerable<Packing SlipData>	Employee	Gets the list of packing slip data given a sales identifier.

## Hardware profiles controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetHardwareProfileById	string hardwareProfileId	HardwareProfile	Employee	Gets hardware profile by id.
GetHardwareStationProfiles	QueryResultSettings queryResultSettings	PageResult<HardwareStationProfile>	Employee	Gets collection of hardware station profiles.

## Income expense account controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetIncomeExpenseAccounts	int incomeExpenseAccountType, QueryResultSettings queryResultSettings	PageResult<IncomeExpenseAccount>	Employee	Gets the income or expense accounts.

## Kits controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
DisassembleKitTransactions	KitTransaction	KitTransaction	Employee	Performs kit (disassembly) transaction operations.

## Gift card controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetGiftCardInquiry	string giftCardId	GiftCard	Employee, Customer, Anonymous, Application	Get gift card with additional information by identifier.

## Image controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetImageBlob	long imageId	MediaBlob	Employee, Customer, Anonymous, Application	Gets image blob by image identifier.

## Store safe controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetStoreSafes	QueryResultSettings settings	PageResult<StoreSafe>	Employee,	Get store safe list.

## Warehouse controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetWarehouseById	string inventLocation	PageResult<StoreSafe>	Employee, Customer	Gets a Warehouse by its record identifier.
SearchWarehouses	string searchText, QueryResultSettings queryResultSettings	PageResult<Warehouse>	Application, Employee, Customer	Retrieves a list of warehouses that matches the given search text.
GetLocations	string inventLocation, QueryResultSettings queryResultSettings	PageResult<WarehouseLocation>	Application, Employee, Customer	Gets the warehouse locations of the specified Warehouse.
SearchLocations	string inventLocation, string searchText, QueryResultSettings queryResultSettings	PageResult<WarehouseLocation>	Application, Employee, Customer	Retrieves a list of warehouse locations for the given warehouse that matches the given search text.

## Recommendation controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
Get		PageResult<Recommendation>	Application, Employee, Customer, Anonymous	Gets the list of recommendations.
GetElements	string listId, RecommendationCriteria criteria, QueryResultSettings queryResultSettings	PagedResult<RecommendedElement>	Application, Employee, Customer, Anonymous	Gets the collection of recommended elements given the (optional) contextual information as criteria.

# Transfer order controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
Get	QueryResultSettings queryResultSettings	PageResult<Transfer Order>	Employee	Gets open transfer orders for the store.
Commit	string orderId	Void	Employee	Commits a transfer order.
GetTransferOrderJournals	string orderId, QueryResultSettings queryResultSettings	PageResult<Transfer OrderJournal>	Employee	Gets the transfer order journals of the specified transfer order.
GetTransferOrderLines	string orderId, QueryResultSettings queryResultSettings	PageResult<Transfer OrderLine>	Employee	Gets the transfer order lines.
CreateTransferOrderLines	string orderId, IEnumerable<TransferOrderLine> transferOrderLines, QueryResultSettings queryResultSettings	PageResult<Transfer OrderLine>	Employee	Creates the transfer order lines.
UpdateTransferOrderLines	string orderId, IEnumerable<TransferOrderLine> transferOrderLines, QueryResultSettings queryResultSettings	PageResult<Transfer OrderLine>	Employee	Updates the transfer order lines.
DeleteTransferOrderLines	string orderId, IEnumerable<TransferOrderLine> transferOrderLines, QueryResultSettings queryResultSettings	PageResult<Transfer OrderLine>	Employee	Deletes the transfer order lines.
GetTransferOrderComments	string orderId, QueryResultSettings queryResultSettings	PageResult<Comment>	Employee	Gets the comments of the specified transfer order.
AddTransferOrderComment	string orderId, string commentedBy, string comment	Comment	Employee	Gets the comments of the specified transfer order.
GetTransferPackingSlip	string orderId, string voucherId, ReceiptRetrievalCriteria criteria, QueryResultSettings queryResultSettings	PageResult<Receipt>	Employee	Gets the packing slip for the specified transfer order journal.
PatchEntity	TransferOrder entity	TransferOrder	Employee	Saves a transfer order to the local database.

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetEntityByKey	string orderId	TransferOrder	Employee	Gets a transfer order by order identifier.
DeleteEntity	TransferOrder entity	void	Employee	Deletes the specified transfer order.
CreateEntity	TransferOrder entity	TransferOrder	Employee	Creates transfer order.

## Purchase order controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
Get	QueryResultSettings queryResultSettings	PageResult<Purchase Order>	Employee	Gets open purchase orders for the store.
Commit	string orderId	Void	Employee	Commits a purchase order.
PatchEntity	PurchaseOrder entity	PurchaseOrder	Employee	Saves a purchase order to the local database.
GetEntityByKey	string orderId	PurchaseOrder	Employee	Get a purchase order by order identifier.

## Org units controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
Get	QueryResultSettings queryResultSettings	PageResult<OrgUnit >	Application,Employee , Customer, Anonymous	Gets all organization as IQueryable.
GetOrgUnitLocations ByArea	SearchArea searchArea, QueryResultSettings queryResultSettings	PageResult<OrgUnitL ocation>	Application,Employee , Customer, Anonymous	Finds stores in a defined area.
SearchOrgUnitLocati ons	OrgUnitLocationSear chCriteria orgUnitLocationSear chCriteria, QueryResultSettings queryResultSettings	PageResult<OrgUnitL ocation>	Application,Employee , Customer, Anonymous	Search stores with specified filter criteria within current fulfillment group.
GetAvailableInventor y	string itemId, string variantId, string barcode, QueryResultSettings queryResultSettings	PageResult<OrgUnit Availability>	Application,Employee , Customer, Anonymous	Get available inventory across all stores for an item identifier or barcode.

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetProductAvailability	long productId, QueryResultSettings queryResultSettings	PageResult<OrgUnit Availability>	Application,Employee , Customer, Anonymous	Get available inventory across all stores for a product.
SearchProductAvailability	long productId, OrgUnitAvailabilitySe archCriteria orgUnitAvailabilitySe archCriteria, QueryResultSettings queryResultSettings	PageResult<OrgUnit Availability>	Application,Employee , Customer, Anonymous	Search available inventory across all stores for a product.
GetAvailableInventoryNearby	IEnumerable<ItemUn it> itemIds, SearchArea searchArea, QueryResultSettings queryResultSettings	PageResult<OrgUnit Availability>	Application,Employee , Customer, Anonymous	Get available inventory of nearby stores for given list of items in defined search area.
GetTillLayout	int? height, int? width	TillLayout	Application,Employee , Customer, Anonymous	Gets a single till layout.
GetOrgUnitConfigura tion		ChannelConfiguratio n	Application,Employee , Customer, Anonymous	Gets the configuration for the current organization unit.
Search	SearchStoreCriteria storeSearchCriteria, QueryResultSettings queryResultSettings	PageResult<OrgUnit >	Application,Employee , Customer, Anonymous	Searches for organization unit by the given search query.
GetTerminalInfo	string orgUnitNumber, int deviceType, QueryResultSettings queryResultSettings	PageResult<Terminal Info>	Employee,	Retrieves terminal and device association information data of the store.
GetProductAvailability ByDimensions	IEnumerable<string> inventLocationIds, long productId, IEnumerable<Produc tDimensionCombinat ion> productDimensionCo mbinations, QueryResultSettings queryResultSettings	PageResult<OrgUnit Availability>	Application,Employee , Customer, Anonymous	Gets orgUnit availabilities at each specified inventory location based on the given product dimensions.
GetStoreHours	string storeNumber	StoreHours	Application,Employee , Customer, Anonymous	Retrieve the store hours for a given store number.

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetEntityByKey	string orgUnitNumber	OrgUnit	Application,Employee , Customer, Anonymous	Gets organization entity by key.

## Catalogs controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetCatalogs	long channelId, bool activeOnly, QueryResultSettings queryResultSettings	PageResult<ProductCatalog>	Application,Employee , Customer, Anonymous	Gets catalogs by OData query.

## Categories controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetCategories	long channelId, QueryResultSettings queryResultSettings	PageResult<Category>	Application,Employee , Customer, Anonymous	Gets categories by OData query.
GetChildren	long channelId, long categoryId, QueryResultSettings queryResultSettings	PageResult<Category>	Application, Employee, Anonymous	Gets subcategories by given Channel Id and Category Id.
GetAttributes	long categoryId, QueryResultSettings queryResultSettings	PageResult<AttributeCategory>	Application	Gets categories' attributes by OData query.
Get	QueryResultSettings queryResultSettings	PageResult<Category>	Application, Employee, Anonymous	Gets full list of categories as IQueryable.

## AppInfo controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
UpdateApplicationVersion	string appVersion	void	Employee	Updates the POS device's current application version.

## Attribute controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetAttributeDefinitions	AttributeDefinitionCriteria attributeDefinitionCriteria, QueryResultSettings queryResultSettings	PageResult<AttributeDefinition>	Employee	Gets the attribute definitions by an attribute group identifier.

## Attribute group controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetAttributeGroupDefinitions	AttributeGroupDefinitionCriteria attributeGroupDefinitionCriteria, QueryResultSettings queryResultSettings	PageResult<AttributeGroupDefinition>	Employee	Gets the attribute group definitions by collection of attribute group identifiers.

## Audit event controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
RegisterAuditEvent	AuditEvent auditEvent	void	Employee	Performs the audit event saving operation.
RegisterAndGetAuditEvent	AuditEvent auditEvent	AuditEvent	Anonymous, Customer, Device, Employee, Application	Performs the audit event saving operation.

## Shifts controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetShift	long shiftId, string terminalId	Shift	Employee	Gets the shift by shift id and terminal id.
GetByStatus	int statusValue, QueryResultSettings queryResultSettings	PageResult<Shift>	Employee	Gets the shifts by status.
GetByStatusFilterByUserRole	int statusValue, bool filterByUserRole, QueryResultSettings queryResultSettings	PageResult<Shift>	Employee	Gets the shifts by status.

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetByRetrievalCriteria	ShiftRetrievalCriteria shiftRetrievalCriteria, QueryResultSettings queryResultSettings	PageResult<Shift>	Employee	Gets the shifts by retrieval criteria.
UpsertAndValidateShifts	long? shiftId, string terminalId, IEnumerable<Shift> shifts	bool	Employee	Inserts or update given shifts and validate them.
DeleteShifts		bool	Employee	Delete shifts is not supported in the online context.
Open		Shift	Employee	Opens a new shift.
Close	long shiftId, string terminalId, string transactionId, bool forceClose	Shift	Employee	Closes the shift for the given terminal.
BlindClose	long shiftId, string terminalId, string transactionId, bool forceClose	Shift	Employee	Blind closes a shift.
ForceDelete	long shiftId, string terminalId, string transactionId	void	Employee	Forcefully deletes a shift. Used to delete invalid shifts.
Resume	long shiftId, string terminalId, string cashDrawer	Shift	Employee	Resumes a shift.
Use	long shiftId, string terminalId	Shift	Employee	Uses an existing shift.
Suspend	long shiftId, string terminalId, string transactionId	Shift	Employee	Suspends a shift.
PostShift	Shift shift	HttpResponseMessage	Employee	Handles POST requests that create new shift
PatchShift	long shiftId, string terminalId, Delta<Shift> delta	Shift	Employee	Handles Patch request that update existing shift.
GetXReport	long shiftId, string terminalId, string transactionId, string hardwareProfileId	Receipt	Employee	Gets receipt for X report.

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetZReport	string transactionId, string hardwareProfileId	Receipt	Employee	Gets receipt for Z report.
ValidateCashDrawerLimit	string shiftTerminalId, long shiftId	void	Employee	Gets all suspended carts for given shift.
GetSuspendedCartsByShift	string shiftTerminalId, long shiftId, QueryResultSettings queryResultSettings	PageResult<SuspendedCart>	Employee	voids the suspended transactions for given shift.
VoidSuspendedCarts	long shiftId, string shiftTerminalId	void	Employee	voids the suspended transactions for given shift.

## Async service controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetDownloadInterval	string dataStoreName	string	Device	Gets download interval.
GetUploadInterval	GetUploadInterval	string	Device	Gets upload interval.
GetTerminalDataStoreName	string terminalId	string	Device	Gets data store name.
GetDownloadLink	string dataStoreName, long downloadSessionId	string	Device	Gets download link.
GetDownloadSessions	string dataStoreName, QueryResultSettings queryResultSettings	PageResult<DownloadSession>	Device	Gets the download sessions.
GetInitialDownloadSessions	string dataStoreName, QueryResultSettings queryResultSettings	PageResult<DownloadSession>	Device	Gets initial download sessions.
GetUploadJobDefinitions	string dataStoreName, QueryResultSettings queryResultSettings	IEnumerable<string>	Device	Gets the download sessions.
UpdateDownloadSession	DownloadSession downloadSession	bool	Device	Update download session status.
PostOfflineTransactions	IEnumerable<string> offlineTransactionForMPOS	bool	Device	Posts offline transactions.

## Card type controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetCardTypes	QueryResultSettings queryResultSettings	PageResult <CardType Info>	Application,Employee , Customer, Anonymous	Returns the list of card types.
GetSupportedPaymentCardTypes	QueryResultSettings queryResultSettings	PageResult <string>	Application,Customer ,Anonymous	Returns the list of payment cards supported by the payment connector.

## Commission sales group controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetCommissionSalesGroups	QueryResultSettings queryResultSettings	PageResult <Commiss ionSalesGroup>	Employee	Gets collection of commission sales groups for the channel.
SearchCommissionSalesGroups	string searchText, QueryResultSettings queryResultSettings	PageResult <Commiss ionSalesGroup>	Employee	Searches for the commission sales groups for the channel for a given search text.

## Environment configuration controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetEnvironmentConfiguration		EnvironmentConfigur ation	Anonymous, Employee, Application	Gets a single environment configuration.
GetExtensionProfile		ExtensionProfile	Anonymous, Employee, Application	Gets the extension profile which can be used to download extension package and communicate with micro-services.

## Extension package definition controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetExtensionPackageDefinitions	QueryResultSettings queryResultSettings	IEnumerable<Extensi onPackageDefinition >	Device, Employee, Application	Gets the configured extension package definitions.

## Extensible enumeration package definition controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetExtensibleEnumerations	QueryResultSettings queryResultSettings	IEnumerable<ExtensibleEnumerationContainer>	Device, Employee, Application, Anonymous, Customer, Storefront	Gets all extensible enumeration classes.

## Loyalty card controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
IssueLoyaltyCard	LoyaltyCard loyaltyCard	LoyaltyCard	Employee, Customer	Issues a new loyalty card.
GetLoyaltyCard	string cardNumber	LoyaltyCard	Employee, Customer	Gets a loyalty card.
GetCustomerLoyaltyCards	string accountNumber, QueryResultSettings queryResultSettings	PageResult<LoyaltyCard>	Employee, Customer	Gets the customer loyalty cards.
GetLoyaltyCardTransactions	string cardNumber, string rewardPointId, QueryResultSettings queryResultSettings	PageResult<LoyaltyCardTransaction>	Employee, Customer	Gets the loyalty card transactions.
GetLoyaltyRewardPointActivityTimeline	string cardNumber, string rewardPointId, QueryResultSettings queryResultSettings	PageResult<LoyaltyRewardPointActivity>	Employee, Customer	Gets the timeline activity for the reward point of a loyalty card.
GetLoyaltyRewardPointActivityTimelineForExpiredPoints	string cardNumber, string rewardPointId, QueryResultSettings queryResultSettings	PageResult<LoyaltyRewardPointActivity>	Employee, Customer	Gets the expired points timeline activity for the reward point of a loyalty card.
GetLoyaltyRewardPointsExpiringSoon	string cardNumber, string rewardPointId, int daysToExpiry, QueryResultSettings queryResultSettings	PageResult<LoyaltyRewardPointActivity>	Employee, Customer	Gets the loyalty card reward points that are going to expire soon.

## Non sales transaction tender operations controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
-----	-----------	--------------	--------------------------	-------------

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetNonSalesTransactions	string shiftId, string shiftTerminalId, int nonSalesTenderTypeValue, QueryResultSettings queryResultSettings	PageResult<NonSalesTransaction>	Employee	Gets the aggregated amount for non sale tender operation.
CreateNonSalesTransaction	NonSalesTransaction nonSalesTransaction	NonSalesTransaction	Employee	Performs saving drawer type of operations like declare start amount / tender removal / float entry.
GetAffiliations	QueryResultSettings queryResultSettings	PageResult<Affiliation>	Employee	Gets affiliations.

## Operations controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetOperationPermissionById	int operationId	OperationPermission	Employee	Gets Operation permission by using operation identifier.
GetOperationPermissions	QueryResultSettings queryResultSettings	PageResult<OperationPermission>	Employee	Returns a collection of operation permissions.
SearchJournalTransactions	TransactionSearchCriteria searchCriteria, QueryResultSettings queryResultSettings	PageResult<Transaction>	Employee	Returns a collection of transactions matching the specified search criteria.
GetInventoryAvailableToPromise	long productId, string itemId, string inventoryLocationId, QueryResultSettings queryResultSettings	PageResult<InventoryAvailableToPromise>	Employee	Get available inventory across all stores for a product.
VoidSuspendedTransactions	IEnumerable<string> suspendedCartIds	void	Employee	Void the suspended transactions specified by given cart ids.

## Shift reconciliation lines controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
-----	-----------	--------------	--------------------------	-------------

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetShiftReconciliationLines	ShiftReconciliationLineRetrievalCriteria shiftReconciliationLineRetrievalCriteria, QueryResultSettings queryResultSettings	PageResult<ShiftReconciliationLine>	Employee	Gets download interval.
ReconcileLines	IEnumerable<ShiftReconciliationLine> lines, string description	void	Employee	Reconciles the lines.
UndoReconciliation	IEnumerable<ShiftReconciliationLine> lines	void	Employee	Unreconciles all the lines that are a part of any of the groups in the lines passed in.

## Stock count journal controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
Get	QueryResultSettings queryResultSettings	PageResult<StockCountJournal>	Employee	Gets StockCountJournal entities as IQueryable.
Sync	QueryResultSettings queryResultSettings	PageResult<StockCountJournal>	Employee	Syncs the Stock Count journal from AX to RetailServer DB and gets the current list of SC journal from DB.
SyncTransactions	string journalId, QueryResultSettings queryResultSettings	PageResult<StockCountJournalTransaction>	Employee	Syncs the Stock Count journal from AX to RetailServer and gets the current list of journal transactions.
RemoveJournal	string journalId	void	Employee	Deletes the stock count journals from local.
RemoveTransaction	string journalId, string itemId, string inventSizeld, string inventColorId, string inventStyleId, string configId	void	Employee	Deletes the stock count journal transaction from local.

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
RemoveStockCountLineByLineId	string journalId, long stockCountLineId	void	Employee	Deletes the stock count journal transaction from local by stock count line identifier.
RemoveStockCountLineByProductRecId	string journalId, long productRecId	void	Employee	Deletes the stock count journal transaction from local by product identifier.
Commit	string journalId	void	Employee	Commits the list of Stock journal transactions to AX.
GetEntityByKey	string journalId	StockCountJournal	Employee	Creates journal entity.
UpdateEntity	StockCountJournal entity	StockCountJournal	Employee	Updates journal entity.
PatchEntity	StockCountJournal entity	StockCountJournal	Employee	Partially updates journal entity.

## Scan result controller

API	PARAMETER	RETURN VALUE	SUPPORTED COMMERCE ROLES	DESCRIPTION
GetEntityByKey	string scannedText	ScanResult	Employee	Gets the ScanResult entity by key.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Create a Retail Server extension API (Retail SDK version 10.0.11 and later)

2/18/2021 • 8 minutes to read • [Edit Online](#)

This topic explains how to create a new Retail Server application programming interface (API), and how to expose it so that point of sale (POS) or other clients can consume it. Modification of the existing Retail Server APIs isn't supported.

This topic applies to Retail software development kit (SDK) version 10.0.11 and later.

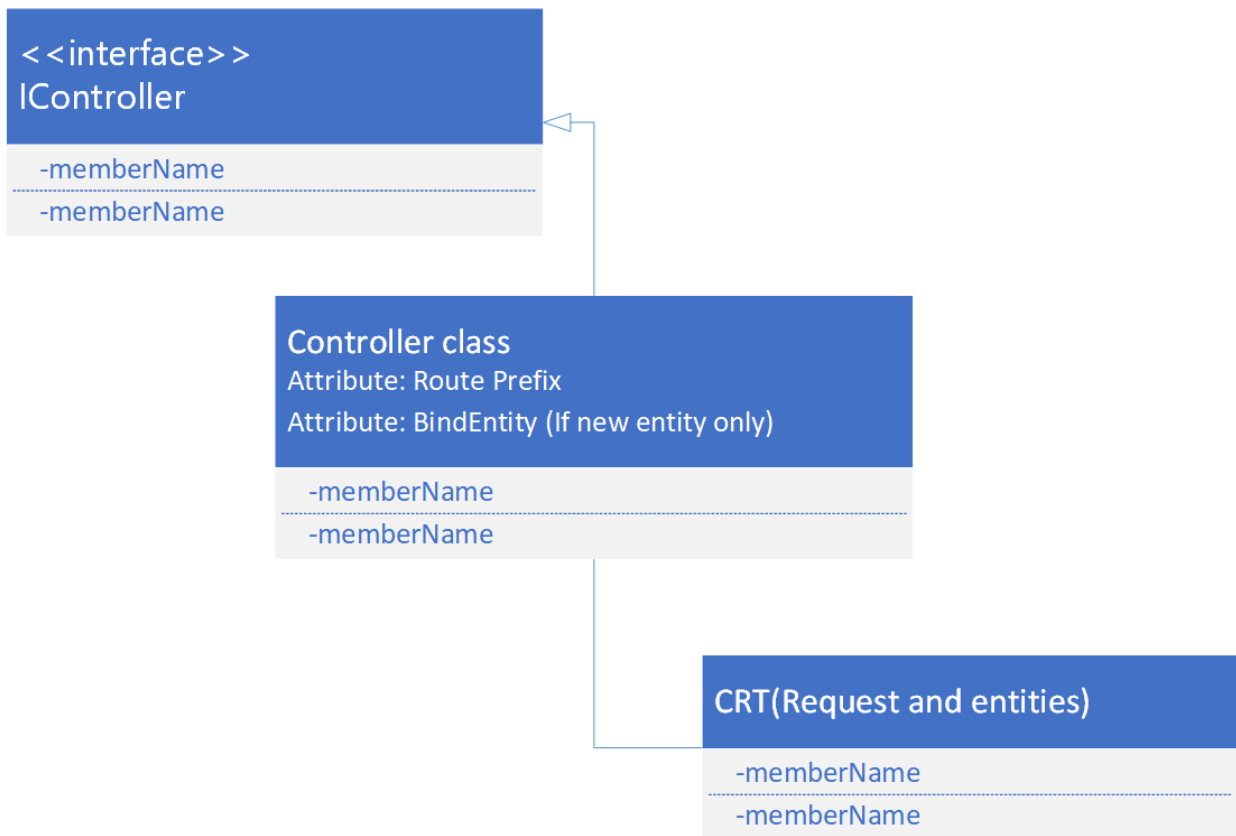

The Retail SDK includes only a few samples of end-to-end Retail Server extensions that include the Commerce runtime (CRT). You can use these samples as templates to start your extensions. You can find the sample extensions in the `RetailSDK\SampleExtensions\RetailServer` folder.

## End-to-end sample repository in the Retail SDK

SAMPLE EXTENSION (RETAILSDK\SAMPLEEXTENSIONS\RETAILSERVER)	CRT SAMPLE (RETAILSDK\SAMPLEEXTENSIONS\COMMERCERUNTIME)	POS SAMPLE (RETAILSDK\POS\EXTENSIONS)
Extensions.StoreHoursSample	Extensions.StoreHoursSample	StoreHoursSample
Extensions.SalesTransactionSignatureSample	Extensions.SalesTransactionSignatureSample	SalesTransactionSignatureSample
Extensions.PrintPackingSlipSample	Extensions.PrintPackingSlipSample	
Extensions.CrossLoyaltySample	Extensions.CrossLoyaltySample	

## Extension class diagram

The following illustration shows the class structure of the extension.

**NOTE**

Retail server does not support loading both IController and CommerceController extensions. If you include both type of extensions, then Retail server load will fail. Extensions should have either IController or CommerceController. If you are migrating to the IController extension, migrate all the Retail server extensions to IController.

## Create a new Retail Server API

1. Create the CRT extension. You must create the CRT extension before you create the Retail Server extension. A Retail Server API should have no logic except logic that calls the CRT with the parameters.
2. Create a new C# class library project that uses the Microsoft .NET Framework version netstandard 2.0 as the target framework. Alternatively, use one of the Retail Server samples in the Retail SDK as a template.
3. In the Retail Server extension project, add a reference to your CRT extension library or project. This reference lets you call the CRT request, response, and entities.
4. In the Retail Server extension project, add the **Microsoft.Dynamics.Commerce.Runtime.Hosting.Contracts** package using the NuGet package manager. The NuGet packages can be found in the **RetailSDK\pkgs** folder.
5. Create a new public controller class and extend it from **IController**. This controller class will contain the method that the Retail Server API must expose, the controller class must be public.
6. Inside the controller class, add methods to call the CRT request. Don't extend the new controller class from existing controller classes such as **CustomerController**, **SalesOrdersController**, or **ProductController**. Extension classes must extend only the **IController** class.
7. Add the **RoutePrefix** attribute on the controller class (Controller class name).

```
[RoutePrefix("SimpleExtension")]
```

8. Add the **BindEntity** attribute on the controller class. This attribute is required if you're creating a new controller and exposing an entity.

```
[BindEntity(typeof(SimpleEntity))]
```

**NOTE**

Steps 7 and 8 are required if the extension class is bound to an entity. These steps are not required for an unbounded controller class returning simple types, not any entity.

The following sample code creates a simple Retail Server API to return an entity, a string, and a bool value. The CRT request and response used in the sample is not included in this sample. For an example of the CRT request and response, see [Commerce runtime \(CRT\) extensibility and triggers](#).

**Sample code for a controller class bounded to a custom entity****NOTE**

Extension code should not bound the existing OOB entity, such as Customer or Product.

```

// New extended controller.
[RoutePrefix("SimpleExtension")]
[BindEntity(typeof(SimpleEntity))]
public class SimpleExtensionController : IController
{
    /// <summary>
    /// The action to get the string value.
    /// </summary>
    /// <param name="context">The context parameters.</param>
    /// <param name="stringValue">The string value parameters.</param>
    /// <returns>The string value.</returns>
    [HttpPost]
    [Authorization(CommerceRoles.Customer, CommerceRoles.Employee)]
    public async Task<string> GetStringValue(IEndpointContext context, string stringValue)
    {
        GetStringValueResponse resp = await context.ExecuteAsync<GetStringValueResponse>
            (new GetStringValueRequest(stringValue)).ConfigureAwait(false);
        return resp.StringValue;
    }

    /// <summary>
    /// The action to get the bool value.
    /// </summary>
    /// <param name="context">The context parameters.</param>
    /// <param name="boolValue">The string value parameters.</param>
    /// <returns>The bool value.</returns>
    [HttpPost]
    [Authorization(CommerceRoles.Customer, CommerceRoles.Employee)]
    public async Task<bool> GetBoolValue(IEndpointContext context, string boolValue)
    {
        GetBoolValueResponse resp = await context.ExecuteAsync<GetBoolValueResponse>
            (new GetBoolValueRequest(boolValue)).ConfigureAwait(false);
        return resp.BoolValue;
    }

    /// <summary>
    /// The action to get the simple entity.
    /// </summary>
    /// <param name="context">The context parameters.</param>
    /// <param name="name">The name parameters.</param>
    /// <returns>The simple entity.</returns>
    [HttpPost]
    [Authorization(CommerceRoles.Customer, CommerceRoles.Employee)]
    public async Task<SimpleEntity> GetSimpleEntity(IEndpointContext context, string name)
    {
        GetSimpleEntityResponse resp = await context.ExecuteAsync<GetSimpleEntityResponse>
            (new GetSimpleEntityRequest(name)).ConfigureAwait(false);
        return resp.SimpleEntityObj;
    }
}

```

### Sample code for a controller class not bounded to a custom entity

```

namespace Contoso.UnboundController.Sample
{
    using System.Threading.Tasks;
    using Microsoft.Dynamics.Commerce.Runtime.DataModel;
    using Microsoft.Dynamics.Commerce.Runtime.Hosting.Contracts;

    /// <summary>
    /// An extension unbounded controller sample.
    /// </summary>
    public class UnboundController : IController
    {
        /// <summary>
        /// A simple GET endpoint to demonstrate GET endpoints on an unbound controller.
        /// </summary>
        /// <returns>A simple true value to indicate the endpoint was reached.</returns>
        [HttpGet]
        [Authorization(CommerceRoles.Anonymous, CommerceRoles.Application, CommerceRoles.Customer,
CommerceRoles.Device, CommerceRoles.Employee, CommerceRoles.Storefront)]
        public Task<bool> SampleGet()
        {
            return Task.FromResult(true);
        }

        /// <summary>
        /// A simple POST endpoint to demonstrate POST endpoints on an unbound controller.
        /// </summary>
        /// <returns>A simple true value to indicate the endpoint was reached.</returns>
        [HttpPost]
        [Authorization(CommerceRoles.Customer, CommerceRoles.Device, CommerceRoles.Employee)]
        public Task<bool> SamplePost()
        {
            return Task.FromResult(true);
        }
    }
}

```

The Retail Server APIs support different authorization roles. Access to the controller method is permitted based on the authorization roles that are specified in the controller method **Authorizations** attribute. The following example shows the supported authorization roles. Extension code should not use the **CommerceAuthorization** attribute instead of the **Authorizations** attribute. The **CommerceAuthorization** attribute is only supported in SDK versions earlier than 10.0.11.

```

// Represents the type of logon type.
[DataContract]
public static class CommerceRoles
{
    // Anonymous Role.
    [DataMember]
    public const string Anonymous = "Anonymous";

    // SharePoint Role used by Connector.
    [DataMember]
    public const string Storefront = "Storefront";

    // Employee Role.
    [DataMember]
    public const string Employee = "Employee";

    // Customer Role.
    [DataMember]
    public const string Customer = "Customer";

    // Represents the Device level of authentication.
    [DataMember]
    public const string Device = "Device";

    // Represents Application level of authentication.
    [DataMember]
    public const string Application = "Application";

    // The list of all possible Microsoft.Dynamics.Commerce.Runtime.DataModel.CommerceRoles values.
    public static readonly string[] All;
}

```

## Support paging in Retail Server APIs

Starting in release 10.0.18, if the API requires paging you can add the **QueryResultSettings** parameter to the API and pass the value from the client. **QueryResultSettings** contains **PagingInfo** and other parameters for records to fetch or skip.

The extension can pass **QueryResultSettings** to the CRT request, which the CRT request can use when there is a database query.

The full sample code is available in the Retail SDK:

RetailSDK\SampleExtensions\CommerceRuntime\Extensions.StoreHoursSample\StoreHoursDataService.cs  
 RetailSDK\SampleExtensions\RetailServer\Extensions.StoreHoursSample\StoreHoursController.cs"

```

[HttpPost]
[Authorization(CommerceRoles.Anonymous, CommerceRoles.Customer, CommerceRoles.Device,
CommerceRoles.Employee)]
public async Task<PagedResult<SampleDataModel.StoreDayHours>> GetStoreDaysByStore(IEndpointContext
context, string StoreNumber, QueryResultSettings queryResultSettings)
{
    var request = new GetStoreHoursDataRequest(StoreNumber) { QueryResultSettings =
queryResultSettings };
    var hoursResponse = await context.ExecuteAsync<GetStoreHoursDataResponse>
(request).ConfigureAwait(false);
    return hoursResponse.DayHours;
}

```

```

private async Task<Response> GetStoreDayHoursAsync(GetStoreHoursDataRequest request)
{
    ThrowIf.Null(request, "request");

    using (DatabaseContext databaseContext = new DatabaseContext(request.RequestContext))
    {
        var query = new SqlPagedQuery(request.QueryResultSettings)
        {
            DatabaseSchema = "ext",
            Select = new ColumnSet("DAY", "OPENTIME", "CLOSINGTIME", "RECID"),
            From = "CONTOSORETAILSTOREHOURSVIEW",
            Where = "STORENUMBER = @storeNumber",
        };

        query.Parameters["@storeNumber"] = request.StoreNumber;
        return new GetStoreHoursDataResponse(await
        databaseContext.ReadEntityAsync<DataModel.StoreDayHours>(query).ConfigureAwait(false));
    }
}

```

### Register the extension

1. Build the extension project, and copy the binary to the `\RetailServer\webroot\bin\Ext` folder.
2. Update the Commerce Scale Unit `web.config` file in the `\RetailServer\webroot` folder by adding the new extension library name in the `extensionComposition` section.

```

<extensionComposition>
  <!-- Use fully qualified assembly names for ALL if you need to support loading from the Global
  Assembly Cache.
  If you host in an application with a bin folder, this is not required. -->
  <add source="assembly" value="SimpleExtensionSample" >
</extensionComposition>

```

3. In Internet Information Services (IIS), restart the Commerce Scale Unit to load the new extension.

### Validate the extension

1. To verify that the extension loaded successfully, you can browse the Retail Server metadata. Confirm that your entities and methods appear in the list. To browse the metadata, open a URL in the following format in a web browser:

```
https://RS-URL/Commerce/$metadata
```

2. To call the Retail Server extension in your client, you must generate the client Typescript proxy. You can then use the proxy to call your new Retail Server APIs from the client.

You don't have to add or include any `EdmModelExtender` files in the extension with the Retail Server extensions APIs. The files are required only if you're using Retail SDK version 10.0.10 or earlier.

### Debugging RS extension

To debug the RS extension project in Visual Studio. Go to **Debug > Attach to Process**. Select `w3wp.exe` (the IIS process for Retail Server). If there are multiple `w3wp.exe` processes, use the correct process based on the process ID. The retail server process ID can be found using **IIS > Worker processes** or by using the command prompt and the `tasklist` command.

## Generate the Typescript proxy for POS

The POS uses the Typescript proxy to access the Retail Server APIs and CRT entities. The proxy class acts as

manger class or wrapper to access the Retail server APIs without the proxy extension manually finding the Retail server API and entities metadata.

### Steps to generate the proxy files

1. In Visual Studio 2017, open the sample proxy template project from `\RetailSDK\Code\SampleExtensions\TypeScriptProxy\TypeScriptProxy.Extensions.StoreHoursSample\Proxies.TypeScriptProxy.Extensions.StoreHoursSample.csproj` in Visual Studio 2017. Rename the project if a new name is required.
2. Add the Retail Server extension project to this proxy template project as a project reference project. Remove the existing `StoreHoursSample` project reference.
3. Right-click the `Proxies.TypeScriptProxy.Extensions.StoreHoursSample.csproj` project, and then select `Edit Proxies.TypeScriptProxy.Extensions.StoreHoursSample.csproj`.
4. Under the `<RetailServerExtensionAssemblies>` node, specify your extension Retail Server assembly name. The following example shows how to add the assembly name.

```
<ItemGroup>
  <RetailServerExtensionAssemblies
    Include="..\..\RetailServer\Extensions.Sample\bin\$(Configuration)\net461\$(AssemblyNamePrefix).RetailServer.Extension.Sample.dll" />
</ItemGroup>
```

5. Under the `<Copy>` node, update the `DestinationFolder` path of your POS extension folder, so that generated proxy files are automatically copied to the POS extension folder automatically. The generated proxy files will also be copied to `\RetailSDK\Code\SampleExtensions\TypeScriptProxy\TypeScriptProxy.Extensions.StoreHoursSample\DataService`. The following example shows how to update the path.

```
<Copy SourceFiles="@{(GeneratedDataServiceContracts)"
  DestinationFolder="$(SdkRootPath)\POS\Extensions\Sample\DataService" SkipUnchangedFiles="true" />
```

6. After the changes are completed, build the proxy project to generate the TypeScript proxy files. When the build is completed, the proxy files will be available in the `\RetailSDK\Code\SampleExtensions\TypeScriptProxy\TypeScriptProxy.Extensions.StoreHoursSample\DataService` folder and the folder that is specified in the `Copy` command. The path and folder path can vary, depending on the folder structure.

## Retail server extension in offline

A Retail Server extension built using the `Microsoft.Dynamics.Commerce.Runtime.Hosting.Contracts` API can be used in an offline implementation. You don't need to generate a separate C# proxy library. Copy the Retail Server extension library in the `\Microsoft Dynamics 365\70\Retail Modern POS\ClientBroker\ext` folder and update the `RetailProxy.MPOSOOffline.ext` config file to include the this library. This extension must only generate the Typescript proxy. SDK samples can be found in the `\RetailSDK\SampleExtensions\TypeScriptProxy` folder.

The following example shows how to update the `add` element in the `RetailProxy.MPOSOOffline.ext` configuration file.

```
<?xml version="1.0" encoding="utf-8"?>
<retailProxyExtensions>
  <composition>
    <add source="assembly" value="Contoso.RetailServer.StoreHoursSample" />
  </composition>
</retailProxyExtensions>
```

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Create a new Retail Server extension API (Retail SDK version 10.0.10 and earlier)

2/18/2021 • 5 minutes to read • [Edit Online](#)

This document explains how to create a new Commerce Scale Unit application programming interface (API), and how to expose it so that POS or other clients can consume it. Modification of the existing Commerce Scale Unit APIs isn't supported.

This topic applies to Retail SDK version 10.0.10 and earlier.

The Retail software development kit (SDK) includes only a few samples of end-to-end Commerce Scale Unit extensions that include the Commerce Runtime (CRT). You can use these samples as templates to start your extensions. You can find the sample extensions in the RetailSDK\SampleExtensions\RetailServer folder.

## NOTE

The CommerceController extension model will be soon deprecated. You will need to migrate all Retail server extensions to IController. Having both CommerceController and IController is not supported. For more information about IController, see [Create a new Retail Server extension API \(Retail SDK version 10.0.11 and later\)](#).

## End-to-end sample repository in the Retail SDK

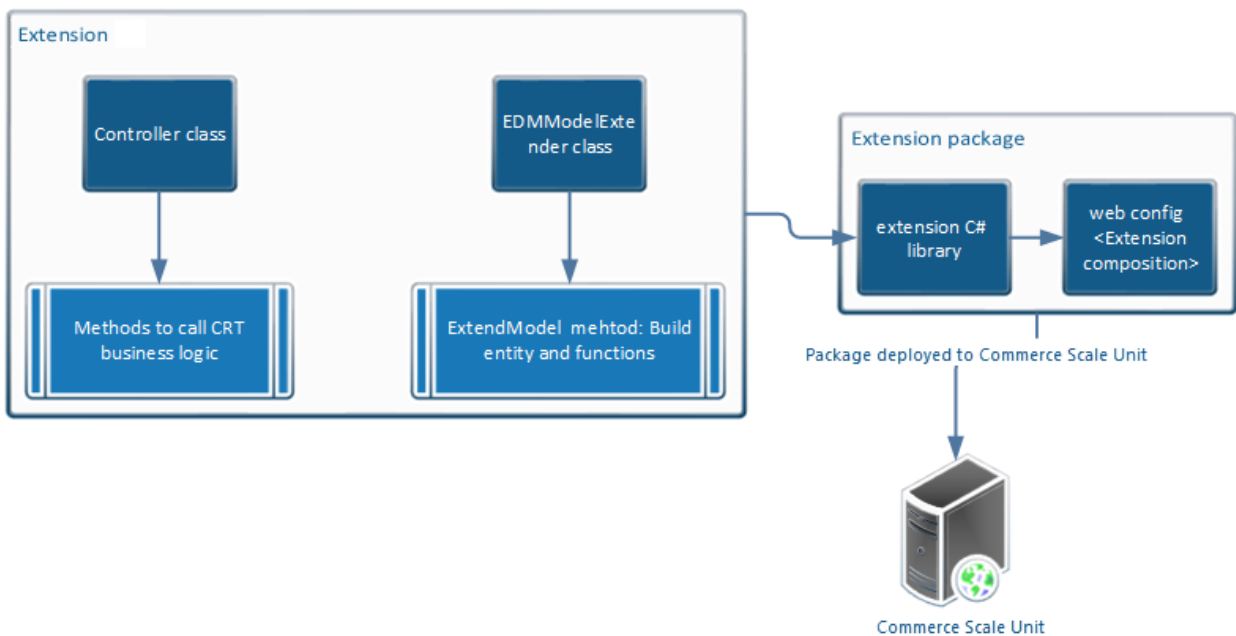

SAMPLE EXTENSION (RETAILSDK\SAMPLEEXTENSIONS\RETAILSERVER)	CRT SAMPLE (RETAILSDK\SAMPLEEXTENSIONS\COMMERCERUNTIME)	POS SAMPLE (RETAILSDK\POS\EXTENSIONS)
Extensions.StoreHoursSample	Extensions.StoreHoursSample	StoreHoursSample
Extensions.SalesTransactionSignatureSample	Extensions.SalesTransactionSignatureSample	SalesTransactionSignatureSample
Extensions.PrintPackingSlipSample	Extensions.PrintPackingSlipSample	
Extensions.CrossLoyaltySample	Extensions.CrossLoyaltySample	

## Create a new extension

Follow the steps in this section to create a new Commerce Scale Unit extension.

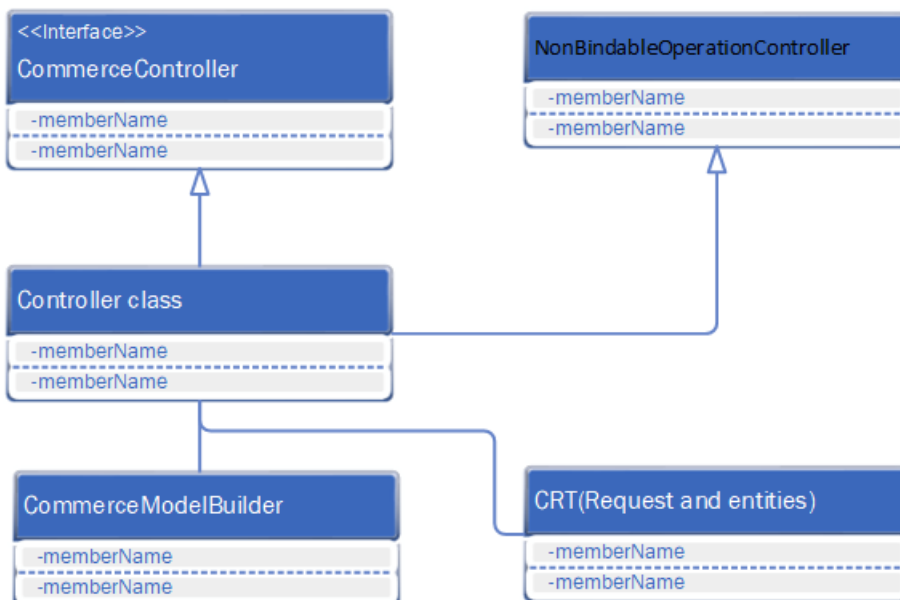

### End-to-end flow

The following illustration shows the flow of the extension.

### Extension class diagram

The following illustration shows the class structure of the extension.

#### NOTE

Retail server does not support loading both IController and CommerceController extensions. If you include both type of extensions, then Retail server load will fail. Extensions should have either IController or CommerceController. If you are migrating to the IController extension, migrate all the Retail server extensions to IController.

### Steps

1. Before you create the Commerce Scale Unit extension, create the CRT extension. Commerce Scale Unit APIs should have no logic except logic that calls the CRT with the parameters.
2. Create a new C# class library project that uses the Microsoft .NET Framework version netstandard 2.0 as the target framework.
3. In the Commerce Scale Unit extension project, add a reference to your CRT extension library or project. This reference lets you call the CRT request and response. It also lets you use the entities from the Commerce Scale Unit extension project.

4. In the Commerce Scale Unit extension project, create a new controller class that extends **NonBindableOperationController** or **CommerceController**. The base class depends on your scenario. This controller class will contain the method that must be exposed by the Commerce Scale Unit API. Inside the controller class, add methods to call the CRT request.

```

/// <summary>;
/// The controller to retrieve a new entity.
/// <summary>
[ComVisible(false)]
public class SampleController : CommerceController<SampleEntity, long>;
{
    ///<summary>;
    /// Gets the controller name used to load extended controller.
    /// <summary>
    public override string ControllerName
    {
        get { return "SampleEntity"; }
    }
    /// <summary>;
    /// Gets the sample entity.
    /// <summary>;
    /// <param name="parameters">The parameters to this action.</param>
    /// <returns>The list of sample entity.</returns>
    [HttpPost]
    [CommerceAuthorization(CommerceRoles.Anonymous, CommerceRoles.Customer, CommerceRoles.Device,
CommerceRoles.Employee)]
    public System.Web.OData.PageResult<SampleEntity> GetSampleEntity(ODataActionParameters
parameters)
    {
        if (parameters == null)
        {
            throw new ArgumentNullException("parameters");
        }
        var runtime = CommerceRuntimeManager.CreateRuntime(this.CommercePrincipal);
        QueryResultSettings queryResultSettings = QueryResultSettings.SingleRecord;
        queryResultSettings.Paging = new PagingInfo(10);
        var request = new CRTDataRequest((string)parameters["key"]) { QueryResultSettings =
queryResultSettings };
        PagedResult<SampleEntity> sample = runtime.Execute<CRTDataResponse>(request, null);
        return this.ProcessPagedResults(sample);
    }
}

```

5. Create an **EdmModelExtender** (EDM) class that extends the **IEdmModelExtender** interface. This class contains the abstract data model that is used to describe the data that a Commerce Scale Unit API exposes. An Open Data Protocol (OData) Metadata Document is a representation of a service's data model that is exposed for client consumption. The central concepts in the EDM are entities, relationships, entity sets, actions, and functions.

The **IEdmModelExtender** interface contains the abstract **ExtendModel** method. When you extend this interface, you must implement the **ExtendModel** method. Inside the **ExtendModel** method, you build the EDM entities and functions that will be exposed to the client by using the **CommerceModelBuilder** class.

The **CommerceModelBuilder** class contains the build method that is used to build the entities and functions.

METHOD NAME	RETURN TYPE	DESCRIPTION
BuildEntity<TEntity>() where TEntity : class	EntityTypeConfiguration<TEntity>	This method builds an entity.

METHOD NAME	RETURN TYPE	DESCRIPTION
BuildEntitySet<TEntity>(string entitySetName) where TEntity : class	EntitySetConfiguration<TEntity>	This method builds an entity set.
BuildComplexType<TComplexType>() where TComplexType : class	ComplexTypeConfiguration<TComplexType>	This method builds a complex entity type.
BuildEnumType<TEnumType>()	EnumTypeConfiguration<TEnumType>	This method builds an enumeration type.
BindAction(string actionName)	ActionConfiguration	This method binds an action in the model builder. An action represents an HTTP POST request.
BindEntityAction<TEntity>(string actionName) where TEntity : class	ActionConfiguration	This method binds an entity action of the model. An action represents an HTTP POST request.
BindEntitySetAction<TEntity>(string actionName) where TEntity : class	ActionConfiguration	This method binds an entity set action. An action represents an HTTP POST request.
BindFunction(string functionName)	FunctionConfiguration	This method binds a function in the model builder. A function represents a HTTP GET request.
BindEntityFunction<TEntity>(string functionName) where TEntity : class	FunctionConfiguration	This method binds an entity function of the model. A function represents an HTTP GET request.
BindEntitySetFunction<TEntity>(string functionName) where TEntity : class	FunctionConfiguration	This method binds an entity set function. A function represents an HTTP GET request.

The following example shows how to extend the EDM model.

```

/// <summary>;
/// The class to extend the EDM model.
/// <summary>;
[Export(typeof(IEdmModelExtender))]
[ComVisible(false)]
public class EdmModelExtender : IEdmModelExtender
{
    /// <summary>;
    /// Extends the EDM model.
    /// <summary>;
    /// <param name="builder">The builder to build the EDM model.</param>
    public void ExtendModel(CommerceModelBuilder builder)
    {
        ThrowIf.Null(builder, "builder");
        // Extends entity sets.
        builder.BuildEntitySet<SampleEntity>("SampleEntity");
        // Extends entity set actions.
        var action = builder.BindEntitySetAction<SampleDataModel.StoreDayHours>("GetSampleEntity");
        action.Parameter<string>("Key");
        action.ReturnsCollectionFromEntitySet<SampleEntity>("SampleEntity");
    }
}

```

## NOTE

Do not duplicate the entity name in the EdmModelExtender class for the same entity. This will create multiple manager and Adapter classes during proxy generation. For example, if **CustomEntity1** is the new entity created by the extension code, in the EdmModelExtender, if the entity is named **CustomEntity1Sample**, then use the same name wherever it used. Do not use a different name for the same entity.

```
builder.BuildEntitySet< CustomEntity1>(**"CustomEntity1Sample");  
action.ReturnsCollectionFromEntitySet< CustomEntity1>(**"CustomEntity1Sample");
```

6. Build the extension project, and drop the binary into the `\RetailServer\webroot\bin\Ext` folder.
7. Update the Commerce Scale Unit web.config file in the `\RetailServer\webroot` folder by adding the new extension library name in the **extensionComposition** section.

```
<extensionComposition>  
<!-- Please use fully qualified assembly names for ALL if you need to support loading from the Global  
Assembly Cache.  
If you host in an application with a bin folder, this is not required. -->  
<add source="assembly" value="SampleExtension" >;  
</extensionComposition>
```

8. In Microsoft Internet Information Services (IIS), restart Commerce Scale Unit to load the new extension.
9. To verify that the extension was successfully loaded, you can browse the Commerce Scale Unit metadata, and confirm that your entities and methods appear in the list.

To browse the metadata, open a URL in the following format in a web browser:

```
https://Your Commerce Scale Unit URL/Commerce/$metadata
```

10. To call the Commerce Scale Unit extension in your client, you must generate the Commerce proxy. You can then use the proxy to call your new Commerce Scale Unit APIs from the client.

For information about how to generate the proxy, see [Typescript and C# proxies for Retail point of sale \(POS\)](#).

## NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Typescript and C# proxies for Retail point of sale (POS)

2/18/2021 • 6 minutes to read • [Edit Online](#)

When you create a new Retail Server API, you must generate the Commerce proxy by using the tools that are available as part of the Retail software development kit (SDK). For example, you must generate the Commerce proxy if you add a new Retail Server API.

## The Commerce proxy and when to use it

All clients use the proxy API to interact with Retail Server. The Commerce proxy abstracts the interface between Retail Server and the Commerce runtime (CRT). For example, you create a new entity and some business logic as request/response operations in CRT, and you add a new Retail Server API to expose that entity and those request/response operations. You now want to access the entity and the request/response operations in the point of sale (POS) to do some client logic. You can manually create all the entities and request/response metadata in the POS, and access the Retail Server API by using the correct parameters. However, this approach involves lots of additional overhead, because you must duplicate the entities, manager, and request/response code in two places, and you must also write lots of code.

The Commerce proxy reduces this effort by automatically generating the proxy for all the custom entities and request/response operations that are added in Retail Server. The proxy tool generates the required interface and all the required metadata, and abstracts the actual implementation. In that way, you can include the files in the extension projects, and can access the Retail Server APIs and the entities by using the metadata and interface that are generated.

## Proxy types

There two types of proxy to support cross-platform scenarios:

- **Typescript proxy** – The POS uses the Typescript proxy to access the Retail Server APIs and CRT entities. If the POS uses Retail Server, it requires the Typescript proxy. Otherwise, the POS can't communicate with the Retail Server for any operations or workflows.
- **C# proxy** – The POS uses the C# proxy when it's offline. (When the POS is offline, it communicates directly with CRT, without using Retail Server.) The POS also uses this proxy for the Dynamics e-Commerce platform. If you want your customization to work when the POS is offline, and you want your e-Commerce client to access the Retail Server APIs, you must generate the C# proxy.

The steps to generate the Typescript proxy and the C# proxy differ. The rest of this topic explains how to generate each type of proxy.

## Generate the Typescript proxy (10.0.11 or lower) Retail Server

If you are using Microsoft Dynamics Commerce version 10.0.12 or greater, follow the steps mentioned in [Create a new Retail Server extension API](#).

## IMPORTANT

Run MSBuild from the Retail SDK root folder to restore the CommerceProxyGenerator.exe package. Use the Visual Studio developer command prompt or MSBuild command prompt to restore all the packages in the reference folder before generating the proxy. If you do not perform this step, the CommerceProxyGenerator.exe package will not be available in the RetailSDK\Reference folder.

Use the CommerceProxyGenerator.exe file from the Retail SDK\Reference\Microsoft.Dynamics.Commerce.Tools.CoreProxyGenerator.<version\_number>\tools folder to generate the typescript proxy for the POS.

1. Before you generate the proxy, copy the customized Retail Server API, CRT, and other dependent libraries to the **Retail SDK\Reference** folder.
2. Open a Command Prompt window as an administrator, and go to the ...\**Retail SDK\Reference\Microsoft.Dynamics.Commerce.Tools.CoreProxyGenerator <version\_number>\tools** folder. Run the following command to generate the proxy. The proxy files will be generated in the same folder.

### POS Typescript proxy

```
CommerceProxyGenerator.exe <Path>\Microsoft.Dynamics.Retail.RetailServerLibrary.dll  
<FilePathNameForRetailServerExtensionDLL> /application:typescriptextensions
```

### e-Commerce Typescript proxy

```
CommerceProxyGenerator.exe <Path>\Microsoft.Dynamics.Retail.RetailServerLibrary.dll  
<FilePathNameForRetailServerExtensionDLL> /application:typescriptmoduleextensions
```

## NOTE

Use the Microsoft.Dynamics.Retail.RetailServerLibrary.dll file from  
\RetailSDK\References\Microsoft.Dynamics.Commerce.Tools.ExtensionsProxyGenerator.<version\_number>\build.

### Example

```
CommerceProxyGenerator.exe  
C:\\RetailSDK\\References\\Microsoft.Dynamics.Commerce.Tools.ExtensionsProxyGenerator.9.21.20042.5\\build\\M  
icrosoft.Dynamics.Retail.RetailServerLibrary.dll  
C:\\RetailSDK\\References\\Microsoft.Dynamics.RetailServer.CrossLoyaltySample.dll /a:typescriptextensions
```

In the above command, replace **Microsoft.Dynamics.RetailServer.CrossLoyaltySample.dll** with the name of your custom Retail Server extension library. Include the generated files in your POS project. The command generates two files that are based on your extension libraries: DataServiceEntities.g.ts and DataServiceRequests.g.ts.

## Generate the C# proxy (Commerce version 10.0.11 or lower)

## IMPORTANT

Retail Server extension built using this the Microsoft.Dynamics.Commerce.Runtime.Hosting.Contracts API can be used in and offline implementation, no need to generate separate C# proxy library. This step is required only for Commerce version 10.0.11 or lower or Retail Server extensions not using the Microsoft.Dynamics.Commerce.Runtime.Hosting.Contracts.

For each Retail Server extension, you must generate a separate proxy.

1. Navigate to **RetailSDK\SampleExtensions\RetailProxy\RetailProxy.Extensions.StoreHoursSample**.
2. In Microsoft Visual Studio, open the **Proxies.RetailProxy.Extensions.StoreHoursSample** project file.
3. Right-click, and select to unload the project.
4. Right-click the project, and select to edit the **Proxies.RetailProxy.Extensions.StoreHoursSample.csproj** file.
5. In the first property group section, update the following nodes:
  - **<RootNamespace>** – Specify your custom namespace.
  - **<AssemblyName>** – Specify your custom output library name for the proxy.
6. Update the **CommerceProxyGeneratorExtendedAssemblyPaths** element by specifying the name of your Retail Server extension library.

Here is an example.

```
<CommerceProxyGeneratorExtendedAssemblyPaths
Include="..\..\RetailServer\Extensions.StoreHoursSample\bin\$(Configuration)\net451\$(AssemblyNamePrefix).RetailServer.StoreHoursSample.dll" />
```

## NOTE

**.RetailServer.StoreHoursSample.dll** is the name of the Retail Server extension assembly, and the rest of the value is the prefix (if there is a prefix) and the path of the assembly where the proxy engine can find this assembly. The proxy is generated based on this assembly.

7. Save the file, and load the project again.
8. Rename the project according to your extension pattern.
9. After the project is loaded, delete the **StoreDayHoursManager.cs** file from the **Adapters** folder.
10. Add all the relevant CRT and Retail Server libraries to the proxy project as project or assembly references.
11. Rebuild the project.

You will see that a new **Interfaces.g.cs** file is generated inside the **Adapters** folder.

## NOTE

Before you build the proxy project, rebuild all your CRT and Retail Server extension libraries, and drop them into the **RetailSDK\References** folder.

12. Include the new **Interfaces.g.cs** file in the proxy project. However, don't modify this file.

13. Under the **Adapters** folder, add a new class file, and name it according to your extension pattern.
14. Extend the class from the interface manager class, and implement only the interface methods that are required.

#### NOTE

You can find the name of the interface manager class in the `Interfaces.g.cs` file.

In the following example, **IStoreDayHoursManager** is the name of the interface.

```
public interface IStoreDayHoursManager : Microsoft.Dynamics.Commerce.RetailProxy.IEntityManager
{
}
```

For the full sample code, see the **Proxies.RetailProxy.Extensions.StoreHoursSample** project under **RetailSDK\SampleExtensions\RetailProxy\RetailProxy.Extensions.StoreHoursSample**.

15. Inside the methods you will call the actual CRT request/response. Avoid including any logic in the proxy project. The proxy project should just call the CRT request/response.
16. Build the project.
17. Copy the output assembly, and paste it in the **RetailSDK\References** folder.
18. Navigate to the **RetailSDK\Assets** folder, and open the **RetailProxy.MPOSOffline.ext.config** file.
19. In the **composition** section, register the name of your new proxy library (that is, the assembly that was generated after you built your proxy project).

Here is an example.

```
<add source="assembly" value="Contoso.Commerce.RetailProxy.StoreHoursSample" />
```

In this example, the proxy library is named **Contoso.Commerce.RetailProxy.StoreHoursSample**. You should specify the name of your proxy library in the **value** field.

20. For manual testing, open the **RetailProxy.MPOSOffline.ext.config** file under **C:\Program Files (x86)\Microsoft Dynamics 365\70\Retail Modern POS\ClientBroker\ext**. Update the **composition** section with the name of the custom proxy library.

Here is an example.

```
<add source="assembly" value="Contoso.Commerce.RetailProxy.StoreHoursSample" />
```

21. For e-Commerce, you must initialize the proxy for the extensions before you call it from your e-Commerce project. In your e-Commerce **Startup.cs** file (or an equivalent, such as web project initialization), initialize **RetailServerContext** with the Extended data model(EDM) model for your Retail proxy extension. Otherwise, you will receive a runtime error when you try to call the proxy. You must complete this step only one time.

Here is an example.

```
RetailServerContext.Initialize(new IEdmModelExtension[]
{
    // /* BEGIN SDKSAMPLE_STOREHOURS
    new Contoso.Commerce.RetailProxy.StoreHoursSample.EdmModel(),
    // END SDKSAMPLE_STOREHOURS */
});
```

#### **NOTE**

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Consume Retail Server APIs in external applications

2/18/2021 • 7 minutes to read • [Edit Online](#)

This topic describes how to consume the Retail Server APIs in external applications. Retail Server exposes the Open Data Protocol (OData) web endpoint so that external applications can consume the APIs. Retail Server also hosts the Commerce runtime (CRT) business logic and exposes it as OData endpoints. These endpoints are known as the Retail Server APIs.

External applications can consume the OData service through HTTPS. Retail Server provides multiple options for consuming the APIs:

- **Retail server proxy** – A strongly typed way to consume the APIs. There are multiple types of proxies that are exposed for different application types:
  - **C# proxy** – Server-side and native applications can consume the C# binary (class library) to access the APIs and other entities.
  - **TypeScript proxy** – Client applications can consume the .ts proxy file to access the APIs and other entities.
- **OData client** – The APIs can also be consumed from OData clients, from Postman, or by generating an HTTPS request to the Retail Server URL.

To browse the metadata, open the Retail Server URL in the following format in a web browser. The result is a list of all the Retail Server APIs, and input and output parameters.

```
https://RS-URL/Commerce/$metadata
```

## Security and authentication that are required to consume APIs

Access to each API is natively restricted according to the following roles:

- **Employee** – Access to APIs that are associated with this role requires point of sale (POS) device activation (a device token) and an authenticated employee.
- **Customer** – Access to APIs that are associated with this role requires an authenticated customer. E-Commerce sites generally use these APIs for operations such as retrieving order history and changing customer details.
- **Application** – Access to APIs that are associated with this role requires application-level authentication, such as Azure Active Directory (Azure AD) service-to-service authentication.
- **Anonymous** – APIs that are associated with this role are primarily used by e-Commerce sites without user authentication.
- **Customized APIs** – Access to APIs that are associated with this role can be restricted by using methods such as POS device activation, customer authentication, and anonymous authentication.

External application integration requires only the **Application** authentication flow to access the APIs. E-commerce application integration requires **Customer** authentication.

This topic is focused on setting up **Application** authentication flows and accessing the APIs by using the **Application** authentication context.

Before the APIs are accessed from an external application, the external application must be registered in Azure App registration, and details of the registered application must be added in the Commerce Headquarters.

For more information about authentication flows, see [Dynamics 365 Commerce authentication flows](#).

## Register the application in Azure App registration

Application registration establishes a trust relationship between your app and the Microsoft identity platform. The trust is unidirectional: your app trusts the Microsoft identity platform, not the other way around. Follow these steps to create the app registration.

1. Sign in to the [Azure portal](#).
2. If you have access to multiple tenants, use the **Directory + subscription** filter on the top menu to select the tenant that you want to register an application in.
3. Search for and select **Azure Active Directory**.
4. Under **Manage**, select **App registrations**, and then select **New registration**.
5. Enter a name for your application. Users of your app might see this name, and you can change it later.
6. Specify who can use this application as **Accounts in this organizational directory only (Microsoft only - Single tenant)**.
7. In the **Redirect URI** field, leave the default value. Don't change anything.
8. Select **Register** to complete the initial app registration.

When registration is completed, the Azure portal shows the **Overview** pane for the app registration. This pane includes the **Application (client) ID** field. The value of this field is known as the *application ID* or the *client ID*. It uniquely identifies your application in the Microsoft identity platform.

### Add a client secret

The client secret is also known as an *application password*. It's a string value that your app can use instead of a certificate to identify itself.

1. In the Azure portal, in **App registrations**, select your application.
2. Select **Certificates & secrets > New client secret**.
3. Add a description for your client secret.
4. Select a duration.
5. Select **Add**.
6. Be sure to record the secret's value so that you can use it in your client application code. **The secret's value is never displayed again after you leave this page.**

## Register the app in the Finance and Operations app so that Retail Server trusts it

1. In Commerce Headquarters, go to **Retail and Commerce > Headquarters setup > Parameters > Commerce shared parameters**.
2. On the **Identity providers** FastTab, select the provider that begins with `HTTPS://sts.windows.net/`. The values on the **Relying parties** FastTab are set based on your selection.
3. On the **Relying parties** FastTab, select **Add**. Enter the client ID that was generated during the app registration in Azure. Set the **Type** field to **Confidential** and the **UserType** field to **Application**.
4. On the Action Pane, select **Save**.
5. Select the new relying party, and then, on the **Server resource IDs** FastTab, select **Add**. In the **Server Resource ID** column, enter the Retail Server URL.
6. On the Action Pane, select **Save**.
7. Go to **Retail and commerce > Retail and commerce IT > Distribution Schedule**, and run Commerce Data Exchange (CDX) job 1110.

# Access the APIs by using Postman

Several third-party tools let you authenticate with Azure services, compose and send Web API requests, and view responses. Postman is one of the most popular tools. [Download and install the Postman client tool.](#)

For this example, you will access the **GetOrderHistory** API. This API retrieves the order history for a specific customer. It can be accessed only by using the **Employee**, **Customer** or **Application** authorization context. Because your application has the **Application** authorization context, it can access the **GetOrderHistory** API and get the customer order history.

To access the API, you first generate the authorization token. You then use that authorization token to access the API.

For the full list of APIs, see [Commerce Scale Unit customer and consumer APIs.](#)

## Generate an authorization token by using Postman

1. In Postman, create a GET request that has the following request URL and body parameters.

### Request URL

```
https://login.microsoftonline.com/{tenant-id}/oauth2/token
```

#### NOTE

You can get the tenant ID from the **Overview** pane for your Azure app registration. It's shown next to the client ID.

### Body parameters

KEY	VALUE
grant_type	client_credentials
client_id	The client ID that was generated during Azure app registration
client_secret	The client secret that was generated during Azure app registration
resource	The Retail Server URL

2. After the request has finished running, the **access\_token** value will be generated in the response body. Copy this token value. You will use it to connect to the Retail Server.

## Get order history by using Postman

- In Postman, create a POST request that has the following request URL, parameters, and header parameters.

### Request URL

```
<https://Retail>serverurl/Commerce/Customers('2001')/GetOrderHistory
```

#### NOTE

Replace 2001 with your own customer ID.

#### Parameters

KEY	VALUE
\$top	10
api-version	7.3

#### Header parameters

KEY	VALUE
OUN	The operating unit number of this retail channel
authorization	id_token { access_token }

#### NOTE

For `access_token`, copy and paste the `access_token` value that was generated in the authorization request. Then prefix it with `id_token`.

After the request has finished running, the response body will contain the customer order history.

## Access the Retail Server APIs by using a console application

1. Use Visual Studio 2017 to create a console application.
2. In the `app.config` file, include the following configuration.

```
<appSettings>
  <add key="aadClientId" value="client id generated during app registration in Azure" />
  <add key="aadClientSecret" value="client secret generated during app registration in Azure" />
  <add key="aadAuthority" value="https://sts.windows.net/tenant id/" />
  <add key="retailServerUrl" value="https://RetailserverURL/Commerce" />
  <add key="resource" value="https://REtailServerURL" />
  <add key="operatingUnitNumber" value="OUN value" />
</appSettings>
```

#### Update the configuration settings with actual values

1. Use the NuGet package manager for the project to add the following NuGet packages.
  - Microsoft.IdentityModel.Clients.ActiveDirectory
  - Microsoft.Dynamics.Commerce.RetailProxy

The `Microsoft.Dynamics.Commerce.RetailProxy` NuGet package can be added from the `RetailSDK\pkgs` folder. In the NuGet manager, add a local repository for the `RetailSDK\pkgs` folder.

2. In the `Program.cs` file, add the following variables.

```
private static string clientId;
private static string clientSecret;
private static Uri retailServerUrl;
private static string resource;
private static string operatingUnitNumber;
private static Uri authority;
```

3. In the **Program.cs** file, add the **GetConfiguration** method to read the app settings.

```
private static void GetConfiguration()
{
    clientId = ConfigurationManager.AppSettings["aadClientId"];
    clientSecret = ConfigurationManager.AppSettings["aadClientSecret"];
    authority = new Uri(ConfigurationManager.AppSettings["aadAuthority"]);
    retailServerUrl = new Uri(ConfigurationManager.AppSettings["retailServerUrl"]);
    operatingUnitNumber = ConfigurationManager.AppSettings["operatingUnitNumber"];
    resource = ConfigurationManager.AppSettings["resource"];
}
```

4. In the **Program.cs** file, add the **CreateManagerFactory** method to get the access token.

```
private static async Task<ManagerFactory> CreateManagerFactory()
{
    Microsoft.IdentityModel.Clients.ActiveDirectory.AuthenticationContext authenticationContext = new
    Microsoft.IdentityModel.Clients.ActiveDirectory.AuthenticationContext(authority.ToString(), false);
    AuthenticationResult authResult = null;
    authResult = await authenticationContext.AcquireTokenAsync(resource, new
    ClientCredential(clientId, clientSecret));

    ClientCredentialsToken clientCredentialsToken = new
    ClientCredentialsToken(authResult.AccessToken);
    RetailServerContext retailServerContext = RetailServerContext.Create(retailServerUrl,
    operatingUnitNumber, clientCredentialsToken);
    ManagerFactory factory = ManagerFactory.Create(retailServerContext);
    return factory;
}
```

5. Add the **GetOrderHistory** method to read the orders.

```
private static async Task<Microsoft.Dynamics.Commerce.RetailProxy.PagedResult<SalesOrder>>
GetOrderHistory(string customerId)
{
    QueryResultSettings querySettings = new QueryResultSettings
    {
        Paging = new PagingInfo() { Top = 10, Skip = 10 }
    };

    ManagerFactory managerFactory = await CreateManagerFactory();
    ICustomerManager customerManage = managerFactory.GetManager<ICustomerManager>();
    return await customerManage.GetOrderHistory(customerId, querySettings);
}
```

6. In the **main** method, call the **GetOrderHistory** method to read the records.

```
static void Main(string[] args)
{
    GetConfiguration();
    Microsoft.Dynamics.Commerce.RetailProxy.PagedResult<SalesOrder> orderHistory = Task.Run(async ()
=> await GetOrderHistory("2001")).Result;
    Console.WriteLine(orderHistory.FirstOrDefault<SalesOrder>().Id);
}
```

#### **NOTE**

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

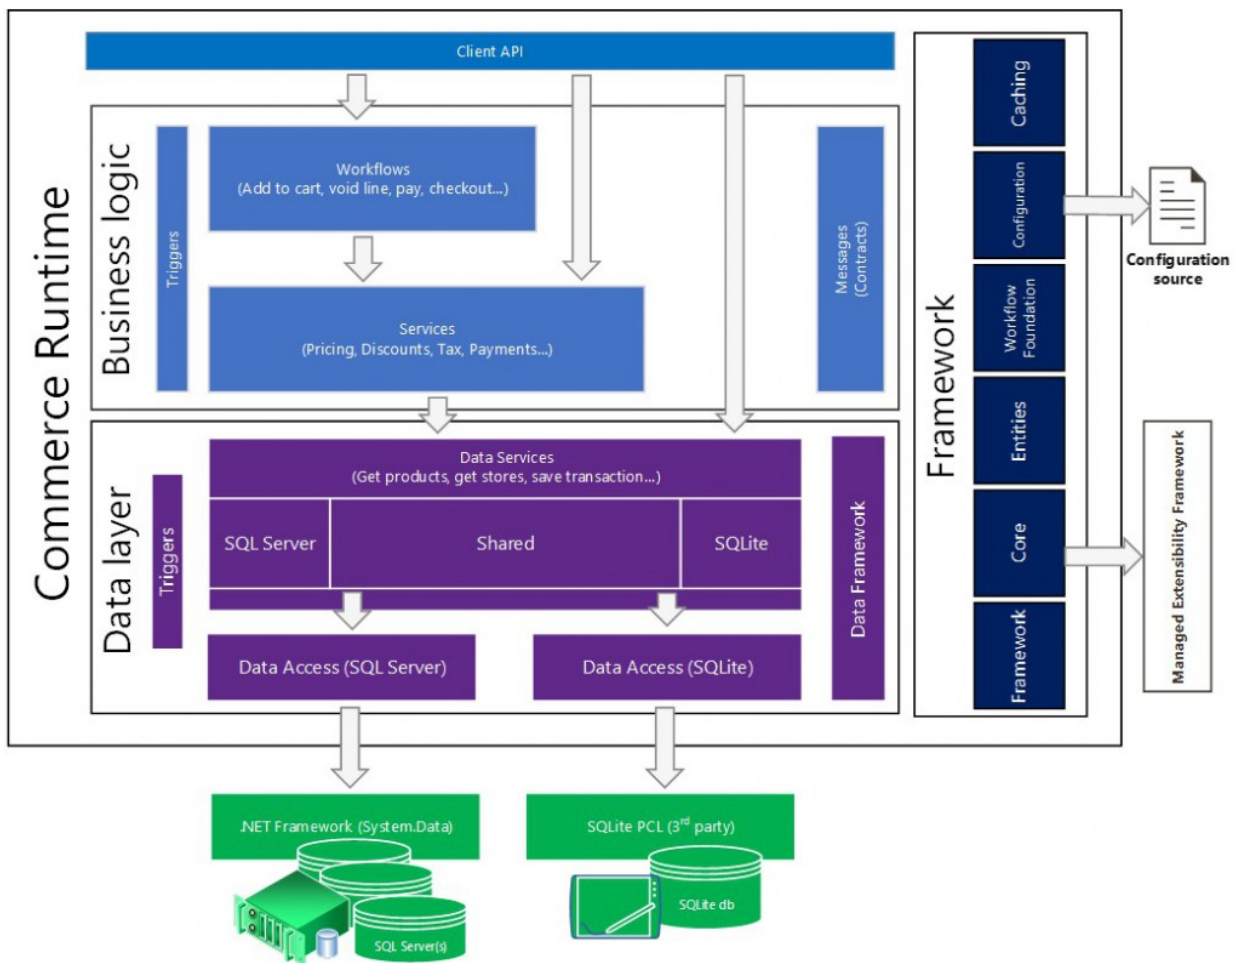

# Commerce runtime (CRT) architecture and configuration

2/18/2021 • 2 minutes to read • [Edit Online](#)

This article provides information about the architecture and configuration of Commerce Runtime (CRT). The CRT is a collection of portable .NET libraries that encapsulate business logic. It serves as the engine for the commerce channel.

## Commerce Runtime architecture

The following diagram shows the components of the Microsoft Dynamics 365 Commerce Runtime (CRT).

### Data access

On top of the database is a data access layer. In the data access layer, raw data is translated into objects in memory. For example, an object might be a product. Products have attributes, such as price and color. The data access layer has functions that you can use to manipulate the objects. Stored procedures pass packets of data from the database to data entities that can be used in services and workflows. You can update the packets of data to include new fields that you add in Commerce.

### Services

On top of the data access layer is a services layer. Services query for real-time data. You can use these services to customize existing functionality, or you can add your own services that include new functionality.

### Workflows

On top of the services layer is the workflow layer. A workflow is a collection of services and business logic that, together, define business processes. For example, when a customer adds an item to the cart, you can use a workflow to get the price, perform validation, check the inventory quantity, calculate shipping charges, calculate tax, and calculate discounts. You can use the workflows that are included in Commerce, or you can create new workflows. You can even use a workflow to connect to a third-party system as part of your business processes.

## API

On top of the workflow layer is the application programming interface (API) layer. You can use the API for tasks such as getting information about items, calculating prices, calculating shipping charges, and placing orders. You can extend the API to fit your business processes.

## Commerce Runtime configuration

Services are enumerated as types in the CRT configuration file. You can add types in the CRT configuration file to control which services are loaded in the CRT. Services are loaded in the order in which they are listed in the configuration file. All the default services are loaded automatically. However, if you add a new service above one of the default services, the new service replaces the default service.

### NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Commerce runtime (CRT) services

2/18/2021 • 12 minutes to read • [Edit Online](#)

Commerce runtime (CRT) is a collection of portable .NET libraries that contain the core business logic for the commerce channel and pricing functionality. To add or modify any business logic, you should customize CRT. Retail Modern POS or Cloud POS calls CRT to request that it perform business logic. CRT processes the request and then sends the response back to point of sale. POS is like a thin client, all the business logic should be done in CRT.

A CRT service is a group of requests/responses. Any time that you do something in POS, POS sends a request to Commerce Scale Unit, and Commerce Scale Unit calls CRT. CRT processes the request and sends back the response.

This topic shows some important requests/responses that you can customize for your business scenario.

There are three main layers in CRT:

- Services
- Workflow
- Data Access

All CRT customization for business logic can be done in Services, Workflow or Data Access layers, other core layers that are required for CRT to work are runtime, authentication, and data access managers and you should avoid any customization on these layers.

## NOTE

Detailed information about all CRT classes can be found in the Retail SDK, which is found at RetailSDK\Documents\CommerceRuntimeMessages.chm.

## Overall flow

The overall flow looks like this:

CRT service request < > Zero or more workflow requests < > Zero or more data access requests

For example, multiple workflow and data access requests are called to perform the **Create sales order** service request.

## CRT services

Each CRT service contains one or more requests/responses. For example, the Customer service in CRT contains all the customer-related requests/responses. Each request/response is run in a different flow.

### Default CRT services

Many services in CRT support the functionality of the channel and store operations. You can add your own services or extend the existing services. The following table describes some of the services that you might customize for various business services.

For more information about each service, see the CRT request/response document in the Retail software development kit (SDK), at ...RetailSDK\Code\Documents\CommerceRuntimeMessages.chm.

SERVICE	DESCRIPTION
AddressService	This service verifies addresses and gets location information, such as cities, counties, or states.
BarcodeService	This service processes the barcode that was scanned, based on the mask and barcode types, and calculates the quantity and price from the barcode.
CartService	This service gets the cart from the transaction and sales transaction service from the transaction tables.
ChargeService	This service implements logic that calculates automatic charges, price charges, and shipping charges for transactions.
CouponService	This service validates and updates coupon-related requests.
CurrencyService	This service converts currencies, based on exchange rates.
CustomerService	This service contains customer related operations such as Save customer, purchase history, get customer and customer balance.
EmployeeService	This service gets employee-related information and employees by store.
FormattingService	This service implements logic for the format of numbers, currencies, and dates.
GiftCardService	This service provides information about internal activities that are related to gift cards, such as issuing the gift card, getting the balance, and adding value.
LoyaltyService	This service implements a program that rewards repeat customers.
NotificationService	This service maintains the POS notification service.
PaymentService	This service lets you connect your online store to a payment service to provide credit card authorization and use preconfigured payment processing. You can also extend the payment service to add additional third-party payment processors.
ProductService	This service gets product-related and variant-related information.
ProductsService	This service gets information that is related to products and variants.
PricingService	This service gets the price of an item in real time. The price is adjusted, based on the base price and any applicable discounts. Discounts can be customized for each retailer.

SERVICE	DESCRIPTION
ProductAvailabilityService	This service calculates the quantities of products that are available to sell.
ReasonCodeService	This service calculates and gets the required reason code for POS operations or any workflow.
ReceiptService	This service gets and formats the receipt details.
RoundingService	This service rounds the tender amount, based on the tender type and store.
SalesOrderService	This service creates a sales order, based on a customer shopping cart.
SearchProductsService	This service searches products, based on the input text.
ShippingService	This service calculates shipping costs and determines shipping options for the current order.
StockCountService	This service creates, commits, and synchronizes stock journals.
StoreOperationService	This service maintains store-related operation services, such as Save and Drop, Tender declaration, and Search journal.
TaxService	This service calculates the sales tax for the current order. You can use sales tax information provided, or from a third-party sales tax service.
TotalingService	This service calculates the totals on the sales transactions and sales lines.

For extension scenarios, you can add CRT triggers, create new services, and override any of the requests in the service class. For information about how to extend and understand CRT extension patterns, see [Commerce runtime \(CRT\) extensibility](#).

#### NOTE

CRT extension code should not refer to or use any of the CRT business logic classes, methods, or handlers (such as classes from `Runtime.Workflow`, `Runtime.Services`, or `Runtime.DataServices`). These classes are not backward compatible, which could break extensions during an upgrade. Extensions should only use request, response, and entity classes from `Runtime.*.Messages`, `Runtime.Framework`, `Runtime.Data`, and `Runtime.Entities`.

## AddressService

The Address service supports the following requests/responses for various extension scenarios.

REQUEST	PURPOSE
GetCountryRegionsServiceRequest	This request gets the list of countries and regions that are supported.

REQUEST	PURPOSE
GetStateProvincesServiceRequest	This request gets the list of states or provinces that are supported for the country or region.
GetCitiesServiceRequest	This request gets the list of cities that are supported for the state or region.
GetDistrictServiceRequest	This request gets the list of districts that are supported.
GetZipCodesServiceRequest	This request gets the list of ZIP Codes that are supported.
GetFromZipPostalCodeServiceRequest	This request gets the list of postal codes supported.
GetAddressFormattingServiceRequest	This request gets the address format for the specified country or region.

### BarcodeService

REQUEST	PURPOSE
ProcessMaskSegmentsServiceRequest	This request processes the barcode, based on the barcode mask configuration.
GetBarcodeTypeServiceRequest	This request gets the types of barcodes that are supported.
CalculateQuantityFromPriceServiceRequest	This request calculates the price and quantity, based on the barcode that is scanned or entered.

### CartService

REQUEST	PURPOSE
GetSalesTransactionsServiceRequest	This request gets the sales transaction from Headquarters.
GetCartServiceRequest	This request gets the cart from the sales transaction table by using the cart ID.
CalculateSalesTransactionServiceRequest	This request calculates the various sales transaction totals, based on the specified calculation mode.
CalculateEstimatedShippingAuthorizationAmountServiceRequest	This request calculates the estimated shipping authorization amount on the transaction.
ConvertSalesTransactionToCartServiceRequest	This request converts the sales transaction to a cart transaction, based on transaction ID that is passed.

### CouponService

REQUEST	PURPOSE
UpdateCouponCodesOnCartServiceRequest	This request updates the coupon codes status in Headquarters, based on the coupons that are used in the cart.

REQUEST	PURPOSE
ValidateCouponCodesServiceRequest	This request validates the coupon code that is entered in the transactions.
UpdateCouponUsageServiceRequest	This request updates coupon usage for the transaction.

### CustomerService

REQUEST	PURPOSE
SaveCustomerServiceRequest	This request is called when you save a customer from the POS.
GetCustomersServiceRequest	This request gets the selected customer details.
CustomersSearchServiceRequest	This request is run when you search for a customer from the POS.
GetCustomerGroupsServiceRequest	This request gets the customer group details.
InitiateLinkToExistingCustomerServiceRequest	This request is an internal request for backward compatibility.
FinalizeLinkToExistingCustomerServiceRequest	This request is an internal request for backward compatibility.
UnlinkFromExistingCustomerServiceRequest	This request is an internal request for backward compatibility.
GetCustomerBalanceServiceRequest	This request gets the balance of the customer's account.
GetOrderHistoryServiceRequest	This request gets the customer's order history.
GetPurchaseHistoryServiceRequest	This request gets the history of the customer's recent purchases.
CustomerSearchByFieldsServiceRequest	This request is run when you search customer by using fields such as name, phone number etc. (hint search).
GetCustomerSearchFieldsServiceRequest	This request gets the list of customer search fields (hint fields).

### PricingService

REQUEST	PURPOSE
CalculatePricesServiceRequest	This request calculates the price for each item that is added to the cart and on the search screen.
CalculateDiscountsServiceRequest	This request calculates the discount for each item that is added to the cart.
GetIndependentPriceDiscountServiceRequest	This request calculates the price for each item on the price check screen and in other non-transaction-related flows.

REQUEST	PURPOSE
ValidateDiscountsServiceRequest	This request validates the discount that is entered, based on the employee.
GetAllPeriodicDiscountsServiceRequest	This request gets all the periodic discounts that are configured.
GetDiscountCodesServiceRequest	This request gets all the discount codes that are configured.

### ProductService

REQUEST	PURPOSE
ProductSearchServiceRequest	This request gets the product list, based on the search text from the POS. (This is an old request. For customization, use the new <b>SearchProductsServiceRequest</b> request instead.)
GetProductServiceRequest	This request gets the product, based on the product ID.
GetProductRefinersRequest	This request retrieves the product refiner values.

### ProductsService

REQUEST	PURPOSE
GetProductsServiceRequest	This request gets the products, based on the products IDs that are provided.
GetVariantProductsServiceRequest	This request gets specific variations of master type products.

### ReasonCodeService

REQUEST	PURPOSE
GetReasonCodesServiceRequest	This request gets the required reason code for the workflow or POS operation.
CalculateRequiredReasonCodesServiceRequest	This request calculates the required reason code for the workflow or POS operation.
CalculateCartRequiredReasonCodesServiceRequest	This request calculates the required reason code for the cart workflow.
CalculateDropAndDeclareTransactionRequiredReasonCodesServiceRequest	This request calculates the required reason code for the drop and tender declaration transaction.
CalculateNonSalesTransactionRequiredReasonCodesServiceRequest	This request calculates the required reason code for the non-sales transaction, such as tender declaration.
GetReturnOrderReasonCodesServiceRequest	This request gets the required reason code for the return transaction.
ValidateReasonCodeLineForUpdateServiceRequest	This request validates the reason code lines that are added during the save cart request.

## ReceiptService

REQUEST	PURPOSE
GetReceiptServiceRequest	This request gets the receipt type and generates the receipt data, based on the receipt type.
GetCustomReceiptFieldServiceRequest	Override this request, and add custom logic for your custom fields that are added in the receipt.
GetEmailReceiptServiceRequest	This request gets the formatted receipts that will be used for print and email scenarios.
PopulateTaxSummaryIndiaServiceRequest	This request populates the tax summary for India transaction.

## SearchProductsService

REQUEST	PURPOSE
SearchProductsServiceRequest	This request is run when you search for a product from the POS.

## TaxService

REQUEST	PURPOSE
CalculateTaxServiceRequest	This request calculates taxes on the transaction.
AssignTaxCodesServiceRequest	This request assigns tax codes on the transaction's taxable items before the tax calculation. The default tax calculation handler of the <b>CalculateTaxServiceRequest</b> request uses this message.
PopulateTaxRatesRequest	This request populates tax rates for the recalled transaction. No tax percentage information is persisted for tax lines. This message handler restores the information.

## Workflow layer

On top of the Services layer is the Workflow layer. A workflow is a collection of services and business logic that together define business processes. For example, when a customer adds an item to the cart, you can use a workflow to get the price, do validation, check the inventory quantity, calculate shipping, calculate tax, and calculate discounts. You can customize the existing workflows, or you can create new workflows. You can even use a workflow to connect to a third-party system as part of your business processes.

Just like services, workflows use the request/response pattern. The request object inherited from the base CRT [Request](#) class. The response object inherited from the base CRT [Response](#) class. A workflow also has a request handler class that extends the [WorkflowRequestHandler<TRequest, TResponse>](#) class. To create a workflow, you create a request class and a response class, and you then create a request handler class that contains the business logic for the workflow.

For example, when you create a cash-and-carry transaction or a customer order, many different steps or workflows are completed before the order is created. One of the workflow steps in the order process is the Save cart request. The Save cart request workflow is responsible for saving any changes that are made to the cart from the POS. For example, when you add an item to the cart, change the quantity, and so on, anything that you

do in the POS will cause a call to the SaveCart to save the changes to the POS and database.

### Default workflows and handlers

The following table lists the default workflow requests and response. CRT services call the workflows request and response based on the operation you perform in POS. You can customize any of these workflows request and response according to your business scenario.

REQUEST	HANDLER	PURPOSE
AddOrderInvoiceToCartRequest	AddOrderInvoiceToCartRequestHandler	This request adds the invoice to the cart as a cart line.
AddOrRemoveDiscountCodesRequest	AddOrRemoveDiscountCodesRequestHandler	This request adds discount codes to the cart or removes them from the cart.
CancelOrderRequest	CancelOrderRequestHandler	This request is triggered when you cancel an order from the POS.
CopyCartRequest	CopyCartRequestHandler	This request creates an identical shopping cart that has the specified cart type.
GetAddressRequest	GetAddressRequestHandler	This request gets the address from the list.
GetCardPaymentAcceptPointRequest	GetCardPaymentAcceptPointRequestHandler	This request shows the accepting page for card payment.
GetCartRequest	GetCartRequestHandler	This request gets the shopping cart, based on the cart search criteria.
GetDiscountCodesRequest	GetDiscountCodesRequestHandler	This request gets the discount codes.
GetOrdersRequest	GetOrdersRequestHandler	This request gets sales orders.
GetPromotionsRequest	GetPromotionsRequestHandler	This request gets the shopping cart together with promotion lines for the cart and the cart items.
GetScanResultRequest	GetScanResultRequestHandler	This request gets the entity details, based on the details that are scanned or typed.
GetSupportedCardTypesRequest	GetSupportedCardTypesRequestHandler	This request retrieves the card types that are supported for the specified currency.
IssueOrAddToGiftCardRequest	IssueOrAddToGiftCardRequestHandler	This request issues a gift card or adds to a gift card's balance.
PickAndPackOrderRequest	PickAndPackOrderRequestHandler	This request represents a request for picking list creation and packing slip creation for a customer order.

REQUEST	HANDLER	PURPOSE
PickupAtStoreRequest	PickupAtStoreRequestHandler	This request represents a request for pick-up at the store.
RecalculateOrderRequest	RecalculateOrderRequestHandler	This request represents a request for the recalculate order workflow.
RecallCustomerOrderRequest	RecallCustomerOrderRequestHandler	This request gets sales orders and converts them into a cart.
RecallSalesInvoiceRequest	RecallSalesInvoiceRequestHandler	This request gets invoices.
ResumeCartRequest	ResumeCartRequestHandler	This request represents a request to resume a cart that was suspended.
SaveCartLinesRequest	SaveCartLinesRequestHandler	This request represents a request for create, update, delete, or void operations on the cart line.
SaveCartRequest	SaveCartRequestHandler	This request is triggered when you make any changes in that POS that affect the cart.
SaveCustomerOrderRequest	SaveCustomerOrderRequestHandler	This request initiates a request to save the customer order, based on the specified cart identifier and payment card information.
SaveReasonCodeLineRequest	SaveReasonCodeLineRequestHandler	This request adds or updates a reason code on the cart line.
SaveTenderLineRequest	SaveTenderLineRequestHandler	This request adds, removes, or updates a tender line for the given shopping cart.
SaveVoidTransactionRequest	SaveVoidTransactionRequestHandler	This request voids a transaction.
SubmitSalesTransactionRequest	SubmitOrderRequestHandler	This request initiates a request to submit the sales transaction, based on the specified cart identifier.
SuspendCartRequest	SuspendCartRequestHandler	This request represents a request to suspend the cart.
TransferCartRequest	TransferCartRequestHandler	This request transfers the specified shopping cart.
UpdateCommissionSalesGroupRequest	UpdateCommissionSalesGroupHandler	This request encapsulates a request for updating the sales representative on the cart or the cart line.
UploadOrderRequest	UploadOrderRequestHandler	This request uploads the sales order.
ValidateCartForCheckoutRequest	ValidateCartForCheckoutRequestHandler	This request validates the cart for checkout.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Commerce runtime (CRT) extensibility

2/18/2021 • 22 minutes to read • [Edit Online](#)

This topic describes various ways that you can extend the commerce runtime (CRT). It explains the concept of extension properties, and shows how to add them to a CRT entity so that they are persistent and so that they aren't persistent.

CRT contains the core business logic. If you want to add or modify any business logic, you should customize CRT. All the CRT code is developed by using C#, and then it's compiled and released as class libraries (.NET assemblies). Point of sale (POS) is a thin client. All the business logic is done in CRT. POS calls CRT to perform any business logic, and then CRT processes the information and sends it back to POS.

Every CRT service consists of a group of one or more requests and responses. POS sends a request to Retail Server, and Retail Server calls CRT. CRT then processes the request and sends back the response.

For example, the Product service in CRT contains all the product-related requests and responses, each of which is run in a different flow. Likewise, the Customer service in CRT contain all the customer-related requests and responses. The following table shows the requests in the Customer service.

REQUEST	PURPOSE
SaveCustomerServiceRequest	This request is called when you save a customer from POS.
GetCustomersServiceRequest	This request is used to get the details of the selected customer.
CustomersSearchServiceRequest	This request is run when you do a customer search from POS.
GetCustomerGroupsServiceRequest	This request is used to get the details of the customer group.
InitiateLinkToExistingCustomerServiceRequest	This internal request is for backward compatibility.
FinalizeLinkToExistingCustomerServiceRequest	This internal request is for backward compatibility.
UnlinkFromExistingCustomerServiceRequest	This internal request is for backward compatibility.
GetCustomerBalanceServiceRequest	This request gets the balance for the customer account.
GetOrderHistoryServiceRequest	This request gets the customer's order history.
GetPurchaseHistoryServiceRequest	This request gets the history of the customer's recent purchases.
CustomerSearchByFieldsServiceRequest	This request is run when you search for customers by using fields (hint search).
GetCustomerSearchFieldsServiceRequest	This request gets the list of customer search fields (hint fields).

# CRT extension patterns

Before you learn about the CRT extension patterns, you should understand how a CRT extension can be created. CRT is just a collection of C# class libraries (.NET assemblies). You can create a class library project in C# and do all the CRT extension by using the patterns that are shown in the following subsections. Always use the samples that Microsoft provides as templates for your extension, because these samples have the correct assembly references, Microsoft .NET Framework version, output type, and build parameters. Additionally, all the other required parameters are preconfigured. You can find the CRT sample extension in the Retail software development kit (SDK), at ...\\RetailSDK\\SampleExtensions\\CommerceRuntime.

## NOTE

As of version 10.0.16 of Finance and Operations apps, all class libraries for CRT extension projects must use .NET Standard 2.0 for the target framework.

## Create a new CRT service

You can create new functionality or a new feature.

## Override the existing service

You can completely override existing functionality or customize it according to your business flow. Here are some examples:

- You want to override the POS search functionality to search from an external system instead of searching in a local database or Commerce headquarters. Alternatively, you can do an override, call the standard functionality, and do some additional custom logic.
- Search for a customer in a local database or Commerce headquarters, search for the customer in an external system, and then merge or modify the results.

Avoid overriding the handler. You can implement most of the CRT extension scenarios by using pre-triggers or post-triggers. Overrides are required only when you want to completely replace the existing functionality.

## CRT data service and data service with entities

You can use the CRT data service to read data or entities from the channel database.

## NOTE

CRT extension code should not refer to or use any of the CRT business logic classes, methods, or handlers (such as classes from `Runtime.Workflow`, `Runtime.Services`, or `Runtime.DataServices`). Because these classes aren't backward compatible, extensions could be broken during an upgrade. Extensions should use only request, response, and entity classes from `Runtime.*.Messages`, `Runtime.Framework`, `Runtime.Data`, and `Runtime.Entities`.

## Triggers

You can run additional logic before or after any request.

In the pre-trigger, you can do some validation, custom logic, and so on.

In the post-trigger, you can add some custom information to the request and send it to POS. Alternatively, you can modify the result that is returned from the standard functionality or do some additional business logic.

For information about how to create CRT trigger extensions, see [Commerce runtime \(CRT\) triggers extension](#).

## Extension properties

You can add custom properties to any CRT entity and send it to POS. Extension properties are key-value pairs. If you set an extension property in POS, it will be available in CRT. Likewise, if you set an extension property in CRT, it will be available in POS. You can also set extension properties at the level of the request, the response, or the

request context. By default, extension properties aren't stored in and read from the database. To read or set extension properties, you must write custom code. However, that custom code is automatically sent between POS and CRT.

For example, you want to capture and show some additional information to the Customer entity in POS. In this case, you can add a post-trigger to fetch all your custom properties for customers, add them to the Customer entity as extension properties, and then send those extension properties to POS.

You can also send extension properties from POS to CRT and store them in your custom table. Alternatively, you can do some custom logic based on those properties, or send it to Commerce headquarters.

All CRT entities, such as products, customers, transactions, and parameters, support extension properties.

#### NOTE

Attributes are also supported (configuration-driven development). For extension properties, you must create a custom table and store the data. However, attributes are configuration driven and aren't required to create table fields. Therefore, no code is required for read and update operations.

For details about the attributes, see the following topics:

- [Order attributes](#)
- [Customer attributes](#)

#### Extend Commerce Data Exchange - Real-time Service classes

You can do synchronous call from CRT to Commerce headquarters.

For information about how to extend Commerce Data Exchange - Real-time service, see [Extend Commerce Data Exchange - Real-time Service](#).

## Retail Server extension

For information about how to create new Retail Server APIs, see [Create a new Retail Server extension API](#).

## Register the CRT extension

### Online

For online mode (that is, when POS is connected to Retail Server), after you've finished extending CRT, put the extension library in the `\RetailServer\webroot\bin\Ext` folder. In the `CommerceRuntime.Ext.config` file, update the **composition** section with the information about the custom library, as shown in the following example.

```
<add source="assembly" value="your custom library name" />
```

For example, if the name of your custom library is `Contoso.Commerce.Runtime.CustomerSearchSample`, add the following line in the **composition** section.

```
<add source="assembly" value="Contoso.Commerce.Runtime.CustomerSearchSample" />
```

### Offline

For offline mode, after you've finished extending CRT, put the custom library in the `\Program Files (x86)\Microsoft Dynamics 365\70\Retail Modern POS\ClientBroker\ext` folder. In the `CommerceRuntime.MPOSOOffline.ext.config` file, update the **composition** section with the information

about the custom library, as shown in the following example.

```
<add source="assembly" value="your custom library name" />.
```

## Register the extension configuration in the CommerceRuntime.Ext.config file

Your extension can register key-value configurations in the **CommerceRuntime.Ext.config** file in the **<settings>** node.

The **<settings>** node is a collection of key-value pairs that is used to configure the CommerceRuntime components. The convention is to prefix the keys for settings with a representation of the functional area that the keys are configuring, and to use a period (.) as the separator between prefixes and keys. Extension configuration values must be prefixed with **ext**, because the CRT initialization enforces this convention. Any extension that doesn't have that prefix won't be loaded. More prefixes can be added to represent the subarea that the keys are configuring. The following example shows a key-value pair.

```
<add name="ext.SalesTransaction.Storage.CartSerializationFormat" value="XML" />
```

For HTTP binding time-outs on calls to Commerce Data Exchange - Real-time Service, configure the time-out in seconds per method. This time-out value is limited by the **maxExtensionTimeoutInSeconds** value, which is set in the **CommerceRuntime.config** file.

```
<add  
name="ext.RealTimeServiceClient.TimeoutInSeconds.InvokeExtensionMethod.ContosoRetailStoreHours_UpdateStoreHours" value="300" />
```

To read the key value from the CRT extension configuration, use **RequestContext.Runtime.Configuration**. The following example shows how to retrieve a value.

```
string key =  
context.Runtime.Configuration.GetSettingValue("ext.SalesTransaction.Storage.CartSerializationFormat") ??  
string.Empty;
```

The preceding steps are used for manual deployment and testing on your development box. To package the extension and deploy it to production or user acceptance testing (UAT), use the information in the packaging document.

## Debug CRT

### Attach the CRT extension project online

To debug CRT from POS, attach the CRT extension project to the **w3wp.exe** process (the Internet Information Services [IIS] process for Retail Server) when POS is connected to Retail Server.

### Attach the CRT extension project offline

For offline debugging, attach the CRT extension project to the **dllhost.exe** process.

## NOTE

CRT extension code should not refer to or use any of the CRT business logic classes, methods, or handlers (such as classes from `Runtime.Workflow`, `Runtime.Services`, or `Runtime.DataServices`). Because these classes aren't backward compatible, extensions could be broken during an upgrade. Extensions should use only request, response, and entity classes from `Runtime.*.Messages`, `Runtime.Framework`, `Runtime.Data`, and `Runtime.Entities`.

## Sample to create a new CRT service class

You can create a new service class, and implement one or more requests and responses. Use this approach to create a new feature.

Implement the following classes for a new CRT service:

- **Request class** – This class is the POS, Retail Server, e-commerce, or CRT workflow class that is the request to do something.
- **Response class** – This class returns the response, based on the request to the caller.
- **Handler class** – This class contains the core logic for the request. In the handler class, you can call other requests, do custom logic, and perform other tasks.

For serialization to work, the new request type must implement the `[DataContract]` and `[DataMember]` attributes.

### Request class

```
using System.Runtime.Serialization;
using Microsoft.Dynamics.Commerce.Runtime.Messages;

[DataContract]
public sealed class GetStoreHoursDataRequest : Request
{
    public GetStoreHoursDataRequest(string storeNumber)
    {
        this.StoreNumber = storeNumber;
    }

    [DataMember]
    public string StoreNumber { get; private set; }
}
```

### Response class

The new response type resembles the request type.

```
[DataContract]
public sealed class GetStoreHoursDataResponse : Response
{
    public GetStoreHoursDataResponse(PagedResult dayHours)
    {
        this.DayHours = dayHours;
    }

    [DataMember]
    public PagedResult DayHours { get; private set; }
}
```

Next, you must create a new CRT service that uses the request and response types.

# Create a new CRT service class

1. Implement the new service.

```
public class StoreHoursDataService : IRequestHandlerAsync
```

2. Implement two members of the interface. The **SupportedRequestTypes** member returns a list of all requests that this service can handle. The **execute** method is the method that CRT calls if a request for this service is run.

```
public IEnumerable<Type> SupportedRequestTypes
{
    get
    {
        return new[]
        {
            typeof(GetStoreHoursDataRequest),
            typeof(UpdateStoreDayHoursDataRequest),
        };
    }
}

public async Task<Response> Execute(Request request)
{
    if (request == null)
    {
        throw new ArgumentNullException("request");
    }

    Type reqType = request.GetType();
    if (reqType == typeof(GetStoreHoursDataRequest))
    {
        return await
this.GetStoreDayHoursAsync((GetStoreHoursDataRequest)request).ConfigureAwait(false);
    }
    else if (reqType == typeof(UpdateStoreDayHoursDataRequest))
    {
        return await
this.UpdateStoreDayHoursAsync((UpdateStoreDayHoursDataRequest)request).ConfigureAwait(false);
    }
    else
    {
        string message = string.Format(CultureInfo.InvariantCulture, "Request '{0}' is not
supported.", reqType);
        Console.WriteLine(message);
        throw new NotSupportedException(message);
    }
}

private async Task<Response> GetStoreDayHoursAsync(GetStoreHoursDataRequest request)
{
    ThrowIf.Null(request, "request");

    using (DatabaseContext databaseContext = new DatabaseContext(request.RequestContext))
    {
        var query = new SqlPagedQuery(request.QueryResultSettings)
        {
            DatabaseSchema = "ext",
            Select = new ColumnSet("DAY", "OPENTIME", "CLOSINGTIME", "RECID"),
            From = "CONTOSORETAILSTOREHOURSVIEW",
            Where = "STORENUMBER = @storeNumber",
        };

        query.Parameters["@storeNumber"] = request.StoreNumber;
        return new GetStoreHoursDataResponse(await
```

```

databaseContext.ReadEntityAsync<DataModel.StoreDayHours>(query).ConfigureAwait(false));
    }
}

private async Task<Response> UpdateStoreDayHoursAsync(UpdateStoreDayHoursDataRequest request)
{
    ThrowIf.Null(request, "request");
    ThrowIf.Null(request.StoreDayHours, "request.StoreDayHours");
    if (request.StoreDayHours.DayOfWeek < 1 || request.StoreDayHours.DayOfWeek > 7)
    {
        throw new
DataValidationException(DataValidationErrors.Microsoft_Dynamics_Commerce_Runtime_ValueOutOfRange);
    }

    InvokeExtensionMethodRealtimeRequest extensionRequest = new
InvokeExtensionMethodRealtimeRequest(
        "ContosoRetailStoreHours_UpdateStoreHours",
        request.StoreDayHours.Id,
        request.StoreDayHours.DayOfWeek,
        request.StoreDayHours.OpenTime,
        request.StoreDayHours.CloseTime);
    InvokeExtensionMethodRealtimeResponse response = await
request.RequestContext.ExecuteAsync<InvokeExtensionMethodRealtimeResponse>
(extensionRequest).ConfigureAwait(false);
    ReadOnlyCollection<object> results = response.Result;

    long recId = Convert.ToInt64(results[0]);

    using (var databaseContext = new DatabaseContext(request.RequestContext))
    {
        ParameterSet parameters = new ParameterSet();
        parameters["@bi_Id"] = recId;
        parameters["@i_Day"] = request.StoreDayHours.DayOfWeek;
        parameters["@i_OpenTime"] = request.StoreDayHours.OpenTime;
        parameters["@i_ClosingTime"] = request.StoreDayHours.CloseTime;
        await databaseContext.ExecuteStoredProcedureNonQueryAsync("
[ext].UPDATESSTOREDAYHOURS", parameters, resultSettings: null).ConfigureAwait(false);
    }

    return new UpdateStoreDayHoursDataResponse(request.StoreDayHours);
}

```

3. Register the CRT extension as described earlier in this topic.

The preceding sample code is missing the implementation of **UpdateStoreDayHoursDataRequest** and **UpdateStoreDayHoursDataResponse**. The full sample code is available in the Retail SDK, at **RetailSDK\SampleExtensions\CommerceRuntime\Extensions.StoreHoursSample**.

## Implement a new CRT service that handles a single new request

It's slightly easier to create a single-request service.

```

namespace Contoso
{
    namespace Commerce.Runtime.CrossLoyaltySample
    {
        using System;
        using System.Threading.Tasks;
        using Messages;
        using Microsoft.Dynamics.Commerce.Runtime;
        using Microsoft.Dynamics.Commerce.Runtime.Messages;

        /// <summary>
        /// Service class responsible executing the service requests.
        /// </summary>
        public class CrossLoyaltyCardService : SingleAsyncRequestHandler<GetCrossLoyaltyCardRequest>
        {
            /// <summary>
            /// Process method.
            /// </summary>
            /// <param name="request">The request with the loyalty number.</param>
            /// <returns>The discount value.</returns>
            protected override async Task<Response> Process(GetCrossLoyaltyCardRequest request)
            {
                if (request == null)
                {
                    throw new ArgumentNullException("request");
                }

                var serviceResponse = new GetCrossLoyaltyCardResponse(0);

                //Business logic

                return await Task.FromResult(serviceResponse);
            }
        }
    }
}

```

## Implement a CRT service that overrides the functionality of an existing request

In some cases, the request and response types are sufficient, but you must change the out-of-box service implementation logic to perform different logic, or you must integrate with an external service to perform that logic. An override of the default implementation must be done only when you want to completely replace the logic. For example, if you don't want to use the out-of-box tax implementation but want to use third-party tax logic instead, override the tax service request. Most other scenarios can be achieved by adding a pre-trigger or post-trigger to the request. Try to avoid overriding the request. When you override the request, the custom logic will be run, and you might not get the future enhancements that are done in this overridden request.

Additionally, registration in the **commerceRuntime.ext.Config** file must precede registration of the service that should be overridden. This registration order is important because of the way that the Managed Extensibility Framework (MEF) loads the extension dynamic-link libraries (DLLs). The types that are higher in the file take precedence.

To override any CRT request, follow the pattern in the following example that overrides the out-of-box **CreateOrUpdateCustomerDataRequest** request.

```

namespace Contoso
{
    namespace Commerce.Runtime.EmailPreferenceSample
    {
        using System.Threading.Tasks;
        using System.Transactions;
        using Microsoft.Dynamics.Commerce.Runtime;
        using Microsoft.Dynamics.Commerce.Runtime.Data;
        using Microsoft.Dynamics.Commerce.Runtime.DataModel;
        using Microsoft.Dynamics.Commerce.Runtime.DataServices.Messages;
        using Microsoft.Dynamics.Commerce.Runtime.Messages;

        /// <summary>
        /// Create or update customer data request handler.
        /// </summary>
        public sealed class CreateOrUpdateCustomerDataRequestHandler :
            SingleAsyncRequestHandler<CreateOrUpdateCustomerDataRequest>
        {
            /// <summary>
            /// Executes the workflow to create or update a customer.
            /// </summary>
            /// <param name="request">The request.</param>
            /// <returns>The response.</returns>
            protected override async Task<Response> Process(CreateOrUpdateCustomerDataRequest request)
            {
                ThrowIf.Null(request, "request");

                return new SingleEntityDataServiceResponse<Customer>(customer);
            }
        }
    }
}

```

## Run the base handler in the extension

### NotHandledResponse

If the overridden logic runs the base handler for some scenarios, execution of the base handler can be achieved by returning **new NotHandledResponse()**. If **NotHandledResponse** is returned, the CRT framework will use the extension that is requesting to run the base or out-of-band logic, and will run the out-of-band handler.

**NotHandledResponse** can be used in scenarios where the extension runs the base handler logic. For example, if the overridden request runs the base handler logic, it can return **NotHandledResponse** for the base handler to run. Alternatively, if the extension runs custom logic and base logic, the extension code can return **NotHandledResponse** after it runs the custom logic.

```

private Response
GetCustomReceiptFieldForSalesTransactionReceipts(GetLocalizationCustomReceiptFieldServiceRequest request)
{
    ThrowIf.Null(request.SalesOrder, nameof(request.SalesOrder));

    string receiptFieldName = request.CustomReceiptField;
    string receiptFieldValue = string.Empty;

    if (request.SalesOrder.TaxCalculationType == TaxCalculationType.GTE)
    {
        switch (receiptFieldName)
        {
            case "Sample":
                receiptFieldValue = this.GetGstRegistrationNumber(request);
                break;
            default:
                return new NotHandledResponse();
        }
    }
    else
    {
        return new NotHandledResponse();
    }

    int receiptFieldLength = request.ReceiptItemInfo == null ? 0 : request.ReceiptItemInfo.Length;
    var returnValue = ReceiptStringUtils.WrapString(receiptFieldValue, receiptFieldLength);

    return new GetCustomReceiptFieldServiceResponse(returnValue);
}

```

## Run an extension request for a channel type

Sometimes, an extension request must be run only for a specific channel type. For example, the request might have to be run for the online channel but not for the retail channel (physical store). In these cases, before you run the request, check the channel type. Then run the custom logic, or run the base logic by calling **NotHandledResponse()**.

```

if (requestContext.GetChannel().OrgUnitType == RetailChannelType.RetailStore)
{
    // run your extension code here.
}
else
{
    return new NotHandledResponse();
}

```

## Implement a new CRT entity and use it in the new CRT service

Any new entity must inherit from the **CommerceEntity** type. When you use this type, lots of low-level functionality is automatically handled for you. The following example is taken from the **StoreHours** sample. It shows how to create an entity that is bound to the database table. This scenario is common.

```

public class StoreDayHours : CommerceEntity
{
    private const string DayColumn = "DAY";
    private const string OpenTimeColumn = "OPENTIME";
    private const string CloseTimeColumn = "CLOSINGTIME";
    private const string IdColumn = "RECID";

    public StoreDayHours()
        : base("StoreDayHours")
    {
    }

    [DataMember]
    [Column(DayColumn)]
    public int DayOfWeek
    {
        get { return (int)this[DayColumn]; }
        set { this[DayColumn] = value; }
    }

    [DataMember]
    [Column(OpenTimeColumn)]
    public int OpenTime
    {
        get { return (int)this[OpenTimeColumn]; }
        set { this[OpenTimeColumn] = value; }
    }

    [DataMember]
    [Column(CloseTimeColumn)]
    public int CloseTime
    {
        get { return (int)this[CloseTimeColumn]; }
        set { this[CloseTimeColumn] = value; }
    }

    [Key]
    [DataMember]
    [Column(IdColumn)]
    public long Id
    {
        get { return (long)this[IdColumn]; }
        set { this[IdColumn] = value; }
    }
}

```

When you want to use the new entity in a service, the process is straightforward. As was described earlier in this topic, you create a new service that is derived from **IRequestHandler**. You then either use or return the new entity. The following example shows how to read the entity from the database and return it as part of the response.

```

private async Task<Response> GetStoreDayHoursAsync(GetStoreHoursDataRequest request)
{
    ThrowIf.Null(request, "request");

    using (DatabaseContext databaseContext = new DatabaseContext(request.RequestContext))
    {
        var query = new SqlPagedQuery(request.QueryResultSettings)
        {
            DatabaseSchema = "ext",
            Select = new ColumnSet("DAY", "OPENTIME", "CLOSINGTIME", "RECID"),
            From = "CONTOSORETAILSTOREHOURSVIEW",
            Where = "STORENUMBER = @storeNumber",
        };

        query.Parameters["@storeNumber"] = request.StoreNumber;
        return new GetStoreHoursDataResponse(await databaseContext.ReadEntityAsync<DataModel.StoreDayHours>
(query).ConfigureAwait(false));
    }
}

```

#### NOTE

Commerce entities aren't thread safe. Therefore, the same object should not be read or modified when another thread is writing to it. This restriction applies to custom entities and out-of-box entities in the extension code. You should avoid having two different threads when you do synchronous read or write activities for the same shared object.

In the preceding example, the CRT runtime engine automatically makes a query to the channel database via the registered data adapter. It queries a type that has the name `crt.ISVRetailStoreHoursView`, and generates a **where** clause and columns as specified in the code. The customizer is responsible for providing the SQL objects as part of the customization.

## Using extension properties on CRT entities, requests, and responses

One way to add new data to an existing CRT entity is to use extension properties. Extension properties are key-value pairs on the entity. By default, these key-value pairs don't persist in the database. To make an extension property persist, you must write custom code.

## Using extension properties on CRT entities with persistence

Any extension property that you add to an entity stays in memory for POS and CRT for the lifetime of either the object or the transaction, depending on the scenario. The extension property also travels across application boundaries. For example, if you add an extension property in Retail Modern POS and then call Retail Server or CRT, the key-value pair is available during the whole flow. Additionally, if that entity is sent during a call to Commerce Data Exchange - Real-time Service, the key-value pair is available during the process.

#### NOTE

For Commerce headquarters, extension properties are sent only for customers and orders.

However, as was mentioned earlier, the extension property doesn't persist by default. If you want an extension property to persist, you must do data modeling to ensure that you make the correct design choices about where the data should reside. We recommend that you use a new table and a join. This approach fits most requirements well. The `EmailPreference` sample in the Retail SDK provides a good end-to-end example.

### Location of the sample code in the Retail SDK

...\RetailSDK\SampleExtensions\CommerceRuntime\Extensions.EmailPreferenceSample

## Location of the scripts

...\RetailSDK\Documents\SampleExtensionsInstructions\EmailPreference

## Syntax to set an extension property on an entity

```
public virtual void SetProperty(string key, object value);  
entity.SetProperty("key", value);
```

## Example

### Scenario

A new extension table and fields that were created for the Customer entity and extension must read those fields from the extension table and send them to POS.

When you extend the channel database, it's always a good idea to include the primary key from the main table in the extension table. That is, don't have a direct relation, and then read the data from the extension table by using the primary key.

### Steps

1. Create the extension table for the Customer entity in the channel database extension schema that has the primary key of the main table.
2. Identify the CRT data request that reads the Customer entity.
3. Add a post-trigger for the data request. You will then be able to use the primary key of the Customer table to query your extension table to read the custom fields.

### NOTE

You can get the primary key for the entity in the post-trigger request. That request will have the entity object, and that entity object will have all the required fields.

4. Add the custom fields as extension properties to the shared parameters entity in the CRT post-trigger, and send it to POS.

## Reading extension properties in triggers

The request that reads the data from the Customer table is `GetCustomerDataRequest`. The following example shows how you can add a post-trigger for this request.

```
namespace Contoso  
{  
    namespace Commerce.Runtime.EmailPreferenceSample  
    {  
        using System;  
        using System.Collections.Generic;  
        using System.Threading.Tasks;  
        using Microsoft.Dynamics.Commerce.Runtime;  
        using Microsoft.Dynamics.Commerce.Runtime.Data;  
        using Microsoft.Dynamics.Commerce.Runtime.DataModel;  
        using Microsoft.Dynamics.Commerce.Runtime.DataServices.Messages;  
        using Microsoft.Dynamics.Commerce.Runtime.Messages;  
  
        /// <summary>  
        /// Class that implements a post trigger for the GetCustomerDataRequest request type.  
        /// </summary>  
        public class GetCustomerTriggers : IRequestTriggerAsync  
        {
```

```

    /// <summary>
    /// Gets the supported requests for this trigger.
    /// </summary>
    public IEnumerable<Type> SupportedRequestTypes
    {
        get
        {
            return new[] { typeof(GetCustomerDataRequest) };
        }
    }

    /// <summary>
    /// Post trigger code to retrieve extension properties.
    /// </summary>
    /// <param name="request">The request.</param>
    /// <param name="response">The response.</param>
    public async Task OnExecuted(Request request, Response response)
    {
        ThrowIf.Null(request, "request");
        ThrowIf.Null(response, "response");

        var customer = ((SingleEntityDataServiceResponse<Customer>)response).Entity;

        if (customer == null)
        {
            return;
        }

        var query = new SqlPagedQuery(QueryResultSettings.SingleRecord)
        {
            DatabaseSchema = "ext",
            Select = new ColumnSet(new string[] { "EMAILOPTIN" }),
            From = "CUSTOMEREXTENSIONVIEW",
            Where = "ACCOUNTNUM = @accountNum AND DATAAREAID = @dataAreaId"
        };

        query.Parameters["@accountNum"] = customer.AccountNumber;
        query.Parameters["@dataAreaId"] =
request.RequestContext.GetChannelConfiguration().InventLocationDataAreaId;
        using (var databaseContext = new DatabaseContext(request.RequestContext))
        {
            var extensionsResponse = await databaseContext.ReadEntityAsync<ExtensionsEntity>
(request).ConfigureAwait(false);
            ExtensionsEntity extensions = extensionsResponse.FirstOrDefault();

            var emailOptIn = extensions != null ? extensions.GetProperty("EMAILOPTIN") : null;
            if (emailOptIn != null)
            {
                customer.SetProperty("EMAILOPTIN", emailOptIn);
            }
        }
    }

    /// <summary>
    /// Pre trigger code.
    /// </summary>
    /// <param name="request">The request.</param>
    public async Task OnExecuting(Request request)
    {
        // It's only stub to handle async signature.
        await Task.CompletedTask;
    }
}
}
}

```

#### NOTE

You must change this query, based on your new field and table, or whatever condition you're using. When you design the table, make sure that you have the primary key field from the parent table, so that you can query it by using the CRT entity. Most CRT entities should have the primary key field in them, such as the **RecId** field or another relevant unique field that is used to select the record.

## Saving extension properties by overriding the handler

### Scenario

You created a new extension table for Customer. When values for the extension field for Customer come from POS or CRT, you want to store the values in your custom table.

#### NOTE

You can set extension properties either in a trigger or by overriding the handler. If you just set some extension properties by reading from your extension table, you can use triggers.

### Steps

1. Create your extension table for Customer in the channel table that has the primary key relation to the main table. (In this case, the main table is CustTable.)
2. Identify the CRT data request that sets data in CustTable.
3. Override the handler, and call the base request to set values in the main table (CustTable) and then in the extension table.

#### NOTE

Extension code can pass additional properties that are required for the extension procedure or view. Extension properties can be saved in the CRT pre-triggers or post-triggers. You don't have to override the CRT handler. You should avoid overriding the handler, because most of the CRT extension scenarios can be achieved in pre-triggers or post-triggers.

The example that follows doesn't have the SQL scripts that are used. You can find the full sample code and scripts in the following locations in the Retail SDK.

### Location of the sample code in the Retail SDK

...\RetailSDK\SampleExtensions\CommerceRuntime\Extensions.EmailPreferenceSample

### Location of the scripts

...\RetailSDK\Documents\SampleExtensionsInstructions\EmailPreference

### Example

```

namespace Contoso
{
    namespace Commerce.Runtime.EmailPreferenceSample
    {
        using System.Threading.Tasks;
        using System.Transactions;
        using Microsoft.Dynamics.Commerce.Runtime;
        using Microsoft.Dynamics.Commerce.Runtime.Data;
        using Microsoft.Dynamics.Commerce.Runtime.DataModel;
        using Microsoft.Dynamics.Commerce.Runtime.DataServices.Messages;
        using Microsoft.Dynamics.Commerce.Runtime.Messages;

        /// <summary>
        /// Create or update customer data request handler.
        /// </summary>
        public sealed class CreateOrUpdateCustomerDataRequestHandler :
        SingleAsyncRequestHandler<CreateOrUpdateCustomerDataRequest>
        {
            /// <summary>
            /// Executes the workflow to create or update a customer.
            /// </summary>
            /// <param name="request">The request.</param>
            /// <returns>The response.</returns>
            protected override async Task<Response> Process(CreateOrUpdateCustomerDataRequest request)
            {
                ThrowIf.Null(request, "request");

                using (var databaseContext = new DatabaseContext(request.RequestContext))
                using (var transactionScope = new TransactionScope())
                {
                    // Execute original functionality to save the customer.
                    var requestHandler = new
                    Microsoft.Dynamics.Commerce.Runtime.DataServices.SqlServer.CustomerSqlServerDataService();
                    var response =
                    (SingleEntityDataServiceResponse<Customer>)requestHandler.Execute(request);

                    // Execute additional functionality to save the customer's extension properties.
                    if (!request.Customer.ExtensionProperties.IsNullOrEmpty())
                    {
                        // The stored procedure will determine which extension properties are saved to which
                        tables.

                        ParameterSet parameters = new ParameterSet();
                        parameters["@TVP_EXTENSIONPROPERTIES"] = new
                        ExtensionPropertiesExtTableType(request.Customer.RecordId, request.Customer.ExtensionProperties).DataTable();
                        await databaseContext.ExecuteStoredProcedureNonQueryAsync("
                        [ext].UPDATECUSTOMEREXTENSIONPROPERTIES", parameters, resultSettings: null).ConfigureAwait(false);
                    }

                    transactionScope.Complete();

                    return response;
                }
            }
        }
    }
}

```

### Syntax to enable the property to be read later

```
var property = entity.GetProperty("EXTENSION_PROPERTY_ADDED");
```

## Using extension properties on CRT request and response types

Like entities, request and response types can be extended to set and get extension properties. However, they

persist only for the lifecycle of the request and won't be available in POS. If you want to save them to the database, you must write custom code.

```
request.SetProperty("PropertyName", true);
response.SetProperty("PropertyName2", true);
var PropertyName = request.GetProperty("PropertyName");
var BoolPropertyName2 = response.GetProperty("PropertyName2");
```

### Setting or reading extension properties in POS

You can set extension properties in POS and send them to CRT by using the POS APIs. Alternatively, you can send extension properties at the entity level.

To set an extension property on the cart line, you use `SaveExtensionPropertiesOnCartLinesClientRequest`. Likewise, for the cart header, you use `SaveExtensionPropertiesOnCartClientRequest`.

Here is an example.

```
let sampleExtensionProperty = <ProxyEntities.CommerceProperty>{
    Key: "sampleExtensionProperty",
    Value: <ProxyEntities.CommercePropertyValue>{
        BooleanValue: false
    }
};
this.context.runtime.executeAsync(new
SaveExtensionPropertiesOnCartClientRequest([sampleExtensionProperty]));
```

## Reading the extension property from the cart in POS

```
let getCartRequest: GetCurrentCartClientRequest<GetCurrentCartClientResponse> = new
GetCurrentCartClientRequest<GetCurrentCartClientResponse>();
return this.context.runtime.executeAsync(getCartRequest).then((value:
ICancelableDataResult<GetCurrentCartClientResponse>) => {
    let cart: Commerce.Proxy.Entities.Cart = (<GetCurrentCartClientResponse>value.data).result;

    // Gets the extension property from the cart.

    let sampleExtensionPropertyValue: boolean;
    if (!ObjectExtensions.IsNullOrEmpty(cart) &&
!ObjectExtensions.IsNullOrEmpty(cart.ExtensionProperties)) {
        let SampleCommerceProperties: ProxyEntities.CommerceProperty[] =
cart.ExtensionProperties.filter((extensionProperty: ProxyEntities.CommerceProperty) => {
            return extensionProperty.Key === "sampleExtensionProperty";
        });
        sampleExtensionPropertyValue = SampleCommerceProperties.length > 0 ?
SampleCommerceProperties[0].Value.BooleanValue : false;
    } else {
        sampleExtensionPropertyValue = false;
    }

    //Resolve the promise according to your scenario and method.

    return Promise.resolve({ canceled: false });
});
```

Likewise, you can read the extension property from all the other entities, such as products, customers, and addresses.

# Manage secrets for retail channels

2/18/2021 • 3 minutes to read • [Edit Online](#)

This topic explains how to manage secrets when you're using an extension with channels that require access to secrets. Extensions will not be able to deploy any custom certificates in Commerce scale unit or add thumbprints or secrets in web.config files. The recommended approach for managing secrets is to use the Azure Key Vault, as noted in this topic.

## Key Vault setup

1. The extension developer follows these development steps:
  - a. Create a test secret in Microsoft Azure Key Vault.
  - b. Configure the head-office client to connect to Key Vault.
  - c. On the **Key Vault Parameters** page (**Head Office > Key Vault Parameters**), specify an extension key name for the Key Vault secret. The same name must be used in the next step.
  - d. Use the **GetUserDefinedSecretStringValueServiceRequest** Commerce Runtime (CRT) application programming interface (API) to get the secret. Pass a unique secret name to identify the secret.
  - e. As part of the documentation of the extension setup, state the secret name that is referenced in the extension. We recommend that the extension developer use a namespace for the secret name, because this approach helps prevent conflicts with other extensions.
2. The IT pro or implementation partner follows these deployment and configuration steps:
  - a. Apply the extension to the customer environment. For details, see [Apply updates to cloud environments](#).
  - b. Upload the desired secrets to Key Vault (or enter them). For details, see [What is Azure Key Vault?](#)
  - c. On the **Key Vault Parameters** page (**Head Office > Key Vault Parameters**), configure the head-office client to connect to Key Vault.
  - d. On the **Key Vault Parameters** page, specify the extension secret name for the Key Vault secret in the head-office client.

## Consume the secret in the CRT extension

To consume the secret in the extension, add the following request and response.

REQUEST/RESPONSE	PARAMETERS	DESCRIPTION
<code>GetUserDefinedSecretStringValueServiceRequest</code>	string <b>secretName</b>	The request class that is used to get user-defined secrets from Headquarters.
<code>GetUserDefinedSecretStringValueServiceResponse</code>	string <b>SecretStringValue</b>	The response class that is used to get user-defined secrets from Headquarters. The response returns a <b>SecretStringValue</b> value, and extensions can type-cast this value to <b>X509Certificate2</b> or use it as string value.

To read the secret in the CRT extension, follow these steps.

1. Create a new CRT extension project (C# class library project type). Use the sample templates from the Retail software development kit (SDK) (**RetailSDK\SampleExtensions\CommerceRuntime**).
2. In the CRT extension, you can create a new request/response, or you can add a pre-trigger or post-trigger for the existing CRT request, and then call it. In the following example, a trigger was added for **SaveCartRequest**. It calls **GetUserDefinedSecretStringValueServiceRequest** to read the secret by passing the secret key that is configured in Headquarters. You don't have to write custom code to read the secret from Headquarters. You can use the request and response to read the value.

```

public class CustomSaveCartTrigger : IRequestTrigger
{
    /// <summary>
    /// Gets the list of supported request types.
    /// </summary>
    public IEnumerable<Type> SupportedRequestTypes
    {
        get
        {
            return new[]{ typeof(SaveCartRequest) };
        }
    }

    /// <summary>
    /// Pre trigger code.
    /// </summary>
    /// <param name="request">The request.</param>
    public void OnExecuting(Request request)
    {
        ThrowIf.Null(request, "request");
        Type requestedType = request.GetType();
        if (requestedType == typeof(SaveCartRequest))
        {
            // Sample code to get the secret in string format.

            string result = null;

            GetUserDefinedSecretStringValueServiceRequest keyVaultRequest = new
            GetUserDefinedSecretStringValueServiceRequest("SecretName");
            GetUserDefinedSecretStringValueServiceResponse keyVaultResponse =
            request.RequestContext.Execute<GetUserDefinedSecretStringValueServiceResponse>(keyVaultRequest);
            result = keyVaultResponse.SecretStringValue;

            GetUserDefinedSecretCertificateServiceRequest
            getUserDefinedSecretCertificateServiceRequest = new
            GetUserDefinedSecretCertificateServiceRequest(profileId: null, secretName: "SecretName", thumbprint:
            null, expirationInterval: null);
            GetUserDefinedSecretCertificateServiceResponse
            getUserDefinedSecretCertificateServiceResponse =
            request.RequestContext.Execute<GetUserDefinedSecretCertificateServiceResponse>
            (getUserDefinedSecretCertificateServiceRequest);

            X509Certificate2 Certificate =
            getUserDefinedSecretCertificateServiceResponse.Certificate;

            // custom code to additional processing with secrets.
        }
    }

    /// <summary>
    /// Post trigger code.
    /// </summary>
    /// <param name="request">The request.</param>
    /// <param name="response">The response.</param>

    public void OnExecuted(Request request, Response response)
    {
    }
}

```

3. Build the CRT extension project.
4. Copy the output class library, and paste it into ...\**RetailServer**\webroot\bin\Ext for manual testing.
5. In the **CommerceRuntime.Ext.config** file, update the extension composition section with the custom library information. Here is an example.

```
<add source="assembly" value="your custom library name" />
```

## Credential rotation

When this approach is used for credential management, credential rotation is more streamlined. To update a secret, an IT admin just has to update the secret in Key Vault. No change is required to the extension. After a secret is updated, the new value starts to be used when the cache expires.

## Offline support

Offline support for credentials requires that the extension code handle failover to offline when Key Vault credentials aren't available or accessible.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Commerce runtime (CRT) extensibility and triggers

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic explains trigger support for the Dynamics 365 commerce runtime (CRT). CRT supports pre-triggers and post-triggers for every request.

## CRT trigger overview

Commerce runtime (CRT) triggers give you a way to extend the CRT workflow, and let you add business logic before and after every CRT request is executed. The following two methods are used:

- **OnExecuting** – This method is invoked before a request has been processed by a corresponding **IRequestHandler** implementation.
- **OnExecuted** – This method is invoked after the request has been processed by a corresponding **IRequestHandler** implementation.

## CRT trigger extension

To implement a trigger, you must complete these tasks, as shown in the code example that follows:

1. Implement **IRequestTriggerAsync**.
2. Specify **SupportedRequestTypes** to define the request types that the trigger must be executed for.
3. Write a trigger implementation in the **OnExecuting** method if business logic must be run before the request is addressed.
4. Write a trigger implementation in the **OnExecuted** method if business logic must be run after the request is addressed.

**Sample trigger implementation for Get customer data request:**

```

using Microsoft.Dynamics.Commerce.Runtime;
using Microsoft.Dynamics.Commerce.Runtime.DataServices.Messages;
using Microsoft.Dynamics.Commerce.Runtime.Messages;
using System;
using System.Collections.Generic;
using System.Threading.Tasks;

public class GetCustomerTriggers : IRequestTriggerAsync
{
    /// <summary>
    /// Gets the supported requests for this trigger.
    /// </summary>
    public IEnumerable<Type> SupportedRequestTypes
    {
        get
        {
            return new[] { typeof(GetCustomerDataRequest) };
        }
    }

    /// <summary>
    /// Post trigger code.
    /// </summary>
    /// <param name="request">The request.</param>
    /// <param name="response">The response.</param>
    public async Task OnExecuted(Request request, Response response)
    {
        //Custom logic

        // The only stub to handle async signature
        await Task.CompletedTask;
    }

    /// <summary>
    /// Pre trigger code
    /// </summary>
    /// <param name="request">The request.</param>
    public async Task OnExecuting(Request request)
    {
        // custom logic
        await Task.CompletedTask;
    }
}

```

### Register the extension

Copy and paste the extension library to ...\**RetailServer\webroot\bin\ext folder** and update the **commerceRuntime.ext.config** file with the custom extension library information under composition section. In this example, **Contoso.Commerce.Runtime.Services** is the custom extension name.

For the CRT extension to work in offline mode, update ...\**Microsoft Dynamics 365\70\Retail Modern POS\ClientBroker\ext\CommerceRuntime.MPOSOOffline.ext.config** with the extension library information under the composition section. Then copy and paste the extension library to ...\**Microsoft Dynamics 365\70\Retail Modern POS\ClientBroker\ext**.

### Debugging CRT

To debug CRT from POS, attach the CRT extension project to the w3wp.exe (IIS process for Retail server) when POS is connected to Retail server. For offline mode, attach the CRT extension project to the dllhost.exe process.

# Block transactions by using triggers

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic shows how you can use a trigger to block an invoice or credit transaction.

This topic shows how you can block an invoice or credit transaction.

1. Open Visual Studio as an administrator. Create a new Visual C# Class Library (Portable) project and name it CRTTriggerExtension. If you get a message that the selection makes this project incompatible with Visual Studio 2010, click **OK**.
2. In Solution Explorer, rename default class1.cs to GetCustomersServiceRequestTrigger.cs.
3. Right-click the **Reference** node in the project and add the following references. The location of the references will depend on the deployment topology.
  - Microsoft.Dynamics.Commerce.Runtime.Entities.dll
  - Microsoft.Dynamics.Commerce.Runtime.Framework.dll
  - Microsoft.Dynamics.Commerce.Runtime.Services.Messages.dll
4. Add the following **using** statement to the GetCustomersServiceRequestTrigger.cs file.

```
using Microsoft.Dynamics.Commerce.Runtime.Messages;  
using Microsoft.Dynamics.Commerce.Runtime.Services.Messages;  
using Microsoft.Dynamics.Commerce.Runtime;
```

5. Rename class1.cs in the code to GetCustomersServiceRequestTrigger and then add the IRequestTrigger interface declaration.

```
using System;  
using System.Collections.Generic;  
using System.Linq;  
using Microsoft.Dynamics.Commerce.Runtime;  
using Microsoft.Dynamics.Commerce.Runtime.Services.Messages;  
using Microsoft.Dynamics.Commerce.Runtime.Messages;  
  
namespace CRTTriggerExtension  
public class GetCustomersServiceRequestTrigger : IRequestTrigger  
{
```

6. Implement the IRequestTrigger interface trigger. Right-click the IRequestTrigger class, select **Quick Actions**, and then click **Implement Interface**. Visual Studio will implement the interface. You can also place the cursor on IRequestTrigger, press **Ctrl+**, and select **Implement Interface**.
7. The empty interface members SupportedRequestTypes, OnExecuted, and OnExecuting methods are shown in the following code example.

```

public class GetCustomersServiceRequestTrigger : IRequestTrigger
{
    public IEnumerable<Type> SupportedRequestTypes
    {
        get
        {
            throw new NotImplementedException();
        }
    }

    public void OnExecuted(Request request, Response response)
    {
        throw new NotImplementedException();
    }

    public void OnExecuting(Request request)
    {
        throw new NotImplementedException();
    }
}

```

8. Commerce Scale Unit uses the GetCustomersServiceRequest object to get the customer details from Commerce Runtime (CRT) and uses the GetCustomersServiceRequest object to add the customer to the transaction. Before adding the customer to the transaction you need to check whether the customer is blocked. To do this, implement a post trigger for this request and check whether the customer is blocked. If the customer is blocked, then throw the exception to MPOS.
9. In the SupportedRequestTypes method tell the CRT that you are going to add the trigger for GetCustomersServiceRequest. The following code example shows how to add GetCustomersServiceRequest as a supported type.

```

public IEnumerable<Type> SupportedRequestTypes
{
    get
    {
        return new[] { typeof(GetCustomersServiceRequest) };
    }
}

```

10. Check if the customer is blocked in the OnExecuted (post trigger) method with the following code.

```

public void OnExecuted(Request request, Response response)
{
    if (response == null)
    {
        throw new ArgumentNullException("request");
    }

    var getCustomersServiceResponse = (GetCustomersServiceResponse)response;
    if(getCustomersServiceResponse.Customers.FirstOrDefault().Blocked == true)
    {
        string message = string.Format("Failed to add customer '{0}' to cart. Blocked customers are not allowed for transactions.",
            getCustomersServiceResponse.Customers.FirstOrDefault().AccountNumber);
        throw new
CartValidationException(DataValidationErrors.Microsoft_Dynamics_Commerce_Runtime_CustomerAccountIsBlocked, message);
    }
}

```

11. Finally, update the OnExecuting method with the following code.

```
public void OnExecuting(Request request)
{
    if (request == null)
    {
        throw new ArgumentNullException("request");
    }
}
```

12. Click **Save**.

**NOTE**

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Loyalty extension sample

2/18/2021 • 4 minutes to read • [Edit Online](#)

## Scenario

A retailer wants customers to be able to earn loyalty points and pay by using loyalty points in a single transaction.

## Scenario details

The retailer has set up a loyalty scheme for the channel and associated that scheme with a loyalty program. The loyalty scheme includes some earning and redemption rules. The retailer wants customers to be able to partially pay a transaction amount by using their loyalty points. The customers should then be able to earn loyalty points for the remaining transaction amount that they pay by using other payment methods.

## Assumptions

Because of the flexibility that the loyalty setup provides, this scenario can quickly become very complex. We have made some assumptions to reduce the complexity of this sample. However, these assumptions aren't far removed from the real-world examples. Here are the assumptions:

- No tiers are associated with the loyalty program.
- There is a single loyalty scheme and a single loyalty reward point type.
- There is a single earning rule that applies to all product categories. For example, this rule might specify that, for every \$1 that the customer spends, the customer earns 0.1 reward point.
- There is a single redemption rule that applies to all product categories. For example, this rule might specify that one reward point is equivalent to \$1.

### NOTE

The earning and redemption rules that are mentioned here are just examples. For this sample, we have hard-coded the values. For a production scenario, the values should be read from the database instead.

## Customization approach

We implement this customization in two steps. In step 1, points will be earned as though loyalty points weren't used in the transaction. Then, in step 2, the extra points that were earned will be reduced, based on the points that were redeemed.

There are six service requests for the loyalty feature:

- GetLoyaltyCardStatusServiceRequest
- CalculateLoyaltyRewardPointsServiceRequest
- IssueLoyaltyCardServiceRequest
- FillInLoyaltyRewardPointLinesForSalesServiceRequest
- FillInLoyaltyRewardPointLinesForReturnServiceRequest
- FillInLoyaltyRewardPointLinesForEarnOrDeductServiceRequest

To calculate the reward points for a cash-and-carry transaction, the system uses

**FillInLoyaltyRewardPointLinesForSalesServiceRequest** for sales transaction lines. This request, in turn, uses **FillInLoyaltyRewardPointLinesForEarnOrDeductServiceRequest** to do the actual reward calculation. Similarly, the system uses **FillInLoyaltyRewardPointLinesForReturnServiceRequest** for return transaction lines, and this request also uses **FillInLoyaltyRewardPointLinesForEarnOrDeductServiceRequest** to do the actual reward calculation. In the out-of-box implementation of the loyalty feature, customers can't both redeem and earn loyalty points in the same transaction. In other words, if the sales transaction has a tender line for the loyalty card, **FillInLoyaltyRewardPointLinesForSalesServiceRequest** doesn't call **FillInLoyaltyRewardPointLinesForEarnOrDeductServiceRequest** to calculate the reward points.

To enable loyalty points to be redeemed and earned in the same transaction, we will work with one service request, **FillInLoyaltyRewardPointLinesForSalesServiceRequest**.

### **Step 1**

For our scenario, we must implement **FillInLoyaltyRewardPointLinesForSalesServiceRequest** in such a way that it always calls **FillInLoyaltyRewardPointLinesForEarnOrDeductServiceRequest** to calculate the reward points. However, this change will cause the system to calculate extra earned points, based on the amount that the customer pays by using loyalty points. Therefore, we must be able to reduce the earned points by an appropriate amount. This adjustment is done in step 2.

### **Step 2**

We take advantage of the post trigger mechanism that the extensibility framework provides on **FillInLoyaltyRewardPointLinesForSalesServiceRequest**. In the post trigger, we will use the earning and redemption rules to determine how many extra points were earned for each reward point that was redeemed. We will then subtract those extra points to get the correct amount.

**Implement FillInLoyaltyRewardPointLinesForSalesServiceRequest**

```

namespace Contoso
{
    namespace Commerce.Runtime.EarnRedeemLoyalty
    {
        using System;
        using Microsoft.Dynamics.Commerce.Runtime;
        using Microsoft.Dynamics.Commerce.Runtime.DataModel;
        using Microsoft.Dynamics.Commerce.Runtime.DataServices.Messages;
        using Microsoft.Dynamics.Commerce.Runtime.Services.Messages;
        using System.Collections.Generic;
        using Microsoft.Dynamics.Commerce.Runtime.Messages;
        public class FillInLoyaltyRewardPointLinesForSalesHandler : IRequestHandler
        {
            /// <summary>
            /// Gets the collection of supported request types by this handler.
            /// </summary>
            public IEnumerable<Type> SupportedRequestTypes
            {
                get
                {
                    return new[]
                    {
                        typeof(FillInLoyaltyRewardPointLinesForSalesServiceRequest),
                    };
                }
            }
            /// <summary>
            /// Entry point to FillInLoyaltyRewardPointLinesForSalesServiceRequest service.
            /// </summary>
            /// <param name="request">The request to execute.</param>
            /// <returns>Returns the SalesTransaction object with the one or more LoyaltyRewardPointLines.
            </returns>
            public Response Execute(Request request)
            {
                ThrowIf.Null(request, "request");
                var LoyaltyRewardPointLinesForSalesServiceRequest =
                (FillInLoyaltyRewardPointLinesForSalesServiceRequest)request;
                SalesTransaction salesTransaction =
                LoyaltyRewardPointLinesForSalesServiceRequest.SalesTransaction;
                // Call the service to calculate the loyalty reward points.
                var fillInLoyaltyRewardPointLinesForEarnOrDeductServiceRequest = new
                FillInLoyaltyRewardPointLinesForEarnOrDeductServiceRequest(salesTransaction,
                LoyaltyRewardPointLinesForSalesServiceRequest.EarnSchemeLines, LoyaltyRewardPointEntryType.Earn);
                var fillInLoyaltyRewardPointLinesForEarnOrDeductServiceResponse =
                request.RequestContext.Execute<SingleEntityDataServiceResponse<SalesTransaction>>
                (fillInLoyaltyRewardPointLinesForEarnOrDeductServiceRequest);
                salesTransaction = fillInLoyaltyRewardPointLinesForEarnOrDeductServiceResponse.Entity;
                return new SingleEntityDataServiceResponse<SalesTransaction>(salesTransaction);
            }
        }
    }
}

```

**Implement the post trigger for FillInLoyaltyRewardPointLinesForSalesServiceRequest**

```

namespace Contoso
{
    namespace Commerce.Runtime.Sample.EarnRedeemLoyalty
    {
        using System;
        using System.Collections.Generic;
        using System.Linq;
        using Microsoft.Dynamics.Commerce.Runtime;
        using Microsoft.Dynamics.Commerce.Runtime.Messages;
        using Microsoft.Dynamics.Commerce.Runtime.Services.Messages;
        using Microsoft.Dynamics.Commerce.Runtime.DataModel;
        class AdjustLoyatyRewardsTrigger : IRequestTrigger
        {
            public IEnumerable<Type> SupportedRequestTypes
            {
                get { return new[] { typeof(FillInLoyaltyRewardPointLinesForSalesServiceRequest) }; }
            }
            public void OnExecuted(Request request, Response response)
            {
                ThrowIf.Null(request, "request");
                var LoyaltyRewardPointSalesServiceRequest =
(FillInLoyaltyRewardPointLinesForSalesServiceRequest)request;
                SalesTransaction salesTransaction = LoyaltyRewardPointSalesServiceRequest.SalesTransaction;

                if (salesTransaction.LoyaltyRewardPointLines != null)
                {
                    decimal totalRedeemedPoints = 0m;
                    decimal extraEarnedPoints = 0m;

                    // Find the redeemed reward lines in the transaction and calculate the total redeemed
reward points
                    IEnumerable<LoyaltyRewardPointLine> redeemLoyaltyRewardPointLines =
salesTransaction.LoyaltyRewardPointLines.Where<LoyaltyRewardPointLine>(line => line.EntryType ==
LoyaltyRewardPointEntryType.Redeem);
                    if (redeemLoyaltyRewardPointLines.Count() > 0)
                    {
                        foreach (var rewardPointLine in redeemLoyaltyRewardPointLines)
                        {
                            totalRedeemedPoints += rewardPointLine.RewardPointAmountQuantity;
                        }
                        // Calculate the number of extra earned points for every redeemed point.
                        // If the earning rules stated that for every $1 spent, the user earns X points and
redemption rule was that Y points equal $1 then, for every redemption point the user earns X/Y extra earn
points.
                        // Based on the above logic, in this sample, for every redeemed point the user earns
.1/1 = .1 extra earned points.
                        extraEarnedPoints = .1m * totalRedeemedPoints;
                    }
                    // Reduce the amount of earned points by the extraEarnedPoints calculated above.
                    IEnumerable<LoyaltyRewardPointLine> earnLoyaltyRewardPointLines =
salesTransaction.LoyaltyRewardPointLines.Where<LoyaltyRewardPointLine>(line => line.EntryType ==
LoyaltyRewardPointEntryType.Earn);
                    if (earnLoyaltyRewardPointLines.Count() > 0)
                    {
                        earnLoyaltyRewardPointLines.FirstOrDefault().RewardPointAmountQuantity -=
extraEarnedPoints;
                    }
                }
            }
            public void OnExecuting(Request request)
            { }
        }
    }
}

```

# Extension points for packing slips during order fulfillment

2/18/2021 • 4 minutes to read • [Edit Online](#)

When you generate packing slips for customer orders from the point of sale (POS), you might want to print the item weight on the packing slip. You might also want to add custom information about the package, information about how to call the shipping carrier for the shipping rates, or information about how to return the package. To handle these scenarios, extension points for the packing slip process for order fulfillment have been added in Headquarters, in the commerce runtime (CRT), which is the business logic layer, and in the POS. These extension points let you add custom flow and logic through extensions.

## POS

In the POS, a new request handler that is named **PrintPackingSlipClientRequestHandler** lets you override extensions. This request is called when you select the **Print packing slip** button in the POS. By overriding this request, you can use custom logic in the POS. For example, you can call your own printing methods and print additional information.

For example, by default, you can print the packing slip in PDF format. By overriding the POS client request, you can print the packing slip in a different format. Alternatively, you can check for a specific condition, and then print or stop printing the packing slip, based on that condition. You can also do validation before you print, and prevent printing or custom logic. However, if you want to change the actual data that is printed, you must modify the business logic in CRT and Headquarters.

### Override PrintPackingSlipClientRequestHandler

To override any request in the POS, use the following override handler pattern in the POS.

### Example

```
import { PrintPackingSlipClientRequestHandler } from
"PosApi/Extend/RequestHandlers/StoreFulfillmentRequestHandlers";
import { PrintPackingSlipClientRequest, PrintPackingSlipClientResponse } from "PosApi/Consume/SalesOrders";
import { ClientEntities } from "PosApi/Entities";
/**
 * Override request handler class for printing packing slip request.
 */
export default class PrintPackingSlipClientRequestHandlerExt extends PrintPackingSlipClientRequestHandler {
  /**
   * Executes the request handler asynchronously.
   * @param {PrintPackingSlipClientRequest<PrintPackingSlipClientResponse>} The request containing the
   response.
   * @return {Promise<ICancelableDataResult<PrintPackingSlipClientResponse>>} The cancelable promise
   containing the response.
   */
  public executeAsync(request: PrintPackingSlipClientRequest<PrintPackingSlipClientResponse>):
  Promise<ClientEntities.ICancelableDataResult<PrintPackingSlipClientResponse>> {
    // Do the extension logic here before calling the default handler.
    return this.defaultExecuteAsync(request);
  }
}
```

After you override the request, update the manifest.json file with the new request handler information.

```
"requestHandlers": [  
  {  
    "modulePath": "Handlers/PrintPackingSlipClientRequestHandlerExt"  
  }  
]
```

## CRT

Similar to the POS client request handler, new requests have been added in the CRT to enable extension of custom logic.

### **MarkAsPickedRealtimeRequest**

The **MarkAsPickedRealtimeRequest** request marks the fulfillment lines as picked. You can add custom logic before the line is marked as picked. For example, you can change a property. Later, the picked line information will be used to print the packing slip. Based on your scenario, you can override this request, or add pre-triggers or post-triggers.

For example, for the fulfillment lines, you want to calculate item weight, and so on. In this case, you can customize the service.

#### **NOTE**

If the logic that you require for your customization must be determined in Headquarters, you can customize at the Headquarters level instead of customizing in the CRT. For example, if you want to get the item weight for each line, but that information is available only in Headquarters. In this case, you can customize the relevant real-time service methods and then return the result from Headquarters to the CRT.

### **PackFulfillmentLinesRealtimeRequest**

The **PackFulfillmentLinesRealtimeRequest** request updates the status of the fulfillment lines to **Partially packed** or **Packed**. Based on your scenario, you can override this service, or add pre-triggers or post-triggers.

## Headquarters

In Headquarters new real-time service methods have been added to get the packing slip information, and to add custom information or logic through extension. If your customization requires that data or logic be done in Headquarters, you can customize these methods by using the extension patterns. Additionally, if you require an extension scenario that uses the transaction service client class, you can call these methods from the CRT.

### **RetailTransactionServiceFulfillment**

All the new methods that are related to the packing slip process for order fulfillment were added in the **RetailTransactionServiceFulfillment** class.

#### **GetPackingSlipsData**

The **GetPackingSlipsData** method returns all the packing slip information by passing the sales ID as a parameter.

#### **GetFulfillmentLinesByPackingSlipId**

The **GetFulfillmentLinesByPackingSlipId** method returns the fulfillment lines, based on the packing slip ID. For example, you can use this method if you have the packing slip ID, and you want to get the sales lines that are relevant to that packing slip ID.

#### **MarkFulfillmentLinesAsPacked**

The **MarkFulfillmentLinesAsPacked** method updates the status of the fulfillment lines to packed by taking the fulfillment details as a parameter in XML string format. The POS calls the CRT to mark the selected lines from

the POS user interface (UI) as picked. The **MarkAsPickedRealtimeRequest** request in the CRT then calls the **MarkFulfillmentLinesAsPacked** real-time service method in Headquarters to set the line status as **Packed**.

To add custom logic or return additional information when the line is marked as packed and returned for printing, you can customize the **packingSlipExtensionPoint** method.

### **packingSlipExtensionPoint**

You can customize the **packingSlipExtensionPoint** method to add custom logic or return custom information together with the packing slip ID. This custom information includes packing information or a delivery note. This method is typically added for extensions for custom scenarios. This method is called from the **MarkFulfillmentLinesAsPacked** method by using the chain of command extensibility point. The **MarkFulfillmentLinesAsPacked** method is run from the real-time service call that the CRT code makes.

# Channel database extensions

2/18/2021 • 12 minutes to read • [Edit Online](#)

The channel database (channel DB) holds transactional and master data from one or more commerce channels, such as an online store or a brick-and-mortar store. The master data is pushed down from the Headquarters (HQ) to the channel database using the commerce data exchange (CDX). The transactional data stored in the channel database is pulled back to the headquarters using the CDX.

In this topic we explain how to extend the channel database for different scenarios. The steps here apply only to Dynamics 365 Finance and Commerce.

Before discussing the different scenarios for extension, it's important to understand the recent enhancements to channel DB extensions.

We have made some improvements to how extensions are handled during an upgrade. We recommend using one of the following environment configurations:

- Microsoft Dynamics 365 for Finance and Operations, Enterprise edition (July 2017) with application update 5.
- Microsoft Dynamics 365 Retail 7.2 with application update 5, which will be available soon.
- Microsoft Dynamics 365 Retail 7.3, which includes application update 5.
- Microsoft Dynamics 365 for Finance and Operations 7.3, which includes application update 5.

## Ext schema

In Finance and Commerce there is a now schema called the **ext schema** to support extensions. In previous versions, if you wanted to add an extension to channel DB, you would add it to the CRT or AX schema. In both Finance and Commerce, you cannot change the CRT, AX, or DBO schemas. All changes must be made in the **ext schema**. If you modify anything in the CRT or AX schemas, then deployment in Lifecycle Services (LCS) will fail. An error message states that you don't have permission to modify the CRT, AX, and DBO schemas. Extensions will not have permission to read the CRT, AX, and DBO schema definition during deployment, do not include any queries in the extension script to read the CRT, AX, and DBO schema definition.

### NOTE

If you want to increase any channel DB field length, you must create an extensibility request in LCS, increasing the EDT length or decimal precision. Changes will not be automatically pushed to the channel DB, and extensions will not have permissions to change or modify anything in the channel DB - CRT, AX or DBO schema. If you modify anything in the CRT or AX schemas, then deployment in LCS will fail.

## Best practices for channel DB extensions

- Don't modify anything in the CRT, AX, or DBO schemas. Use the **ext schema** for all extension scenarios.
- If available, we recommend getting data through commerce runtime data services, as opposed to accessing channel DB artifacts directly from CRT, AX, or DBO objects.

### Don't do this

The following is an example of what you should not do. Instead, you should use the CRT data service to get the primary key value and then use the primary key to insert into your extension table.

```

MERGE INTO [ax].RETAILCUSTPREFERENCE  --DONT access ax schema object
USING (SELECT DISTINCT
tp.PARENTRECID, tp.PROPERTYVALUE as [EMAILOPTIN], ct.ACCOUNTNUM, ct.DATAAREAID
FROM @TVP_EXTENSIONPROPERTIESTABLETYPE tp
JOIN [ax].CUSTTABLE ct on ct.RECID = tp.PARENTRECID  --DONT access ax schema object
WHERE tp.PARENTRECID <> 0 and tp.PROPERTYNAME = 'EMAILOPTIN') AS SOURCE
ON [ax].RETAILCUSTPREFERENCE.RECID = SOURCE.PARENTRECID
and [ax].RETAILCUSTPREFERENCE.DATAAREAID = SOURCE.DATAAREAID --DONT access ax schema object
and [ax].RETAILCUSTPREFERENCE.ACCOUNTNUM = SOURCE.ACCOUNTNUM
WHEN MATCHED THEN
UPDATE SET [EMAILOPTIN] = source.[EMAILOPTIN]
WHEN NOT MATCHED THEN
INSERT
(
    RECID
    ,DATAAREAID
    ,EMAILOPTIN
    ,ACCOUNTNUM
)
VALUES
(
    SOURCE.PARENTRECID
    ,SOURCE.DATAAREAID
    ,SOURCE.EMAILOPTIN
    ,SOURCE.ACCOUNTNUM
);
SELECT @i_Error = @@ERROR;
IF @i_Error <> 0
BEGIN
    SET @i_ReturnCode = @i_Error;
    GOTO exit_label;
END;

```

### Don't do this

- Don't create any new extension tables, views, or procs in crt, ax, or dbo schema. All extension artifacts must be done in ext schema.
- Don't use any of the crt, ax or dbo schema data types in ext schema. Create custom types in ext schema and use it.
- Don't modify any views, procedures, functions, or any of the database artifacts.
- Avoid accessing or calling database artifacts from your extensions, if possible. Instead, use the CRT data service to get data. The benefits of using the data service are that it will continue to be supported until the SLA, even if breaking changes are made to the database schema in the future. However, there will be instances in which the CRT data service does not expose the data that you need. In these cases, it is still possible to access this data by creating a view which joins on a channel DB artifact. Creating views can be a powerful tool to structure the data in a format you need at a database level, as opposed to doing it in memory through CRT extensions.
- Don't access any dbo.objects from extension scripts because dbo schema objects will not be available in Commerce scale unit deployments.

```

CREATE VIEW [ext].[CONTOSORETAILSTOREHOURSVIEW] AS
(
    SELECT
        sdht.DAY,
        sdht.OPENTIME,
        sdht.CLOSINGTIME,
        sdht.RECID,
        rst.STORENUMBER
    FROM [ext].[CONTOSORETAILSTOREHOURSTABLE] sdht
    INNER JOIN [ax].RETAILSTORETABLE rst ON rst.RECID = sdht.RETAILSTORETABLE
)

```

## Adding extensions

1. If you are creating an extended table and want to sync the data back to HQ, then the table must have the same primary key and clustered index as the HQ table in the extended table, if not, the CDX sync will fail. If you need to pull the data from the extension table to HQ, then the REPLICATIONCOUNTERFROMORIGIN identity column ([REPLICATIONCOUNTERFROMORIGIN] [int] IDENTITY(1,1) NOT NULL,) is required in the extension table.
2. All extension table columns must have the NOT NULL constraint enforced. During upgrade, if the column value is blank it will be updated with NULL values and it may cause a runtime exception in CRT if the null value is not handled properly.
3. All the extension tables should have grant permission on **UserRole** and **DeployExtensibilityRole**.

```

--Tables:

GRANT SELECT, INSERT, UPDATE, DELETE ON OBJECT::[ext].[RETAILCUSTPREFERENCE] TO [UsersRole]
GO

GRANT SELECT, INSERT, UPDATE, DELETE ON OBJECT::[ext].[RETAILCUSTPREFERENCE] TO
[DeployExtensibilityRole]
GO

--Stored procedures:

GRANT EXECUTE ON [ext].[EXTSTOREDPROCEDURE] TO [UsersRole];
GO

GRANT EXECUTE ON [ext].[EXTSTOREDPROCEDURE] TO [PublishersRole];
GO

GRANT EXECUTE ON [ext].[EXTSTOREDPROCEDURE] TO [DeployExtensibilityRole];
GO

```

4. Grant **DataSyncUsersRole** permission if your table is going to send or receive data from HQ.

```

GRANT SELECT, INSERT, UPDATE, DELETE, ALTER ON OBJECT::[ext].[EXTTABLENAME] TO [DataSyncUsersRole]
GO

```

5. Always prefix your table, for example **ContosoRetailTransactionTable**, so that you can avoid conflicts with other customizations.

## Attributes

We extended the attribute framework in HQ to support attributes for Customers, Customer orders, cash and carry transactions and call center orders.

## Customer attributes

With the new customer attribute framework, you can use configurations to add new fields to the customer add/edit or customer details screens in POS or HQ. After configuring the customer attribute group in commerce parameters, POS and HQ will automatically show up the new attribute without any code change or customization. The screen layout designer will also be configured to show the customer attributes in the transaction screen - **Customer** panel.

## Order attributes

The attribute framework was extended to support attributes in cash and carry transactions, customer orders, and call center orders. You can edit and set values directly in HQ or in CRT. All this can be done through configurations, without any database changes. (You can customization the attribute values for core business logic, not required for basic CRUD operations.) Previously, you had to create new tables in HQ and channel DB, and then modify CRT to do this. Now all the attribute creation can be done through configuration.

## Adding a new table

In this scenario we will explain how to create a new table and add it to the channel DB. All extension code has access to the **ext schema**.

- Create a new table in the channel database in the **ext schema** either using SQL Server Management Studio Designer or using SQL scripts. The following is an example SQL script.

```
-- Create the extension table to store the custom fields.
IF (SELECT OBJECT_ID('[ext].[CONTOSORETAILSTOREHOURSTABLE]')) IS NULL
BEGIN
CREATE TABLE [ext].[CONTOSORETAILSTOREHOURSTABLE](
[RECID] [bigint] NOT NULL,
[DAY] [int] NOT NULL DEFAULT ((0)),
[OPENTIME] [int] NOT NULL DEFAULT ((0)),
[CLOSINGTIME] [int] NOT NULL DEFAULT ((0)),
[RETAILSTORETABLE] [bigint] NOT NULL DEFAULT ((0)),
[REPLICATIONCOUNTERFROMORIGIN] [int] IDENTITY(1,1) NOT NULL,
[ROWVERSION] [timestamp] NOT NULL,
[DATAAREAID] [nvarchar](4) NOT NULL,
CONSTRAINT [I_CONTOSORETAILSTOREHOURSTABLE_RECID] PRIMARY KEY CLUSTERED
(
[RECID] ASC
) WITH (PAD_INDEX = OFF, STATISTICS_NORECOMPUTE = OFF, IGNORE_DUP_KEY = OFF, ALLOW_ROW_LOCKS = ON,
ALLOW_PAGE_LOCKS = ON) ON [PRIMARY]
) ON [PRIMARY]
ALTER TABLE [ext].[CONTOSORETAILSTOREHOURSTABLE] WITH CHECK ADD CHECK (([RECID]<>(0)))
END
GO
GRANT SELECT, INSERT, UPDATE, DELETE ON OBJECT::[ext].[CONTOSORETAILSTOREHOURSTABLE] TO
[DataSyncUsersRole]
GO
```

### NOTE

If the new extension table data needs to be pulled to Retail headquarters using Commerce Data Exchange (CDX), then the extension table must include the

```
REPLICATIONCOUNTERFROMORIGIN identity column ([REPLICATIONCOUNTERFROMORIGIN] [int] IDENTITY(1,1) NOT NULL,), [ROWVERSION] [timestamp] NOT NULL
```

and [DATAAREAID] [nvarchar](4) NOT NULL (required if the table data is per company). This is required for a CDX pull job. REPLICATIONCOUNTERFROMORIGIN is not required if the data is pushed from Retail headquarters to channel database, this is only needed if the data is pulled from channel database to Retail headquarters.

## Extending an existing table

If you are extending existing table, then you must either use attributes if supported for that entity or create and extended table (new table) with same primary key as the parent table. The following script extends a table.

```
CREATE TABLE [ext].[RETAILTRANSACTIONTABLE](
  [TRANSACTIONID] [nvarchar](44) NOT NULL, -- FK to [crt].RETAILTRANSACTIONTABLE
  [ISB2BSALES] [int] NOT NULL DEFAULT (0),
  [EXTERNALID] [nvarchar](20) NOT NULL DEFAULT (''),
  CONSTRAINT [EXT_RETAILTRANSACTIONTABLE_PK] PRIMARY KEY CLUSTERED
  (
    [TRANSACTIONID]
  ) WITH (PAD_INDEX = OFF, STATISTICS_NORECOMPUTE = OFF, IGNORE_DUP_KEY = OFF, ALLOW_ROW_LOCKS = ON,
  ALLOW_PAGE_LOCKS = ON) ON [PRIMARY]
) ON [PRIMARY]
GO
GRANT INSERT ON [ext].[RETAILTRANSACTIONTABLE] TO [DataSyncUsersRole];
GO
GRANT DELETE ON [ext].[RETAILTRANSACTIONTABLE] TO [DataSyncUsersRole];
GO
GRANT UPDATE ON [ext].[RETAILTRANSACTIONTABLE] TO [DataSyncUsersRole];
GO
GRANT SELECT ON [ext].[RETAILTRANSACTIONTABLE] TO [DataSyncUsersRole];
GO
```

## Adding new views, stored procedure, functions, and defined types

All new stored procedures, views or functions must be created in the **ext** schema. Don't access or call our database artifacts from your procedures, views, or functions.

## Deployment checks

The deployment process determines if there are any modification to the database artifacts. If you have attempted to modify the CRT, AX, or DBO schema objects, or access them for any scenario directly in SQL, then deployment will fail.

## Extension scripts and deployment

Channel Database extensions are provided by authoring one or more T-SQL script files and including them in a [deployable package](#). This process is described in the [Retail SDK](#) documentation.

Extension script files must be written using [T-SQL](#) and compatible with [Azure SQL Database](#). The script files must end with the `.sql` file extension, any other files will be ignored or may induce a packaging or deployment failure. If you intend to deploy your Channel Database extensions as part of Commerce Scale Unit or Modern POS offline, the scripts must also be compatible with the version of SQL Express and/or SQL Server that will be used for those components.

During deployment and installation, the extension scripts are executed in alphabetical order based on the script file name. Each script is run to completion and then a metadata record is added to the Channel Database's CRT.RETAILUPGRADEHISTORY table to track the completion of that extension script. The script will not be executed again for the same Channel Database in subsequent deployments if that metadata record is present. If a script fails during execution and does not complete successfully, its metadata will not be stored and the script will be rerun on subsequent deployments.

If the deployment or installation is combined with an update of the product, the extension scripts are run after the product update.

To author a successful Channel Database extension, you must adhere to the following guidelines.

## Use a naming convention that ensures stable order when sorted alphabetically

Because extension scripts are executed in alphabetical order based on the file name, you should establish a naming convention that ensures that the correct execution order is used when sorted.

One example would be naming files with the following pattern: `<ISO 8601 date>_<descriptio>.sql`, where `<ISO 8601 date>` is a ISO 8601 formatted date and `<description>` is descriptive text to identify the purpose of the script. For instance, `"20180501_CustomerDetails.sql"` and `"20181102_CustomerDetailsIndex.sql"`. The former would represent an extension script authored on May 1, 2018 that is related to "Customer Details" feature and the latter an extension script associated to indexes related to the previous feature authored on November 2, 2018.

Another simpler alternative is to use an incremental numeric prefix, such as `"0001_CustomerDetails.sql"` and `"0002_CustomerDetailsIndex.sql"`.

If one script depends on another having executed successfully, you must name then in a way that ensures that the file name in alphabetical order matches the required execution order.

## Do not alter extension scripts that have been published

If you have released a deployable package or installer extension that contains Channel Database extension scripts, do not alter those scripts. Extension scripts are run only once per Channel Database instance. If you alter published scripts and those scripts may have already been run against a Channel Database, the modifications to an already executed script will not be applied to the database.

Instead, provide the modifications in a new script file. Consider the naming convention noted above to ensure that it runs after its dependencies.

## Do not remove old extension scripts that have been published

Your deployable package or installer extension must represent a cumulative update for your database extensions. There should be no dependencies on previous versions of an extension package or installer. A customer should be able to apply your extension package or installer without depending on a previous version of your package or extension.

If your extension scripts have been published as part of a deployable package or installer extension, do not remove them from subsequent updates in your package or installer. To account for disaster recovery, upgrade and scale out scenarios, extension packages may be used to bring a new instance of the Channel Database to the same version of the last deployed extension package.

## Extension scripts must be idempotent and reentrant

Although extension scripts are run only once per Channel Database, scripts may fail due to authoring errors or transient SQL errors, like time outs or transaction deadlocks. The extension scripts must be idempotent and reentrant to account for those failure scenarios. If the extension script fails due to any error, it may be rerun. Rerunning the script should not adversely affect the database.

## Do not assume that the Channel Database data is perennial

The Channel Database is a transactional database that provides storage support for operations performed by Commerce Scale Unit. All data that is stored in the Channel Database that must be kept for long periods of time must be uploaded to the headquarters through the [Commerce Data Exchange](#). Data uploaded to the headquarters can be accessed by the [Commerce Data Exchange Real-time Service](#).

## Do write backward compatible channel database extensions

The Channel Database is expected to be backward compatible. This means that updating only the Channel Database without updating Commerce Scale Unit or POS must not prevent existing Commerce Scale Unit or POS operations from functioning correctly. During deployment flows, the different components of your Commerce Scale Unit and Modern POS are updated in the inverse order of dependency. This means that the Channel Database is the first component to be updated, and Commerce Scale Unit or POS are updated next. If

Commerce Scale Unit or POS fails to update successfully, those components are rolled back to restore them to their previous working state. However, in such situations, the Channel Database is not rolled back to prevent data loss. If your extensions are not backward compatible, they may fail to work properly until a successful deployment is performed.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Enable custom Commerce Data Exchange synchronization via extension

2/18/2021 • 19 minutes to read • [Edit Online](#)

This topic explains how you can extend the Commerce initialization class to support custom Commerce Data Exchange (CDX) synchronization. For this extension, you use the new extension points that were added in Microsoft Dynamics 365 for Finance and Operations platform update 8 or Microsoft Dynamics 365 Retail platform update 8.

CDX is a system that transfers data between Commerce Headquarters (HQ) and channels, such as online stores or brick-and-mortar stores. The data transfer between HQ and the channel database is controlled by scheduler jobs. Each scheduler job contains a list of scheduler subjobs. The scheduler subjobs contain the names of the source tables and destination tables, and the transfer field mapping of those tables. There are two ways to configure the data synchronization between HQ and the channel database:

- Configure all the custom jobs and subjobs by using the configuration user interface (UI) for CDX.
- Extend the Commerce initialization class by using the extension points that are provided to support custom jobs and subjobs for both push and pull.

The advantage of using the Commerce initialization class is that you don't have to configure the custom jobs in different environments (dev, test, and production). Instead, you can run the CDX initialization by using the **Initialize commerce scheduler** dialog box from **Retail and Commerce > Headquarters setup > Commerce scheduler > Initialize commerce scheduler**. Information about the custom job for the data synchronization is then automatically created in CDX.

There are various scenarios for data transfer between HQ and the channel database:

- Send data from a new HQ table to a new channel database table by using a download job.
- Pull data from a new channel database table to a new HQ table by using a push job.

## Send data from a new HQ table to a new channel database table by using a download job

Before you push or pull data, you must understand various metadata definitions in the XML resource file. The resource file contains the custom job information that will be initialized in your environment to push and pull data. Here is a list of the resource files that you must configure:

- **ChannelDBSchema** – The extension schema that you created in the channel database.
- **TargetTableSchema** – The extension schema that you created in the channel database to add your custom tables.
- **AxTableName** – The table name.
- **IsUpload** – A flag that determines whether the job is a push job or a pull job. (In other words, the flag indicates whether you want to send data from HQ to the channel database or pull data from the channel database to HQ). The default value is **false**, which indicates that you're sending data from HQ to the channel database.
- **ScheduledByJob** – This resource file contains one or more subjobs.
- **Subjob** – Each table is added as a subjob, and each subjob is scheduled by one or more scheduler jobs.
- **TargetTable** – The name of the channel database table. This table is the target table that the push job or pull job must send data to. If a value isn't specified, the system assumes that name of the target table and the

name of the source table are the same.

If you created a new HQ table and a new channel database table, follow these steps to push the data between the two tables.

1. Create a custom project and use the Application Object Tree (AOT) to add a custom table.
2. Create a new resource file to add all custom job information. Here is the template for the resource file.

```
<RetailCdxSeedData ChannelDBMajorVersion="7" ChannelDBSchema="ext" Name="AX7">
  <Jobs>
  </jobs>
  <Subjobs>
    <Subjob Id="" TargetTableSchema="" TargetTableName="">
  </Subjobs>
</RetailCdxSeedData>
```

#### NOTE

The **DataAreaid** column name should not be explicitly included in the field mapping. This is automatically added by Commerce Data Exchange (CDX). If added, an error will occur during initialization of the retail scheduler.

3. Use the AOT to create a new XML resource. In the XML file for the resource, specify the new table and new job details, as shown in the following example.

#### NOTE

You can either add the new table as part of the existing job, or create a new job and add this table. In this case, we are creating a new job, where the job ID is **7000** and the custom table is named **ContosoRetailSeatingArrangementData**.

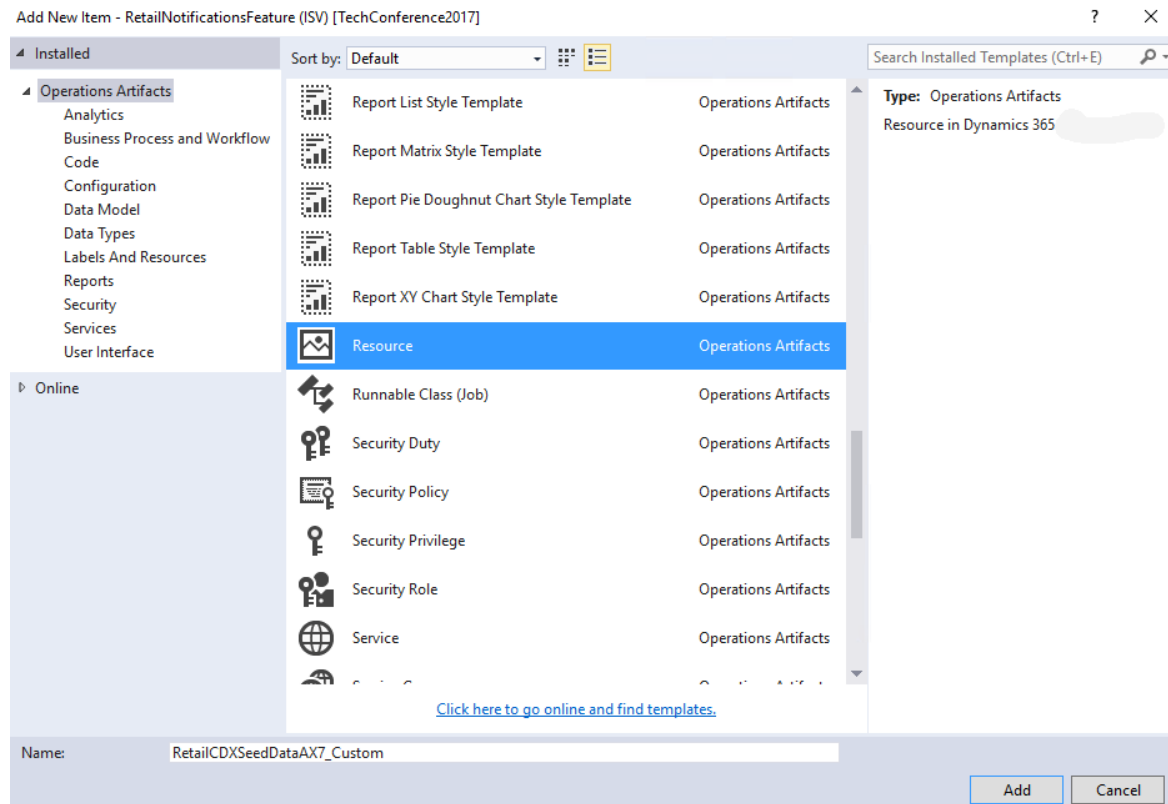

```
<RetailCdxSeedData ChannelDBMajorVersion="7" ChannelDBSchema="ext" Name="AX7">
  <Jobs>
    <Job DescriptionLabelId="REX4520710" Description="Custom job" Id="7000"/>
  </Jobs>
  <Subjobs>
    <Subjob Id="ContosoRetailSeatingArrangementData" TargetTableSchema="ext"
AxTableName="ContosoRetailSeatingArrangementData">
      <ScheduledByJobs>
        <ScheduledByJob>7000</ScheduledByJob>
      </ScheduledByJobs>
      <AxFields>
        <Field Name="seatNumber"/>
        <Field Name="capacity"/>
        <Field Name="channelRecId"/>
        <Field Name="RecId"/>
      </AxFields>
    </Subjob>
  </Subjobs>
</RetailCdxSeedData>
```

By default, the name of the target table isn't specified here. The system assumes the name of the target table on the channel side is the same as the name of the source table on the Commerce side (**AXTableName**). However, the name of the target table on the channel side might sometimes differ from the name of the source table. In this case, in the **<Subjob>** node, you can use the **<TargetTableName>** attribute to set the name of the target table on the channel side.

Similarly, in the mapping section, only the names of fields on the Commerce side are specified (**AxFields**). By default, it's assumed that the same field name is also used on the channel side. However, the field name on the corresponding channel table might sometimes differ from the field name on the

Commerce side. In this case, in the mapping, you can use the **ToName** attribute of the <Field> node to set the name of the field on the channel side.

4. Right-click the project, and then select **Add > New Item**.
5. In the **Add New item** dialog box, select **Resources**, name the resource file **RetailCDXSeedDataAX7\_Custom**, and then select **Add**.

6. In the **Select a Resource file** dialog box, find the resource file that you created in step 2, and then select **Open**.
7. Add a new class that should be used to handle the **registerCDXSeedDataExtension** event. Search for the **RetailCDXSeedDataBase** class, and then open it in the designer. Right-click the **registerCDXSeedDataExtension** delegate, and then select **Copy event handler**.
8. Go to the event handler class that you created and paste the following event handler code into it.

```
if (originalCDXSeedDataResource == resourceStr(RetailCDXSeedDataAX7))
{
    resources.addEnd(resourceStr(RetailCDXSeedDataAX7_Custom));
}
```

## NOTE

Because there are two definitions for CDX seed data in the system, you must specify that your extension CDX seed data should be added only if the CDX seed data that is being generated is the version that you're trying to extend. If the `if` condition is removed, your extension CDX seed data could also be applied on top of the N-1 CDX seed data and cause unintended results. As a best practice, try to avoid any other customization on CDX/Retail scheduler sync framework class in X++. This could impact the flow of data when extra processing is performed. The suggested pattern is to have a separate class and batch job to process the uploaded data.

You don't have to create separate resource files for the various scenarios that are mentioned later. You can have one file that contains all the custom job information and register that file from the extension class.

When the initialization class runs, it looks for any extension that implements this handler. If an extension is found, the runtime will also initialize the custom information that is found in the resource file.

9. Go to **Retail and Commerce > Headquarters setup > Commerce scheduler > Initialize commerce scheduler**.
10. Run the CDX initialization by clicking the **OK** button on **Initialize commerce scheduler** dialog.

## Pull data from a new channel database table to a new HQ table by using a push job

To pull data from a new channel table to HQ, you have two options:

- Create a new resource file and add the new resource to the event handler as a second line, as shown here.

```
if (originalCDXSeedDataResource == resourceStr(RetailCDXSeedDataAX7))
{
    resources.addEnd(resourceStr(RetailCDXSeedDataAX7\_Custom));
    resources.addEnd(resourceStr(RetailCDXSeedDataAX7\_Custom1));
}
```

- Update the existing resource file with the new information, so that you don't have to add a new line. To upload you set the **IsUpload** attribute to **true** in the resource file and add information about your custom pull job, as shown in the following example.

```
<Subjob Id="ContosoRetailSeatReservationTrans" TargetTableSchema="ext" IsUpload="true"
ReplicationCounterFieldName="ReplicationCounterFromOrigin"
AxTableName="ContosoRetailSeatReservationTrans">
    <ScheduledByJobs>
        <ScheduledByJob>P-1000</ScheduledByJob>
    </ScheduledByJobs>
    <AxFields>
        <Field Name="transactionId"/>
        <Field Name="storeId"/>
        <Field Name="terminalId"/>
        <Field Name="contactPhoneNo"/>
        <Field Name="numberOfCustomers"/>
        <Field Name="customerName"/>
        <Field Name="reservationDate"/>
        <Field Name="reservationTime"/>
        <Field Name="replicationCounterFromOrigin"/>
    </AxFields>
</Subjob>
```

## NOTE

If you are creating an extended table and want to sync the data back to HQ, then the table must have the same primary key and clustered index as the HQ table in the extended table, if not, the CDX sync will fail. If you need to pull the data from the extension table to HQ, then the REPLICATIONCOUNTERFROMORIGIN identity column ([REPLICATIONCOUNTERFROMORIGIN] [int] IDENTITY(1,1) NOT NULL,) is required in the extension table.

You can either add this new table as part of the existing pull job (P-0001) or create a new pull job.

## Other scenarios

For the remaining push and pull scenarios, only the information for the sample resource file is described, because initialization is the same as we described in the previous sections.

### Push existing headquarters tables to channel database that are not part of CDX configurations

In this case, the extension should create a new sub job with the same name as the core table and create the same table in the channel database ext schema and map it. Because CDX doesn't support multiple sub jobs for the same table, the sub job name must match the core table name to avoid any future conflicts. In the future, the headquarters table may be added for CDX push/pull by out-of-band (OOB) products with the sub job name same as the core table. CDX framework will automatically merge if there are any duplicate sub job names.

### Push existing columns that aren't mapped as part of any subjobs

You can push the existing unmapped column to either new extension columns or existing columns in the channel database, as shown in the following example.

```
<Subjob Id="RetailChannelTable" TargetTableSchema="ext">
  <AxFields>
    <Field Name="Payment"/>
    <!-- Existing column which was not pushed to channel db-->
    <Field Name="PaymMode"/>
    <!-- Existing column which was not pushed to channel db-->
    <Field Name="ContosoRetailWallPostMessage"/>
    <!-- New column from the extended table -->
  </AxFields>
</Subjob>
```

If the table has a primary key that isn't **RecId**, your extension table on the channel side should also contain the non-**RecId** primary keys, as shown in the following example.

```
<Subjob Id="RetailCustTable" TargetTableSchema="ext">
  <AxFields>
    <Field Name="ReturnTaxGroup_w"/>
    <!-- Existing column which was not pushed to channel db-->
    <Field Name="SSNNumber"/>
    <!-- New column from the extended table-->
  </AxFields>
</Subjob>
</Subjobs>
```

### Pull new columns to an existing table

If you add new columns and want to pull in part of the existing table, use the following code.

```
<Subjob Id="RetailTransactionTable" TargetTableName="CONTOSORETAILTRANSACTIONTABLE" TargetTableSchema="ext"
OverrideTarget="false">
  <AxFields>
    <Field Name="ContosoRetailSeatNumber"/>
    <Field Name="ContosoRetailServerStaffId"/>
  </AxFields>
</Subjob>
```

### Move an existing subjob to another subjob

To move an existing subjob to another job, you can change the **ScheduledByJob** attribute in the resource file and it is run as part of the event handler.

```
<Subjob Id="DirPartyTable">
  <ScheduledByJobs>
    <ScheduledByJob>1000</ScheduledByJob>
    <!--add existing subjob to another job-->
  </ScheduledByJobs>
```

## CDX sample - Pull new columns to an existing table

In Microsoft Dynamics 365 Retail App update 5, we added a new sample in **RetailSDK\Documents\SampleExtensionsInstructions\ExtensionTables**, it has all the sample SQL scripts, ax project files for different CDX extension scenarios, please use it as a reference for different CDX extension scenarios.

In the next sections, we discuss the steps and best practices for customizing transactional tables by using extension tables. Another section shows how to customize CDX to upload the customized (extension) tables on the channel side back to Commerce. We have also included a section that describes how to test the customization.

### Setup steps

We recommend that you implement these changes on an untouched Retail software development kit (SDK). Alternatively, you can put the SDK under source control, such as Microsoft Azure DevOps, so that you can easily revert your changes at any step. To begin, you import the \*.axpp package that is located in the SDK. You then run the SQL update script on your channel database.

1. Import the package on the Commerce side that contains the customization code:
  - a. Copy the ExtensionTablesAndCDXCustomization.axpp file from the RetailSDK\Documents\SampleExtensionsInstructions\ExtensionTables folder and paste in your extension project folder.
  - b. Start Microsoft Visual Studio.
  - c. Select **Dynamics 365 > Import project**.
  - d. In the **Import project** dialog box, specify the path of the .axpp file you copied in step 1.
  - e. Select either **Current solution** or **New solution**, according to your preference.
  - f. Select **OK** to begin to import the package.

After the import is completed, you have the files in Solution Explorer.

- g. Build the solution.
- h. Right-click the project, and then select **Synchronize database**.

2. Run the SQL update script:

- a. Copy the **ContosoRetailExtensionTablesUpdate.sql** file from the Retail SDK folder. You can run the other sample files in a similar manner.
- b. Open the script in Microsoft SQL Server Browser, and run the script against your channel database.

This step creates the extension tables that are required in order to customize the transactional tables. Note that the script also creates other tables that are used for other sample scenarios.

### Extend the data in the sample

The table extension on the Commerce side is already created in the sample. To create it manually, follow these steps.

1. Start Visual Studio.
2. On the menu, select **View > Application Explorer**.
3. Select **Data Model > Tables > RetailTransactionTable**, right-click **RetailTransactionTable**, and then select **Create extension**.

As a best practice, you should change the default name to something like

**RetailTransactionTable.ContosoRetailExtension**. Always add your unique prefix. In this sample, **ContosoRetail** is used as a unique prefix. By using a unique prefix, you help prevent naming conflicts if a table is extended by multiple independent software vendors (ISVs).

4. In the new **RetailTransactionTable.ContosoRetailExtension** table, create two new fields:

**Type=string, name=ContosoRetailServerStaffId**: Set the **Extended data type** property to **RetailStaffId**. **Type=int, name=ContosoRetailSeatNumber**: Set the **Extended data type** property to **ContosoRetailSeatNumber**.

5. Save the changes, and build your project.
6. Right-click your project, and then select **Synchronize the database**.

#### NOTE

As a best practice, the unique prefix is added to the new column names to help prevent future naming conflicts. A naming conflict can occur if another ISV creates a column that has the same name, or if Microsoft releases an update that uses a column that has the same name. Even though the extension table is created in a different AOT asset, the new columns are added to the original table in SQL.

### Extend the database on the channel side

From the Retail SDK folder, open and run the SQL Server **ContosoRetailExtensionTablesUpdate.sql** script. Several items are created and configured:

- The **[ext].ContosoRetailTransactionTable** table that has the foreign key and custom (extension) fields is created. In addition to the extension columns that we added in the tables, the extension table on the channel side must have the same primary key columns as the original table on the channel side. Therefore, **[ext].RetailTransactionTable\_ContosoRetailExtension** has the four primary key columns that are used in **[ax].RetailTransactionTable**. As a best practice, when you add the primary key columns to the extension table on the channel side, keep the names of the columns the same as the names of the primary key column on the original table.
- CDX is configured to upload and pull the custom columns from the channel extension table back to Commerce. The **RetailCDXSeedDataAX7** resource contains the information for the table mapping from Commerce to the channel database. CDX uses this information to create the required data transfer

scheduler jobs and subjobs. To include your new extension tables or columns in the data transfer, you must provide a resource file that specifies the customization for the CDX data transfer. As a best practice, use the following naming convention to prevent conflicts:

**RetailCDXSeedDataAX7\_ContosoRetailExtension.** (Here, **ContosoRetail** is your unique extension.)

The sample CDX resource file in the Retail SDK contains additional customizations. However, for our example of RetailTransactionTable extension, the section in the following code is the only section that is required to pull data from the channel side back to HQ.

```
<RetailCdxSeedData Name="AX7" ChannelDBSchema="ext" ChannelDBMajorVersion="7">
  <Subjobs>
    <!--Adding additional columns to (existing) RetailTransactionTable and wants to pull it back to
    HQ.For upload subjobs, set the OverrideTarget property to "false", as illustrated below. This will tell CDX
    to use the table defined by TargetTableName and TargetTableSchema as extension table on this subjob.-->
    <Subjob Id="RetailTransactionTable" TargetTableName ="CONTOSORETAILTRANSACTIONTABLE"
    TargetTableSchema="ext" OverrideTarget="false">
      <!--Notice that there is no mention of the <ScheduledByJobs></ScheduledByJobs> because the
      subjob is already part of an upload job. -->
      <AxFields>
        <!--If you notice the existing columns are not listed here in the <Field> tag, it's because
        the existing fields are already mapped in the main RetailCdxSeedData resource file, we only add the delta
        here. -->
        <Field Name="ContosoRetailSeatNumber" />
        <Field Name="ContosoRetailServerStaffId" />
      </AxFields>
    </Subjob>
  </Subjobs>
</RetailCdxSeedData>
```

**Description of the fields used in this resource file:**

**ChannelDBSchema='ext'** – This field is included so that the resource reads from the extension schema in the channel database.

**Subjob Id= "RetailTransactionTable"** – You must make sure that the SubJob ID is the same as the original subjob id for that table. so that the extensibility framework can determine that you're customizing the existing subjob. If you use new subjob di, system will throw duplicate subjob error for the same table.

**TargetTableName = "CONTOSORETAILTRANSACTIONTABLE"** - Your channel extension table name.

**TargetTableSchema="ext"** - Your channel extension schema. Currently we support the extension schema name only as ext.

**OverrideTarget="false"** - For upload subjobs (the ones that bring data from the channel to the headquarters), OverrideTarget when set to "false" will tell CDX that the table defined by TargetTableName is an extension table and data will be uploaded along with the primary table already defined in the subjob.

If OverrideTarget is set to "true" the table defined by TargetTableName will override the primary table for the subjob (default value fields will be omitted during the pull job and only the extension fields will be considered). For instance, in this sample, if you set this value to true, this would mean that instead of uploading the data from ax.RetailTransactionTable, CDX would only upload the data from ext.CONTOSORETAILTRANSACTIONTABLE.

The **AxTableName** attribute isn't specified, because the framework can already determine the **AxTableName** value that the specified subjob uses as a sink. You only have to specify the differences when you customize the RetailCDXSeedDataAX7 resource. Any data that the framework can infer doesn't have to be added by extensions. Similarly, in the **</AXFields?>** section, you can see that we specified only the custom or new fields, because the extensibility framework can determine the list of remaining fields from the specified subjob ID.

- The CDX module that has the CDX customization resource is updated. To apply the customization that is specified in RetailCDXSeedDataAX7\_ContosoRetailExtension, you must subscribe to the

registerCDXSeedDataExtension delegate. By subscribing to this event, you help guarantee that the customization is applied when initialization of the CDX seed data is run.

#### Subscribe to the registerCDXSeedDataExtension delegate

1. Select **View > Application Explorer**.
2. Search for the **RetailCDXSeedDataBase** class.
3. Right-click the class, and then select **Open in designer**.
4. In the designer, in the list of delegates and methods, select the **registerCDXSeedDataExtension** delegate.
5. Right-click, and then select **Copy event handler**. The method signature that you must implement is copied, so that CDX picks up the customized resource for CDX seed data.
6. Create a new class, and give it a name, such as **ContosoRetailCDXSeedDataAX7EventHandler**. You can specify any name. However, as a best practice, be sure to prefix the class name with your prefix.
7. Paste the code that you copied in step 5.

```
class ContosoRetailCDXSeedDataAX7EventHandler
{
    /// <summary>
    /// Registers the extension CDX seed data resource to be used during CDX seed data generation.
    /// </summary>
    /// <param name="result">The result object which is used to return the resource name.</param>
    [SubscribesTo(classStr(RetailCDXSeedDataBase), delegateStr(RetailCDXSeedDataBase,
registerCDXSeedDataExtension))]
    public static void RetailCDXSeedDataBase_registerCDXSeedDataExtension(str
originalCDXSeedDataResource, List resources)
    {
    }
}
```

8. The CDX extensibility framework calls this method when you select the Commerce initialization. To help guarantee that the CDX extensibility module uses the CDX customization, paste the following code into the preceding method.

```
if (originalCDXSeedDataResource == resourceStr(RetailCDXSeedDataAX7))
{
    resources.addEnd(resourceStr(RetailCDXSeedDataAX7_ContosoRetailExtension));
}
```

Before you add your custom resource to the list, you must verify that the originalCDXSeedDataResource resource that is being processed is RetailCDXSeedDataAX7. Otherwise, you might cause unintended results.

9. To initialize or reinitialize the CDX module with the customized configuration, follow these steps:
  - a. Go to **Retail and Commerce > Headquarters setup > Commerce scheduler > Scheduler jobs > Initialize commerce scheduler**.
  - b. In the dialog box that appears, select **Delete existing configuration**.
  - c. Select **OK** to start the initialization.

When the initialization is completed, the CDX scheduler jobs, subjob definitions, and distribution schedules are updated by using the original RetailCDXSeedDataAX7 resource and the customized RetailCDXSeedDataAX7\_ContosoRetailExtension resource.

## Validate the customization

1. Verify that your customization works correctly:
  - a. After the initialization is completed, go to **Retail and Commerce > Headquarters setup > Commerce scheduler**, and then select the **Scheduler subjobs** link.
  - b. On the subjobs table, search for the **RetailTransactionTable** subjob ID.
  - c. In the details area, under the **Channel field mapping** section, verify that the new custom (extension) columns are listed in the mapping.
2. Test that the CDX job will upload and pull from the original and extension tables on the channel side(a view combining original and extensible tables is generated by the CDX framework):
  - a. Create some transactions in Retail Modern POS (MPOS).
  - b. Because the extension table isn't used in the Commerce Runtime (CRT) and MPOS, you must manually insert data into the extension table. Run the following script after you change the required values.

```
INSERT INTO [ext].[CONTOSORETAILTRANSACTIONTABLE] (  
    [CONTOSORETAILSEATNUMBER],  
    [CONTOSORETAILSERVERSTAFFID],  
    [TRANSACTIONID],  
    [STORE],  
    [CHANNEL],  
    [TERMINAL],  
    [DATAAREAID])  
VALUES (  
    1, /*normally this needs to be an existing seat number from ContosoRetailSeatingData table,  
    but for this test add any number*/  
    '000160' /*add any staff ID here*/,  
    'HOUSTON-HOUSTON-11-101', /*add the transaction id you just created */  
    'HOUSTON', /*add the store used to create the transaction */  
    5637144592, /*add the channel RecId of the store used to create the transaction*/  
    'HOUSTON-11', /*add the terminalId used to create the transaction*/  
    'USRT' /*add the dataareaId used by the store*/)   
GO
```

Repeat this step for the other transactions. Don't add corresponding data in [ext].[CONTOSORETAILTRANSACTIONTABLE] for some of the transactions that you created in MPOS. In this way, you can verify that the data from [ax].RetailTransactionTable is pulled and uploaded even if there is no corresponding data in the extension table.

- c. Go to **Dynamics 365 > Retail and Commerce > Retail and Commerce IT**, and then select **Distribution schedule**.
  - d. In the list of distribution schedules, select **P-0001**. This distribution schedule contains the **RetailTransactionTable** subjob that you customized.
  - e. On the Action Pane, select **Run**. When the confirmation message appears, select **Yes**.
  - f. On the Action Pane, select **History** to open the **History** page, where you can verify that the uploaded session was completed successfully.
  - g. On the **History** page, verify that there is a new upload session record. Also verify that the status of the record is set to **Applied**, and that the **Rows Affected** value isn't **0** (zero).
3. If the upload session is applied successfully, go to **Retail and Commerce > Inquiries and reports > Store transactions**, and search for the new transactions that you just uploaded. Verify that the transactions, seat number, and server staff ID custom columns have the expected values.

Additionally, verify that the transactions that don't have a corresponding record in the

[ext].ContosoRetailTransactionTable extension table on the channel side are also uploaded. Verify that these transactions have default values for the seat number and server staff ID. The seat number should be set to **0** (zero), and the server staff ID should be set to **000160**.

#### **MPOS offline transaction sync**

Switch MPOS to offline mode and do some transaction. Switch back to online and verify that the data is synced properly from the offline database to the channel database and then to headquarters.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Define and set order attributes

2/18/2021 • 14 minutes to read • [Edit Online](#)

Previously, the attribute framework supported attributes only in online orders. However, the framework has been extended so that it now supports attributes in cash-and-carry transactions, customer orders, and call center orders. This enhancement lets you edit and set attribute values for orders directly in Commerce Headquarters, the point of sale (POS), and the Commerce runtime (CRT).

Headquarters now includes pages for editing and updating attribute values, which means that you can set the values for call center orders in Headquarters. In POS, use the Attributes panel to set or update the attribute value in POS. If you don't need to use a user interface and just want to add business logic, you can add the business logic directly in CRT. You can create new attributes by using the Headquarters configurations. No database changes are required. Previously, you had to create new tables in Headquarters and the channel database, and then modify those tables.

## Why and when you should order attributes

If you want to add new fields to cash-and-carry transactions, customer orders, or call center orders, and if you want to capture the information in the POS or Headquarters, use order attributes. Previously, to add a new field to a cash-and-carry transaction (transaction header or lines) or a customer order in the POS, you had to create a new extension table in Headquarters and the channel database, and then make inline changes to CRT and POS code to handle the various screens and operations. You also had to configure Commerce Data Exchange to synchronize the data between the channel database and Headquarters. However, order attributes now let you complete all these actions through configuration. You don't have to write any code or create custom extension tables, but you still need to create the core business logic and the POS UI.

This first version supports only the **String** attribute type, but future versions will support other attribute types. If you want the data to come from the master table, and that data involves complex search logic and core business logic in X++, you should use extension properties.

### NOTE

We only support attributes on customer orders and cash-and-carry transactions, no other transaction types are supported.

## Define attribute types

First, you must define the attribute types and assign valid ranges to them.

1. Go to **Product information management > Setup > Categories and attributes > Attribute types**.
2. On the **Attribute types** page, select **New** to add a new attribute type.
3. Enter a name for the attribute type.
4. On the **General** FastTab, in the **Type** field, select the type of data that can be entered for attributes that are assigned to this data type.
5. If the attribute type is **Decimal** or **Integer**, select a unit of measure.
6. If the attribute type is **Text**, you can define a fixed list of values for it. Select the **Fixed list** check box, and then, on the **Values** FastTab, enter the list of values.
7. To define a range of valid values for the attribute type, select the **Value range** check box. Then, on the **Range** FastTab, enter the valid range of values.

## Define the attributes

Next, you must define the attributes. Follow these steps for each attribute that you want to define.

1. Go to **Product information management > Setup > Categories and attributes > Attributes**.
2. On the **Attributes** page, select **New** to add a new attribute.
3. Enter a name, friendly name, and description for the attribute. Additionally, enter any Help text that should be shown to the user for the attribute.
4. In the **Attribute type** field, select the attribute type to assign to the attribute.
5. Depending on the attribute type, in the **Default value** field, enter the value or range of values that is shown by default when the attribute is assigned to a channel.
6. Select **Translate**. Then, on the **Text translation** page, enter the name, description, friendly name, and Help text for the attribute in additional languages.

## Define attribute groups

1. Go to **Product information management > Setup > Categories and attributes > Attribute groups**.
2. On the **Attribute groups** page, select **New** to add a new attribute group.
3. Enter a name for the attribute group. Then, on the **General** FastTab, enter a friendly name, a description, and any Help text for the attribute group.
4. On the **Attributes** FastTab, select **Add** to add attributes to the attribute group. In the **Default value** field, you can enter a default value for the selected attributes.
5. Select **Translate**. Then, on the **Text translation** page, enter the description, friendly name, and Help text for the attribute group in additional languages.

## Link the attribute group to the channel

1. Go to **Retail and Commerce > Channels > Stores > All stores**.
2. Select the channel that the attributes on the **Channel** page should be linked to.
3. On the **Set up** tab, select **Sales order attributes** under **Attribute group**.
4. On the **Sales order attribute groups** page, select **New** to link the attribute group to the channel.
5. In the **Name** field, select the attribute group to link to the channel.
6. In the **Apply attributes to** field, select one of the following options:
  - **Header** – The attributes will apply only to the transaction header.
  - **Lines** – The attribute will apply only to the transaction lines.
  - **Default** – The attribute will apply to both the transaction header and the transaction lines.
7. Select **Save**.

## Run the distribution jobs

1. Go to **Retail and Commerce > Retail and Commerce IT > Distribution schedule**.
2. Select **Products (1040)**, and then, on the Action Pane, select **Run now**. When you're prompted, select **Yes**. This step is required only if you added any new attributes, attribute types, or attribute groups.
3. Select **Channel configuration job (1070)**, and then, on the Action Pane, select **Run now**. When you're prompted, select **Yes**.

## Show order attributes in the POS transaction screen using the

# Attribute control (this feature is available in version 8.1.3 and later)

## Headquarters

1. Select **Retail and Commerce > Channel setup > POS Setup > POS > Screen layouts**.
2. On the screen layout page, click **New** to create a new screen layout, or select an existing screen layout.
3. Enter the ID and name for the screen layout.
4. On the **Layout sizes** FastTab, select the **Add** button to add new layout sizes for the POS.
5. In the **Name** field, select the POS screen resolution.
6. On the **Layout sizes** FastTab, click the **Layout designer** button.
7. If you're prompted, select **Yes** to download and install the Designer Host by using the **Install/Run** button.
8. When you're prompted, enter the Microsoft Dynamics 365 user name and password to start the designer.
9. After the designer is started, drag the Attributes panel anywhere in the screen layout designer and adjust the size according to your screen width.
10. When you've finished, select **OK** to save your changes.
11. Close the screen layout designer by clicking the **Close** button (X) in the upper-right corner. When you're prompted, select **Yes** to save your changes.
12. Go to **Retail and Commerce > Retail and Commerce IT > Distribution schedule**.
13. Select the Registers job (1090), and then, on the Action Pane, select **Run now**. When you're prompted, select **Yes**.

## POS

1. Start POS, and add any item to a transaction. You should see the Attribute panel in the transaction screen with the configured attributes both for header and lines.
2. Click the **Edit** icon in the attribute panel to update the attribute value.
3. Click the header or lines tab in the attribute panel to view the header or lines attribute.
4. The lines attribute will refresh automatically based on the lines selected in the transaction.

## Set attribute values for call center orders

After you configure the order attributes for the channel, go to **Customer service** or **All Sales orders**, and create a new call center order.

1. After or during the creation of a customer order, if you want to set an attribute value for the transaction header, on the Action Pane, go to the **Commerce** tab, select **Attributes**.
2. On the **Sales order attributes values** page, you can set the values for the attributes. The list of attributes on this page is based on the attribute group that you configured for the channel.
3. To set attribute values at the line level, on the **Sales order** page, select the **Lines** view, and then select the line to set the attribute value for. Under **Sales order lines group**, select **Retail and Commerce > Attributes**.
4. Repeat step 3 for all the sales lines that you want to set the values for.

## View the attributes values for cash-and-carry transactions in Headquarters

After you've run the distribution job and pulled a cash-and-carry transaction into Headquarters, you can view the attribute values for that transaction. The POS doesn't provide a UI for viewing order attributes. Therefore, to view the order attribute values, you must extend the POS.

1. Go to **Retail and Commerce > Inquires and reports > Store transactions**.
2. To view the transaction header attributes, on the Action Pane, select **Attributes**.
3. To view the transaction lines attributes, on the Action Pane, select **Transaction > Sales transaction**.

4. On the **Sales transactions** page, select any line, and then, on the Action Pane, select **Attributes** to view the line attributes.

#### NOTE

Only the attributes that are configured as part of your attribute group and linked to the channel will appear in the Headquarters UI.

## Extend attributes to add business logic in CRT

A new sample that has been added to the Retail SDK adds business logic for order attributes in CRT. This sample includes code only for the business logic. It doesn't show how to save or read the attributes, because read and write operations for attributes are automated.

The sample implements the following scenario: When you suspend a cart, you set an attribute value. When you resume the cart, you want to clear that value. A pre-trigger was added for **SuspendCartRequest**, and the business logic was written. You can extend any trigger or override any request in CRT to set the logic, based on your scenario.

#### NOTE

Before adding attribute to the cart, check whether the attribute already exists in the cart or cartline. If the attribute already exists, then don't add the attribute again, instead update it. If a duplicate attribute is added to the cart or cartline, then CRT will display a runtime error. Sample code for this scenario can be found in sample code section below.

You can find the full sample code in the Retail SDK at Retail SDK\SampleExtensions\CommerceRuntime\Extensions.TransactionAttributesSample.

- Create a new C# portable class library project, and paste in the following code.

```
public class CustomSuspendCartTrigger : IRequestTrigger
{
    // summary
    // Gets the list of supported request types.
    public IEnumerable<Type> SupportedRequestTypes
    {
        get
        {
            return new [ ] { typeof(SuspendCartRequest)};
        }
    }

    // Pre-trigger code.

    // summary
    // param name="request" The request param
    public void OnExecuting(Request request)
    {
        ThrowIf.Null(request, "request");
        Type requestedType = request.GetType();
        if (requestedType == typeof(SuspendCartRequest))
        {
            SuspendCartRequest suspendCartRequest = request as SuspendCartRequest;
            // Get the cart.
            var getCartServiceRequest = new GetCartServiceRequest(
                new CartSearchCriteria(suspendCartRequest.CartId), QueryResultSettings.SingleRecord);
            Cart cart = request.RequestContext.Execute<GetCartServiceResponse>
            (getCartServiceRequest).Carts.Single();
            // Update the transaction header attribute for customer order.
            if (cart.CartType == CartType.CustomerOrder)
```

```

        if (cart.CartType == CartType.CustomerOrder)
        {
            bool cartUpdated = CustomCartHelper.CreateUpdateTransactionHeaderAttribute(
                cart, reserveNow: false, updateAttribute: true);
            if (cartUpdated)
            {
                // Save the cart after updating the header attribute.
                var saveCartRequest = new SaveCartRequest(cart);
                request.RequestContext.Execute<SaveCartResponse>(saveCartRequest);
            }
        }
    }
}

// Post-trigger code.

// summary
// param name="request" The request param
// param name="response" The response param
public void OnExecuted(Request request, Response response)
{
}

// Sample code to check for the duplicate attribute, before adding attributes to the cart check
whether the attribute already exists if so then don't add the attribute again, instead update it.

public static class CustomCartHelper
{
    /// <summary>
    /// Updates the transaction header attribute.
    /// </summary>
    /// <param name="cart">The cart.</param>
    /// <param name="reserveNow">The value of the transaction header attribute.</param>
    /// <param name="updateAttribute">A flag indicating whether or not to override an existing
attribute value.</param>
    /// <returns>A flag indication whether or not the cart was updated.</returns>
    public static bool CreateUpdateTransactionHeaderAttribute(Cart cart, bool reserveNow, bool
updateAttribute)
    {
        ThrowIf.Null(cart, "cart");
        bool cartUpdated = false;
        IList<AttributeValueBase> transactionAttributes = cart.AttributeValues;
        string reserveNowAttributeName = "Reserve now";
        string reserveNowAttributeValue = reserveNow ? "Yes" : "No";
        AttributeValueBase reserveNowAttribute = transactionAttributes.SingleOrDefault(attribute =>
attribute.Name.Equals(reserveNowAttributeName));

        if (reserveNowAttribute == null)
        {
            transactionAttributes.Add(new AttributeTextValue() { Name = reserveNowAttributeName,
TextValue = reserveNowAttributeValue });
            cartUpdated = true;
        }
        else if (updateAttribute && !
((AttributeTextValue)reserveNowAttribute).TextValue.Equals(reserveNowAttributeValue))
        {
            ((AttributeTextValue)reserveNowAttribute).TextValue = reserveNowAttributeValue;
            cartUpdated = true;
        }

        return cartUpdated;
    }
}

```

Extend attributes to do some business logic in the POS

## NOTE

The following changes are required only if you are running the application with version 8.1.2 or earlier. Starting in 8.1.3, you can use the Attributes panel to set or update the attribute value in POS. With this control you no longer need to write any additional code or create UI to set the attribute value in POS. In the attribute control UI has been added to set or update the attribute value. Refer to the **Show Order attributes in the POS transaction screen using the Attribute control** section in this document for more details.

A new sample that has been added to the Retail SDK sets the business logic for order attributes in the POS. This sample includes code only for the business logic. It doesn't show how to save or read attribute values, because read and write operations for attributes are automated. You can set the values for attributes in either CRT or the POS, based on your scenario. If your values are based on customer input, set them in the POS client. If some business logic is involved, set the values in CRT.

The sample implements the following scenario: You create a business-to-business (B2B) order and want to set the B2B attribute value (**Yes** or **No**), based on customer input. **PreEndTransactionTrigger** was extended in the POS to set the values. You can extend any POS trigger or override the request as appropriate.

You can find the full sample code in the Retail SDK at Retail SDK\POS\Extensions\B2BSample.

## NOTE

Only the configured attributes will appear in the Headquarters UI, even if you set or add attributes and attribute values in the code. If an attribute isn't part of the attribute group that you linked to the channel, it won't appear in the Headquarters UI.

1. From the Retail SDK, open **ModernPOS.sln\CloudPos.sln**.
2. In the Retail SDK, create a new extension folder under the **POS.Extension** project.
3. In the new extension folder, add a new **manifest.json** file.
4. Paste in the following code.

```
{
  "$schema": "..manifestSchema.json",
  "name": "Pos_Extensibility_B2BSample",
  "publisher": "Microsoft",
  "version": "7.2.0",
  "minimumPosVersion": "7.2.0.0",
  "components": {
    "resources": {
      "supportedUICultures": [ "en-US" ],
      "fallbackUICulture": "en-US",
      "culturesDirectoryPath": "Resources/Strings",
      "stringResourcesFileName": "resources.resjson"
    },
    "extend": {
      "triggers": [
        {
          "triggerType": "PreEndTransaction",
          "modulePath": "TriggerHandlers/PreEndTransactionTrigger"
        }
      ]
    }
  }
}
```

5. Create a new TypeScript file to implement **PreEndTransactionTrigger**, and add the following code.

```
...
```

```

/**
 * Executes the trigger functionality.
 * @param {Triggers.IPreEndTransactionTriggerOptions} options The options provided to the trigger.
 */

public execute(options: Triggers.IPreEndTransactionTriggerOptions):
Promise<ClientEntities.ICancelable {
    console.log("Executing PreEndTransactionTrigger with options " + JSON.stringify(options) + ".");
    let currentCart: ProxyEntities.Cart;
    return this.context.runtime.executeAsync<GetCurrentCartClientResponse>(new
GetCurrentCartClientRequest())
then((getCurrentCartClientResponse:
ClientEntities.ICancelableDataResult<GetCurrentCartClientResponse>):
    Promise<ClientEntities.ICancelableDataResult<GetCurrentCartClientResponse>> => {
        currentCart = getCurrentCartClientResponse.data.result;
        // Gets the current customer.
        let result: Promise<ClientEntities.ICancelableDataResult<GetCurrentCartClientResponse>>;
        if (!ObjectExtensions.isNullOrUndefined(currentCart) &&
!ObjectExtensions.isNullOrUndefined(currentCart.CustomerId)) {
            let getCurrentCustomerClientRequest: GetCustomerClientRequest<GetCustomerClientResponse =
new GetCustomerClientRequest(currentCart.CustomerId);
            result = this.context.runtime.executeAsync<GetCustomerClientResponse>
(getCurrentCustomerClientRequest);
        } else {
            result = Promise.resolve({ canceled: false, data: new GetCustomerClientResponse(null) });
        }
        return result;
    })
.then((getCurrentCustomerClientResponse:
ClientEntities.ICancelableDataResult<GetCustomerClientResponse>):
    Promise<ClientEntities.ICancelableDataResult<ShowMessageDialogClientResponse>> => {
        let currentCustomer: ProxyEntities.Customer = getCurrentCustomerClientResponse.data.result;
        // If the cart is a customer order with a B2B customer, then we display a dialog to determine if
the order should be B2B.
        let result: Promise<ClientEntities.ICancelableDataResult<ShowMessageDialogClientResponse>>;
        if (!ObjectExtensions.isNullOrUndefined(currentCart)
&& currentCart.CustomerOrderModeValue ===
ProxyEntities.CustomerOrderMode.CustomerOrderCreateOrEdit
&& !ObjectExtensions.isNullOrUndefined(currentCustomer)
&& this.isCustomerB2B(currentCustomer)) {
            let yesButton: ClientEntities.Dialogs.IDialogResultButton = {
                id: PreEndTransactionTrigger.DIALOG_YES_BUTTON_ID,
                label: this.context.resources.getString("string_0"), "Yes"
                result: PreEndTransactionTrigger.DIALOG_RESULT_YES
            };
            let noButton: ClientEntities.Dialogs.IDialogResultButton = {
                id: PreEndTransactionTrigger.DIALOG_NO_BUTTON_ID,
                label: this.context.resources.getString("string_1"), "No"
                result: PreEndTransactionTrigger.DIALOG_RESULT_NO
            };
            let showMessageDialogClientRequestOptions: ClientEntities.Dialogs.IMessageDialogOptions = {
                title: this.context.resources.getString("string_2"), "B2B Order"
                subTitle: StringExtensions.EMPTY,
                message: this.context.resources.getString("string_3"), "Do you want to mark this order
as a B2B order?"
                button1: yesButton,
                button2: noButton
            };
            let showMessageDialogClientRequest:
ShowMessageDialogClientRequest<ShowMessageDialogClientResponse> =
new ShowMessageDialogClientRequest(showMessageDialogClientRequestOptions);
            result = this.context.runtime.executeAsync<ShowMessageDialogClientResponse>
(showMessageDialogClientRequest);
        } else {
            result = Promise.resolve({ canceled: false, data: new ShowMessageDialogClientResponse(null)
});
        }
        return result;
    })
});

```

```

.then((showMessageDialogClientResponse:
ClientEntities.ICancelableDataResult<ShowMessageDialogClientResponse>):
    Promise<ClientEntities.ICancelableDataResult<SaveAttributesOnCartClientResponse>> => {
        // Save the B2B attribute value depending on the dialog result.
        let messageDialogResult: ClientEntities.Dialogs.IMessageDialogResult =
showMessageDialogClientResponse.data.result;
        let result: Promise<ClientEntities.ICancelableDataResult<SaveAttributesOnCartClientResponse>>;
        if (!ObjectExtensions.isNullOrUndefined(messageDialogResult)) {
            let attributeValue: ProxyEntities.AttributeTextValue = new
ProxyEntities.AttributeTextValueClass();
            attributeValue.Name = PreEndTransactionTrigger.B2B_CART_ATTRIBUTE_NAME;
            attributeValue.TextValue = messageDialogResult.dialogResult ===
PreEndTransactionTrigger.DIALOG_RESULT_YES?
            PreEndTransactionTrigger.B2B_ATTRIBUTE_VALUE_TRUE :
            PreEndTransactionTrigger.B2B_ATTRIBUTE_VALUE_FALSE;
            let attributeValues: ProxyEntities.AttributeValueBase[] = [attributeValue];
            let saveAttributesOnCartRequest:
SaveAttributesOnCartClientRequest<SaveAttributesOnCartClientResponse> =
                new SaveAttributesOnCartClientRequest(attributeValues);
            result = this.context.runtime.executeAsync(saveAttributesOnCartRequest);
        } else {
            result = Promise.resolve({ canceled: false, data: new
SaveAttributesOnCartClientResponse(null) });
        }
        return result;
    });
}
/**
 * Returns whether or not the given customer is a B2B customer.
 * @param {ProxyEntities.Customer} customer The customer.
 * @returns {boolean} Whether or not the given customer is a B2B customer.
 */
private isCustomerB2B(customer: ProxyEntities.Customer): boolean {
    let isB2B: boolean = false;
    if (!ObjectExtensions.isNullOrUndefined(customer.Attributes)) {
        for (let i: number = 0; i < customer.Attributes.length; i++) {
            let currentAttribute: ProxyEntities.CustomerAttribute = customer.Attributes[i];
            if (currentAttribute.Name === PreEndTransactionTrigger.B2B_CUSTOMER_ATTRIBUTE_NAME) {
                if
(!ObjectExtensions.isNullOrUndefined(currentAttribute.AttributeValue.BooleanValue)) {
                    isB2B = currentAttribute.AttributeValue.BooleanValue;
                }
                break;
            }
        }
    }
    return isB2B;
} } } }

```

# Customer attributes

2/18/2021 • 5 minutes to read • [Edit Online](#)

We extended the attribute framework in Headquarters to support attributes for customers, customer orders, cash-and-carry transactions, and call center orders.

## NOTE

The attributes are read-only. However, in the case of customer or order attributes, you can edit and set values at the level of the individual customer or order.

The new customer attribute framework lets you use configurations to add new fields to the customer master record. Those fields then automatically appear on the **Customer add/edit** or **Customer details** screen in Point of Sale (POS) or Headquarters. After you configure the customer attribute group in the Commerce parameters, POS and Headquarters automatically show the new attribute. No code change or customization is required. You can also use the screen layout designer to configure the customer card on the POS transaction screen so that it shows the customer attributes.

## Why and when you should configure customer attributes

If you want to add new fields to the customer master record, and capture the information in POS or Headquarters, you can use this feature. Previously, to add a new field to the customer master record and show it in POS and Headquarters, you had to create a new extension table in Headquarters and the channel database, and make inline modifications to Commerce runtime (CRT) and POS code. You had to write code in CRT and POS to read/write to the extension fields and show them in POS. You had to handle this in various POS views and scenarios, such as the **Customer details** screen and the **Customer** panel on the transaction screen. In addition, in CRT, you had to handle all insert, select, and update operations. However, the new functionality lets you complete all these steps through configuration so you don't have to write any code or create custom extension tables.

The first version of this functionality doesn't support **datetime** and **reference** attribute types. For those attribute types, you should use extension properties and custom controls to show the details in POS.

## Configure customer attributes in POS and Headquarters

### Define attribute types

1. Select **Product information management > Setup > Categories and attributes > Attribute types**.
2. On the **Attribute types** page, select **New** to add a new attribute type.
3. Enter a name for the attribute type.
4. On the **General** FastTab, in the **Type** field, select the type of data that can be entered for attributes that are assigned to this data type.
5. If the attribute type is **Decimal** or **Integer**, select a unit of measure.
6. To define a fixed list of values for the attribute type, select the **Fixed list** check box. Then, on the **Values** FastTab, add the list of values.

**NOTE**

The **Fixed list** check box is available only for the **Text** attribute type.

Alternatively, to define a range of valid values for the attribute type, select the **Value range** check box. Then, on the **Range** FastTab, enter the valid range of values.

**Define attributes**

1. Select **Product information management > Setup > Categories and attributes > Attributes**.
2. On the **Attributes** page, select **New** to add a new attribute.
3. Enter the name, friendly name, description, and any Help text that should be shown to the user for the attribute.
4. In the **Attribute type** field, select the attribute type to assign to the attribute.
5. Depending on the attribute type, in the **Default value** field, enter the value or the range of values that is shown by default when this attribute is assigned to a customer.
6. Select **Translate** to open the **Text translation** page, where you can enter the name, description, friendly name, and Help text for the attribute in additional languages.
7. Repeat steps 2 through 6 to add more attributes.

**Define an attribute group**

1. Select **Product information management > Setup > Categories and attributes > Attribute groups**.
2. On the **Attribute groups** page, select **New** to add a new attribute group.
3. Enter the name, and then, on the **General** FastTab, enter the friendly name, description, and any Help text for the attribute group.
4. On the **Attributes** FastTab, select **Add** to add attributes to the attribute group. In the **Default value** field, you can enter a default value for the selected attributes.
5. Select **Translate** to open the **Text translation** page, where you can enter the description, friendly name, and Help text for the attribute group in additional languages.

**Link the attribute group to the customers**

1. Select **Retail and Commerce > Headquarters setup > Parameters > Commerce parameters**.
2. On the **General** tab, in the **Customer attribute group** field, select the attribute group that should be shown in POS.

**Run the distribution jobs**

1. Select **Retail and Commerce > Retail and Commerce IT > Distribution schedule**.
2. Select the **Customers job (1010)**, and then, on the Action Pane, select **Run now**. When you're prompted, select **Yes**.
3. Select the **Global configuration job (1110)**, and then, on the Action Pane, select **Run now**. When you're prompted, select **Yes**.

**View customer attributes****Headquarters**

1. Select **Retail and Commerce > Customers > All customers**.
2. On the Action Pane, in **Retail and Commerce**, in the **Attribute** section, select **Retail attributes** to view or edit the attribute values.

**POS**

- Start POS, and then either open the **Customer Add/Edit** screen to set or update the attribute values for the customer, or open the **Customer details** screen to view the configured attributes.

**Show customer attributes in the POS transaction screen**

## Headquarters

1. Select **Retail and Commerce > Channel setup > POS Setup > POS > Screen layouts**.
2. On the **screen layout** page, select **New** to create a new screen layout, or select an existing screen layout.
3. Enter the ID and name for the screen layout.
4. On the **Layout sizes** FastTab, select the **Add** button to add new layout sizes for the POS.
5. In the **Name** field, select the POS screen resolution.
6. On the **Layout sized** FastTab, select the **Layout designer** button.
7. If you're prompted, select **Yes** to download and install the Retail Designer Host by using the **Install/Run** button.
8. When you're prompted, enter the Microsoft Dynamics 365 user name and password to start the designer.
9. After the designer is started, drag the **Customer** card anywhere in the screen layout designer.
10. Right-click the **Customer** card, and then select **Customize**.
11. When the page for the **Customization - Customer** card appears, select the required attributes in the **Available columns** section, and then select the right arrow button (>) to move them to the **Selected columns** section. You can move the attributes up or down by selecting the **Up** or **Down** buttons.
12. When you've finished, select **OK** to save your changes.
13. Close the screen layout designer by selecting the **Close** button (X) in the upper-right corner. When you're prompted, select **Yes** to save your changes.
14. Select **Retail and Commerce > Retail and Commerce IT > Distribution schedule**.
15. Select the **Registers** job (1090), and then, on the Action Pane, select **Run now**. When you're prompted, select **Yes**.

## POS

1. Start POS, and add a customer to a transaction.
2. Open the transaction screen to view the attributes that have been added.

### NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Retail software development kit (SDK) samples

2/18/2021 • 9 minutes to read • [Edit Online](#)

This topic describes the samples that are included in the Retail SDK.

## Override message handler sample

**Scenario:** Sometimes, one of Fabrikam's customers is in the customer relationship management (CRM) system but isn't imported into Microsoft Dynamics 365 Commerce. Therefore, Fabrikam wants to look up the customer from the CRM system and the point of sale (POS). Here are the business requirements:

- Search for customers from the CRM system and the POS.
- Merge the results, and show a unified result set in Retail Modern POS (MPOS).

Here are some situations where you might use the override message handler:

- You want to use a third-party inventory system for stock updates and inquiries.
- You want to integrate with an external tax system for tax calculation.
- You want to integrate with a third-party loyalty system.

Here are the basic tasks in the sample:

1. Override and implement the existing customer search request, because we are changing the existing search behavior so that an external search is performed.
2. After the external search is completed, call the standard search request, and merge both results.

Here is the code for these tasks.

```
public sealed class CustomerSearchRequestHandler : SingleRequestHandler<CustomersSearchRequest,
CustomersSearchResponse>
{
    /// <summary>
    /// Executes the workflow to retrieve customer information.
    /// </summary>
    /// <param name="request">The request.</param>
    /// <returns>The response.</returns>
    protected override CustomersSearchResponse Process(CustomersSearchRequest request)
    {
        ThrowIf.Null(request, "request");
        ThrowIf.Null(request.Criteria, "request.Criteria");
        // Execute custom customer search logic here.
        CustomersSearchResponse externalResponse = this.ExternalCustomerSearch(request.Criteria.Keyword);
        // Execute original customer search logic.
        var requestHandler = new
Microsoft.Dynamics.Commerce.Runtime.Workflow.CustomerSearchRequestHandler();
        CustomersSearchResponse originalResponse =
            request.RequestContext.Runtime.Execute<CustomersSearchResponse>(request, request.RequestContext,
requestHandler, skipRequestTriggers: false);
        return new
CustomersSearchResponse(externalResponse.Customers.Union(originalResponse.Customers).AsPagedResult());
    }
}
```

The full sample code is in the RetailSDK\SampleExtensions\CommerceRuntime\Extensions.CustomerSearchSample folder of the software development kit (SDK).

## Best practice

If you're planning to completely change the behavior of an existing request or response, or if you want to use your logic in addition to the standard logic, override the standard message handler.

# Request handler triggers and extension properties sample

**Scenario:** Fabrikam wants to collect customer email preferences for email marketing. Here are the business requirements:

- Enable a customer's email preferences to be collected and updated from the POS.
- A customer's email preferences should become effective immediately.

Here are some situations where you might use extension properties:

- You want to extend entities such as the customer and sales order, but you don't want to create a new separate entity.
- As new entity fields are read from or written to the database, they should be sent between the commerce runtime (CRT) and the POS, and updated in the client.
- You want temporary internal flags that can be used to control the flow of custom logic.
- You want to set custom receipt fields that the receipt customization will access when receipts are generated.

The following steps show the CRT code changes. For MPOS and the channel database, see the full sample. Notice that the following samples differ from previous code, where changes to the standard database artifacts were required. (For example, to expose new columns as extension properties, changes to the view were required. To receive a list of extension properties and update these properties together with standard fields, changes to the stored procedure were required.) Eventually, as we move to a model that doesn't have inline changes, merge conflicts should not occur even when the database is updated. Therefore, our new recommendation is that you make separate database calls to read, write, and update entities.

1. **Read the entity.** Implement the post-trigger for `GetCustomerDataRequest`, read the value from channel database, and add the value to the extension property.

```

public class GetCustomerTriggers : IRequestTrigger
{
    public IEnumerable<Type> SupportedRequestTypes
    {
        get { return new[] { typeof(GetCustomerDataRequest) }; }
    }
    public void OnExecuted(Request request, Response response)
    {
        // Check if default handler found a customer.
        var customer = ((SingleEntityDataServiceResponse<Customer>)response).Entity;
        if (customer == null)
        {
            return;
        }
        // Read from a custom view mapped to a custom table.
        var query = new SqlPagedQuery(QueryResultSettings.SingleRecord)
        {
            Select = new ColumnSet(new string[] { "EMAILOPTIN" }),
            From = "CUSTOMEREXTENSIONVIEW",
            Where = "ACCOUNTNUM = @accountNum AND DATAAREAID = @dataAreaId"
        };
        query.Parameters["@accountNum"] = customer.AccountNumber;
        query.Parameters["@dataAreaId"] =
request.RequestContext.GetChannelConfiguration().InventLocationDataAreaId;
        using (var databaseContext = new SqlServerDatabaseContext(request))
        {
            // Use ExtensionEntity which will map all columns to extension properties.
            ExtensionsEntity extensions = databaseContext.ReadEntity<ExtensionsEntity>
(query).FirstOrDefault();
            var emailOptIn = extensions != null ? extensions.GetProperty("EMAILOPTIN") : null;
            // If the EmailOptIn is found, set it at a new extension property at the Customer.
            if (emailOptIn != null)
            {
                customer.SetProperty("EMAILOPTIN", emailOptIn);
            }
        }
    }
}

```

2. **Write the entity.** Override the handler for `CreateOrUpdateCustomerDataRequest` to run the original request handler and the custom stored procedure inside a transaction scope. If the database transaction isn't required, a post-trigger suffices here.

```

protected override SingleEntityDataServiceResponse<Customer>
Process(CreateOrUpdateCustomerDataRequest request)
{
    using (var databaseContext = new SqlServerDatabaseContext(request))
        using (var transactionScope = new TransactionScope())
            {
                // Execute original functionality to save the customer.
                var requestHandler = new
Microsoft.Dynamics.Commerce.Runtime.DataServices.SqlServer.CustomerSqlServerDataService();
                var response = (SingleEntityDataServiceResponse<Customer>)requestHandler.Execute(request);
                // Execute additional functionality to save the customer's extension properties.
                if (!request.Customer.ExtensionProperties.IsNullOrEmpty())
                    {
                        // The stored procedure will determine which extension properties are saved to which
tables.
                        ParameterSet parameters = new ParameterSet();
                        parameters["@TVP_EXTENSIONPROPERTIESTABLETYPE"] = new
ExtensionPropertiesTableType(request.Customer.RecordId,
request.Customer.ExtensionProperties).DataTable();
                        databaseContext.ExecuteStoredProcedureNonQuery("UPDATECUSTOMEREXTENSIONPROPERTIES",
parameters);
                    }
                transactionScope.Complete();
                return response;
            }
}

```

Before you try this sample, be sure to create the custom tables, views, and stored procedures in the channel database. Additionally, make the relevant changes to MPOS. The full sample code, together with additional comments, is in the RetailSDK\SampleExtensions\CommerceRuntime\Extensions.EmailPreferenceSample folder of the SDK. For information about how to create custom database artifacts, see the RetailSDK\Documents\SampleExtensionsInstructions\EmailPreference folder of the SDK.

#### NOTE

The above code sample and the sample script in the RetailSDK\Documents\SampleExtensionsInstructions\EmailPreference folder use [crt].EXTENSIONPROPERTIESTABLETYPE. Starting in version 7.3 we no longer support using crt or ax schema objects/data types in ext schema. You must create your custom extension table property type in ext schema and use it.

#### Best practice

Because the order of triggers isn't guaranteed when the triggers are chained, and because of the internal cache mechanism, the pre-triggers should not change the *request* message, and the post-triggers should not change the *response* message. Extension properties are allowed, because no core properties are being changed. You should use pre-triggers and post-triggers to handle extension properties. You should also use pre-triggers to do validation and post-triggers to do additional actions.

## Custom fields and custom receipt types sample

**Scenario:** Fabrikam wants to print a special receipt whenever products that have a warranty are sold. Sales receipts should include the warranty expiration date, the warranty ID, and other information. Here are the business requirements:

- Print special receipts.
- Print additional warranty information on sale receipts.

The following steps shows the HQ configuration and CRT code changes for the custom fields:

# Configure Headquarters for custom fields

At the headquarters (HQ), create two custom receipt fields: **EXPIRATIONDATE** for the warranty expiration date and **WARRANTYID** for the warranty ID. Add these fields to the receipt format layout.

1. Sign in to HQ.
2. Go to **Retail and Commerce > Channel setup > POS setup > POS profiles > Language text**.
3. On the **POS** tab, select **Add** to add a new POS language text.

The text that appears in the **Receipt** panel can be localized. Therefore, you can create multiple texts in different languages for the same text ID. Here is an example.

LANGUAGE ID	TEXT ID	TEXT
en-US	1	WARRANTYID
en-UK	1	WARRANTYID

4. On the Action Pane, select **Save** to save your changes.
5. Go to **Retail and Commerce > Channel setup > POS setup > POS profiles > Custom fields**.
6. On the Action Pane, select **New** to add a new custom field, and specify the following information:
  - a. In the **Name** field, enter the name of the custom field.
  - b. In the **Type** field, select **Receipt**.
  - c. In the **Caption text ID** field, specify the text ID that you used in step 3.

Here is an example.

NAME	TYPE	CAPTION TEXT ID
WARRANTYID	Receipt	1

7. On the Action Pane, select **Save** to save your changes.
8. Go to **Retail and Commerce > Channel setup > POS setup > POS > Receipt formats**.
9. Select an existing or create a new receipt format and then select **Designer** on the Action Pane.
10. If you're prompted to confirm that you want to open the application, select **Open**, and then follow the installation instructions.
11. After the designer is installed, you're asked for Azure Active Directory (Azure AD) credentials. Enter the information to start the designer.
12. In the designer, drag and drop the Custom field from the left pane to the receipt designer.
13. Save the changes.
14. Go to **Retail and Commerce > Retail and Commerce IT > Distribution schedule**.
15. Select the **Channel configuration (1070)** job, and then select **Run now**.

## Sample code to implement Custom fields

To add the custom fields to the sales receipts or any receipt format, implement `GetSalesTransactionCustomReceiptFieldServiceRequest` and the business logic for the custom fields in

CRT, as shown in the following code.

```
public IEnumerable<Type> SupportedRequestTypes
{
    get
    {
        return new[] { typeof(GetSalesTransactionCustomReceiptFieldServiceRequest) };
    }
}
public Response Execute(Request request)
{
    Type requestedType = request.GetType();
    if (requestedType == typeof(GetSalesTransactionCustomReceiptFieldServiceRequest))
    {
        return this.GetCustomReceiptFieldForSalesTransactionReceipts(
(GetSalesTransactionCustomReceiptFieldServiceRequest)request);
    }
    throw new NotSupportedException(string.Format("Request '{0}' is not supported.", request.GetType()));
}
```

### Add the business logic for the custom fields

```
private GetCustomReceiptFieldServiceResponse GetCustomReceiptFieldForSalesTransactionReceipts(
GetSalesTransactionCustomReceiptFieldServiceRequest request)
{
    string receiptFieldName = request.CustomReceiptField;
    string returnValue = null;
    switch (receiptFieldName)
    {
        case "WARRANTYID":
            {
                // Write your logic
            }
            break;
        case "EXPIRATIONDATE":
            {
                // Write your logic
            }
            break;
    }
    return new GetCustomReceiptFieldServiceResponse(returnValue);
}
```

### Custom receipt type configuration in HQ

1. Go to **Retail and Commerce > Channel setup > POS setup > POS > Receipt formats**.
2. Create new Receipt format and then select the **Receipt type** and choose one of the CustomReceiptType(1...20).
3. Save the changes.
4. Select **Designer** on the Action Pane.
5. If you're prompted to confirm that you want to open the application, select **Open**, and then follow the installation instructions.
6. After the designer is installed, you're asked for Azure Active Directory (Azure AD) credentials. Enter the information to start the designer.
7. In the designer, drag and drop the required receipt fields from the left pane to the receipt designer.
8. Save the changes.
9. Go to **Retail and Commerce > Retail and Commerce IT > Distribution schedule**.
10. Select the **Channel configuration (1070) job**, and then select **Run now**.

### Sample code to implement Custom receipt type

To add logic for the new receipt type, implement `GetCustomReceiptsRequest` in CRT.

```
protected override GetReceiptResponse Process(GetCustomReceiptsRequest request)
{
    Collection<Receipt> result = new Collection<Receipt>();
    // 2. Now we can handle any additional receipt here.
    switch (request.ReceiptRetrievalCriteria.ReceiptType)
    {
        // An example of getting custom receipts.
        case ReceiptType.CustomReceipt1:
            {
                IEnumerable<Receipt> customReceipts = this.GetCustomReceipts(salesOrder,
request.ReceiptRetrievalCriteria);
                result.AddRange(customReceipts);
            }
            break;
        default:
            // Add more logic to handle more types of custom receipt types.
            break;
    }
    return new GetReceiptResponse(new ReadOnlyCollection<Receipt>(result));
}
```

The full sample code is available in the `RetailSDK\SampleExtensions\CommerceRuntime\Extensions.ReceiptsSample` folder.

#### NOTE

You should call the printing of the custom receipt type from the client. For more information, see [Printing custom receipt from POS](#).

#### Best practice

Avoid making database calls for each custom receipt field. Instead, use extension properties that were previously set on entities. Custom receipt types can be called by any logic (per sales line, one time per some condition). See the sample for a more complete scenario.

#### NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Log extension events to Application Insights

2/18/2021 • 6 minutes to read • [Edit Online](#)

This topic explains how to log events to [Customer Application Insights](#) from Commerce runtime (CRT) and POS extensions.

## Log an event to Application Insights

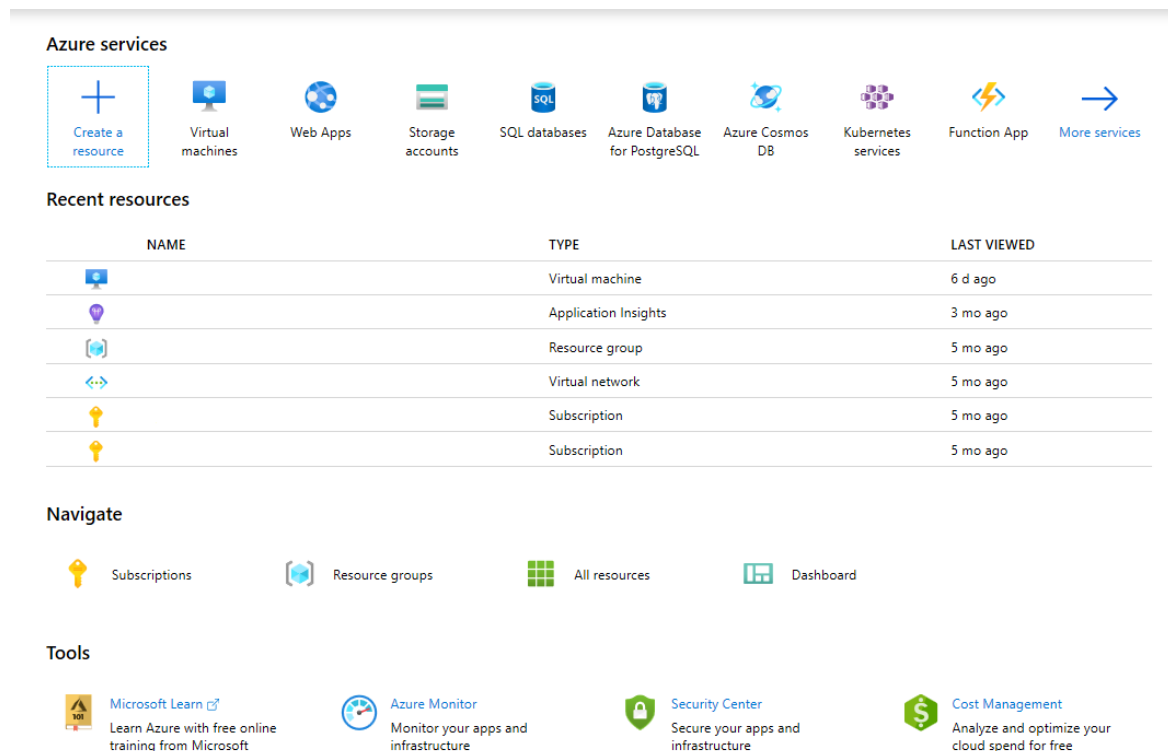

1. Set up Application Insights in the [Microsoft Azure portal](#), and generate the instrumentation key.
2. Extend CRT to log events to Application Insights by using the instrumentation key that you generated.

### NOTE

The `RetailLogger` class is no longer supported. Existing extensions that use this class must be migrated to the new model.

## Set up and configure Application Insights in Azure

1. Open the [Azure portal](#), and sign in by using your Azure subscription credentials.
2. Select **Create a resource**.

**Azure services**

- Create a resource
- Virtual machines
- Web Apps
- Storage accounts
- SQL databases
- Azure Database for PostgreSQL
- Azure Cosmos DB
- Kubernetes services
- Function App
- More services

**Recent resources**

NAME	TYPE	LAST VIEWED
	Virtual machine	6 d ago
	Application Insights	3 mo ago
	Resource group	5 mo ago
	Virtual network	5 mo ago
	Subscription	5 mo ago
	Subscription	5 mo ago

**Navigate**

- Subscriptions
- Resource groups

### Application Insights

Monitor web app performance and usage

[Basics](#) [Tags](#) [Review + create](#)

Create an Application Insights resource to monitor your live web application. With Application Insights, you have full observability into your application across all components and dependencies of your complex distributed architecture. It includes powerful analytics tools to help you diagnose issues and to understand what users actually do with your app. It's designed to help you continuously improve performance and usability. It works for apps on a wide variety of platforms including .NET, Node.js and Java EE, hosted on-premises, hybrid, or any public cloud. [Learn More](#)

Deployment details (Download)

Next steps

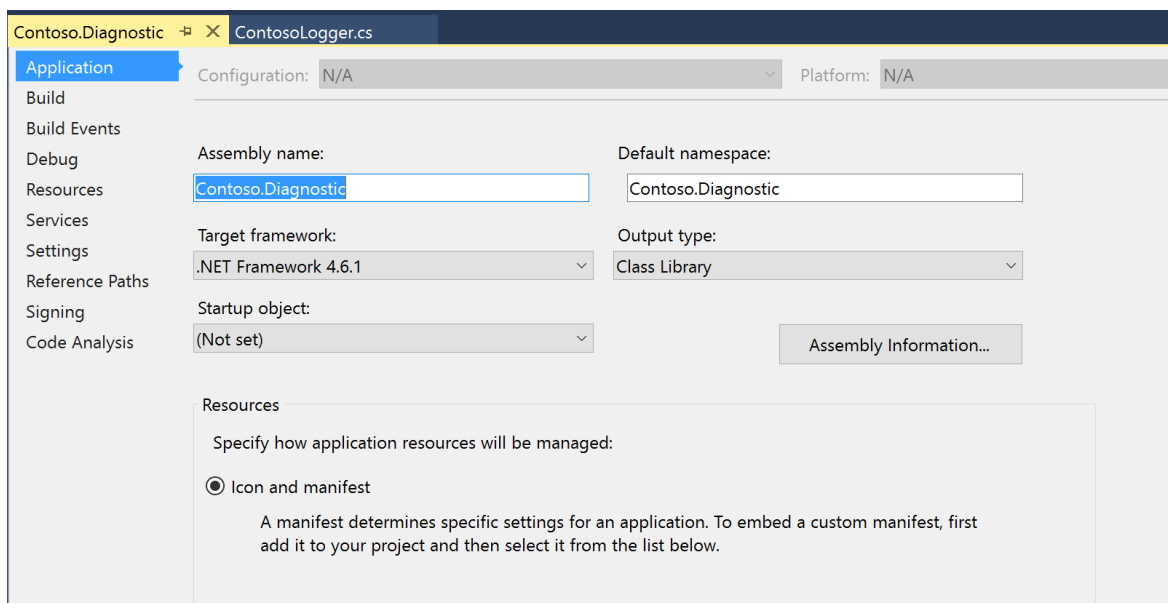

Go to resource

8. Go to the resource, and copy the **Instrumentation Key** value. You will use this value in the CRT code or CRT extension configuration file.

## Extend the CRT extension project to log events to Application Insights

1. Create a new C# class library project, and name it Contoso.Diagnostic.

2. Add references to the following libraries:

- Microsoft.ApplicationInsights
- Netstandard
- Microsoft.Dynamics.Commerce.Runtime.Framework

### NOTE

To install the **Microsoft.ApplicationInsights** assembly reference, install the [Application Insights SDK for ASP.NET Core](#). The reference to **Microsoft.Dynamics.Commerce.Runtime.Framework** can be added from the `..\RetailSDK\Reference` folder.

3. Add a new class file that is named **ContosoLogger**, and copy the following code into it.

```

using Microsoft.ApplicationInsights;
using Microsoft.ApplicationInsights.Extensibility;
using Microsoft.Dynamics.Commerce.Runtime;
using Microsoft.Dynamics.Commerce.Runtime.Extensions;
namespace Contoso.Diagnostic
{
    public static class ContosoLogger
    {
        private static readonly object lockObject = new object();
        private static TelemetryClient client = null;
        public static TelemetryClient GetLogger(RequestContext context)
        {
            if (client == null)
            {
                lock (lockObject)
                {
                    if (client == null)
                    {
                        string key =
context.Runtime.Configuration.GetSettingValue("ext.AppInsightsKey") ?? string.Empty;
                        client = new TelemetryClient(new TelemetryConfiguration(key));
                    }
                }
            }
            return client;
        }
    }
}

```

4. Build the project, and copy the output library and the **Microsoft.ApplicationInsights.dll** file to the **..\RetailServer\webroot\bin\Ext** folder for manual deployment and testing.
5. In the **..\RetailServer\webroot\bin\Ext** folder, open the **CommerceRuntime.Ext.config** file, and update the **<settings>** section with the Applications Insights instrumentation key that you generated earlier. Here is an example.

```
<add name="ext.AppInsightsKey" value="xxxxxxx"/>
```

6. Restart your Commerce Scale Unit.

## Consume the logger in the CRT extension

1. To consume the **ContosoLogger** in the extension, add the **ContosoDiagnostic** and **Microsoft.ApplicationInsights** assembly references to the extension project.
2. To log events, use the **TraceTelemetry** class, and create the traces. Here is an example.

```

using Contoso.Diagnostic;
using Microsoft.ApplicationInsights.DataContracts;
var trace = new TraceTelemetry("CRT executing request", SeverityLevel.Information);
trace.Properties.Add("CustomDimensionColumn1", request.RequestContext.GetTerminalId().ToString());
trace.Properties.Add("CustomDimensionColumn2", "CRT demo - Save Cart request");
ContosoLogger.GetLogger(request.RequestContext).TrackTrace(trace);

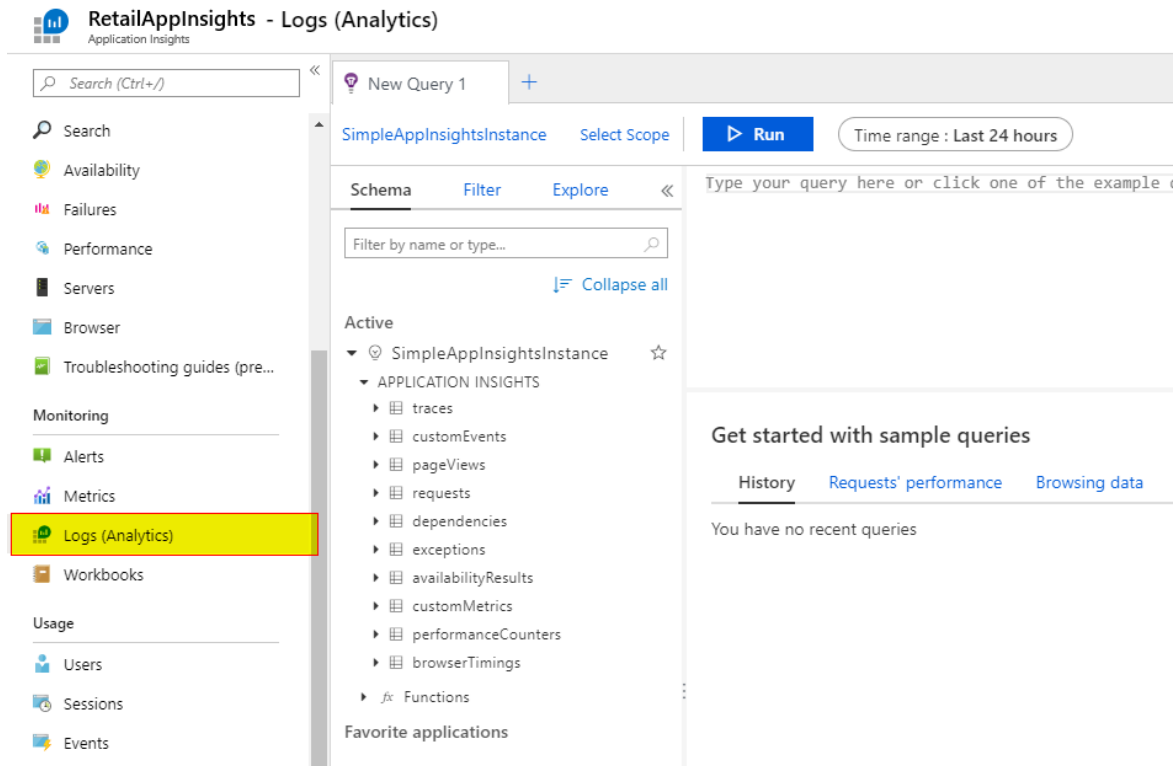

```

### NOTE

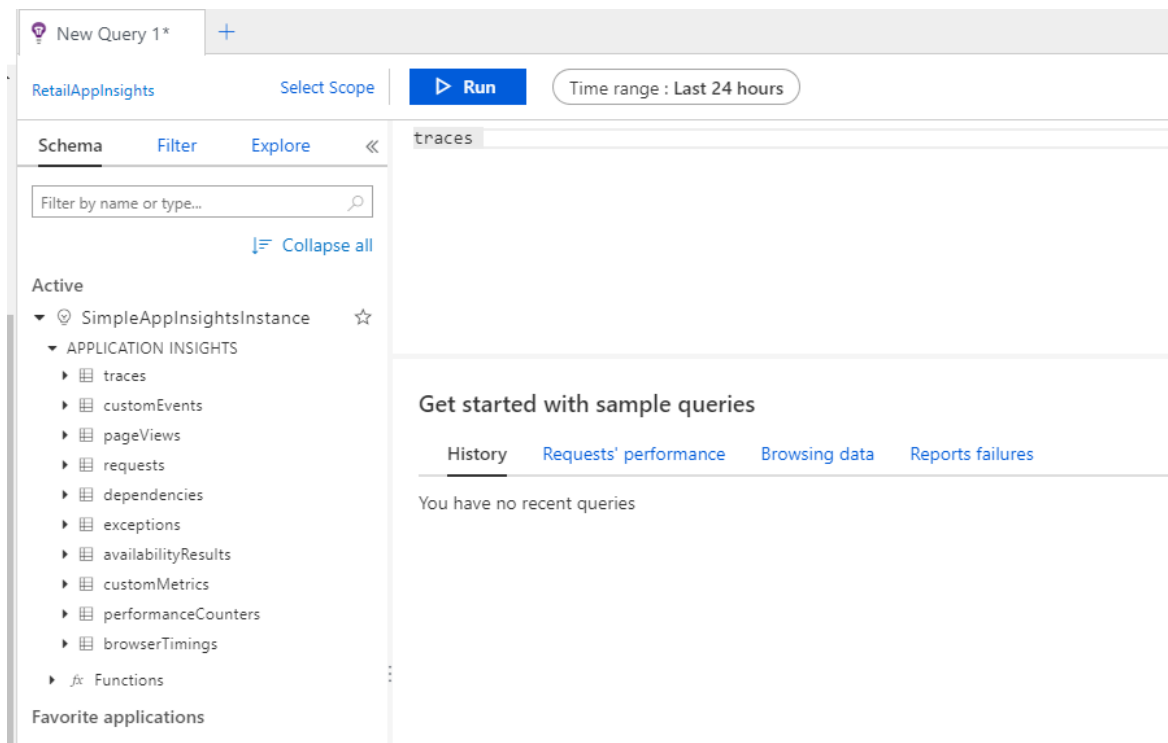

Trace properties are custom dimensions that you can easily add to query the traces.

# Validate the trace events

1. Open the [Azure portal](#), and sign in by using your Azure subscription credentials.
2. Go to the Application Insights instance, and then, under **Monitoring**, select **Logs (Analytics)** to open a new query editor.

3. On the **Schema** tab, double-click **traces** to add it to the query editor. The default time range is **Last 24 hours**.

4. Select **Run** to run the query. The logged event will appear in the results.

Completed. Showing results from the last 24 hours.

TABLE | CHART | Columns ▾

Drag a column header and drop it here to group by that column

timestamp [UTC]	message	severityLevel	itemType	customDimensions	customMeasurements	operation_Name
> 10/24/2019, 8:19:47.033 PM	SaveCartRequest OnExecuting	1	trace	{"TerminalID":"HOUSTON-17"}		
> 10/24/2019, 8:19:54.573 PM	SaveCartRequest OnExecuted	1	trace	{"TerminalID":"HOUSTON-17"}		
> 10/24/2019, 8:17:42.193 PM	SaveCartRequest OnExecuting	1	trace	{"TerminalID":"HOUSTON-17"}		
> 10/24/2019, 8:17:46.136 PM	SaveCartRequest OnExecuted	1	trace	{"TerminalID":"HOUSTON-17"}		

## Build the deployable package

For detailed information about how to build deployable packages, see [Create deployable packages](#).

1. Copy the **Contoso.Diagnostic** and **Microsoft.ApplicationInsights** assemblies to the **\RetailSDK\References** folder.
2. Update the **BuildTools\Customization.settings** file, and add the following entries in the **<ItemGroup>** section.

```
<ISV_CommerceRuntime_CustomizableFile Include="$(SdkReferencesPath)\Contoso.Diagnostic.dll" />
<ISV_CommerceRuntime_CustomizableFile
  Include="$(SdkReferencesPath)\Microsoft.ApplicationInsights.dll" />;
```

3. Open an MSBuild **Command Prompt** window for Microsoft Visual Studio 2015, and run the **build** command in the root of your Retail SDK folder.
4. Enter the following command to generate the deployable package.

```
msbuild /t:rebuild
```

5. In the **RetailSDK\Packages\RetailDeployablePackage** folder, find the deployable package. Go to the **content.folder** folder, and make sure that your three files are in the package (**Packages\RetailDeployablePackage\content.folder\RetailServer\Code\bin\ext**).
6. Upload the deployable package to your Shared asset library in Microsoft Dynamics Lifecycle Services (LCS).
7. In LCS, open your environment's main page, and select **Environment Features > Retail and Commerce > Manage**.
8. Select **Apply Extension**, and select the extension from your library.
9. After the extension has been successfully deployed, open an instance of Modern POS (MPOS) or POS (CPOS) that has been activated against the Commerce Scale Unit.
10. Run the extension scenario that that uses custom Application Insights logging.
11. Refresh the query in Application Insights to verify that the traces from the extension are logged correctly.

## Log events to Application Insights in the POS extension projects

1. In the **RetailSDK\POS\Extensions** folder, create a new folder named **Libraries**.
2. Open a command prompt and navigate to the **Libraries** folder.
3. Install **npm**. The **npm** package can be downloaded and installed from [OpenJS](#).
4. Run this command to install the **npm** package for the JavaScript Application Insights package.

```
npm i --save @microsoft/applicationinsights-web
```

After the package is installed, the **POS/Extensions/Libraries** folder should contain the **node\_modules** folder. The **node\_modules** folder contains the Application Insights library files.

5. Check that the file **POS/Extensions/Libraries/node\_modules/@microsoft/applicationinsights-web/dist/applicationinsights-web.js** exists in the library.

The file name might change in future versions of the Application Insights library. If the path changes, update the library path in steps 8 and 10 to a path that points to the main Application Insights library.

6. Open **ModernPOS.sln** or **CloudPos.sln** from **RetailSDK\POS**.
7. Open the **tsconfig.json** file from the **POS.Extensions** project. Under the **exclude** section, add an entry to the **Libraries** folder.

```
"exclude": [  
  "Libraries"  
],
```

8. Open the **tsconfig.json** file from the **POS.Extensions** project. Under the **compilerOptions** section, add the following properties.

```
"baseUrl": "./",  
"paths": {  
  "applicationinsights-web": [ "Libraries/node_modules/@microsoft/applicationinsights-  
web/dist/applicationinsights-web" ]  
}
```

9. Edit the **Pos.Extensions.csproj** file in the **CopyPosExtensionsFiles** section. Add the following targets to copy the Application Insights library to the POS application, so that the targets can be consumed by the extension code.

```
<JavaScriptFileList Include="Libraries\\**\\*.js">  
  <InProject>false</InProject>  
  <Visible>false</Visible>  
</JavaScriptFileList>
```

10. Include the following node in the **manifest.json** file of the POS extension folder (package) that is consuming the Application Insights library.

```
{  
  "dependencies": [  
    {  
      "alias": "applicationinsights-web",  
      "format": "amd",  
      "modulePath": "../Libraries/node_modules/@microsoft/applicationinsights-  
web/dist/applicationinsights-web"  
    }  
  ]  
}
```

The Application Insights library is now ready to be consumed and used in POS.

## Consume the library and log events

1. Open the **ModernPOS.sln** or **CloudPos.sln** solution from **RetailSDK\POS**.
2. Create a new TypeScript file inside the POS extension folder (package) and name it **AppInsights.ts**.
3. Copy the following code to the file. The code is used by the extensions to track events using Application Insights. Use the instrumentation key created in Azure App Insights.

```
import { ApplicationInsights } from "applicationinsights-web";

/**
 * Example implementation of an Application Insights singleton that can be used to log events and
 * metrics on Application Insights.
 */
export class AppInsights {
    private static _instance: AppInsights = null;
    private _applicationInsights: ApplicationInsights = null;

    /**
     * Gets a global reference to an Application Insights reference that can be used by other
     * extension code.
     * @returns {ApplicationInsights} The ApplicationInsights instance that can be used to log
     * events.
     */
    public static get instance(): ApplicationInsights {
        if (AppInsights._instance === null) {
            AppInsights._instance = new AppInsights();
        }

        return AppInsights._instance._applicationInsights;
    }

    /**
     * Initializes a new instance of AppInsights.
     */
    constructor() {
        this._applicationInsights = new ApplicationInsights({
            config: {
                instrumentationKey: 'YOUR_INSTRUMENTATION_KEY_GOES_HERE'
                /* ...Other Configuration Options... */
            }
        });
        this._applicationInsights.loadAppInsights();
    }
}
```

4. In the extension code, log the events by calling the AppInsights class as shown in the following code example.

```
AppInsights.instance.trackEvent({
    name: "extensionTest",
    properties: {
        "property1": "value1",
        "property2": "value2",
    },
    measurements: {
        "measurement1": 1,
        "measurement2": 2,
    },
});
```

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Create asynchronous Commerce (CRT) APIs in your business logic

2/18/2021 • 9 minutes to read • [Edit Online](#)

## NOTE

This topic applies to Microsoft Dynamics 365 Commerce version 10.0.10 and later.

This topic explains how to create new business logic (application programming interfaces, or APIs) for the Commerce Runtime (CRT) by using the new asynchronous framework. The Commerce API framework now supports an asynchronous programming model for extensions and out-of-box Commerce handlers.

Before this framework enhancement was added, requests could be run only synchronously. Long operations, like input/output (I/O) operations, database queries, or network requests, blocked the execution thread. Now that support for the asynchronous model has been added to the Commerce runtime (CRT), you can use asynchronous versions of these operations. Asynchronous requests unblock the execution thread.

The Commerce API framework now supports the **Task** and **Task<T>** classes that are supported by the **async** and **await** keywords for the extension CRT request handlers. You should use the asynchronous Commerce API framework for all new extension APIs and the out-of-box asynchronous Commerce API in extensions.

## Async classes/interface added in the Commerce API framework:

The following asynchronous classes and interfaces were added in the Commerce API framework.

CLASS/INTERFACE	DESCRIPTION
SingleAsyncRequestHandler	The base class for asynchronous handlers that support only one request.
IRequestHandlerAsync	The interface for the asynchronous request handler.
IRequestTriggerAsync	The interface for the request trigger.
CommerceControllerAsync	The base class for asynchronous extension Retail server controller class.
DatabaseContext	The base class for asynchronous database execution methods.

The following asynchronous methods were added in the Commerce API framework.

CLASS/INTERFACE	METHOD	DESCRIPTION
SingleAsyncRequestHandler	Task<TResponse> Process	The execute method that will be overridden by each derived class.
	Task<Response> Execute	The method that represents the entry point of the request handler.

CLASS/INTERFACE	METHOD	DESCRIPTION
IRequestHandlerAsync	Task<Response> Execute (Request request)	The interface for the asynchronous request handler.
IRequestTriggerAsync	Task OnExecuting(Request request)	The method that is invoked before the request has been processed by <b>IRequestHandler</b> .
IRequestTriggerAsync	Task OnExecuted(Request request, Response response)	The method that is invoked after the request has been processed by <b>IRequestHandler</b> .
DatabaseContext	async Task<Tuple<int, PagedResult>> ExecuteStoredProcedureAsync(string procedureName, ParameterSet parameters, QueryResultSettings resultSettings)	The method that executes the stored procedure using the specified parameters.
DatabaseContext	async Task<ReadOnlyCollection> ExecuteNonPagedStoredProcedureAsync(string procedureName, ParameterSet parameters, QueryResultSettings resultSettings) where T : CommerceEntity, new()	The method that executes the stored procedure using the specified parameters. The execution is non-paginated.
DatabaseContext	async Task<Tuple<PagedResult, ReadOnlyCollection>> ExecuteStoredProcedureAsync<T1, T2>(string procedureName, ParameterSet parameters, QueryResultSettings resultSettings) where T1 : CommerceEntity, new() where T2 : CommerceEntity, new()	The method that executes the specified stored procedure.
DatabaseContext	async Task<Tuple<int, Tuple<PagedResult, ReadOnlyCollection>>> ExecuteStoredProcedureAsync<T1, T2>(string procedureName, ParameterSet parameters, ParameterSet outputParameters, QueryResultSettings resultSettings) where T1 : CommerceEntity, new() where T2 : CommerceEntity, new()	The method that executes the specified stored procedure.
DatabaseContext	async Task<Tuple<PagedResult, ReadOnlyCollection, ReadOnlyCollection>> ExecuteStoredProcedureAsync<T1, T2, T3>(string procedureName, ParameterSet parameters, QueryResultSettings resultSettings) where T1 : CommerceEntity, new() where T2 : CommerceEntity, new() where T3 : CommerceEntity, new()	The method that executes the specified stored procedure.

CLASS/INTERFACE	METHOD	DESCRIPTION
DatabaseContext	<pre> async Task&lt;Tuple&lt;int, Tuple&lt;PagedResult, ReadOnlyCollection, ReadOnlyCollection&gt;&gt;&gt; ExecuteStoredProcedureAsync&lt;T1, T2, T3&gt;(string procedureName, ParameterSet parameters, ParameterSet outputParameters, QueryResultSettings resultSettings) where T1 : CommerceEntity, new() where T2 : CommerceEntity, new() where T3 : CommerceEntity, new() </pre>	The method that executes the specified stored procedure.
DatabaseContext	<pre> async Task&lt;Tuple&lt;PagedResult, ReadOnlyCollection, ReadOnlyCollection, ReadOnlyCollection&gt;&gt; ExecuteStoredProcedureAsync&lt;T1, T2, T3, T4&gt;(string procedureName, ParameterSet parameters, QueryResultSettings resultSettings) where T1 : CommerceEntity, new() where T2 : CommerceEntity, new() where T3 : CommerceEntity, new() where T4 : CommerceEntity, new() </pre>	The method that executes the specified stored procedure.
DatabaseContext	<pre> async Task&lt;Tuple&lt;int, Tuple&lt;PagedResult, ReadOnlyCollection, ReadOnlyCollection, ReadOnlyCollection&gt;&gt;&gt; ExecuteStoredProcedureAsync&lt;T1, T2, T3, T4&gt;(string procedureName, ParameterSet parameters, ParameterSet outputParameters, QueryResultSettings resultSettings) where T1 : CommerceEntity, new() where T2 : CommerceEntity, new() where T3 : CommerceEntity, new() where T4 : CommerceEntity, new() </pre>	The method that executes the specified stored procedure.

CLASS/INTERFACE	METHOD	DESCRIPTION
DatabaseContext	async Task<Tuple<PagedResult, ReadOnlyCollection, ReadOnlyCollection, ReadOnlyCollection, ReadOnlyCollection, ReadOnlyCollection, Tuple<ReadOnlyCollection>>>> ExecuteStoredProcedureAsync<T1, T2, T3, T4, T5, T6, T7, T8>(string procedureName, ParameterSet parameters, QueryResultSettings resultSettings) where T1 : CommerceEntity, new() where T2 : CommerceEntity, new() where T3 : CommerceEntity, new() where T4 : CommerceEntity, new() where T5 : CommerceEntity, new() where T6 : CommerceEntity, new() where T7 : CommerceEntity, new() where T8 : CommerceEntity, new()	The method that executes the specified stored procedure.
DatabaseContext	Task<Tuple<int, Tuple<PagedResult, ReadOnlyCollection, ReadOnlyCollection, ReadOnlyCollection, ReadOnlyCollection, ReadOnlyCollection, Tuple<ReadOnlyCollection>>>>> ExecuteStoredProcedureAsync<T1, T2, T3, T4, T5, T6, T7, T8>(string procedureName, ParameterSet parameters, ParameterSet outputParameters, QueryResultSettings resultSettings) where T1 : CommerceEntity, new() where T2 : CommerceEntity, new() where T3 : CommerceEntity, new() where T4 : CommerceEntity, new() where T5 : CommerceEntity, new() where T6 : CommerceEntity, new() where T7 : CommerceEntity, new() where T8 : CommerceEntity, new()	The method that executes the specified stored procedure.
DatabaseContext	Task<ReadOnlyCollection> ExecuteStoredProcedureScalarCollectionAsync(string procedureName, ParameterSet parameters, QueryResultSettings resultSettings)	Executes a query that returns a collection of single results.
DatabaseContext	Task ExecuteStoredProcedureNonQueryAsync(string procedureName, ParameterSet parameters, QueryResultSettings resultSettings)	The method that executes the specified stored procedure with the specified parameters.

CLASS/INTERFACE	METHOD	DESCRIPTION
DatabaseContext	Task ExecuteStoredProcedureScalarAsync(string procedureName, ParameterSet parameters, QueryResultSettings resultSettings)	The method that executes the stored procedure using the specified parameters and returns the return value.
DatabaseContext	Task OnExecuting(Request request)	Executes the stored procedure using the specified parameters and returns the return value.
DatabaseContext	Task ExecuteStoredProcedureScalarAsync(string procedureName, ParameterSet parameters, ParameterSet outputParameters, QueryResultSettings resultSettings)	The method that executes the stored procedure using the specified parameters and returns the return value.
DatabaseContext	Task<PagedResult> ReadEntityAsync(IDatabaseQuery query) where T : CommerceEntity, new()	The method that reads an entity from the database.
DatabaseContext	Task ExecuteNonQueryAsync(IDatabaseQuery query)	The method that executes a query that has no output.
DatabaseContext	Task ExecuteScalarAsync(IDatabaseQuery query)	The method that executes a query that has no output.
DatabaseContext	Task<ReadOnlyCollection> ExecuteScalarCollectionAsync(IDatabaseQuery query)	The method that executes a query that returns a collection of single results.

Asynchronous execution is supported for these scenarios:

- New Commerce APIs
  - Asynchronous Commerce Runtime API
  - Asynchronous Retail server controller
- Overrides of the Commerce API handler that is running
- Pre-triggers and post-triggers

## Create a new asynchronous Commerce Runtime API

To create a new asynchronous Commerce API, you must create three classes:

- Create the request class by implementing the **Request** class.
- Create the asynchronous response class by implementing the **Response** class.
- Create the asynchronous handler class.

To create the classes, follow these steps.

1. Create the request class.

```

namespace Contoso
{
    namespace Commerce.Runtime.AsyncRequestSample.Messages
    {
        using System.Runtime.Serialization;
        using System;
        using Microsoft.Dynamics.Commerce.Runtime.Messages;

        /// <summary>
        /// Sample request for AsyncRequestSampleRequest
        /// </summary>
        [DataContract]
        public sealed class AsyncRequestSampleRequest : Request
        {
            /// <summary>
            /// Initializes a new instance of the <see cref="AsyncRequestSampleRequest"/> class.
            /// </summary>
            public AsyncRequestSampleRequest()
            {
            }

        }
    }
}

```

## 2. Create the response class.

```

namespace Contoso
{
    namespace Commerce.Runtime.AsyncSample.Messages
    {
        using System.Runtime.Serialization;
        using Microsoft.Dynamics.Commerce.Runtime.Messages;
        using Microsoft.Dynamics.Commerce.Runtime.DataModel;

        /// <summary>
        /// Defines a simple response class .
        /// </summary>
        [DataContract]
        public sealed class AsyncSampleResponse : Response
        {
            /// <summary>
            /// Initializes a new instance of the <see cref="AsyncSampleResponse"/> class.
            /// </summary>
            /// <param name="CustomerRec">Customer.</param>
            public AsyncSampleResponse(Customer customer)
            {
                this.CustomerRec = customer;
            }

            /// <summary>
            /// Gets the customer related to the request.
            /// </summary>
            [DataMember]
            public Customer CustomerRec { get; private set; }

        }
    }
}

```

## 3. Create the asynchronous handler.

```

using Contoso.Commerce.Runtime.AsyncSample.Messages;
using System.Linq;
using System.Threading.Tasks;
using Microsoft.Dynamics.Commerce.Runtime;
using Microsoft.Dynamics.Commerce.Runtime.DataModel;
using Microsoft.Dynamics.Commerce.Runtime.Services.Messages;

namespace Commerce.Runtime.AsyncSample.Messages
{
    public class AsyncSampleRequestHandler : SingleAsyncRequestHandler<AsyncSampleRequest,
    AsyncSampleResponse>
    {
        protected override async Task<AsyncSampleResponse> Process(AsyncSampleRequest request)
        {
            var customers = await AsyncSampleMethodGetCustomer(request.RequestContext);

            return new AsyncSampleResponse(customers);
        }

        private async Task<Customer> AsyncSampleMethodGetCustomer(RequestContext context)
        {
            //do custom logic here. Execute any custom logic or request asynchronously.
            var getCustomerRequest = new GetCustomersServiceRequest(QueryResultSettings.SingleRecord,
            "2001", SearchLocation.Local);
            var getCustomerResponse = await context.ExecuteAsync<GetCustomersServiceResponse>
            (getCustomerRequest);
            return getCustomerResponse.Customers.SingleOrDefault();
        }
    }
}

```

## Create a new asynchronous Retail server controller

To create an asynchronous Retail server controller extension, extend the controller class from the **CommerceControllerAsync** class, as shown in the following example.

```

namespace Microsoft.Dynamics.Retail.RetailServerLibrary.ODataControllers
{
    using System.Runtime.InteropServices;
    using System.Threading.Tasks;
    using System.Web.Http.Controllers;
    using System.Web.OData;
    using Commerce.Runtime;
    using Commerce.Runtime.Client;
    using Commerce.Runtime.DataModel;

    /// <summary>
    /// The catalogs controller.
    /// </summary>
    [ComVisible(false)]
    public class CustomController : CommerceControllerAsync<MyEntity, string>
    {

        /// <summary>
        /// Gets the controller name.
        /// </summary>
        public override string ControllerName
        {
            get { return "MyEntity"; }
        }

        /// <summary>
        /// Gets the <c>MyEntity</c> entity by key.
        /// </summary>
        /// <param name="key">
        /// The key.
        /// </param>
        /// <returns>
        /// The <see cref="ScanResult"/>.
        /// </returns>
        [CommerceAuthorization(CommerceRoles.Employee)]
        protected override Task<MyEntity> GetEntityByKey(string key)
        {
            return this.GetMyEntityAsync(key);
        }

        /// <summary>
        /// Retrieves the entity information based on <see cref="key"/> input.
        /// </summary>
        /// <param name="key">key input.</param>
        /// <returns>Instance of <see cref="MyEntity"/> that contains entities found by input text.
    </returns>
        public async Task<MyEntity> GetMyEntityAsync(string key)
        {
            ThrowIf.Null(key, nameof(key));

            var request = new MyCustomRequest(key);
            var response = await this.runtime.ExecuteAsync<MyCustomResponse>(request).ConfigureAwait(false);
            return response.Result;
        }
    }
}

```

## Override an out-of-box request handler asynchronously

To override the supported out-of-box request handler, follow this pattern.

For example, to override the out-of-box `GetScanResultRequestHandler` handler, override the handler, and return the response by using `Task` and `await`.

```

namespace Contoso
{
    namespace Commerce.Runtime.Workflow
    {
        using System.Linq;
        using System.Threading.Tasks;
        using Microsoft.Dynamics.Commerce.Runtime;
        using Microsoft.Dynamics.Commerce.Runtime.DataModel;
        using Microsoft.Dynamics.Commerce.Runtime.Messages;
        using Microsoft.Dynamics.Commerce.Runtime.Services.Messages;

        /// <summary>
        /// Workflow that retrieves information based on scan input.
        /// </summary>
        public class GetScanResultRequestHandler : SingleAsyncRequestHandler<GetScanResultRequest,
GetScanResultResponse>
        {
            /// <summary>
            /// Executes the workflow to get scan result.
            /// </summary>
            /// <param name="request">Instance of <see cref="GetScanResultRequest"/>.</param>
            /// <returns>Instance of <see cref="GetScanResultResponse"/>.</returns>
            protected override async Task<GetScanResultResponse> Process(GetScanResultRequest request)
            {
                ThrowIf.Null(request, nameof(request));

                var getBarcodeRequest = new GetBarcodeRequest(request.ScanInfo);
                var getBarcodeResponse = request.RequestContext.Execute<GetBarcodeResponse>
(getBarcodeRequest);
                Barcode barcode = getBarcodeResponse.Barcode;
                BarcodeMaskType maskType = barcode == null ? BarcodeMaskType.None : barcode.Mask.MaskType;
                ScanResult result = new ScanResult(request.ScanInfo.ScannedText) { Barcode = barcode,
MaskType = maskType };

                //For this sample, we skipped lot of logic inside this method. This should be used only for
reference on how to override OOB request. The logic written inside this sample is different from the actual
implementation of this handler.

                result.Product = await this.GetSingleProductByItemId(request.RequestContext,
barcode.ItemBarcode.ItemId, barcode.ItemBarcode.InventoryDimensionId).ConfigureAwait(false);

                return new GetScanResultResponse(result);
            }

            private async Task<SimpleProduct> GetSingleProductByItemId(RequestContext context, string
itemId, string inventDimId)
            {
                //do custom logic here. Execute any custom logic or request asynchronously.

                if (string.IsNullOrEmpty(itemId))
                {
                    return null;
                }

                var lookupClause = new ProductLookupClause { ItemId = itemId, InventDimensionId =
inventDimId };

                var getProductRequest = new GetProductsServiceRequest(
                    context.GetPrincipal().ChannelId,
                    new[] { lookupClause },
                    QueryResultSettings.AllRecords);
                getProductRequest.SearchLocation = SearchLocation.Local; // Scanned products must be found
locally.

                var products = (await context.ExecuteAsync<GetProductsServiceResponse>
(getProductRequest).ConfigureAwait(false)).Products;

                if (products.Results.IsNullOrEmpty() || products.Results.HasMultiple())
                    ,

```

```

        {
            // if product is not found or multiple products founds (not exact match) return 'null'
            return null;
        }

        return products.Results.Single();
    }
}
}
}

```

## Create a trigger asynchronously

To run the logic in the trigger asynchronously, extend the **IRequestTriggerAsync** interface, and add the logic.

```

namespace Contoso
{
    using System;
    using System.Collections.Generic;
    using System.Composition;
    using System.Threading.Tasks;
    using Microsoft.Dynamics.Commerce.Runtime.Messages;
    using Microsoft.Dynamics.Commerce.Runtime.DataServices.Messages;

    /// <summary>
    /// Test implementation of request trigger for <see cref="TestRequest"/>.
    /// </summary>
    public class SampleRequestTriggerAsync : IRequestTriggerAsync
    {
        private readonly Func<Task> onExecutingCallback;
        private readonly Func<Task> onExecutedCallback;

        public TestRequestTriggerAsync()
        {
        }

        [ImportingConstructor]
        public TestRequestTriggerAsync([Import("OnExecutingCallback")]Func<Task> onExecutingCallback,
[Import("OnExecutedCallback")]Func<Task> onExecutedCallback)
        {
            this.onExecutingCallback = onExecutingCallback;
            this.onExecutedCallback = onExecutedCallback;
        }

        /// <summary>
        /// Gets the collection of request types supported by this trigger.
        /// </summary>
        public IEnumerable<Type> SupportedRequestTypes
        {
            get
            {
                return new[]
                {
                    // Add the request for pre or post trigger execution.
                    typeof(GetCustomerDataRequest)
                };
            }
        }

        /// <summary>
        /// Invoked before request has been processed by <see cref="IRequestHandler"/>.
        /// </summary>
        /// <param name="request">The incoming request message.</param>
        /// <returns>The empty Task.</returns>
        public Task OnExecuting(Request request)
    }
}

```

```
public Task OnExecuting(Request request)
{
    if (this.onExecutingCallback != null)
    {
        return this.onExecutingCallback();
    }

    return Task.CompletedTask;
}

/// <summary>
/// Invoked after request has been processed by <see cref="IRequestHandler"/>.
/// </summary>
/// <param name="request">The request message processed by handler.</param>
/// <param name="response">The response message generated by handler.</param>
/// <returns>The empty Task.</returns>
public Task OnExecuted(Request request, Response response)
{
    if (this.onExecutedCallback != null)
    {
        return this.onExecutedCallback();
    }

    return Task.CompletedTask;
}
}
```

# Pre-extended columns in the channel database

2/18/2021 • 4 minutes to read • [Edit Online](#)

Some columns in the channel database are *pre-extended*. In other words, the column length in the channel database exceeds the column length in Microsoft Dynamics 365 Commerce Headquarters. For example, the length of the **INVENTSERIALID** field is 20 characters in the Commerce Headquarters database but 50 characters in the channel database.

Although fields in the channel database are often extended, column lengths for those fields aren't extensible. Therefore, out-of-box column lengths have been increased to support extension scenarios.

## NOTE

If you must extend a field that isn't already pre-extended, you must file an extension request in Lifecycle Services (LCS). For more information, see [Extensibility requests](#).

Although the fields are extended in the channel database, your extension must also extend the field in the Commerce Headquarters database by using the extended data type (EDT) extension model. Additionally, you must extend the corresponding point of sale (POS) or Commerce runtime (CRT) user interface (UI).

If the Commerce Headquarters database isn't extended, either synchronization between the channel database and the Commerce Headquarters database will fail during the P-job or the extra characters will be truncated. Likewise, if the corresponding point of sale (POS) user interface (UI) or the Commerce runtime (CRT) isn't extended, validation will prevent more than the default character length from being entered. The default length is determined by the base column length in the Commerce Headquarters database.

Here are some examples:

- The length of the **INVENTSERIALID** field in the channel database is 50 characters, but the POS UI accepts serial numbers that are a maximum of only 20 characters long. In this case, you must extend the field in both the POS UI and the Commerce Headquarters database.
- The length of the **STREET** field in the channel database is extended to 400 characters, but validation in CRT prevents more than the default length in the Commerce Headquarters database from being accepted. In this case, you must extend both the CRT request handler (**ValidateAddressLengthServiceRequest**) and the Commerce Headquarters database, so that 400 characters are accepted for the **STREET** field.

Extension of the POS UI or CRT handlers isn't required for some fields, because they might be read-only fields in POS. For example, **ECORES** product-related fields are read-only. Because product creation isn't supported in POS, there is no write scenario for products in POS.

## Sample code to override the **ValidateAddressLengthServiceRequest** handler

The following example shows how to override the **ValidateAddressLengthServiceRequest** handler.

```
namespace Contoso
{
    namespace Commerce.Runtime.ReceiptsSample
    {
        using System;
        using System.Collections.Generic;
        using Microsoft.Dynamics.Commerce.Runtime;
```

```

using Microsoft.Dynamics.Commerce.Runtime.Messages;
using Microsoft.Dynamics.Commerce.Runtime.Services.Messages;

public class ValidateAddressLengthServiceRequestExt : IRequestHandler
{
    private static int maxDefaultFullAddressColumnLength = 250;
    private static int maxDefaultStreetColumnLength = 250;
    private static int maxDefaultCountyColumnLength = 10;

    /// <summary>
    /// Gets the collection of supported request types by this handler.
    /// </summary>
    public IEnumerable<Type> SupportedRequestTypes
    {
        get
        {
            return new[]
            {
                typeof(ValidateAddressLengthServiceRequest),
            };
        }
    }

    public Response Execute(Request request)
    {
        if (request == null)
        {
            return null;
        }

        ValidateAddressLengthServiceRequest validateAddressLengthServiceRequest =
(ValidateAddressLengthServiceRequest)request;

        var validationFailures = new List<DataValidationFailure>();

        // Add custom logic to check your desired length.

        if (!string.IsNullOrEmpty(validateAddressLengthServiceRequest?.Address?.FullAddress)
            && validateAddressLengthServiceRequest.Address.FullAddress.Length >
maxDefaultFullAddressColumnLength)
        {
            validationFailures.Add(new DataValidationFailure(
                DataValidationErrors.Microsoft_Dynamics_Commerce_Runtime_AddressLengthExceeded,
                string.Format("The full address exceeds the maximum number of {0} characters
allowed.",
                    maxDefaultFullAddressColumnLength))
            {
                LocalizedMessageParameters = new object[] { maxDefaultFullAddressColumnLength }
            });
        }

        // Add custom logic to check your desired length.

        if (!string.IsNullOrEmpty(validateAddressLengthServiceRequest?.Address?.Street)
            && validateAddressLengthServiceRequest.Address.Street.Length > maxDefaultStreetColumnLength)
        {
            validationFailures.Add(new DataValidationFailure(
                DataValidationErrors.Microsoft_Dynamics_Commerce_Runtime_StreetLengthExceeded,
                string.Format("The street exceeds the maximum number of {0} characters allowed.",
maxDefaultStreetColumnLength))
            {
                LocalizedMessageParameters = new object[] { maxDefaultStreetColumnLength }
            });
        }

        // Add custom logic to check your desired length.

        if (!string.IsNullOrEmpty(validateAddressLengthServiceRequest?.Address?.County)
            && validateAddressLengthServiceRequest.Address.County.Length > maxDefaultCountyColumnLength)

```

```

        {
            validationFailures.Add(new DataValidationFailure(
                DataValidationErrors.Microsoft_Dynamics_Commerce_Runtime_CountyLengthExceeded,
                string.Format("The county exceeds the maximum number of {0} characters allowed.",
                    maxDefaultCountyColumnLength))
                {
                    LocalizedMessageParameters = new object[] { maxDefaultCountyColumnLength }
                });
        }

        if (validationFailures.Count > 0)
        {
            throw new
            DataValidationException(DataValidationErrors.Microsoft_Dynamics_Commerce_Runtime_AggregateValidationError,
                validationFailures, "An error occurred when validating the address.");
        }

        return new NullResponse();
    }
}
}
}
}

```

## Pre-extended columns in the channel database

The following table lists the columns that are pre-extended.

TABLE	COLUMN	LENGTH	EXTENSION IN CRT	EXTENSION IN POS
INVENTSERIAL	INVENTSERIALID	nvarchar(50)		GetSerialNumberClientRequestHandler
LOGISTICSPOSTALADDRESS	ADDRESS	nvarchar(500)	ValidateAddressLength	
LOGISTICSPOSTALADDRESS	STREET	nvarchar(400)	ValidateAddressLength	
LOGISTICSPOSTALADDRESS	COUNTY	nvarchar(60)	ValidateAddressLength	
LOGISTICSADDRESSCITY	COUNTYID	nvarchar(60)		
LOGISTICSADDRESSCOUNTRY	COUNTYID	nvarchar(60)

# Extend Commerce Data Exchange - Real-time Service

2/18/2021 • 3 minutes to read • [Edit Online](#)

This topic explains how you can extend Commerce Data Exchange (CDX) - Real-time service by adding extension methods to the `RetailTransactionServiceEx` class. Real-time Service enables clients to interact with Commerce functionality in real time. Finance and Operation databases and classes can't be accessed directly from Retail server. You should access them through the CDX class extension using the Finance and Operations and Commerce Runtime extension.

To extend Commerce Data Exchange - Real-time Service, you create a new method in the `RetailTransactionServiceEx` class. This method must meet the following criteria:

- The method must be a public static method.
- The return value must be a container that has a length of 2 or more. The first element must be a Boolean value that indicates whether the method call was successful, and a string value that you can use for a comment or error message. The other items in the container can be of any type, and they can even be nested containers.
- The method parameters must be one of the following primitive types:
  - Boolean
  - date
  - int
  - int64
  - str
  - guid
  - Real

## Create and call a new extension method

1. Start Microsoft Visual Studio.
2. On the **Dynamics 365** menu, click **Model management > Create model**.
3. In the **Create model** dialog box, enter the following details.
  - **Model name** - Contoso
  - **Model publisher** - Contoso
  - **Layer** - USR (Select the relevant layer)
  - **Version** - 1.0.0.0
  - **Model display name** - Contoso
4. Click **Next**.
5. In the dialog box, select **Select existing package**, and then select **Application Suite** in the list.
6. Click **Next**.
7. Click **Finish**.
8. In the **New project** dialog box, enter **ContosoRetailTransactionServiceEx** as the project name.

- Click **OK**.
- Right-click the project and select **Add > New item**. In the **Add New Item** window, select **Class** and enter the name of the class as **ContosoRetailTransactionServiceSample**.

To consume the CDX method in Commerce runtime (CRT) you must add the `ExtensionOf` attribute to your class, such as `ExtensionOf(classStr(RetailTransactionServiceEx))`. This means that the class is extending from the `RetailTransactionServiceEx`.

- In the code editor, add the following code.

```
[ExtensionOf(classStr(RetailTransactionServiceEx))]  
final class ContosoRetailTransactionServiceSample  
{  
}
```

- Inside the class, add a new method to do your custom logic. This is the method that you will call from CRT to do the custom logic.

```
[ExtensionOf(classStr(RetailTransactionServiceEx))]  
final class ContosoRetailTransactionServiceSample  
{  
    public static container SerialCheck(str _serialNum)  
    {  
        boolean success = false;  
        str errorMessage;  
        int fromLine;  
  
        ttsbegin;  
  
        try  
        {  
            if (_serialNum)  
            {  
                // check whether the serial number exists  
  
                // Add your custom logic  
  
                errorMessage = "Serial number found";  
            }  
            else  
            {  
                // Add your custom logic  
                success = false;  
                errorMessage = "Serial number not found";  
            }  
        }  
        catch (Exception::Error)  
        {  
            error = RetailTransactionServiceUtilities::getInfologMessages(fromLine);  
        }  
  
        ttscommit;  
  
        // Return sanitized error code.  
        errorMessage = RetailTransactionServiceUtilities::getErrorCode(errorMessage);  
  
        return [success, errorMessage, "Custom values"];  
    }  
}
```

- In Solution Explorer, right-click the project, and then click **Build**.

After you've finished building your new extension methods, the project will be deployed.

## Call the new method from the CRT

1. In your commerce runtime (CRT) extension, include the `Microsoft.Dynamics.Commerce.Runtime.RealtimeServices.Messages` nuget package, if it hasn't already been added.
2. Use the following sample code to call the new method.

```
InvokeExtensionMethodRealtimeRequest extensionRequest = new
InvokeExtensionMethodRealtimeRequest("SerialCheck", "123");
InvokeExtensionMethodRealtimeResponse response = await
request.RequestContext.ExecuteAsync<InvokeExtensionMethodRealtimeResponse>
(extensionRequest).ConfigureAwait(false);
ReadOnlyCollection<object> results = response.Result;

string resValue = (string)results[0];
```

3. From the results object, you can read the response values from Real-time Service.
4. The CRT framework code will check the success/failure state and provide an error message based on the values returned from the CDX methods. If required, the extension code can catch this and provide additional logic.

### NOTE

The `InvokeExtensionMethodRealtimeRequest` method takes two parameters. One parameter is the Real-time Service method name, and the other is the list of parameters that should be used. The method name that is passed should be the same as the method name that you created in the `ContosoRetailTransactionServiceSample` class.

```
public InvokeExtensionMethodRealtimeRequest(string methodName, params object[] parameters)
    : base(methodName, parameters)
{
}
```

## CDX offline

When there is no connectivity to the HQ, client/Retail Server will not be able to call the CDX method. In this case, the extension code should follow the best practice mentioned below:

- Check before calling the CDX method to determine if CRT is connected to the online (Retail server) or the offline (local) database. This can be done both in POS and CRT.

### How to check the connection status

#### POS

Use the `GetConnectionStatusClientRequest` POS API.

#### CRT

```
if(request.RequestContext.Runtime.Configuration.IsMasterDatabaseConnectionString)
{ }
```

- If the connection to the CDX method failed, an error message might display saying that the operation cannot be performed if there is no connectivity to HQ or that you need to have mitigation logic if this operation needs to work if there is no connectivity to the CDX method.

**NOTE**

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Create an end-to-end payment integration for a payment terminal

2/18/2021 • 22 minutes to read • [Edit Online](#)

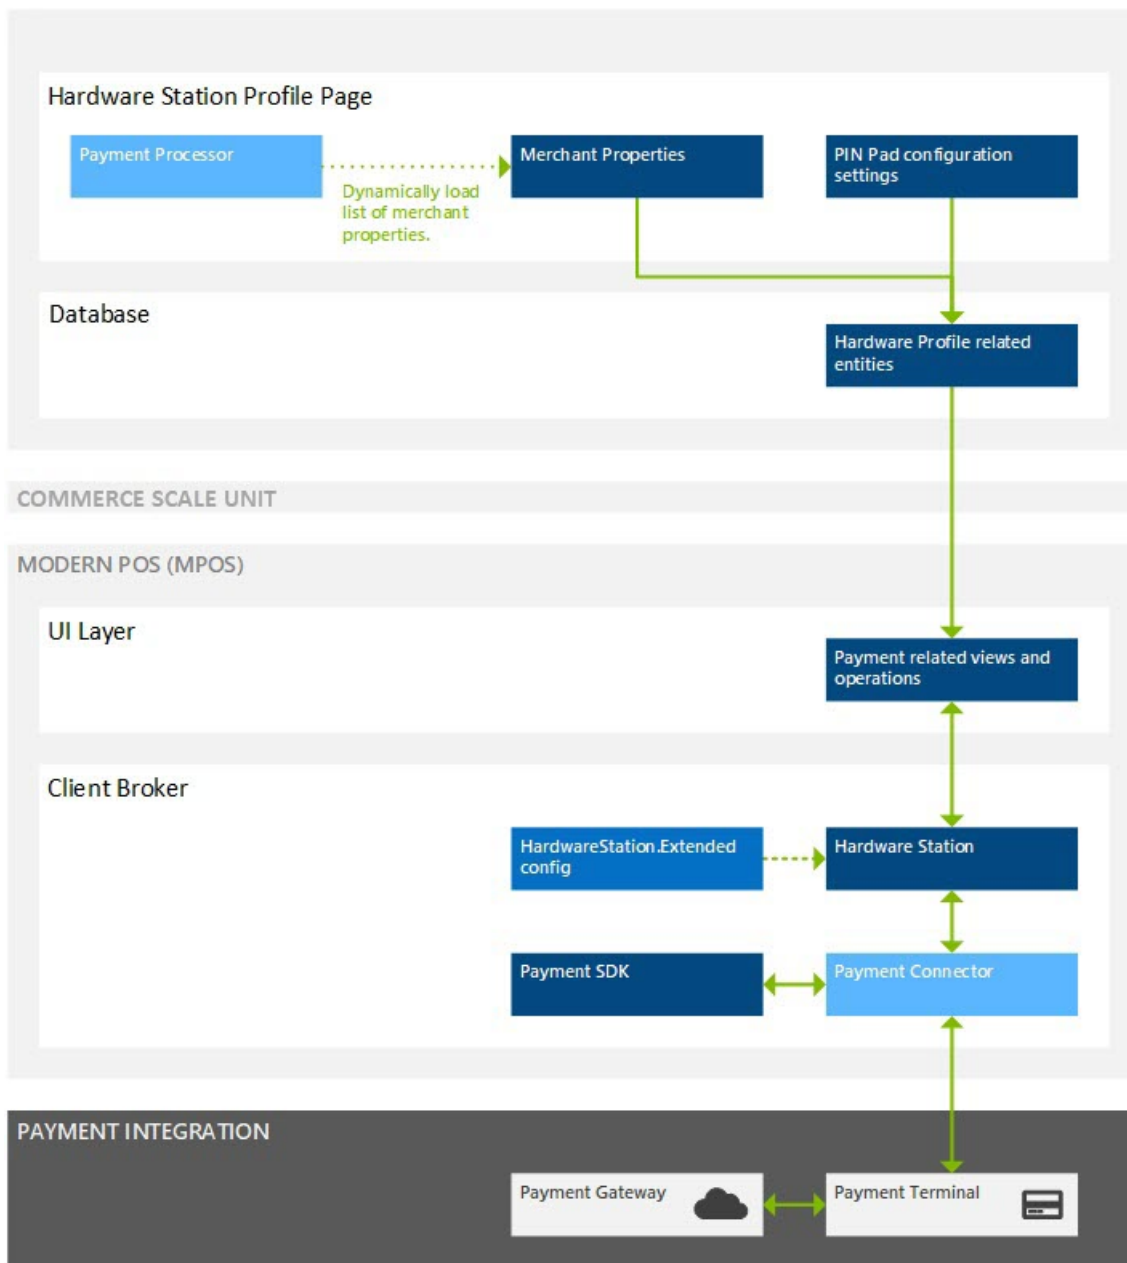

This topic describes how to write a payment integration for Microsoft Dynamics 365 Retail Modern POS and Cloud POS (the POS) for a payment terminal that can directly communicate with the payment gateway.

## Key terms

TERM	DESCRIPTION
Payment connector	An extension library that is written to integrate the POS with a payment terminal.
Payment processor	An extension library that is written to retrieve merchant properties that the payment connector uses.

## Overview

The following illustration shows a high-level overview of the payment terminal integration through the POS. Although this illustration assumes that a local Hardware Station is used to communicate with the payment terminal, the same patterns apply to a shared Hardware Station.

This topic describes the following steps that are required to create an end-to-end payment integration for a payment terminal:

- **Write a payment connector:** The payment connector is the main integration point between the POS and the payment terminal. The section for this step describes how to implement and configure a new payment connector that can relay payment requests (for example, authorize, refund, and void requests) to the payment terminal.
- **Write a payment processor:** The payment processor is used to define the merchant properties that are used as part of the payment integration. The section for this step describes how to implement a new payment processor. It includes information about the interfaces that you should implement and patterns that you should follow.

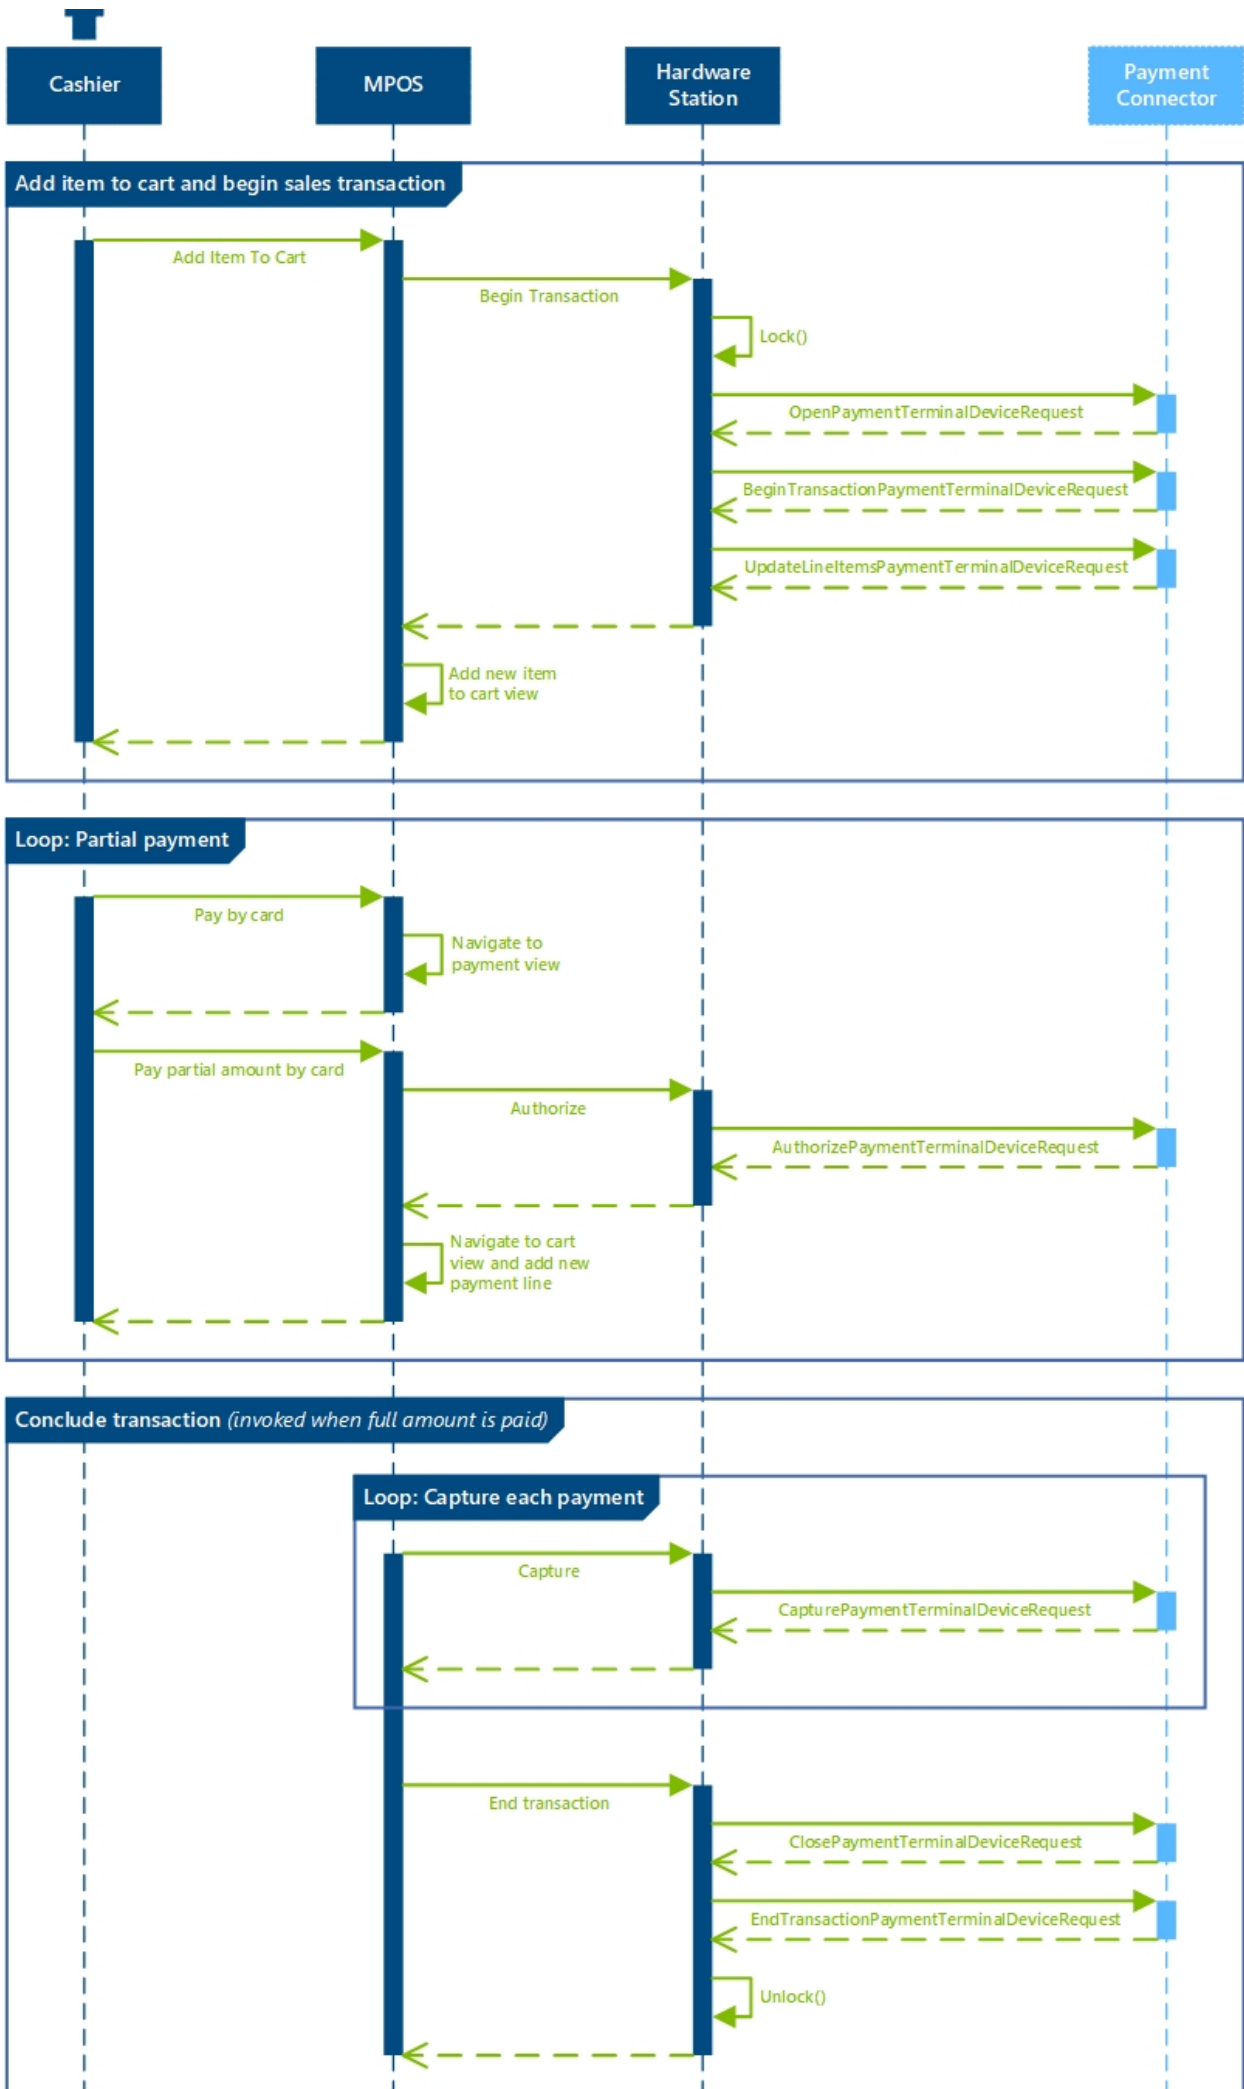

## Write a payment connector

This section describes how to write a new payment connector.

### Understanding the payment flows

The following illustration shows a high-level overview of several payment flows (Begin Transaction, Update Cart Lines, Authorize, Capture, and End Transaction) across the POS, Hardware Station, and payment connector.

## Implement a payment connector

This section below describes how to implement a new payment connector. The examples that are shown here can be found in the **PaymentDeviceSample** class that is located under the **SampleExtensions\HardwareStation\Extension.PaymentSample** folder in the Retail software development kit (SDK).

### Implement the **INamedRequestHandler** interface

All POS payment-related flows are handled through request/response patterns in the Hardware Station. The first step in the process of writing a new payment connector is to create a class that implements the **INamedRequestHandler** interface that is defined in the **Microsoft.Dynamics.Commerce.Runtime.Framework** library.

```
namespace Contoso.Commerce.HardwareStation.PaymentSample
{
    public class PaymentDeviceSample : INamedRequestHandler
    {
        private const string PaymentTerminalDevice = "MOCKPAYMENTTERMINAL";

        /// <summary>
        /// Gets the specify the name of the request handler.
        /// </summary>
        public string HandlerName
        {
            get
            {
                return PaymentDeviceSample.PaymentTerminalDevice;
            }
        }
    }
}
```

The **HandlerName** string is used to configure the payment connector that is used on a given POS register through the client (see the information later in this topic).

### Implement supported payment requests

To process payment-related flows, the payment connector must define the supported request types that it can handle. Additionally, the **Execute** method must be implemented to route each request that the connector supports to a given method. The following example shows the complete list of supported request types and an example of a specific request (that is, an authorize request).

```
namespace Contoso.Commerce.HardwareStation.PaymentSample
{
    /// <summary>
    /// <c>Simulator</c> manager payment device class.
    /// </summary>
    public class PaymentDeviceSample : INamedRequestHandler
    {
        /// <summary>
        /// Gets the collection of supported request types by this handler.
        /// </summary>
        public IEnumerable<Type> SupportedRequestTypes
        {
            get
            {
                return new[]
                {
                    typeof(LockPaymentTerminalDeviceRequest),
                    typeof(OpenPaymentTerminalDeviceRequest),
                    typeof(ClosePaymentTerminalDeviceRequest),
                    typeof(BeginTransactionPaymentTerminalDeviceRequest),
                    typeof(EndTransactionPaymentTerminalDeviceRequest),
                }
            }
        }
    }
}
```

```

        typeof(UpdateLineItemsPaymentTerminalDeviceRequest),
        typeof(AuthorizePaymentTerminalDeviceRequest),
        typeof(CapturePaymentTerminalDeviceRequest),
        typeof(VoidPaymentTerminalDeviceRequest),
        typeof(RefundPaymentTerminalDeviceRequest),
        typeof(FetchTokenPaymentTerminalDeviceRequest),
        typeof(ExecuteTaskPaymentTerminalDeviceRequest),
        typeof(ActivateGiftCardPaymentTerminalRequest),
        typeof(AddBalanceToGiftCardPaymentTerminalRequest),
        typeof(GetGiftCardBalancePaymentTerminalRequest),
        typeof(GetPrivateTenderPaymentTerminalDeviceRequest),
        typeof(CancelOperationPaymentTerminalDeviceRequest),
        typeof(GetTransactionReferencePaymentTerminalDeviceRequest),
        typeof(GetTransactionByTransactionReferencePaymentTerminalDeviceRequest),
        typeof(CashoutGiftCardPaymentTerminalRequest)
    };
}
}

/// <summary>
/// Executes the payment device simulator operation based on the incoming request type.
/// </summary>
/// <param name="request">The payment terminal device simulator request message.</param>
/// <returns>Returns the payment terminal device simulator response.</returns>
public Response Execute(Microsoft.Dynamics.Commerce.Runtime.Messages.Request request)
{
    ThrowIf.Null(request, "request");

    Type requestType = request.GetType();

    if (requestType == typeof(AuthorizePaymentTerminalDeviceRequest))
    {
        return this.AuthorizePayment((AuthorizePaymentTerminalDeviceRequest)request);
    }
    else if (...)
    {
        ...
    }

    return new NullResponse();
}

/// <summary>
/// Authorize payment.
/// </summary>
/// <param name="request">The authorize payment request.</param>
/// <returns>The authorize payment response.</returns>
public AuthorizePaymentTerminalDeviceResponse AuthorizePayment(AuthorizePaymentTerminalDeviceRequest
request)
{
    ThrowIf.Null(request, "request");

    PaymentInfo paymentInfo = Utilities.WaitAsyncTask(() =>
this.AuthorizePaymentAsync(request.Amount, request.Currency, request.VoiceAuthorization,
request.IsManualEntry, request.ExtensionTransactionProperties));

    return new AuthorizePaymentTerminalDeviceResponse(paymentInfo);
}
}
}

```

#### Full list of supported request types

The following table describes all supported requests types that a payment connector can implement.

REQUEST CLASS	PAYMENT FLOW DESCRIPTION
OpenPaymentTerminalDeviceRequest	This request is called before a sales transaction is initiated. It is used to establish a connection to the payment terminal.
BeginTransactionPaymentTerminalDeviceRequest	This request is called when a new sales transaction is initiated. It is used to handle any initialization on the payment terminal (for example, by initializing the transaction screen).
LockPaymentTerminalDeviceRequest	This request is called when a payment terminal is locked for a transaction.
UpdateLineItemsPaymentTerminalDeviceRequest	This request is called when line items in the cart are updated.
AuthorizePaymentTerminalDeviceRequest	This request is called when a payment is initiated in the POS payment view.
CancelOperationPaymentTerminalDeviceRequest	This request is called when a user selects the <b>Cancel</b> button in the payment view dialog box after the payment is initiated but before the payment is completed on the payment terminal.
CapturePaymentTerminalDeviceRequest	This request is called for each payment line when the whole amount in the cart is paid but before the sales transaction is concluded.
VoidPaymentTerminalDeviceRequest	This request is called when a payment line is voided in the cart.
RefundPaymentTerminalDeviceRequest	This request is called when a refund is issued.
FetchTokenPaymentTerminalDeviceRequest	This request is called to fetch a payment token to support deferred payments for customer orders.
EndTransactionPaymentTerminalDeviceRequest	This request is called when the sales transaction is concluded and all payments have been captured.
ClosePaymentTerminalDeviceRequest	This request is called after the sales transaction is concluded. It is used to close the connection to the payment terminal.
ActivateGiftCardPaymentTerminalRequest	This request is called when an external gift card is being activated through the POS.
AddBalanceToGiftCardPaymentTerminalRequest	This request is called when a balance is being added to an external gift card.
GetGiftCardBalancePaymentTerminalRequest	This request is called when the balance on the gift card is being retrieved.
GetPrivateTenderPaymentTerminalDeviceRequest	This request is called when gift card numbers are retrieved from the payment terminal for gift card flows (for example, Issue gift card, Pay by gift card, or Add to gift card).

REQUEST CLASS	PAYMENT FLOW DESCRIPTION
ExecuteTaskPaymentTerminalDeviceRequest	This extension request can be invoked from the POS through customizations. It is used to enable additional payment-related flows.
GetTransactionReferencePaymentTerminalDeviceRequest	This request is called to check the correlation ID. It is used for duplicate payment protection.
GetTransactionByTransactionReferencePaymentTerminalDeviceRequest	This request is used to obtain the previous transaction by correlation ID.
CashoutGiftCardPaymentTerminalRequest	This request is called when a the cash out gift card operation is executed from the POS.

#### OpenPaymentTerminalDeviceRequest

Signature

```
public OpenPaymentTerminalDeviceRequest(string token, string deviceName, SettingsInfo terminalSettings,
PeripheralConfiguration deviceConfig, ExtensionTransaction extensionTransactionProperties);
```

Variables

VARIABLE	DESCRIPTION
token	The unique token value that is generated when the payment terminal is initially locked for the transaction.
deviceName	The name of the device, as defined on the <b>POS hardware profile</b> page in the client.
terminalSettings	The set of payment terminal-specific configuration properties that are defined in the client, such as the minimum amount for signature capture and the debit cash-back limit.
deviceConfig	The set of payment terminal-specific configuration properties in the form of name/value pairs, such as the IP address and port in the case of network devices.
extensionTransactionProperties	The set of extension configuration properties in the form of name/value pairs.

#### BeginTransactionPaymentTerminalDeviceRequest

Signature

```
public BeginTransactionPaymentTerminalDeviceRequest(string token, string paymentConnectorName, string
merchantInformation, string invoiceNumber, bool isTestMode, ExtensionTransaction
extensionTransactionProperties)
```

Variables

VARIABLE	DESCRIPTION
token	The unique token value that is generated when the payment terminal is initially locked for the transaction.

VARIABLE	DESCRIPTION
paymentConnectorName	The name of the payment connector that is used as part of the payment flow. This variable is used if you plan to integrate with payment flows that use the <b>IPaymentProcessor</b> interface.
merchantInformation	The merchant information that is defined on the <b>POS hardware profile</b> page in the client.
invoiceNumber	The unique invoice number that the POS generates to track the sales transaction.
isTestMode	A value that indicates whether the payment connector is being used in testing mode.
extensionTransactionProperties	The set of extension configuration properties in the form of name/value pairs.

**LockPaymentTerminalDeviceRequest**  
Signature

```
public LockPaymentTerminalDeviceRequest(string clientDeviceNumber, string deviceType, string deviceName,
bool isExclusive, bool isOverride)
```

Variables

VARIABLE	DESCRIPTION
clientDeviceNumber	The unique POS device number that is acquiring the lock.
deviceType	The device type that the lock is acquired for as configured in the POS hardware profile (such as "Windows").
deviceName	The device type that the lock is acquired for as configured in the POS hardware profile (such as "MOCKPAYMENTTERMINAL").
isExclusive	Determines whether the lock that is acquired is exclusive.
isOverride	Determines whether this request will override any existing lock.

**UpdateLineItemsPaymentTerminalDeviceRequest**  
Signature

```
public UpdateLineItemsPaymentTerminalDeviceRequest(string token, string totalAmount, string taxAmount,
string discountAmount, string subTotalAmount, IEnumerable<ItemInfo> items, ExtensionTransaction
extensionTransactionProperties = null)
```

Variables

VARIABLE	DESCRIPTION
token	The unique token value that is generated when the payment terminal is initially locked for the transaction.
totalAmount	The total amount on the current sales transaction.

VARIABLE	DESCRIPTION
taxAmount	The tax amount on the current sales transaction.
discountAmount	The discount amount on the current sales transaction.
subTotalAmount	The subtotal amount on the current sales transaction.
items	The list of line items to show.
extensionTransactionProperties	The set of extension configuration properties in the form of name/value pairs.

**AuthorizePaymentTerminalDeviceRequest**  
Signature

```
public AuthorizePaymentTerminalDeviceRequest(string token, string paymentConnectorName, decimal amount,
string currency, TenderInfo tenderInfo, string voiceAuthorization, bool isManualEntry,
Retail.PaymentSDK.Portable.PaymentTransactionReferenceData transactionReferencedata, bool isTippingEnabled,
ExtensionTransaction extensionTransactionProperties)
```

Variables

VARIABLE	DESCRIPTION
token	The unique token value that is generated when the payment terminal is initially locked for the transaction.
paymentConnectorName	The name of the payment connector that is used as part of the payment flow. This variable is used if there is an integration with payment flows that use the <b>IPaymentProcessor</b> interface.
amount	The amount to authorize.
currency	The currency for the amount to authorize.
tenderInfo	The card information that is sent from the POS that is retrieved from an external source (if an external source is present).
voiceAuthorization	The voice approval code that is sent from the POS if voice authorization is required.
isManualEntry	A value that defines whether the card number was entered manually.
transactionReferenceData	Merchant's transaction reference that is sent to the processor.
isTippingEnabled	Indicates if tipping is supported by the payment connector. Optional. The default value is <b>false</b> .
extensionTransactionProperties	The set of extension configuration properties in the form of name/value pairs. Optional. The default value is <b>null</b> .

Response

The **AuthorizePaymentCardPaymentResponse** response object must be returned when the

**AuthorizePaymentTerminalDeviceRequest** request is handled. The response must contain an instance of the **PaymentInfo** object that has the following required properties.

PROPERTY	DESCRIPTION
ApprovedAmount	The amount that was approved for the transaction. Includes tip amount if tipping is enabled.
CardNumberMasked	The masked credit card number. The value must contain at least the first digit of the credit card to support bin range lookup in the POS. (Most devices return the first six digits and the last four digits.)
CardType	The type of card that was used for the payment (for example, <b>Credit</b> or <b>Debit</b> ) by using the <b>Microsoft.Dynamics.Commerce.HardwareStation.CardPayment.CardType</b> entity.
CashbackAmount	For debit transactions, the cash-back amount that was defined on the payment terminal.
Errors	The list of errors that occurred during the authorize call.
IsApproved	A flag that indicates whether the payment was approved.
PaymentSdkData	The response data that is used to support state between the authorize/refund and capture/void calls or cross-channel payment operations.
TipAmount	The tip amount that was selected by the customer on the device.

The **PaymentSdkData** property must contain the following data.

NAMESPACE	NAME	DESCRIPTION	SAMPLE VALUE
Connector	ConnectorName	The name of the <b>IPaymentProcessor</b> interface that is used for the transactions, as described in the "Write a payment processor" section later in this topic.	
AuthorizationResponse	Properties	The list of authorization responses.	See the next table.

The **Properties** field of the **PaymentSdkData** property must contain the following fields.

NAMESPACE	NAME	DESCRIPTION	SAMPLE VALUE
AuthorizationResponse	ApprovedAmount	The amount that was approved for the transaction.	28.08m
AuthorizationResponse	AvailableBalance	The available balance on the card.	100.00m

NAMESPACE	NAME	DESCRIPTION	SAMPLE VALUE
AuthorizationResponse	ApprovalCode	The approval code for the transaction.	Z123456
AuthorizationResponse	ProviderTransactionId	The transaction identifier of the payment provider.	123456789
AuthorizationResponse	AuthorizationResult	The result of the authorization call.	AuthorizationResult.Success.ToString()
AuthorizationResponse	ExternalReceipt	The external receipt data from the payment provider.	<ReceiptData> ... </ReceiptData>
AuthorizationResponse	TerminalId	The unique identifier of the terminal that handled the payment.	000001

The following example shows how to construct the **PaymentSdkData** object.

```
List<PaymentProperty> paymentSdkProperties = new List<PaymentProperty>();
paymentSdkProperties.Add(new PaymentProperty(GenericNamespace.Connector, ConnectorProperties.ConnectorName,
"TestConnector"));

List<PaymentProperty> paymentSdkAuthorizationProperties = new List<PaymentProperty>();
paymentSdkAuthorizationProperties.Add(new PaymentProperty(GenericNamespace.AuthorizationResponse,
AuthorizationResponseProperties.ApprovedAmount, 28.08m));
paymentSdkAuthorizationProperties.Add(new PaymentProperty(GenericNamespace.AuthorizationResponse,
AuthorizationResponseProperties.AvailableBalance, 100.00m));
paymentSdkAuthorizationProperties.Add(new PaymentProperty(GenericNamespace.AuthorizationResponse,
AuthorizationResponseProperties.ApprovalCode, "Z123456"));
paymentSdkAuthorizationProperties.Add(new PaymentProperty(GenericNamespace.AuthorizationResponse,
AuthorizationResponseProperties.ProviderTransactionId, "123456789"));
paymentSdkAuthorizationProperties.Add(new PaymentProperty(GenericNamespace.AuthorizationResponse,
AuthorizationResponseProperties.AuthorizationResult, AuthorizationResult.Success.ToString()));
paymentSdkAuthorizationProperties.Add(new PaymentProperty(GenericNamespace.AuthorizationResponse,
TransactionDataProperties.TerminalId, "000001"));

paymentSdkProperties.Add(new PaymentProperty(GenericNamespace.AuthorizationResponse,
AuthorizationResponseProperties.Properties, paymentSdkAuthorizationProperties.ToArray()));

string paymentSdkData = PaymentProperty.ConvertPropertyArrayToXML(paymentSdkProperties.ToArray());
```

If the payment terminal returns a receipt, you can print it through the POS by setting the following data on the **ExternalReceipt** object that was described earlier.

```
<ReceiptData>
  <Receipt Type='Customer'>
    <Line>Line 1 of receipt.</Line>
    <Line>Line 2 of receipt.</Line>
  </Receipt>
  <Receipt Type='Merchant'>
    <Line>Line 1 of receipt.</Line>
    <Line>Line 2 of receipt.</Line>
  </Receipt>
</ReceiptData>
```

#### Other considerations

If the payment terminal handles the authorize and capture requests in a single call (that is, if *immediate capture* occurs), and the cashier wants to void the transaction, the payment terminal must support reversal of an

immediate capture. When an immediate capture is voided, if the void request fails, the cashier will be asked whether they want to locally void the payment. If the cashier selects **Yes**, the tender is voided only in the POS. No call is made to the payment terminal to void the payment. Basically, this behavior lets the cashier unblock the POS if it can no longer void the payment on the payment terminal. However, this behavior can cause issues, because a lock lasts for three to five days, until the bank reverses it, but the payment is made for immediate capture. Therefore, duplicate payments can occur.

**CancelOperationPaymentTerminalDeviceRequest**  
Signature

```
public CancelOperationPaymentTerminalDeviceRequest(string token)
```

Variables

VARIABLE	DESCRIPTION
token	The unique token value that is generated when the payment terminal is initially locked for the transaction.

**CapturePaymentTerminalDeviceRequest**  
Signature

```
public CapturePaymentTerminalDeviceRequest(string token, decimal amount, string currency, string paymentPropertiesXml, ExtensionTransaction extensionTransactionProperties)
```

Variables

VARIABLE	DESCRIPTION
token	The unique token value that is generated when the payment terminal is initially locked for the transaction.
amount	The amount to capture.
currency	The currency for the amount to capture.
paymentPropertiesXml	The content of the <b>PaymentSdkData</b> object that is returned by the <b>AuthorizePaymentTerminalDeviceRequest</b> or <b>RefundPaymentTerminalDeviceRequest</b> request, and that is used to support stateful properties between the requests.
extensionTransactionProperties	The set of extension configuration properties in the form of name/value pairs.

Other considerations

If the payment terminal handles the authorize and capture requests in a single call, the **CapturePaymentTerminalDeviceRequest** request should be a no-op and should immediately return.

If the payment terminal requires state from the authorize requests to handle the capture call, the properties should be stored in the **PaymentSdkData** object of the **AuthorizePaymentTerminalDeviceResponse** request that is described earlier, and passed through the **paymentPropertiesXml** variable of the **CapturePaymentTerminalDeviceRequest** request.

**VoidPaymentTerminalDeviceRequest**  
Signature

```
public VoidPaymentTerminalDeviceRequest(string token, string paymentConnectorName, decimal amount, string
currency, TenderInfo tenderInfo, string paymentPropertiesXml, ExtensionTransaction
extensionTransactionProperties)
```

Variables

VARIABLE	DESCRIPTION
token	The unique token value that is generated when the payment terminal is initially locked for the transaction.
paymentConnectorName	The name of the payment connector that is used as part of the payment flow. This variable is used if there is an integration with payment flows that use the <b>IPaymentProcessor</b> interface.
amount	The amount for the payment to void.
currency	The currency for the payment to void.
tenderInfo	The card information that is sent from the POS that is retrieved from an external source (if an external source is present).
paymentPropertiesXml	The content of the <b>PaymentSdkData</b> object that is returned by the <b>AuthorizePaymentTerminalDeviceRequest</b> or <b>RefundPaymentTerminalDeviceRequest</b> request, and that is used to support stateful properties between the requests.
extensionTransactionProperties	The set of extension configuration properties in the form of name/value pairs.

**RefundPaymentTerminalDeviceRequest**  
Signature

```
public RefundPaymentTerminalDeviceRequest(string token, string paymentConnectorName, TenderInfo tenderInfo,
decimal amount, string currency, bool isManualEntry, ExtensionTransaction extensionTransactionProperties)
```

Variables

VARIABLE	DESCRIPTION
token	The unique token value that is generated when the payment terminal is initially locked for the transaction.
paymentConnectorName	The name of the payment connector that is used as part of the payment flow. This variable is used if there is an integration with payment flows that use the <b>IPaymentProcessor</b> interface.
tenderInfo	The card information that is sent from the POS that is retrieved from an external source (if an external source is present).
amount	The amount to refund.

VARIABLE	DESCRIPTION
currency	The currency for the amount to refund.
isManualEntry	A value that defines whether the card number was entered manually.
extensionTransactionProperties	The set of extension configuration properties in the form of name/value pairs.

**FetchTokenPaymentTerminalDeviceRequest**  
Signature

```
public FetchTokenPaymentTerminalDeviceRequest(string token, bool isManualEntry, ExtensionTransaction
extensionTransactionProperties)
```

Variables

VARIABLE	DESCRIPTION
token	The unique token value that is generated when the payment terminal is initially locked for the transaction.
isManualEntry	A value that defines whether the card number was entered manually.
extensionTransactionProperties	The set of extension configuration properties in the form of name/value pairs.

**EndTransactionPaymentTerminalDeviceRequest**  
Signature

```
public EndTransactionPaymentTerminalDeviceRequest(string token, ExtensionTransaction
extensionTransactionProperties)
```

Variables

VARIABLE	DESCRIPTION
token	The unique token value that is generated when the payment terminal is initially locked for the transaction.
extensionTransactionProperties	The set of extension configuration properties in the form of name/value pairs.

**ClosePaymentTerminalDeviceRequest**  
Signature

```
public ClosePaymentTerminalDeviceRequest(string token, ExtensionTransaction extensionTransactionProperties)
```

Variables

VARIABLE	DESCRIPTION
token	The unique token value that is generated when the payment terminal is initially locked for the transaction.
extensionTransactionProperties	The set of extension configuration properties in the form of name/value pairs.

**ActivateGiftCardPaymentTerminalRequest**  
Signature

```
public ActivateGiftCardPaymentTerminalRequest(string token, string paymentConnectorName, decimal amount, string currencyCode, TenderInfo tenderInfo, ExtensionTransaction extensionTransactionProperties)
```

Variables

VARIABLE	DESCRIPTION
token	The unique token value that is generated when the payment terminal is initially locked for the transaction.
paymentConnectorName	The name of the payment connector that is used as part of the payment flow. This variable is used if there is an integration with payment flows that use the <b>IPaymentProcessor</b> interface.
amount	The initial amount to add to the gift card during activation.
currency	The currency for the initial amount to add to the gift card during activation.
tenderInfo	The card information that is sent from the POS that is retrieved from an external source (if an external source is present).
extensionTransactionProperties	The set of extension configuration properties in the form of name/value pairs.

**AddBalanceToGiftCardPaymentTerminalRequest**  
Signature

```
public AddBalanceToGiftCardPaymentTerminalRequest(string token, string paymentConnectorName, decimal amount, string currencyCode, TenderInfo tenderInfo, ExtensionTransaction extensionTransactionProperties)
```

Variables

VARIABLE	DESCRIPTION
token	The unique token value that is generated when the payment terminal is initially locked for the transaction.
paymentConnectorName	The name of the payment connector that is used as part of the payment flow. This variable is used if there is an integration with payment flows that use the <b>IPaymentProcessor</b> interface.
amount	The amount to add to the gift card.
currency	The currency for the amount to add to the gift card balance.
tenderInfo	The card information that is sent from the POS that is retrieved from an external source (if an external source present).
extensionTransactionProperties	The set of extension configuration properties in the form of name/value pairs.

**GetGiftCardBalancePaymentTerminalRequest**

Signature

```
public GetGiftCardBalancePaymentTerminalRequest(string token, string paymentConnectorName, string currencyCode, TenderInfo tenderInfo, ExtensionTransaction extensionTransactionProperties)
```

Variables

VARIABLE	DESCRIPTION
token	The unique token value that is generated when the payment terminal is initially locked for the transaction.
paymentConnectorName	The name of the payment connector that is used as part of the payment flow. This variable is used if there is an integration with payment flows that use the <b>IPaymentProcessor</b> interface.
currency	The currency to retrieve the gift card balance in.
tenderInfo	The card information that is sent from the POS that is retrieved from an external source (if an external source present).
extensionTransactionProperties	The set of extension configuration properties in the form of name/value pairs.

**GetPrivateTenderPaymentTerminalDeviceRequest**

Signature

```
public GetPrivateTenderPaymentTerminalDeviceRequest(string token, decimal amount, bool declined, bool isSwipe, ExtensionTransaction extensionTransactionProperties)
```

Variables

VARIABLE	DESCRIPTION
token	The unique token value that is generated when the payment terminal is initially locked for the transaction.
amount	The amount that is set on the POS. (Typically, this variable is used to show the amount on the payment terminal when the card number is retrieved.)
declined	This variable is obsolete.
isSwipe	A value that determines whether the card number should be retrieved through a swipe or manual entry on the payment terminal.
extensionTransactionProperties	The set of extension configuration properties in the form of name/value pairs.

**ExecuteTaskPaymentTerminalDeviceRequest**

Signature

```
public ExecuteTaskPaymentTerminalDeviceRequest(string token, string task, ExtensionTransaction extensionTransactionProperties)
```

Variables

VARIABLE	DESCRIPTION
token	The unique token value that is generated when the payment terminal is initially locked for the transaction.
task	The unique identifier for the task that is being run.
extensionTransactionProperties	The set of extension configuration properties in the form of name/value pairs.

**GetTransactionReferencePaymentTerminalDeviceRequest**  
Signature

```
public GetTransactionReferencePaymentTerminalDeviceRequest(string lockToken, string posTerminalId, string eftTerminalId)
```

Variables

VARIABLE	DESCRIPTION
locktoken	Gets the unique lock token that was generated when the payment terminal was initially locked for the transaction.
posTerminalId	Gets the POS terminal ID associated with the lock token.
extensionTransactionProperties	Gets the EFT terminal ID associated with the transaction and lock token.

**GetTransactionByTransactionReferencePaymentTerminalDeviceRequest**  
Signature

```
public GetTransactionByTransactionReferencePaymentTerminalDeviceRequest(string lockToken, Retail.PaymentSDK.Portable.PaymentTransactionReferenceData transactionReferenceData)
```

Variables

VARIABLE	DESCRIPTION
locktoken	Gets the unique lock token that was generated when the payment terminal was initially locked for the transaction.
Retail.PaymentSDK.Portable.PaymentTransactionReferenceData transactionReferenceData	Gets reference data for the for payment transactions in case the correlation ID is out of sync.

**CashoutGiftCardPaymentTerminalRequest**  
Signature

```
public CashoutGiftCardPaymentTerminalRequest(
    string paymentConnectorName,
    decimal amount,
    string currencyCode,
    TenderInfo tenderInfo,
    ExtensionTransaction extensionTransactionProperties)
```

Variables

VARIABLE	DESCRIPTION
----------	-------------

VARIABLE	DESCRIPTION
paymentConnectorName	The name of the payment connector that is used as part of the payment flow. This variable is used if there is an integration with payment flows that use the IPaymentProcessor interface.
amount	The amount gift card cash out request.
currencyCode	The currency for the gift card cash out request.
tenderinfo	The card information that is sent from the POS that is retrieved from an external source (if an external source is present).
extensionTransactionProperties	The set of extension configuration properties in the form of name/value pairs.

### State in the payment connector

The payment connector can be hosted as part of the dllhost.exe process when it's hosted through the in-process Hardware Station inside the POS. Alternatively, the payment connector can be hosted as a w3wp.exe process when it's hosted in the Hardware Station that is based on Microsoft Internet Information Services (IIS). In some circumstances, both processes can be terminated or stop responding between or during payment flows. Therefore, we recommend that payment connectors not have state dependencies, and that they be able to recover if they are terminated at any point during the payment flow–related requests that are described earlier.

### Configure the payment connector in the Hardware Station config

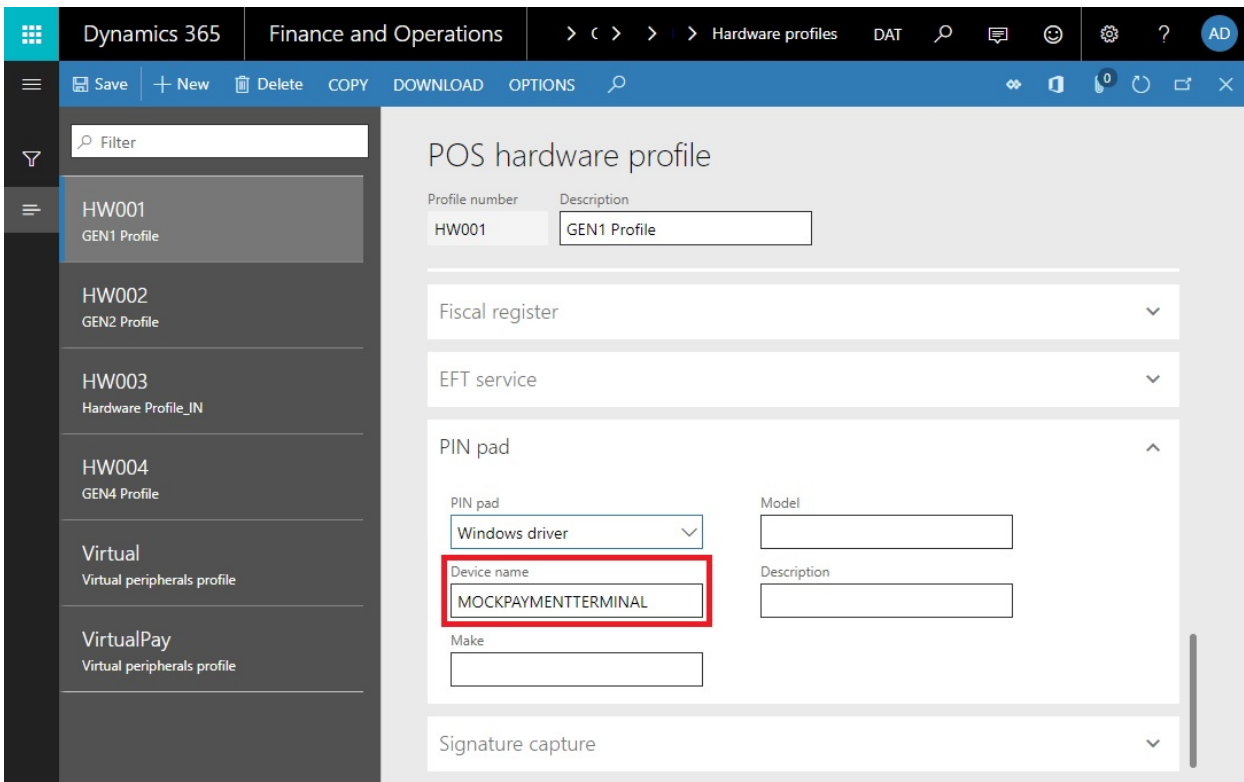

To help guarantee that the Hardware Station loads the payment connector, you must set the corresponding assembly reference in the **HardwareStation.Extension.config** file that is located in the **Assets** folder in the Retail SDK.

```
<?xml version="1.0" encoding="utf-8"?>
<hardwareStationExtension>
  <composition>
    <!--
      Register your own assemblies or types here. The following example registers NewPeripheralDevice
      (and all its request handlers). Any other services are not being overridden:

      <add source="type"
        value="Contoso.Commerce.HardwareStation.NewPeripheralDevice,
Contoso.Commerce.HardwareStation.NewPeripheralDevice" />
      <add source="assembly"
        value="Contoso.Commerce.HardwareStation.NewPeripheralDevice" />
    -->
    <add source="assembly" value="Contoso.Commerce.HardwareStation.PaymentSample" />
  </composition>
</hardwareStationExtension>
```

### Configure the payment connector on the POS hardware profile page in the client

To determine the correct payment connector that should be loaded on the POS, you must set the value of the **PaymentTerminalDevice** property in the **Device name** field on the **PIN pad** FastTab of the **POS hardware profile** page in the client, as shown in the following illustration.

## Write a payment processor

Payment processes are usually used only if a direct connection to a payment gateway is established. This scenario most often occurs in card-not-present sales transactions or more complex card-present scenarios. Additionally, the payment processor is used to process the merchant properties that are configured through the POS hardware profile page in the client.

### NOTE

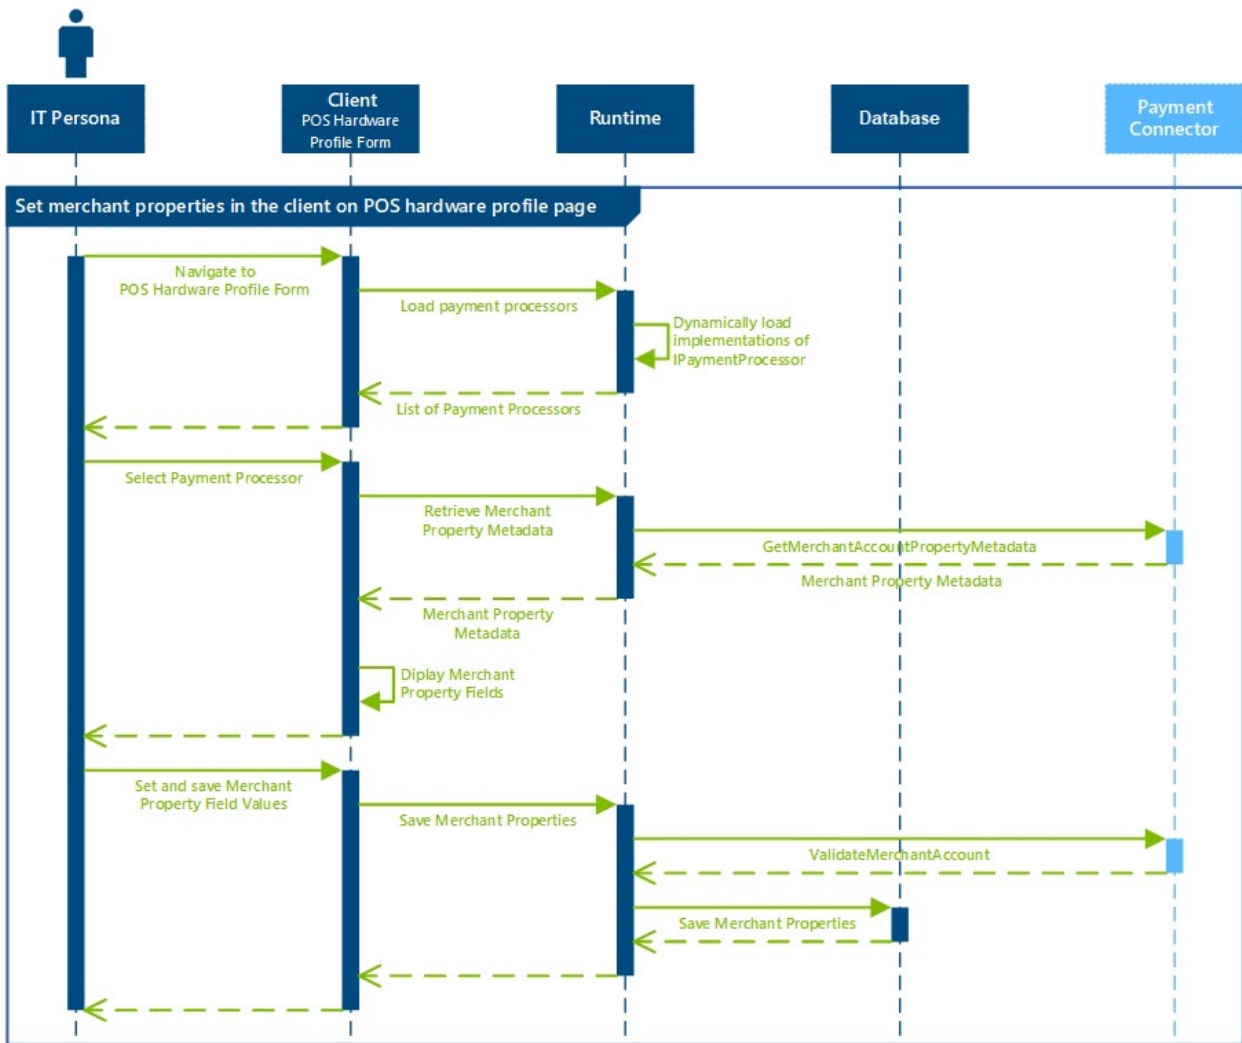

The payment processor is currently required, even if all payment requests are handled directly through the payment terminal and no merchant properties must be set through the POS. For more information about implementing the `IPaymentProcessor` interface, read the [Implementing a payment connector and payment device](#) white paper.

### Understanding the merchant properties flows

The following sections describe how the merchant properties are set on the POS hardware profile page in the client, and how they are passed to the payment connector during payment flows on the POS.

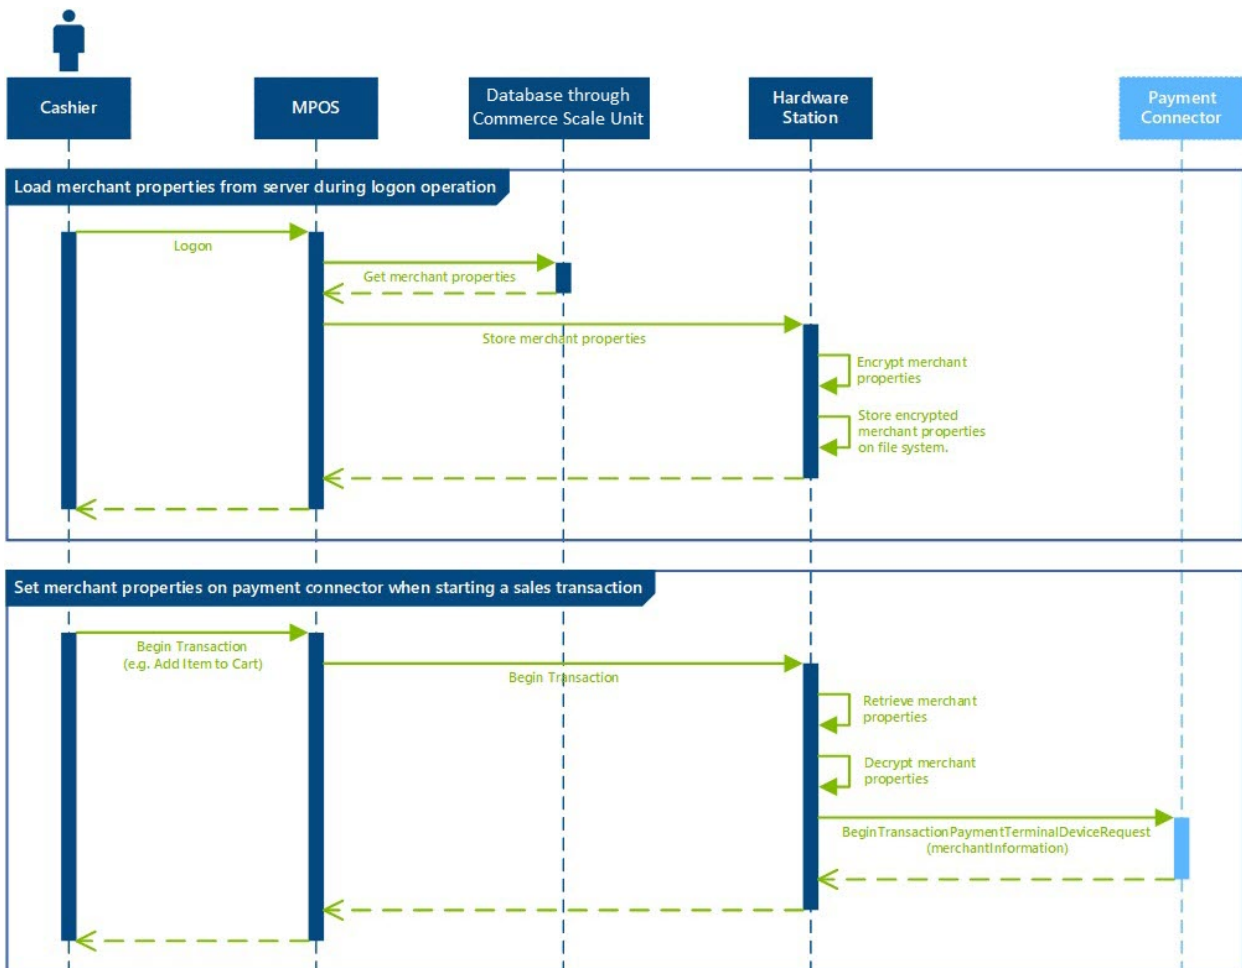

#### Set merchant properties on the POS hardware profile page in the client

The following illustration shows how the merchant properties are set through the POS hardware profile page in the client. To enable the merchant properties to be set, the `IPaymentProcessor` interface that is defined in the `Microsoft.Dynamics.Retail.PaymentSDK` library must be implemented. Two interface methods are required: `GetMerchantAccountPropertyMetadata` and `ValidateMerchantAccount`.

**Set merchant properties on payment connector during POS sales transaction**

The following illustration shows how the merchant properties are retrieved from the database through the Commerce Scale Unit and passed to the payment connector during the `BeginTransactionPaymentTerminalDeviceRequest` request.

### Implement the IPaymentProcessor interface

To handle merchant properties that are related to payment flows, the `IPaymentProcessor` interface that is defined in the `Microsoft.Dynamics.Retail.PaymentsSDK` library must be implemented. The following example shows how to implement the two required interface methods, `GetMerchantAccountPropertyMetadata` and `ValidateMerchantAccount`. Other interface methods can be left blank (for example, they can return `FeatureNotSupportedException`).

```

/// <summary>
/// SampleConnector class (Portable Class Library version).
/// </summary>
public class SampleConnector : IPaymentProcessor
{
    /// <summary>
    /// GetMerchantAccountPropertyMetadata returns the merchant account properties need by the payment
    provider.
    /// </summary>
    /// <param name="request">Request object.</param>
    /// <returns>
    /// Response object.
    /// </returns>
    public Response GetMerchantAccountPropertyMetadata(Request request)
    {
        string methodName = "GetMerchantAccountPropertyMetadata";

        // Check null request
        List<PaymentError> errors = new List<PaymentError>();
        if (request == null)
        {
            errors.Add(new PaymentError(ErrorCode.InvalidRequest, "Request is null."));
            return PaymentUtilities.CreateAndLogResponseForReturn(methodName, this.Name, Platform, locale:
            null, properties: null, errors: errors);
        }
    }
}

```

```

// Prepare response
List<PaymentProperty> properties = new List<PaymentProperty>();
PaymentProperty property;
property = new PaymentProperty(
    GenericNamespace.MerchantAccount,
    MerchantAccountProperties.AssemblyName,
    this.GetAssemblyName());
property.SetMetadata("Assembly Name:", "The assembly name of the test provider", false, true, 0);
properties.Add(property);

Response response = new Response();
response.Locale = request.Locale;
response.Properties = properties.ToArray();
if (errors.Count > 0)
{
    response.Errors = errors.ToArray();
}

PaymentUtilities.LogResponseBeforeReturn(methodName, this.Name, Platform, response);
return response;
}

/// <summary>
/// ValidateMerchantAccount the passed merchant account properties with the payment provider.
/// </summary>
/// <param name="request">Request object to validate.</param>
/// <returns>
/// Response object.
/// </returns>
public Response ValidateMerchantAccount(Request request)
{
    string methodName = "ValidateMerchantAccount";

    // Convert request
    ValidateMerchantAccountRequest validateRequest = null;
    try
    {
        validateRequest = ValidateMerchantAccountRequest.ConvertFrom(request);
    }
    catch (SampleException ex)
    {
        return PaymentUtilities.CreateAndLogResponseForReturn(methodName, this.Name, Platform, locale:
request == null ? null : request.Locale, properties: null, errors: ex.Errors);
    }

    // Validate merchant account
    List<PaymentError> errors = new List<PaymentError>();
    ValidateMerchantProperties(validateRequest, errors);
    if (errors.Count > 0)
    {
        return PaymentUtilities.CreateAndLogResponseForReturn(methodName, this.Name, Platform,
validateRequest.Locale, errors);
    }

    // Create response
    var validateResponse = new ValidateMerchantAccountResponse(validateRequest.Locale,
validateRequest.ServiceAccountId, this.Name);

    // Convert response and return
    Response response = ValidateMerchantAccountResponse.ConvertTo(validateResponse);
    PaymentUtilities.LogResponseBeforeReturn(methodName, this.Name, Platform, response);
    return response;
}
}

```

### Required merchant property fields

The following table shows the required merchant property fields that must be set as part of the

## GetMerchantAccountPropertyMetadata method.

NAMESPACE	NAME	SAMPLE VALUE*
MerchantAccount	PortableAssemblyName	Contoso.Microsoft.PaymentsSample
MerchantAccount	ServiceAccountId	f35989c8-e571-4de1-862a-996c82a2e6b6
MerchantAccount	SupportedCurrencies	AUD;BRL;CAD;CHF;CNY;CZK;DKK;EUR;GBP;HKD;HUF;INR;JPY;KPW;KRW;MXN;NOK;NZD;PLN;SEK;SGD;TWD;USD;ZAR
MerchantAccount	SupportedTenderTypes	Visa;MasterCard;Amex;Discover;Debit

\* You **must** replace the sample values in this column with unique values for your own payment processor.

# Deploy payment connectors

2/18/2021 • 5 minutes to read • [Edit Online](#)

## Overview

This topic guides IT professionals or value-added resellers (VARs) through the process of deploying a payment connector to the appropriate components. We assume that the payment connector has been implemented and tested by the payment provider or the payment independent software vendor (ISV), and that it's ready for validation and subsequent production deployment in a customer environment.

This topic doesn't include information about how to package a payment connector by using the Retail software development kit (SDK). For information about how to download the SDK, see [Retail software development kit \(SDK\) architecture](#). For guidelines about how to package a payment connector, see the Retail SDK packaging document in the downloaded SDK.

This topic also doesn't include information about how to deploy the payment web application, payment front-end processor, or payment back-end processor, because those applications are managed by payment providers or payment ISVs. If you're using Microsoft Dynamics AX 7.0 (February 2016), you must apply KB 3183058 before you create the Commerce deployable package.

## Payment packaging folder

A payment provider or a payment ISV creates a payment connector. The payment connector will include some or all of the following folders:

### NOTE

You can find these folders in `\RetailSDK\PaymentExternals`.

- **IPaymentProcessor Assemblies** – This folder contains the assembly that implements the IPaymentProcessor interface, and its dependent assemblies.
- **Payment Web Files** – This folder contains the callback HTML, JavaScript, or CSS files that are required in order to enable the payment accepting page. Payment connector developers will provide these web files if their payment accepting page requires them.
- **IPaymentDevice Assemblies** – This folder contains the assembly that implements the IPaymentDevice interface and payment request handlers, and the interface's dependent assemblies. These assemblies are used in Hardware station and Modern Point of Sale (Modern POS) to communicate with payment terminal devices, such as VeriFone MX925. If you don't have a payment terminal device, you don't need these files.

To package the payment connector files, copy the payment assemblies to the folder in `\RetailSDK\PaymentExternals`. After the payment assemblies are copied, use **msbuild** from the root of the Retail SDK folder to generate the deployable packages. After the **msbuild** operation is completed, you can find the deployable package in `\RetailSDK\Packages\RetailDeployablePackage`.

- **Retail deployable package** – This package includes payments plus all the other channel extension components. This is this combined package for all extension components. RetailDeployablePackage includes the payment connectors for the following components:
  - Commerce Scale Unit (CSU)
  - Self-service installer, which enables installation of the following:

- Hardware station
- Modern POS
- Commerce scale unit (self-hosted)

#### NOTE

In releases earlier than 10.0.10, the RetailDeployablePackage can be deployed to both AOS and CSU. For later releases, the RetailDeployablePackage can be deployed only to CSU. To deploy the payment connector to AOS application version 10.0.10 and later, follow the information in [Create payment packaging for Application Explorer for self-service deployment](#).

### Upload and deploy deployable packages

1. Open your LCS project page.
2. In the **More tools** section, click **Asset library**.
3. Select **Software package**, and then click the plus sign (+).
4. Enter a name and description, and select the correct package type, as described in the following table.

DEPLOYABLE PACKAGE	DEPLOYABLE PACKAGE TYPE IN LCS
RetailDeployablePackage.zip	Combined commerce package

5. Click **Upload**.
6. Select the zipped package, upload it, and then click **Confirm**.

After you've uploaded your deployable packages to the LCS asset library, you can deploy them to your environments through the LCS portal. After you've validated your deployment in your sandbox environment, you can create a service request to deploy it to your production environment. For more information, see [Apply a deployable package](#).

#### Download and run installers on client computers

The self-service package contains the installers for both Hardware station and Modern POS. After your deployable packages have been applied to your environment, you can download the updated Hardware station and Modern POS installers. For information about how to download Hardware station and Modern POS, and install them on client computers, see [Configure, install, and activate Modern POS \(MPOS\)](#).

## Manual deployment

This section describes how to manually deploy a payment connector. You can use a manual deployment to test locally in a developer environment. This developer environment can be either cloud-hosted or on a downloadable virtual hard disk (VHD). These steps are not applicable for sandbox or production environments.

#### Put the payment connector assemblies and files in the correct locations

Payment connectors are pluggable. In a development environment, you can put the correct files in the correct locations on the server. The following table shows which files should go in which location.

CONNECTOR	CONTENTS OF THE IPAYMENTPROCESSOR ASSEMBLIES FOLDER	CONTENTS OF THE PAYMENT WEB FILES FOLDER	CONTENTS OF THE IPAYMENTDEVICE ASSEMBLIES FOLDER
Application Object Server (AOS)	<Aos.PackageDirectory>/bin/Connectors/ <Aos.WebRoot>/bin/	<Aos.WebRoot>/Connectors/	Not applicable

CONNECTOR	CONTENTS OF THE IPAYMENTPROCESSOR ASSEMBLIES FOLDER	CONTENTS OF THE PAYMENT WEB FILES FOLDER	CONTENTS OF THE IPAYMENTDEVICE ASSEMBLIES FOLDER
Commerce Scale Unit	<RS.WebRoot>/bin/	Not applicable	Not applicable
Cloud POS	Not applicable	<CPOS.WebRoot>/Connectors/	Not applicable
Remote Hardware Station (Internet Information Services [IIS])	<HWS.WebRoot>/bin/	Not applicable	<HWS.WebRoot>/bin/
Modern POS Local Hard Station (Information Protection and Control [IPC])	<MPOS.AppRoot>/ClientBroker/	Not applicable	<MPOS.AppRoot>/ClientBroker/
E-commerce	Not applicable	<ECOM.WebRoot>/Connectors/	Not applicable

Here is a key to the preceding table:

- <Aos.PackageDirectory> is the package directory of AOS. You can find the path from the web.config file for AOS (key = Aos.PackageDirectory).
- <Aos.WebRoot> is the web application root of AOS.
- <RS.WebRoot> is the web application root of Commerce Scale Unit.
- <HWS.WebRoot> is the web application root of a remote Hardware Station.
- <MPOS.AppRoot> is the app installation folder of Modern POS (for example, C:\Program Files (x86)\Microsoft Dynamics AX70\Retail Modern POS).
- <ECOM.WebRoot> is the web application root of an e-commerce website.

The Payment Web Files folder usually contains a subfolder. Be sure to copy the whole subfolder to the target locations.

## Use a payment connector with an e-commerce site

E-commerce sites aren't deployed in LCS-managed environments. You should work with your partner to decide how to host an e-commerce site. If the payment connector requires payment web files, you must deploy those web files to your e-commerce site. If your payment connector doesn't require payment web files, no additional steps are required. For information about how to deploy payment web files to an e-commerce site, see the [Put the payment connector assemblies and files in the correct locations](#) section earlier in this topic.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Incremental capture for back-office invoicing

2/18/2021 • 4 minutes to read • [Edit Online](#)

## IMPORTANT

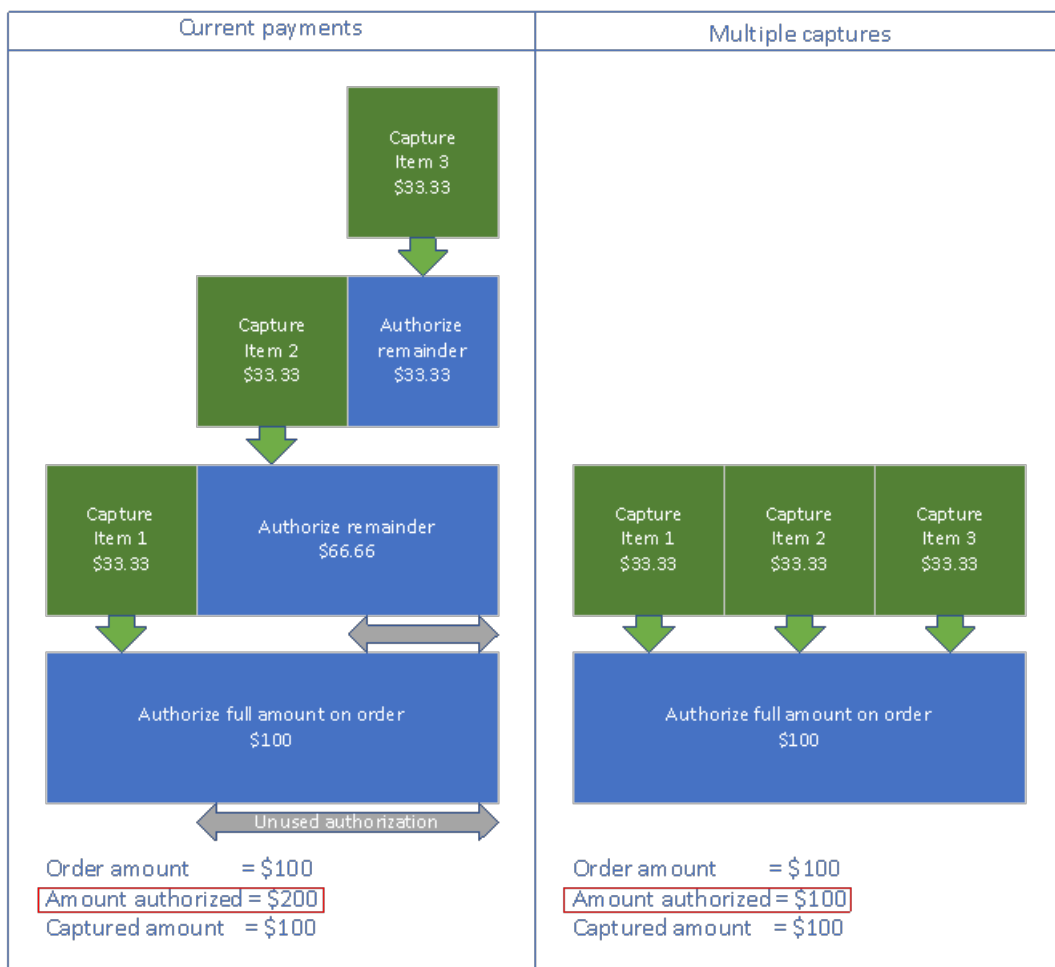

Some or all of the functionality noted in this topic is available as part of a preview release. The content and the functionality are subject to change. For more information about preview releases, see [One version service updates FAQ](#).

This topic describes how the payments software development kit (SDK) supports incremental capture as part of order invoicing. In incremental capture, payment processing supports fulfillment of an order that has multiple invoices. Specifically, as invoices are processed against the order, payment capture requests reference the original payment authorization instead of getting a new payment authorization when previous payment captures have caused the balance due to change.

## Overview

Many merchants fulfill orders in multiple shipments. In Microsoft Dynamics 365 Commerce version 10.0.12 and earlier, the out-of-box process for handling credit card payments for orders that are fulfilled over multiple shipments is to capture payments as those shipments are invoiced and then get a new payment authorization for the balance due for the remaining items that must be shipped. This process ensures that payment capture can be consistently supported across payment processors. However, it also has some downsides. Specifically, when an authorization is partially captured, and then a new authorization is created for the balance due, the old authorization and new authorization might overlap. In this case, open authorizations that exceed the order total might appear against customer payment cards. Therefore, authorizations might exceed open balances that are available for credit cards, or card issuers might block cards from being processed because of suspicion of fraud.

To address these issues, the payments SDK in Commerce version 10.0.13 and later includes incremental capture support for back-office payment captures. Therefore, if a processor supports incremental capture, payment connectors can be updated to capture against a single authorization multiple times over the course of order fulfillment. The following illustration shows the difference between the different payment capture frameworks when multiple captures are done against a single authorization.

In Commerce version 10.0.13, incremental capture is supported as part of back-office invoicing (that is, any invoicing that occurs as part of order fulfillment in the back office). In a later release, support for incremental capture from the point of sale (POS) will be added to the out-of-box Adyen payment connector.

## Turn on incremental capture for back-office invoicing

In the **Feature management** workspace, select the **All** filter to show all available features, and then search for **Extensibility to support incremental credit card capture**. Select the feature, and then select **Enable now**.

## Uptake incremental capture for back-office invoicing

To uptake support for incremental capture as part of back-office invoicing, you must upgrade to the payments SDK that is provided in Commerce version 10.0.13.

## IPaymentReferenceProvider

This version of the payment SDK adds the **IPaymentReferenceProvider** interface. This interface supports using a **PaymentTrackingID** value for each request and response. The **PaymentTrackingID** value can be used to track payment requests. It also ensures that, between back-office invoicing requests and the processor, duplicate requests can be caught before they are re-sent. In this way, it helps prevent duplicate payments.

Here is a sample implementation from the SampleConnector.cs file in the payments SDK.

```

#region ITrackingSupport
/// <summary>
/// Get the payment provider reference to safeguard against duplicate requests.
/// </summary>
/// <param name="command">The payment operation that will use the tracking ID.</param>
/// <param name="amount">The payment transaction amount.</param>
/// <returns>Returns the PaymentTransactionReferenceData.</returns>
/// <remarks>List of supported commands can be seen in the constants defined in <see
cref="Microsoft.Dynamics.Retail.PaymentSDK.Portable.Constants.SupportedCorrelationCommands"/></remarks>
public PaymentTransactionReferenceData GetPaymentReferenceData(string command, decimal amount)
{
    PaymentTransactionReferenceData paymentTransactionReferenceData = new PaymentTransactionReferenceData();
    paymentTransactionReferenceData.Amount = amount;
    paymentTransactionReferenceData.Command = command;
    paymentTransactionReferenceData.IdFromConnector = Guid.NewGuid().ToString();
    paymentTransactionReferenceData.InitiatedDate = DateTime.UtcNow;
    return paymentTransactionReferenceData;
}
#endregion

```

The following sample from the `AuthorizeRequest.cs` file in the payments SDK uses a `PaymentTrackingID` value.

```

authorizeRequest.PaymentTrackingId = PaymentUtilities.GetPropertyStringValue(
    hashtable,
    GenericNamespace.TransactionData,
    TransactionDataProperties.PaymentTrackingId);

```

## Support for multiple captures

If a payment processor supports multiple captures, the `SupportsMultipleCaptures` property for authorization responses from the connector should be set to **True**. If the property is set to **False**, or if it isn't provided, the authorization won't be eligible for incremental capture. In this case, if there is a new balance due after invoicing, a new authorization will be obtained.

Here is a sample from the `AuthorizationResponseProperties.cs` file in the payments SDK.

```

/// <summary>
/// Gets the SupportsMultipleCaptures property.
/// </summary>
public static string SupportsMultipleCaptures
{
    get { return "SupportsMultipleCaptures"; }
}

```

As back-office invoicing processes captures against authorizations that are enabled for multiple capture, the total captured amount is tracked. Capture requests continue to reference the original authorization until it's fully captured.

Authorizations that are expired according to Accounts receivable parameters aren't eligible for incremental capture.

The `SupportsMultipleCaptures` property isn't global. It's specific to the authorization. An environment might have both connectors that support incremental capture and connectors that don't support it.

**NOTE**

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Create custom localized error messages for payment terminal extensions

2/18/2021 • 5 minutes to read • [Edit Online](#)

This topic explains how to create custom localized error messages for payment terminal extensions. These custom error messages are most often used so that the payment terminal can give the cashier who is using the point of sale (POS) terminal relevant information about why a specific payment was unsuccessful. For example, the external payment terminal or gateway might return unique identifiers (such as reference numbers or transaction identifiers) that are relevant for troubleshooting with the payment provider.

## Key terms

TERM	DESCRIPTION
Payment connector	An extension library that is written to integrate the POS with a payment terminal.

## Overview

The remaining sections in this topic describe the following steps for creating custom localized error messages for payment terminal extensions:

- [Create custom error messages](#) – This section explains how to create custom error messages in the payment connector that can be returned and shown in the POS.
- [Create localized error messages](#) – This section explains how to localize the error messages in the payment connector that are returned and shown in the POS.

## Create custom error messages

To trigger a custom error message in the POS, you must set the appropriate error in the **Errors** property of the **paymentInfo** object that is passed to the **AuthorizePaymentTerminalDeviceResponse** object. Specifically, you must set the **isLocalized** parameter on the constructor of the **PaymentError** object to **true** to force the POS to use the custom error message instead of the built-in error message for a declined payment.

```
namespace Contoso.Commerce.HardwareStation.PaymentSample
{
    /// <summary>
    /// <c>Simulator</c> manager payment device class.
    /// </summary>
    public class PaymentDeviceSample : INamedRequestHandler
    {
        /// <summary>
        /// Gets the collection of supported request types by this handler.
        /// </summary>
        public IEnumerable<Type> SupportedRequestTypes
        {
            get
            {
                return new[]
                {
                    typeof(AuthorizePaymentTerminalDeviceRequest),
                    ...
                }
            }
        }
    }
}
```

```

    };
}
}

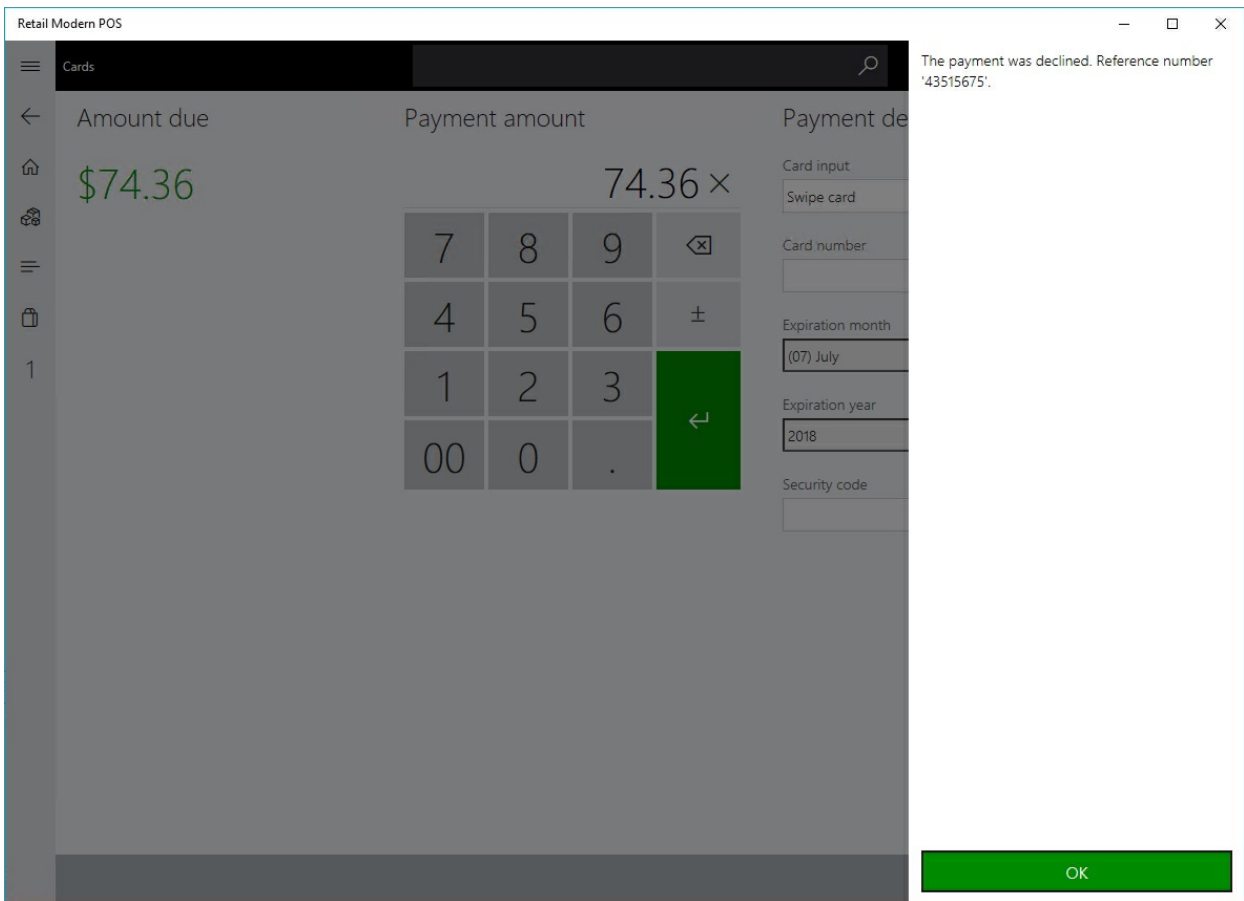

/// <summary>
/// Executes the payment device simulator operation based on the incoming request type.
/// </summary>
/// <param name="request">The payment terminal device simulator request message.</param>
/// <returns>Returns the payment terminal device simulator response.</returns>
public Response Execute(Microsoft.Dynamics.Commerce.Runtime.Messages.Request request)
{
    ThrowIf.Null(request, nameof(request));
    Type requestType = request.GetType();
    Response response;
    if (requestType == typeof(AuthorizePaymentTerminalDeviceRequest))
    {
        response = this.AuthorizePayment((AuthorizePaymentTerminalDeviceRequest)request);
    }
    else if (...)
    {
        ...
    }
    else
    {
        throw new NotSupportedException(string.Format(CultureInfo.InvariantCulture, "Request '{0}'
is not supported.", request));
    }
    return response;
}

/// <summary>
/// Authorize payment.
/// </summary>
/// <param name="request">The authorize payment request.</param>
/// <returns>The authorize payment response.</returns>
public AuthorizePaymentTerminalDeviceResponse AuthorizePayment(AuthorizePaymentTerminalDeviceRequest
request)
{
    ThrowIf.Null(request, "request");
    ...

    // Assuming the external payment terminal/gateway returned a decline and a reference number.
    // Construct the custom error message and set the payment error on the 'paymentInfo' object set
    // on the response.
    PaymentInfo paymentInfo = new PaymentInfo();
    bool isLocalized = true;
    string errorMessage = string.Format("The payment was declined. Reference number '{0}'.",
referenceNumber);
    PaymentError paymentError = new PaymentError(ErrorCode.Decline, errorMessage, isLocalized);
    paymentInfo.Errors = new PaymentError[] { paymentError };
    return new AuthorizePaymentTerminalDeviceResponse(paymentInfo);
}
}
}

```

The following illustration shows how the custom error message appears in the POS.

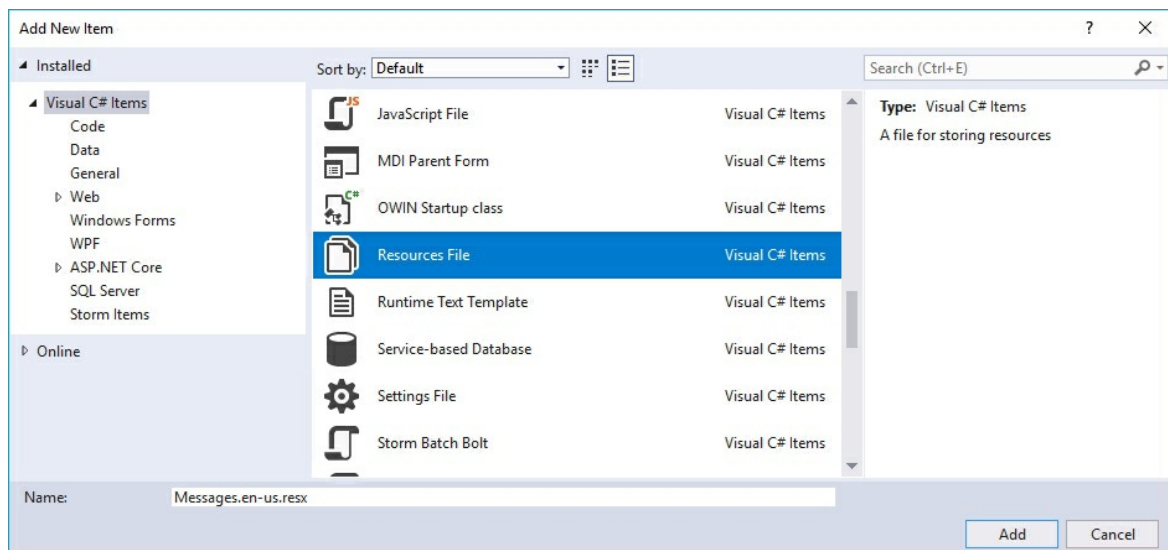

## Create localized error messages

### Create resource files for each locale

To return localized error messages from the payment connector to the POS, you must create localized resource files for each locale that you plan to support. To create a resource file, follow these steps.

1. In Microsoft Visual Studio, right-click the connector project (or a subfolder, as required), and then select **Add > New Item**.
2. In the new **Add New Item** dialog box, select **Visual C# Items** in the left pane and **Resource File** in the center pane.

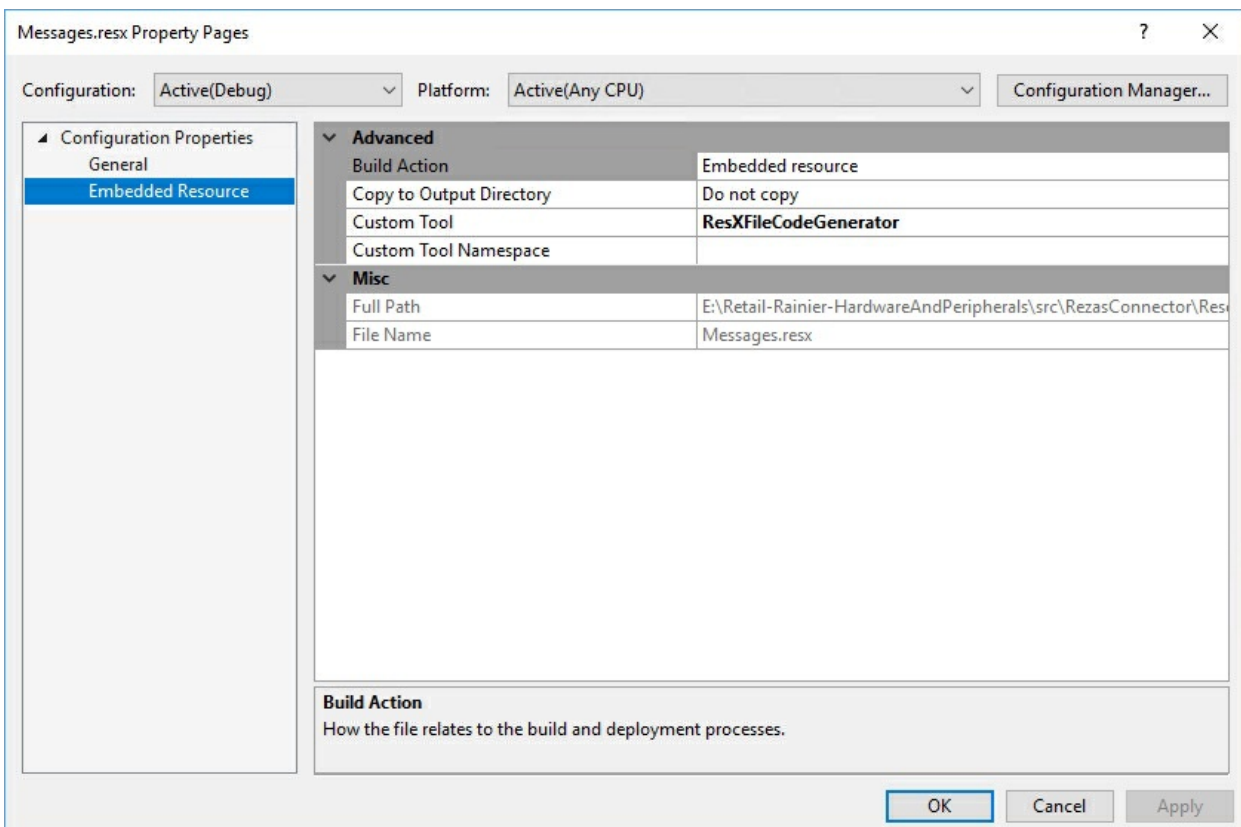

Note that a culture-specific postfix (for example, **en-us**) is required in the file name of every resource file that you create, so that localized satellite assemblies can be generated.

When you've finished, the following resource files should be present in your project. Although the following illustration shows only one extra locale (**en-us**), you can add support for as many locales as you require.

Make sure that a culture-neutral resources file (**Messages.resx** in this example) is defined. This file is used as a fallback if the file for a specific culture is missing.

You must also make sure that the correct properties are set for the resource files in Visual Studio, as shown in the following illustration.

### Create custom localized error messages

Every resource file must contain every error message that you want to customize and localize. The following illustration shows an example of a resource file. Notice that the **CustomPaymentConnector\_Decline** entry is referenced in the code to retrieve the appropriate message for a specific locale. Every resource file for every locale should have an identical set of localized messages.

### Load the localized message in the connector code

The following example shows how you can use the resource files that you created earlier in your payment connector code to load a localized message. The process consists of two steps:

1. Make sure that `terminalSettings` is retrieved during the `OpenPaymentTerminalDeviceRequest` request, to access the locale for the request.
2. During the `AuthorizePaymentTerminalDeviceRequest` call (or equivalent calls), use the `Locale` property on `terminalSettings` to retrieve the correct resource file for the localized message.

#### NOTE

The following example has been significantly simplified to show the mechanics of loading localized messages during the runtime of your payment connector code. However, we recommend that you introduce a new set of classes to manage loading of the appropriate resource file.

```
namespace Contoso.Commerce.HardwareStation.PaymentSample
{
    /// <summary>
    /// <c>Simulator</c> manager payment device class.
    /// </summary>
    public class PaymentDeviceSample : INamedRequestHandler
    {
        // Cached version of the terminal settings retrieved during the OpenPaymentTerminalDeviceRequest
        // call.
        private SettingsInfo terminalSettings;

        // Resource manager to retrieve localized messages.
        private ResourceManager messagesResourceManager;

        /// <summary>
        /// Initializes a new instance of the <see cref="PaymentDeviceSample"/> class.
        /// </summary>
        public PaymentDeviceSample()
        {
            this.messagesResourceManager = new
            ResourceManager("Contoso.Commerce.HardwareStation.PaymentSample.PaymentDeviceSample.Resources.Messages",
            typeof(PaymentDeviceSample).GetTypeInfo().Assembly);
        }

        /// <summary>
        /// Gets the collection of supported request types by this handler.
        /// </summary>
        public IEnumerable<Type> SupportedRequestTypes
        {
            get
            {
                return new[]
                {
                    typeof(OpenPaymentTerminalDeviceRequest),
                    typeof(AuthorizePaymentTerminalDeviceRequest),
                    ...
                };
            }
        }

        /// <summary>
        /// Executes the payment device simulator operation based on the incoming request type.
        /// </summary>
        /// <param name="request">The payment terminal device simulator request message.</param>
        /// <returns>Returns the payment terminal device simulator response.</returns>
        public Response Execute(Microsoft.Dynamics.Commerce.Runtime.Messages.Request request)
        {
            ThrowIf.Null(request, nameof(request));
            Type requestType = request.GetType();
            Response response;
            if (requestType == typeof(OpenPaymentTerminalDeviceRequest))
            {
                response = this.Open((OpenPaymentTerminalDeviceRequest)request);
            }
        }
    }
}
```

```

    }
    else if (requestType == typeof(AuthorizePaymentTerminalDeviceRequest))
    {
        response = this.AuthorizePayment((AuthorizePaymentTerminalDeviceRequest)request);
    }
    else if (...)
    {
        ...
    }
    else
    {
        throw new NotSupportedException(string.Format(CultureInfo.InvariantCulture, "Request '{0}'
is not supported.", request));
    }
    return response;
}

/// <summary>
/// Open the payment terminal.
/// </summary>
/// <param name="request">The open request.</param>
/// <returns>The open response.</returns>
private Response Open(OpenPaymentTerminalDeviceRequest request)
{
    this.terminalSettings = request.TerminalSettings;
    ...
}

# Create Windows installers for payment connectors

2/18/2021 • 3 minutes to read • [Edit Online](#)

This topic describes how to create a Windows installer for a payment connector. This topic is targeted at developers working for or with a payment connector provider, for example, MasterCard or Visa, to describe how to package a payment connector, which can then be shared with implementation partners working for specific customers.

After you've implemented and tested your payment connector in the development environment, you must create an installer to transfer the payment connector to a retailer IT professional or a value-added reseller (VAR) for production deployment. For more information, see [Create an end-to-end payment integration for a payment terminal](#).

## Windows Installer

Microsoft Windows Installer (MSI) is the application and configuration service for Microsoft Windows. You must create an installer that contains all the files that are required in order to deploy a payment connector. The installer itself doesn't deploy the payment connector. It just unzips and copies the connector files to a designated folder. The next section of this topic defines the contents of that folder. You can configure the installer to require that customers accept a user agreement before they can continue with the installation. You can also choose your preferred format for the installer. For example, you can have an .exe file.

## Installer contents

The installer must install the required files in the following structure:

### NOTE

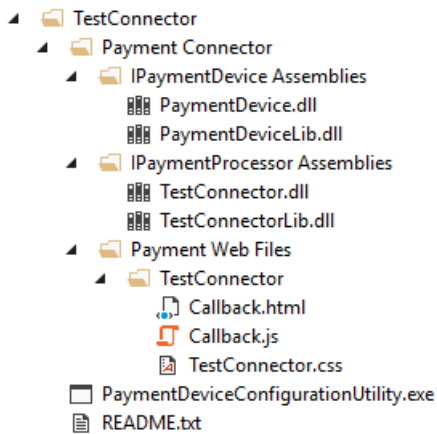

You can find these folders in ...\`RetailSDK\PaymentExternals`.

- **PaymentExternals** – This folder contains up to three subfolders:
  - **IPaymentDevice Assemblies** – This folder contains the assembly that implements the IPaymentDevice interface and its dependent assemblies. These assemblies are used in Hardware station and Retail Modern POS to communicate with payment terminal devices, such as VeriFone MX925. If you don't support a payment terminal device, you can omit this folder.
  - **IPaymentProcessor Assemblies** – This folder contains the assembly that implements the IPaymentProcessor interface and its dependent assemblies.
  - **Payment Web Files** – This folder contains the callback HTML/JavaScript/CSS files that are required in order to enable the payment accepting page. If the payment accepting web app follows the Microsoft implementation guide, these payment web files aren't required, and you can omit this folder. In some cases, the payment accepting page requires that a callback page be deployed to the host application server. In that case, you must include a folder for the callback page:
    - **<Payment\_Connector\_Name>** – To avoid file conflicts from different payment connectors, the payment web files must be placed inside subfolders. We recommend that you use the connector name as the name of the subfolder.
- **Other utility tools** – If you have other utility tools, such as a configuration utility for a payment terminal device, you can include them here. If you don't support any payment terminal devices, you can omit these files. The utility tool should be designed to interact only with the payment terminal devices. It should not

interact with anything in Hardware station or Modern POS. Hardware station and Modern POS will be packaged together with files from the Payment Connector folder.

- **README.txt** – This file describes the contents of the folder and how to use any utilities that are included. The file must also include the payment page URLs that are required in the Cloud POS web.config and Modern POS package.appxmanifest files. If you support any payment terminal devices, the file must also mention the name of the assembly that implements the IPaymentDevice interface. The assembly will be registered in the Hardware Station .config file.

The following illustration shows the file structure for a connector that is named TestConnector.

# Dynamics 365 payment data use

2/18/2021 • 13 minutes to read • [Edit Online](#)

This topic provides an overview of the data that is managed by the payment connectors for Microsoft Dynamics 365.

## Key terms

TERM	DESCRIPTION
Card present	The term <i>card present</i> describes the use of a payment connector to process transactions where a physical card is present, such as at a point of sale (POS) register.
Card not present	The term <i>card not present</i> describes the use of a payment connector to process transactions where a physical card isn't present, such as in call center or e-Commerce scenarios.

## Overview

This topic provides specific details about the following areas with respect to data that is managed by the payment connectors:

- [Data used in card-present scenarios](#) – This section provides a list and descriptions of data fields that are passed to the payment connector for card-present scenarios.
- [Data used in card-not-present scenarios](#) – This section provides a list and descriptions of data fields that are passed to the payment connector for card-not-present scenarios.

## Data used in card-present scenarios

This section describes all data points that are sent to the payment connector for card-present scenarios. The payment connect might not use the data.

### Payment connector request-specific data

#### BeginTransactionPaymentTerminalDeviceRequest

FIELD	DESCRIPTION
merchantInformation	The merchant information that is defined on the <b>POS hardware profile</b> page in the Finance and Operations client.
invoiceNumber	The unique invoice number that the POS generates to track the sales transaction.

#### UpdateLineItemsPaymentTerminalDeviceRequest

FIELD	DESCRIPTION
totalAmount	The total amount on the current sales transaction.

FIELD	DESCRIPTION
taxAmount	The tax amount on the current sales transaction.
discountAmount	The discount amount on the current sales transaction.
subTotalAmount	The subtotal amount on the current sales transaction.
items	The list of product-specific details, such as product names, quantities, or units of measure.

#### AuthorizePaymentTerminalDeviceRequest

FIELD	DESCRIPTION
amount	The amount to authorize.
currency	The currency for the amount to authorize.
voiceAuthorization	The voice approval code that is sent from the POS if voice authorization is required.

#### CapturePaymentTerminalDeviceRequest

FIELD	DESCRIPTION
amount	The amount to capture.
currency	The currency for the amount to capture.
paymentPropertiesXml	The content of the <b>PaymentSdkData</b> object that is returned by the <b>AuthorizePaymentTerminalDeviceRequest</b> or <b>RefundPaymentTerminalDeviceRequest</b> request, and that is used to support stateful properties between the requests. For more details, see the <a href="#">Payment SDK data</a> section later in this topic.

#### VoidPaymentTerminalDeviceRequest

FIELD	DESCRIPTION
amount	The amount of the payment to void.
currency	The currency for the payment to void.
paymentPropertiesXml	The content of the <b>PaymentSdkData</b> object that is returned by the <b>AuthorizePaymentTerminalDeviceRequest</b> or <b>RefundPaymentTerminalDeviceRequest</b> request, and that is used to support stateful properties between the requests. For more details, see the <a href="#">Payment SDK data</a> section later in this topic.

#### RefundPaymentTerminalDeviceRequest

FIELD	DESCRIPTION
amount	The amount to refund.
currency	The currency for the amount to refund.

#### ActivateGiftCardPaymentTerminalRequest

FIELD	DESCRIPTION
amount	The initial amount to add to the gift card during activation.
currency	The currency for the initial amount to add to the gift card during activation.

#### AddBalanceToGiftCardPaymentTerminalRequest

FIELD	DESCRIPTION
amount	The amount to add to the gift card balance.
currency	The currency for the amount to add to the gift card balance.

#### GetGiftCardBalancePaymentTerminalRequest

FIELD	DESCRIPTION
currency	The currency to retrieve the gift card balance in.

#### GetPrivateTenderPaymentTerminalDeviceRequest

FIELD	DESCRIPTION
amount	The amount that is set on the POS. (Typically, this variable is used to show the amount on the payment terminal when the card number is retrieved.)

### Shared data

#### Payment SDK data

FIELD	DESCRIPTION
ApprovedAmount	The amount that was approved for the transaction.
AvailableBalance	The available balance on the card.
ApprovalCode	The approval code for the transaction.
ProviderTransactionId	The transaction identifier of the payment provider.
AuthorizationResult	The result of the authorization call.
ExternalReceipt	The external receipt data from the payment provider.

FIELD	DESCRIPTION
TerminalId	The unique identifier of the terminal that handled the payment.

## Data used in card-not-present scenarios

This section describes data that is sent to the payment connector for card-not-present scenarios. The specific data that each connector processes varies, and a given connector might not use all the data that is provided.

### Payment connector method-specific data

#### Authorization

NAMESPACE	FIELD	DESCRIPTION
MerchantAccount	MerchantId	The merchant information that is defined on the <b>POS hardware profile</b> page in the Finance and Operations client.
PaymentCard	Last4Digits	The last four digits of the card that is used for the payment.
PaymentCard	UniqueCardId	The unique randomized identifier of the card that is used for the payment.
PaymentCard	ExpirationYear	The expiration year of the card that is used for the payment.
PaymentCard	ExpirationMonth	The expiration month of the card that is used for the payment.
PaymentCard	StreetAddress	The street of the billing address that is associated with the card that is used for the payment.
PaymentCard	City	The city of the billing address that is associated with the card that is used for the payment.
PaymentCard	State	The state or province of the billing address that is associated with the card that is used for the payment.
PaymentCard	PostalCode	The postal code of the billing address that is associated with the card that is used for the payment.
TransactionData	IndustryType	The type of channel where the payment occurred (for example, <b>Retail</b> , <b>Direct Marketing</b> , or <b>E-Commerce</b> ).
TransactionData	AllowPartialAuthorization	A value that indicates whether partial authorization is supported.
TransactionData	Amount	The total amount of the transaction.

NAMESPACE	FIELD	DESCRIPTION
TransactionData	CurrencyCode	The currency code for the transaction.
TransactionData	TerminalId	The unique identifier of the terminal where the transaction occurred.
PurchaseLevelData	L2Data	The list of "Level 2" data. For more details, see the <a href="#">L2 data</a> section later in this topic.
PurchaseLevelData	L3Data	The list of "Level 3" data. For more details, see the <a href="#">L3 data</a> section later in this topic.

#### Capture

NAMESPACE	FIELD	DESCRIPTION
MerchantAccount	MerchantId	The merchant information that is defined on the <b>POS hardware profile</b> page in the Finance and Operations client.
TransactionData	Amount	The total amount of the transaction.
TransactionData	CurrencyCode	The currency code for the transaction.
PurchaseLevelData	L2Data	The list of "Level 2" data. For more details, see the <a href="#">L2 data</a> section later in this topic.
PurchaseLevelData	L3Data	The list of "Level 3" data. For more details, see the <a href="#">L3 data</a> section later in this topic.

#### Void

NAMESPACE	FIELD	DESCRIPTION
MerchantAccount	MerchantId	The merchant information that is defined on the <b>POS hardware profile</b> page in the Finance and Operations client.
TransactionData	Amount	The total amount of the transaction.
TransactionData	CurrencyCode	The currency code for the transaction.

#### Refund

NAMESPACE	FIELD	DESCRIPTION
MerchantAccount	MerchantId	The merchant information that is defined on the <b>POS hardware profile</b> page in the Finance and Operations client.

NAMESPACE	FIELD	DESCRIPTION
PaymentCard	Last4Digits	The last four digits of the card that is used for the payment.
PaymentCard	UniqueCardId	The unique randomized identifier of the card that is used for the payment.
PaymentCard	ExpirationYear	The expiration year of the card that is used for the payment.
PaymentCard	ExpirationMonth	The expiration month of the card that is used for the payment.
PaymentCard	StreetAddress	The street of the billing address that is associated with the card that is used for the payment.
PaymentCard	City	The city of the billing address that is associated with the card that is used for the payment.
PaymentCard	State	The state or province of the billing address that is associated with the card that is used for the payment.
PaymentCard	PostalCode	The postal code of the billing address that is associated with the card that is used for the payment.
TransactionData	IndustryType	The type of channel where the payment occurred (for example, <b>Retail</b> , <b>Direct Marketing</b> , or <b>E-Commerce</b> ).
TransactionData	AllowPartialAuthorization	A value that indicates whether partial authorization is supported.
TransactionData	Amount	The total amount of the transaction.
TransactionData	CurrencyCode	The currency code for the transaction.
TransactionData	TerminalId	The unique identifier of the terminal where the transaction occurred.
PurchaseLevelData	L2Data	The list of "Level 2" data. For more details, see the <a href="#">L2 data</a> section later in this topic.
PurchaseLevelData	L3Data	The list of "Level 3" data. For more details, see the <a href="#">L3 data</a> section later in this topic.

#### GetPaymentAcceptPoint

NAMESPACE	FIELD	DESCRIPTION
MerchantAccount	MerchantId	The merchant information that is defined on the <b>POS hardware profile</b> page in the Finance and Operations client.
PaymentCard	Name	The name of the cardholder.
PaymentCard	StreetAddress	The street of the billing address that is associated with the card that is used for the payment.
PaymentCard	City	The city of the billing address that is associated with the card that is used for the payment.
PaymentCard	State	The state or province of the billing address that is associated with the card that is used for the payment.
PaymentCard	PostalCode	The postal code of the billing address that is associated with the card that is used for the payment.
PaymentCard	Country	The country or region of the billing address that is associated with the card that is used for the payment.
PaymentCard	ShowSameAsShippingAddress	A value that identifies whether the billing address is the same as the shipping address.
TransactionData	IndustryType	The type of channel where the payment occurred (for example, <b>Retail</b> , <b>Direct Marketing</b> , or <b>E-Commerce</b> ).
TransactionData	AllowPartialAuthorization	A value that indicates whether partial authorization is supported.
TransactionData	CurrencyCode	The currency code for the transaction.
TransactionData	TerminalId	The unique identifier of the terminal where the transaction occurred.

## Shared data

### L2 data

#### NOTE

L2 data is sent to the connector only if this behavior is explicitly configured through the corresponding connector configuration in the Commerce client.

NAMESPACE	FIELD	DESCRIPTION
L2Data	OrderDateTime	The date and time when the order occurred.
L2Data	OrderNumber	The order number that is associated with the order.
L2Data	InvoiceDateTime	The date and time when the order was invoiced.
L2Data	InvoiceNumber	The invoice number for the order.
L2Data	OrderDescription	The description of the order.
L2Data	SummaryCommodityCode	The commodity code that is associated with the product.
L2Data	MerchantContact	The contact information for the merchant.
L2Data	MerchantTaxId	The unique tax identifier of the merchant.
L2Data	MerchantType	The unique merchant identifier that is maintained by the payment processor.
L2Data	PurchaserId	The unique identifier of the purchaser.
L2Data	PurchaserTaxId	The unique tax identifier of the purchaser.
L2Data	ShipToCity	The city of the shipping address.
L2Data	ShipToCounty	The county of the shipping address.
L2Data	ShipToState_ProvinceCode	The state or province code of the shipping address.
L2Data	ShipToPostalCode	The postal code of the shipping address.
L2Data	ShipToCountryCode	The country or region code of the shipping address.
L2Data	ShipFromCity	The city of the address that the order is shipped from.
L2Data	ShipFromCounty	The county of the address that the order is shipped from.
L2Data	ShipFromState_ProvinceCode	The state or province code of the address that the order is shipped from.

NAMESPACE	FIELD	DESCRIPTION
L2Data	ShipFromPostalCode	The postal code of the address that the order is shipped from.
L2Data	ShipFromCountryCode	The country or region code of the address that the order is shipped from.
L2Data	DiscountAmount	The discount amount that is applied to the specific line item part of the order.
L2Data	MiscCharge	The miscellaneous charges that are applied to the specific line item part of the order.
L2Data	DutyAmount	The duty amount that is applied to the specific line item part of the order.
L2Data	FreightAmount	The freight amount that is applied to the specific line item part of the order.
L2Data	HandlingCharge	The handling charge that is applied to the specific line item part of the order.
L2Data	IsTaxable	A value that identifies whether the specific line item part of the order is taxable.
L2Data	TotalTaxAmount	The total tax amount that is applied to the specific line item part of the order.
L2Data	TotalTaxRate	The total tax rate that is applied to the specific line item part of the order.
L2Data	MerchantName	The name of the merchant.
L2Data	MerchantCity	The city of the address of the merchant.
L2Data	MerchantState	The state or province of the address of the merchant.
L2Data	MerchantCounty	The county of the address of the merchant.
L2Data	MerchantCountryCode	The country or region code of the address of the merchant.
L2Data	MerchantZip	The postal code of the address of the merchant.
L2Data	TaxRate	The tax rate that is applied to the specific line item part of the order.
L2Data	TaxAmount	The tax amount that is applied to the specific line item part of the order.

NAMESPACE	FIELD	DESCRIPTION
L2Data	TaxDescription	The description of the taxes that are applied to the specific line item part of the order.
L2Data	TaxTypeIdentifier	The type identifier of the taxes that are applied to the specific line item part of the order.
L2Data	RequesterName	The name of the requester.
L2Data	TotalAmount	The total amount of the specific line item part of the order.
L2Data	PurchaseCardType	The card type of the purchaser.
L2Data	AmexLegacyDescription1	Legacy American Express description field 1.
L2Data	AmexLegacyDescription2	Legacy American Express description field 2.
L2Data	AmexLegacyDescription3	Legacy American Express description field 3.
L2Data	AmexLegacyDescription4	Legacy American Express description field 4.
L2Data	TaxDetails[].TaxRate	The list of individual tax rates that are applied to the specific line item part of the order.
L2Data	TaxDetails[].TaxDescription	The list of individual descriptions of the taxes that are applied to the specific line item part of the order.
L2Data	TaxDetails[].TaxAmount	The list of individual tax amounts that are applied to the specific line item part of the order.
L2Data	TaxDetails[].TaxTypeIdentifier	The list of type identifiers of the taxes that are applied to the specific line item part of the order.
L2Data	MiscellaneousCharges[].ChargeType	The list of charge types that are applied to the specific line item part of the order.
L2Data	MiscellaneousCharges[].ChargeAmount	The list of charge amounts that are applied to the specific line item part of the order.

### L3 data

**NOTE**

L3 data is sent to the connector only if this behavior is explicitly configured through the corresponding connector configuration in the Commerce client.

NAMESPACE	FIELD	DESCRIPTION
L3Data	SequenceNumber	The sequence number of the item for the order.
L3Data	CommodityCode	The commodity code that is associated with the product.
L3Data	ProductCode	The unique code of the product.
L3Data	ProductName	The name of the product.
L3Data	ProductSKU	The stock keeping unit (SKU) of the product.
L3Data	Descriptor	The description of the product.
L3Data	UnitOfMeasure	The unit of measure of the product.
L3Data	UnitPrice	The unit price of the product.
L3Data	Discount	The discount that is applied to the product.
L3Data	DiscountRate	The discount rate that is applied to the product.
L3Data	Quantity	The quantity of the product.
L3Data	MiscCharge	The miscellaneous charge of the product.
L3Data	NetTotal	The net total amount of the product.
L3Data	TaxAmount	The tax amount of the product.
L3Data	TaxRate	The tax rate of the product.
L3Data	TotalAmount	The total amount of the product.
L3Data	CostCenter	The cost center of the product.
L3Data	FreightAmount	The freight amount of the product.
L3Data	HandlingAmount	The handling amount of the product.
L3Data	CarrierTrackingNumber	The carrier tracking number of the product that is being shipped.

NAMESPACE	FIELD	DESCRIPTION
L3Data	MerchantTaxID	The unique tax identifier of the merchant.
L3Data	MerchantCatalogNumber	The catalog number of the merchant.
L3Data	TaxCategoryApplied	The tax category that is applied to the product.
L3Data	PickupAddress	The street of the pickup address.
L3Data	PickupCity	The city of the pickup address.
L3Data	PickupState	The state or province of the pickup address.
L3Data	PickupCounty	The county of the pickup address.
L3Data	PickupZip	The postal code of the pickup address.
L3Data	PickupCountry	The country or region of the pickup address.
L3Data	PickupDateTime	The date and time of the pickup.
L3Data	PickupRecordNumber	The record number of the pickup.
L3Data	CarrierShipmentNumber	The shipment number of the carrier.
L3Data	UNSPSCCode	The United Nations Standard Products and Services Code (UNSPSC).
L2Data	TaxDetails[].TaxRate	The list of individual tax rates that are applied to the specific line item part of the order.
L2Data	TaxDetails[].TaxDescription	The list of individual descriptions of the taxes that are applied to the specific line item part of the order.
L2Data	TaxDetails[].TaxAmount	The list of individual tax amounts that are applied to the specific line item part of the order.
L3Data	TaxDetails[].TaxTypeIdentifier	The list of type identifiers of the taxes that are applied to the specific line item part of the order.
L3Data	MiscellaneousCharges[].ChargeType	The list of charge types that are applied to the specific line item part of the order.

NAMESPACE	FIELD	DESCRIPTION
L3Data	MiscellaneousCharges[].ChargeAmount	The list of charge amounts that are applied to the specific line item part of the order.

# Enable duplicate payment protection for payment connector

2/18/2021 • 5 minutes to read • [Edit Online](#)

This topic describes how to enable duplicate payment protection functionality in a payment connector that manages the integration with a payment terminal. A *payment connector* is an extension library that is written to integrate the POS with a payment terminal.

## Overview

- [Required reading](#) - List of topics that you should be read before starting the implementation of the duplicate payment protection functionality in a payment connector.
- [Prerequisites](#) - List of prerequisites to enable duplicate payment protection in a payment connector implementation.
- [Understanding duplicate payment protection flows](#) - Describes the various flows where the duplicate payment protection is invoked in the POS.
- [Implement duplicate payment requests](#) - Describes the various payment-related requests that need to be implemented to support the duplicate payment protection feature.

## Required reading

Be sure to read the following topic before enabling duplicate payment protection for a given payment connector.

- [Create an end-to-end payment integration for a payment terminal](#) - The duplicate payment protection feature builds on the payment integration for a payment terminal described in this topic.

## Prerequisites

The following prerequisites must be met before duplicate payment protection can be enabled for a payment connector implementation.

### **Support for unique transaction scope in payment terminal or payment gateway/processor**

In order to enable support for duplicate payment protection, the corresponding payment terminal or payment gateway/processor must provide support for unique transaction scopes. This support is usually handled through a unique payment reference identifier that can be generated by the payment terminal or payment gateway/processor before the payment is being processed. Without support for this unique identifier, the connector will not be able to uniquely match a previously initiated transaction with a successful payment authorization, which is at the core of the duplicate payment protection feature.

## Understanding duplicate payment protection flows

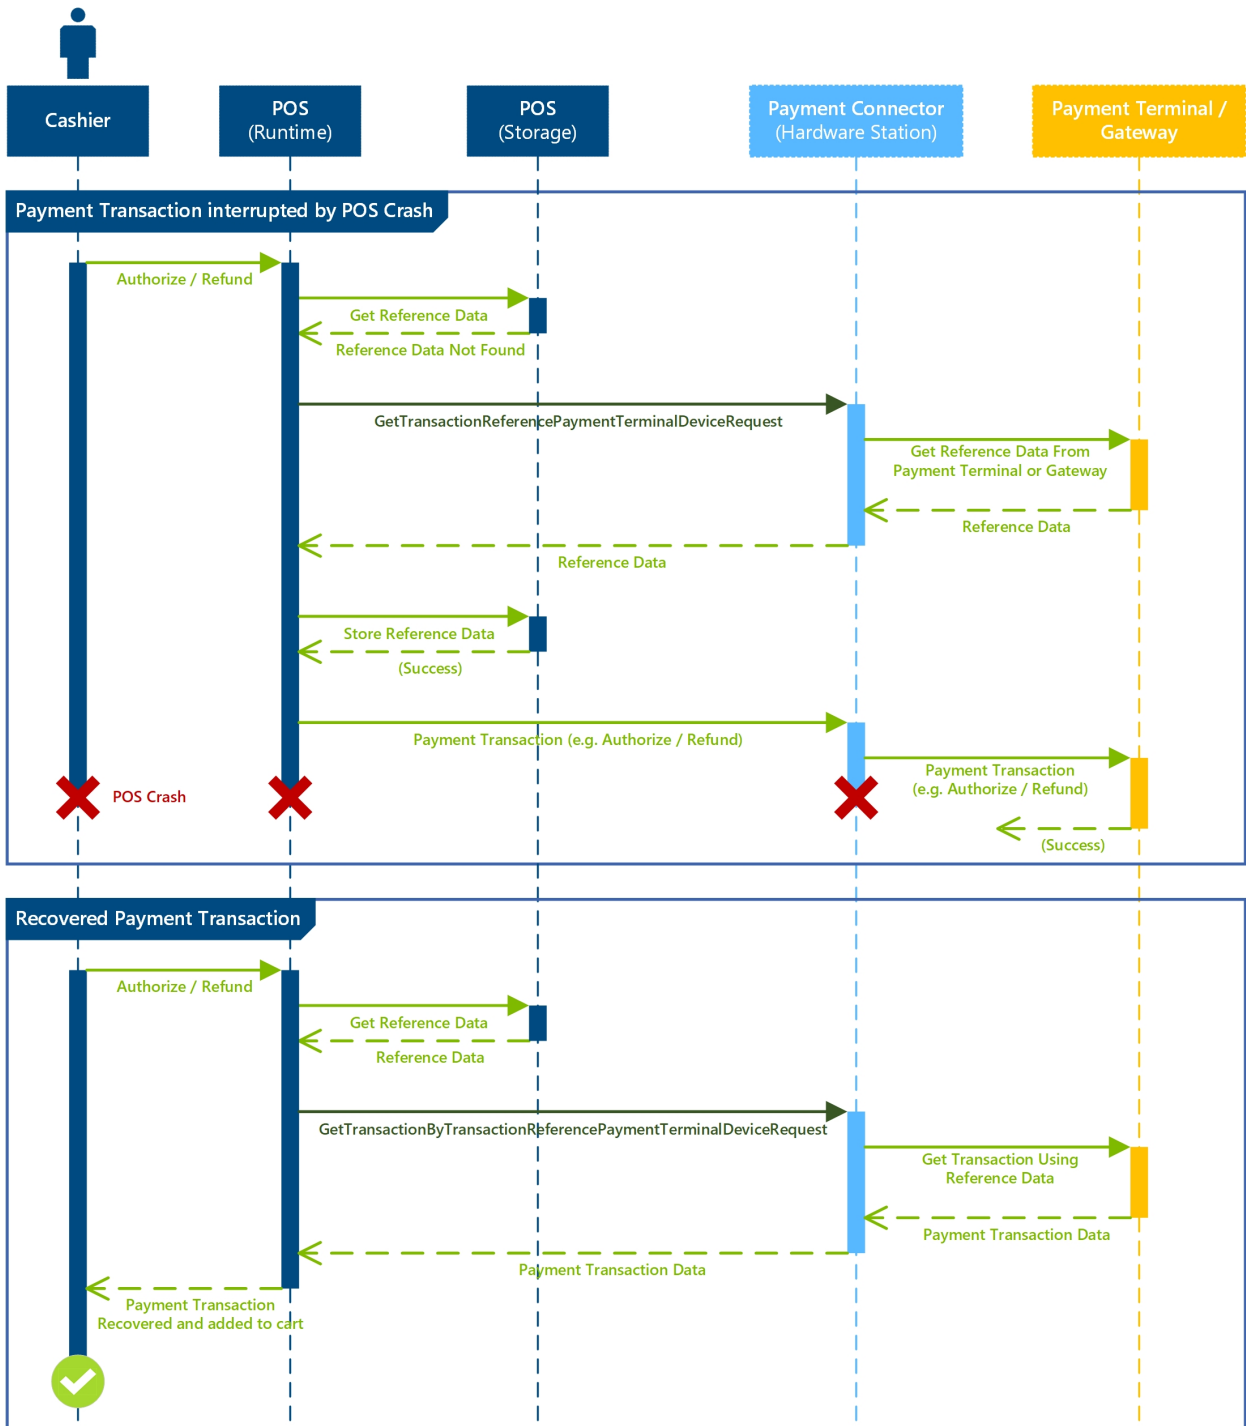

The Retail POS has been extended to invoke the new requests,

`GetTransactionReferencePaymentTerminalDeviceRequest` and

`GetTransactionByTransactionReferencePaymentTerminalDeviceRequest`

in various scenarios across the POS, such as immediately before an **Authorize** request is issued to the payment connector. The purpose of these new requests is to detect and recover successfully processed payment through the payment connector before a new payment request is issued. The following diagram illustrates a simple scenario where a payment request is successfully processed through the payment connector but the POS has crashed before it can receive the response. Subsequently, the POS is able to recover the previously processed payment through the duplicate

payment protection feature.

### Supported POS flows

The following list describes all of the POS flows where the

`GetTransactionByTransactionReferencePaymentTerminalDeviceRequest` is invoked to recover an existing payment.

These are the most commonly executed flows when the POS crashes or loses connectivity to the payment terminal or payment gateway during the processing of a payment transaction.

- Cashier invokes payment for any amount using a card payment
- Cashier invokes payment for any amount using a cash payment
- Cashier attempts to void a line on the cart
- Cashier attempts to void the transaction
- Cashier attempts to suspend the transaction

### Implement duplicate payment requests

The following sample illustrates the requests on the `INamedRequestHandler` payment connector implementation that are required to fully enable the duplicate payment protection feature.

```
namespace Contoso.Commerce.HardwareStation.PaymentSample
{
    /// <summary>
    /// <c>Simulator</c> manager payment device class.
    /// </summary>
    public class PaymentDeviceSample : INamedRequestHandler
    {
        /// <summary>
        /// Gets the collection of supported request types by this handler.
        /// </summary>
        public IEnumerable<Type> SupportedRequestTypes
        {
            get
            {
                return new[]
                {
                    // New request types specific to the duplicate payment protection feature.
                    typeof(GetTransactionReferencePaymentTerminalDeviceRequest),
                    typeof(GetTransactionByTransactionReferencePaymentTerminalDeviceRequest),

                    // Extended with new functionality.
                    typeof(AuthorizePaymentTerminalDeviceRequest)
                };
            }
        }

        /// <summary>
        /// Executes the payment device simulator operation based on the incoming request type.
        /// </summary>
        /// <param name="request">The payment terminal device simulator request message.</param>
        /// <returns>Returns the payment terminal device simulator response.</returns>
        public Response Execute(Microsoft.Dynamics.Commerce.Runtime.Messages.Request request)
        {
            ThrowIf.Null(request, nameof(request));

            Type requestType = request.GetType();

            if (requestType == typeof(GetTransactionReferencePaymentTerminalDeviceRequest))
            {
                return
                this.GetTransactionReference((GetTransactionReferencePaymentTerminalDeviceRequest)request);
            }
            else if (requestType ==
                typeof(GetTransactionByTransactionReferencePaymentTerminalDeviceRequest))
            {
                return
                this.GetTransactionByTransactionReference((GetTransactionByTransactionReferencePaymentTerminalDeviceRequest)
                request);
            }
            else if (requestType == typeof(AuthorizePaymentTerminalDeviceRequest))
            {
                return this.AuthorizePayment((AuthorizePaymentTerminalDeviceRequest)request);
            }
            ...

            return new NullResponse();
        }
    }
}
```

## **GetTransactionReferencePaymentTerminalDeviceRequest / GetTransactionReferencePaymentTerminalDeviceResponse**

### **Description**

The `GetTransactionReferencePaymentTerminalDeviceRequest` is invoked by the Retail POS at the beginning of a payment transaction and sets the scope of the payment. The scope of this request ends once the payment line is successfully added to the cart or an error, indicating that a card cannot be used and returned from the payment connector. The corresponding `GetTransactionReferencePaymentTerminalDeviceResponse` response will contain the corresponding unique identifier generated by the payment connector to look up a payment transaction. Note that the payment connector implementation must not cache the generated ID because the ID must survive the application's restarts, typically the ID should be generated by the Payment Gateway.

#### Request signature

```
public GetTransactionReferencePaymentTerminalDeviceRequest(string lockToken, string posTerminalId, string eftTerminalId);
```

#### Request variables

VARIABLE	DESCRIPTION
lockToken	Unique token value that is generated when the payment terminal is initially locked for the transaction.
posTerminalId	Unique name of the POS register.
eftTerminalId	EFT POS terminal number configured either on the POS register or the shared Hardware Station.

#### Response signature

```
public GetTransactionReferencePaymentTerminalDeviceResponse(string id);
```

#### Response variables

VARIABLE	DESCRIPTION
id	Unique identifier used for the scope of the payment transaction.

#### PaymentTransactionReferenceData

After the `GetTransactionReferencePaymentTerminalDeviceRequest` is executed, the Retail POS will generate a new instance of the `PaymentTransactionReferenceData` class to carry the required contextual data that is needed for the POS to maintain the duplicate payment protection scope. This variable will be stored and maintained in the POS and then used to check for existing transactions during key payment operations.

#### Properties

VARIABLE	DESCRIPTION
Command	Payment related command that was invoked. Possible values are <code>Sale</code> , <code>Refund</code> , <code>Activate</code> , or <code>Load</code> .
IdFromConnector	Unique identifier generated through the <code>GetTransactionReferencePaymentTerminalDeviceRequest</code> request.
InitiatedDate	Date and time when the original payment-related transaction was initiated.

VARIABLE	DESCRIPTION
UniqueTransactionId	Unique identifier for the cart transaction (not specific to a payment itself).
Amount	Amount of the payment transaction being handled.

## AuthorizePaymentTerminalDeviceRequest

### Description

`AuthorizePaymentTerminalDeviceRequest` parameter has now been extended to provide a new constructor that supports the new request, `PaymentTransactionReferenceData`. The purpose of this parameter is to maintain the contextual reference data and stamp the authorization request to the payment terminal or payment gateway/processor with the unique identifier generated by the payment connector and used by the POS to later query for and identify duplicate payments.

## GetTransactionByTransactionReferencePaymentTerminalDeviceRequest / GetTransactionByTransactionReferencePaymentTerminalDeviceResponse

`GetTransactionByTransactionReferencePaymentTerminalDeviceRequest` is invoked by the Retail POS immediately before certain payment-related operations to identify whether an existing payment transaction was already invoked and handled by the payment terminal or payment gateway/processor. If an existing transaction is recovered by the payment connector, it will be returned and short circuit subsequent calls to the connector to trigger a new transaction.

### Request signature

```
public GetTransactionByTransactionReferencePaymentTerminalDeviceRequest(string lockToken,
    PaymentTransactionReferenceData transactionReferenceData);
```

### Request variables

VARIABLE	DESCRIPTION
lockToken	Unique token value that is generated when the payment terminal is initially locked for the transaction.
transactionReferenceData	Property bag containing various properties used to uniquely identify a payment transaction. For more information, see the section <a href="#">PaymentTransactionReferenceData</a> in this topic.

### Response signature

```
public GetTransactionByTransactionReferencePaymentTerminalDeviceResponse(PaymentInfo paymentInfo);
```

### Response variables

VARIABLE	DESCRIPTION
paymentInfo	The recovered payment transaction. This is identical to the payment response returned for any other payment request, such as <b>Authorize</b> or <b>Refund</b> .

# Create Commerce payment packaging for Finance and Operations deployment

2/18/2021 • 3 minutes to read • [Edit Online](#)

This topic explains how to package a payment connector for Finance and Operations deployment in Microsoft Dynamics 365 Commerce.

In releases that are earlier than 10.0.10, you use the Commerce software development kit (SDK) to create a payment connector package. (The Commerce SDK was previously known as the Retail SDK.) In the 10.0.10 release and later, you can use only Visual Studio to create an Application Object Server (AOS) payment connector package. Packages that you create by using this approach can be deployed for both earlier deployments and self-service deployments by using [all-in-one packages](#).

## NOTE

In releases that are earlier than 10.0.10, you can create a single payment package and use it both for Application Explorer and for the commerce channel and cloud components (Commerce Scale unit). In the 10.0.10 release, you must create two packages. One package is for Application Explorer, and you create it by using the Dynamics 365 packaging model. The other package is for the commerce channel and cloud components, and you create it by using the Commerce SDK. The previous approach, where the Commerce SDK is used to create Application Explorer payment packaging, is obsolete (deprecated) as of the 10.0.10 release.

To create a payment package that you can deploy, follow the steps in the next section.

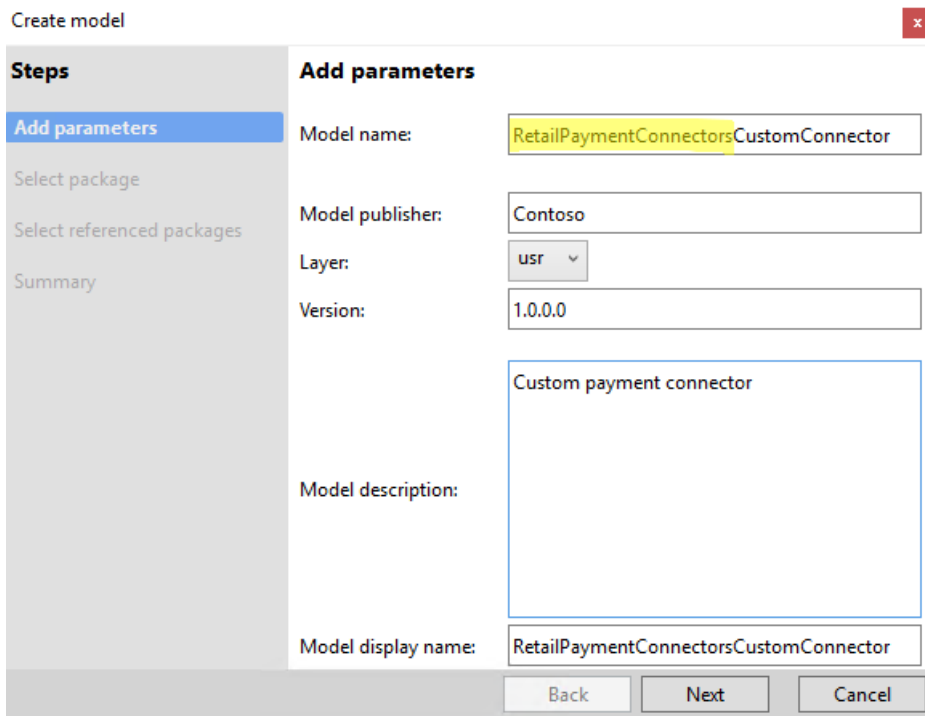

## NOTE

The steps for using the Commerce SDK to create the package for the commerce channel and cloud components haven't changed. For more information, see [Create and deploy connector](#).

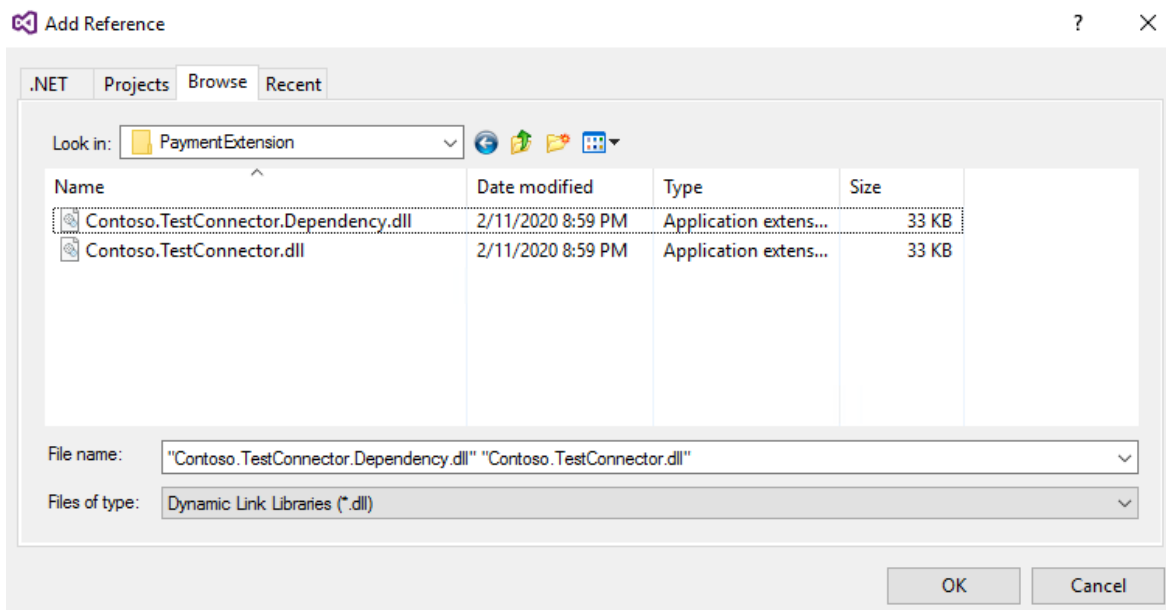

## Create an AOS payment package in the 10.0.10 release

1. In Visual Studio, on the **Dynamics 365** menu, select **Model Management > Create model**.
2. Enter the model name, the model publisher, and other required details. Then select **Next**.

The model name must be prefixed with (that is, start with) **RetailPaymentConnectors**. After this prefix, add information about the custom model name. For example, the model that you create might be named **RetailPaymentConnectorsCustomConnector**. Only model names that begin with the **RetailPaymentConnectors** prefix will be loaded in the Commerce payment connector options.

3. Select the **Create new package** option, and then select **Next**.
4. Select the required referenced package, and then select **Next**.
5. Select **Finish** to finish creating the model.
6. In Solution Explorer, select the project, right-click **References**, and then select **Add Reference**.
7. Add all the payment connector assemblies and their dependencies to the project as references.

8. If your extension needs an HTML and CSS file for the implementation, then add them as a resource file to your project. During deployment, the HTML files will be copied to the AosService\WebRoot\Resources\Html folder. The CSS files will be copied to the AosService\WebRoot\Resources\Styles folder, then accessed with the following URL format.

```
https://AOSUr1/resources/html/Myhtml1.html
https://AOSUr1/resources/styles/Mycss.css
```

#### NOTE

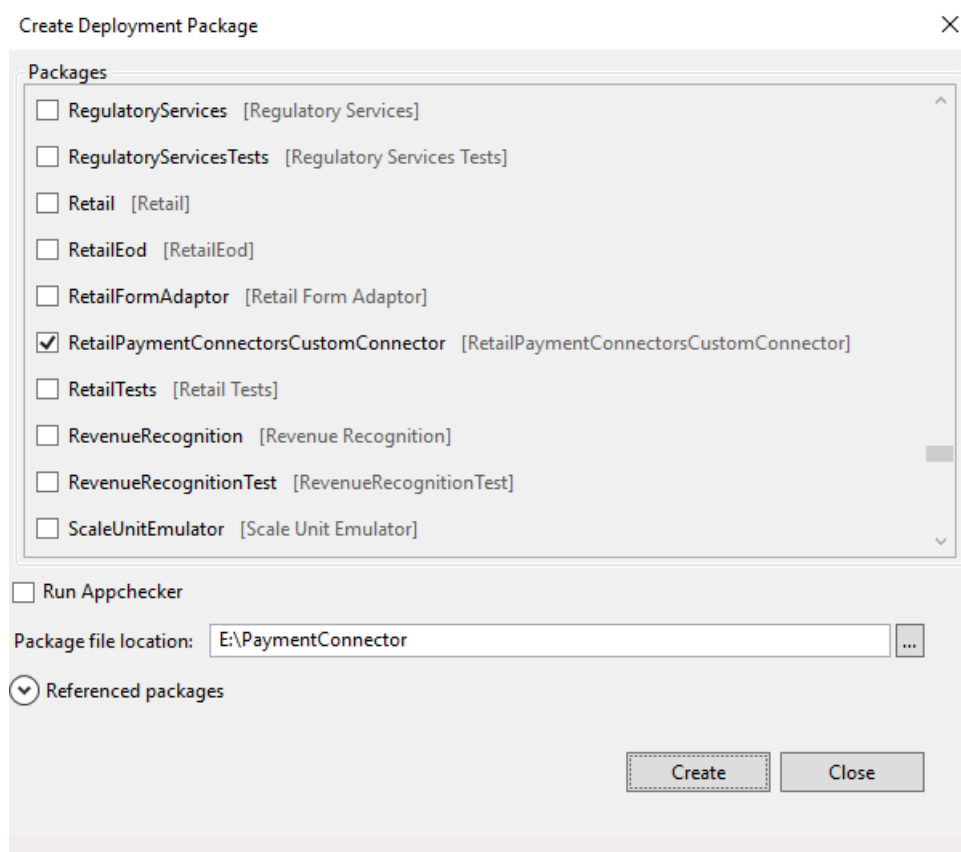

Only HTML and CSS file formats added as Resources to the project will be copied to the AOSService\WebRoot, other file formats added as Resources will not be copied to AOSService\WebRoot. If you need the file in AOSService\WebRoot\ folder then migrate it to HTML file format or host the non-supported file formats externally. IF hosted externally, hosting has to be managed by the customer or partner.

9. If you don't have any other payment X++ extensions that are related to the payment connector, build the solution.

#### NOTE

If there are no other extensions package, then continue with these steps. If you have additional extensions packages, then combine all of them into all-in-one deployable packages. If you do not do this, this package will override other packages. For more information, see [All-in-one deployable packages](#).

10. To create the deployable package, on the Dynamics 365 menu, select **Deploy > Create Deployment Package**.
11. Select the model that you created earlier, specify the location of the package file, and then select **Create**.

Visual Studio builds the model and creates the deployable package.

12. After the deployable package has been created, sign in to Microsoft Dynamics Lifecycle Services (LCS), and then, in your LCS project, select the **Asset Library** tile.
13. Upload the deployable package that you created.

## Apply a deployable package

For information about how to apply a deployable package to an environment, see [Apply updates to cloud](#)

environments.

## Remove a deployable package

For information about how to uninstall or remove a deployable package from an environment, see [Uninstall a package](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Configure online stores

2/18/2021 • 2 minutes to read • [Edit Online](#)

This article provides links to topics that will help you centrally configure and manage an online store.

The topics listed in the following table help you configure Commerce components and the online store in the client.

## Configure an online store

TASK	DETAILS	TOPICS
Configure components.	Set up and maintain information for commerce operations. This information includes stores, taxes, products, gift cards, promotions, and discounts.	<a href="#">Setting up and maintaining Retail</a> (TechNet content for Microsoft Dynamics AX 2012)
Configure a channel navigation hierarchy.	Create a channel navigation category hierarchy to set up a category structure for products that you offer through an online store. You define the category hierarchy, and assign products, product attribute groups, and attribute values to the categories. You then assign the category hierarchy to an online store.	<a href="#">Set up a retail hierarchy</a> (TechNet content for AX 2012) <a href="#">Set up attributes and attribute types</a> (TechNet content for AX 2012) <a href="#">Set up retail attribute groups</a> (TechNet content for AX 2012)
Add the online store to the organization hierarchy.	Before you can assign product assortments or fulfill orders for the online store that you created, or generate reports that include information from that online store, you must assign the store to one or more organization hierarchies. At a minimum, you must assign the online store to an organization hierarchy that includes product assortments.	<a href="#">Set up an online store</a> (TechNet content for AX 2012)
Add modes of delivery to the online store.	Select the delivery methods that the online store offers.	<a href="#">Set up an online store</a> (TechNet content for Microsoft AX 2012)
Map attributes, and add metadata.	Select the options that indicate how the attributes for each category or channel product should behave in the online store on the Microsoft SharePoint site.	<a href="#">Set up an online store</a> (TechNet content for AX 2012)

## Configure online store products

TASK	DETAILS	TOPICS
------	---------	--------

TASK	DETAILS	TOPICS
Add assortments to the online store.	Add the assortments that include the products that you offer in an online store.	<a href="#">Set up an online store</a> (TechNet content for AX 2012)
Manage catalogs.	Use product catalogs to identify the products that you want to offer in your stores.	<a href="#">Key tasks: Create retail product catalogs</a> (TechNet content for AX 2012)
Manage prices.	Set up and use price groups, which are the central link between prices and discounts, and channels, catalogs, affiliations, and loyalty programs.	<a href="#">Setting up prices using price groups</a> (TechNet content for AX 2012) <a href="#">Setting up taxes</a> (TechNet content for AX 2012)
Manage discounts.	Set up and manage price adjustments and four kinds of discounts.	<a href="#">Setting up price adjustments and discounts</a> (TechNet content for AX 2012)
Manage shipping charges.	Set up and manage the shipping charges that are specific to the online store.	<a href="#">Set up shipping charges for online stores</a> (TechNet content for AX 2012)
Manage modes of delivery.	Manage the modes of delivery that the online store offers.	<a href="#">Set up modes of delivery</a> (TechNet content for AX 2012)

## Set up data exchange between Commerce and the online store

TASK	DETAILS	TOPICS
Set up channel integration profiles.	Profiles enable the components to communicate with each other. Set up profiles before you configure data exchange settings.	<a href="#">Set up a Real-time Service profile</a> (TechNet content for AX 2012) <a href="#">Set up a channel profile</a> (TechNet content for AX 2012)

### NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

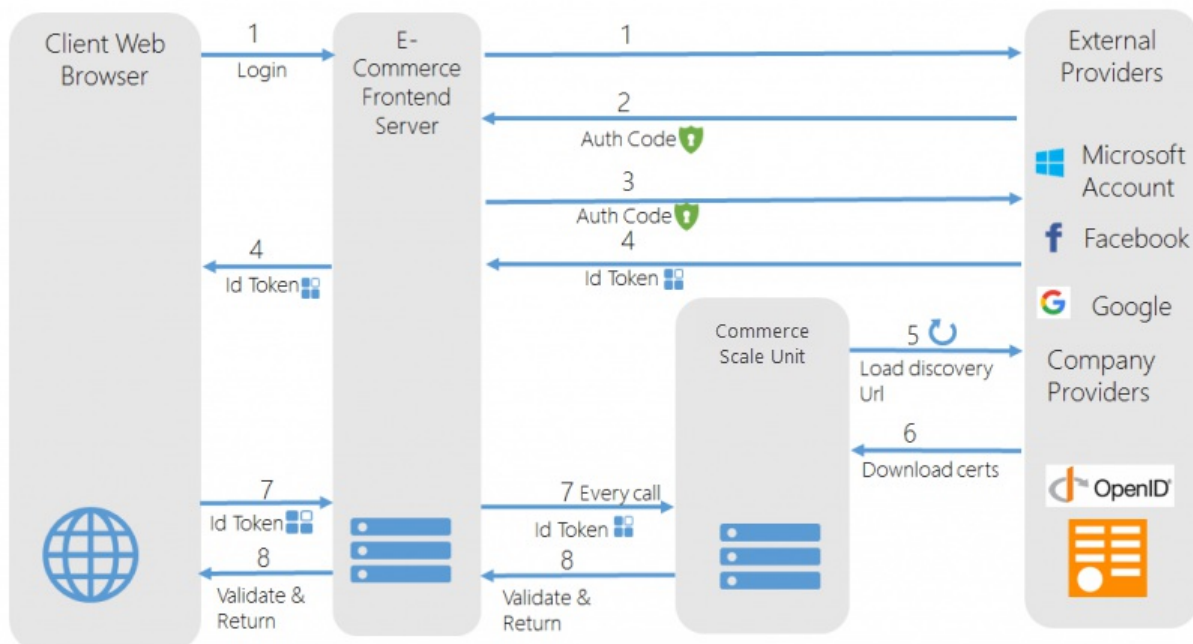

# Configure authentication providers

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic provides an overview of the process for configuring a new OpenID authentication provider.

The E-Commerce platform uses industry-standard [OpenID Connect](#) as the mechanism for authentication. This article covers the pages that you use to register the OpenID providers that are used in an online store. Commerce Scale Unit uses OpenID Connect as the mechanism to support authenticated customers. OpenID Connect is a universally accepted standard that acts as simple and evolved identity provider on top of OAuth 2.0. Commerce Scale Unit can be integrated with both ready-to-use OpenID providers through the Microsoft Azure Access Control service and other independently available providers. In addition, any custom providers that support OpenID connect can be integrated and registered. The following illustration shows the step-by-step handshake that occurs between the Commerce Scale Unit and the E-Commerce front-end server to pass the authentication token for subsequent calls.

Here is a walkthrough of the process for registering OpenID providers so that they can be used in Commerce Scale Unit.

1. From the Retail and Commerce IT workspace, go to **Commerce shared parameters > OpenID providers**. You can use the **OpenID providers** page to register additional providers. For every provider that you support, enter the details of the OpenID provider and the details of the relying parties. Commerce Scale Unit uses this information to request and use an authentication token for subsequent calls.
2. Run distribution schedule 1110.
3. For the test online store, edit the web.config file so that it specifies the correct redirect URL and domain, as shown in the following example. If you're using a third-party online store, this information can be stored as required.

```
redirectUrl=https://usnconeboxax1ecom.cloud.onebox.dynamics.com/en/Pages/OauthV2Redirect/OauthV2Redirect.aspx
```

**NOTE**

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# e-Commerce platform software development kit (SDK)

2/18/2021 • 3 minutes to read • [Edit Online](#)

This topic describes the e-Commerce Platform SDK. The e-Commerce Platform software development kit (SDK) consists of the following components:

- Framework
- Controls
- Publishing (only supported in version 1661 and higher: [Support for Service to Service authentication in Retail Server](#))
- Sample ASP.NET website

## Use the sample ASP.NET website

### Download the Retail SDK

The Retail SDK is available in development environments, and in hotfix packages in a Retail SDK folder.

- If you get the SDK from a development instance, it is immediately ready for configuration and use. For more information, see [Access instances](#).
- If you get the SDK from a hotfix, it is included in the hotfix package as a zipped folder. Hotfixes are cumulative and include all other fixes.

We recommend that you put the SDK in a source control system such as Visual Studio Online.

### Use the Retail SDK to create the sample ASP.NET website

1. Open Visual Studio in Admin mode. This step is necessary for publishing to the inetpub folder.
2. Open C:\Microsoft Dynamics AX70\RetailSdkOnlineStoreOnlineStore.sln contains all the framework components.
3. The sample online store is available at C:\Microsoft Dynamics AX70\RetailSdkSampleExtensionsOnlineStore.
4. Compile and publish the web store front, from within Visual Studio.
5. Update the path of the RetailStorefrontWebSite from IIS Manager.
  - Note that RetailStorefrontWebSite created by the default setup points to C:\Microsoft Dynamics AX70\Retail Store Front\Package.
  - However, the publishing of the web storefront from RetailSDK will drop the files at C:\inetpub\RetailWeb\Storefront.
  - Hence, the physical path of the RetailStorefrontWebSite must be updated to point to "C:\inetpub\RetailWeb\Storefront" to access web storefront on the same ports as before. Another option would be to create a new website and have that point to the inetpub location.
6. Browse to `http://localhost:55080` or access `https://usnconeboxax1ecom.cloud.onebox.dynamics.com/` to see a test ASP.NET website.

### Enable anonymous access

E-Commerce websites must allow anonymous access to work correctly. Ensure that anonymous access is enabled by adding the following key in the Commerce Scale Unit web.config file under app settings.

```
add key="IsAnonymousEnabled" value="true"
```

## Externally accessing the ASP.NET website

The following configuration changes will be required if either of these conditions applies:

- You are accessing web storefront from within a browser that is not on the same box as the e-Commerce server.
- The e-Commerce server and Commerce Scale Unit are on two different boxes.

You will need to update the "retailServerUrl" inside the web.config file of the RetailStorefrontWebSite. The following two fields will need to be updated to use the machine name instead of local host:

```
retailServerUrl=<http://localhost:35080/RetailServer/V1>  
<add key="RetailServerRoot" value="<http://localhost:35080/RetailServer/V1>" />
```

If you are accessing the web storefront over HTTPS, then you will need to update the above URLs to the HTTPS equivalent.

## Operating unit or channel configuration

The e-Commerce website will operate on an operating unit number(channel) specified in the web.config. To change it, change the OU # below. Note that Fabrikam is "077" in the demo data. You will need to update the "retailServerUrl" inside web.config of the RetailStorefrontWebSite. The following two fields will need to be updated to use the machine name instead of local host:

```
<ecommerceControls productUrlFormat="/Pages/ProductDetails/ProductDetails.aspx?itemId={0}"  
retailServerUrl="http://localhost:35080/RetailServer/V1" operatingUnitNumber="068">  
<add key="OperatingUnitNumber" value="068" />
```

# Configure authentication providers

## Authentication providers that you are using

The e-Commerce platform uses OpenID as the mechanism for authentication. You can register any OpenID provider of your choice to the tables below to make this work. You can then log in to test as needed.

1. Edit the web.config file and change it to the following.

```
redirectUrl=https://usnconeboxax1ecom.cloud.onebox.dynamics.com/en/Pages/OauthV2Redirect/OauthV2Redirect.aspx
```

The subsequent steps should only be done to register additional providers.

2. The **Retail Shared Parameters** -> **Open ID Providers** form can be used to register additional providers.
3. Run distribution schedule 1110.

### NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

# Localize Commerce extension resources and label files

2/18/2021 • 4 minutes to read • [Edit Online](#)

This topic explains how to modify labels in the point of sale (POS) user interface (UI), POS messages (error, warning, and information), receipt labels, and error messages for Commerce Scale Unit or Commerce Runtime Services (CRT). You can also add custom error messages for in the same way. However, for new POS extension labels, you should use the localization framework in the POS extension.

## POS labels and messages (error, warning, and information)

This section explains how to modify POS UI labels and POS messages by overriding the default strings.

### Override POS UI labels and messages

You can override the default strings in the POS by using the language text entries on the **Language text** page. Follow these steps to change POS strings.

1. Sign in to Commerce.
2. Go to **Retail and Commerce > Channel setup > POS setup > POS profiles > Language text**.
3. On the **Language text** page, on the **POS** tab, in the **POS language text** grid, select the **Add** button to add the language ID, text ID, and text for the string that you want to override.

For example, you want to change the label of the **Operator ID** field on the POS sign-in page to **Employee ID** for US English (en-us). In this case, add the following entry in the **POS language text** grid.

LANGUAGE ID	TEXT ID	TEXT
en-us	502	Employee ID

#### NOTE

For information about how to get the text ID for POS strings, see the next section.

4. On the Action Pane, select **Save**.
5. Go to **Retail and Commerce > Retail and Commerce IT > Distribution schedule**.
6. Select the **Registers (1090)** job, and then select **Run now**.
7. After the data is pushed, sign off, and then sign in to Cloud POS or Modern POS to see the changed labels.

### Get the text ID for POS strings

To get the text ID for a POS string, open the Modern POS/Cloud POS application. Press F12 to launch the developer command tools and select the **Console** tab to open the JavaScript console. Run the `Commerce.Helpers.DeveloperModeHelper.setDeveloperMode(true)`; command in the JavaScript console to turn on the developer mode.

After enabling the developer mode in the JavaScript console, navigate to the **Settings** page in POS, under the **Developer mode**, set **Developer Mode** to **Yes**. Set **Show Strings IDs** to **Yes**. Sign out of the POS, and then sign in again. The POS now shows the strings IDs in front of all the labels and messages.

## Error messages or receipt strings

This section explains how to modify error messages, or receipt strings, by overriding the default strings. It also explains how you can add new, custom error messages, or receipt strings.

### Override error messages or receipt strings

1. Sign in to Commerce.
2. Go to **Retail and Commerce > Channel setup > POS setup > POS profiles > Language text**.
3. On the **Language text** page, click the **Add** button to add the language ID, text ID, and text for the string that you want to override.

For example, when users enter an incorrect user name or password during sign-in, the POS shows the following error message: "We didn't recognize the user name or password. Please try again." For US English, you want to change the message to "Please enter valid user name or password." In this case, add the following entry in the **language text** grid.

LANGUAGE ID	TEXT ID	TEXT
en-us	Microsoft_Dynamics_Commerce_Runtime_InvalidAuthenticationCredentials	Please enter valid user name or password

#### NOTE

For information about how to get the text ID for error messages and receipt strings, see the next section.

4. On the Action Pane, select **Save**.
5. Go to **Retail and Commerce > Retail and Commerce IT > Distribution schedule**.
6. Select the **Registers (1090)** job, and then select **Run now**.

### Get the text ID for messages or receipt strings

1. Go to ...\**RetailSDK\Documents\Resources**.
2. In Visual Studio, open one of the following resource files:
  - **To modify error messages:** `RuntimeExceptionMessages.resx`
  - **To modify receipt strings:** `RuntimeReceiptMessages.resx`

For every message in the resource file, Visual Studio shows a name and a value.

3. In the **Value** column, search for the text that you want to change.
4. Copy the name that corresponds to that value. You enter this name as the text ID in the **language text** grid.

### Add custom error messages or receipt strings

You can also add new error messages or new receipt strings, on the **Language text** page. In this way, you support localization instead of hard-coding everything in the code.

### IMPORTANT

The text ID of all your new messages must start with **Microsoft\_Dynamics\_Commerce\_**.

For example, you want to add a new exception message in US English (en-us) and UK English (en-uk). In this case, add entries that resemble the follow entries on the **Language text** page.

LANGUAGE ID	TEXT ID	TEXT
en-us	Microsoft_Dynamics_Commerce_Custo mld1	My new message in US English
en-uk	Microsoft_Dynamics_Commerce_Custo mld1	My new message in UK English

### NOTE

In this example, **CustomId1** is the text ID for the new message. You can use any text ID that you want, provided that it starts with **Microsoft\_Dynamics\_Commerce\_**.

The following example shows how to use this new message in your CRT extension code.

```
throw new CommerceException("Microsoft_Dynamics_Commerce_CustomId1", ExceptionSeverity.Warning, null,
"Custom error")
    {
        LocalizedMessage = "My new message in US English.",
        LocalizedMessageParameters = new object[] { }
    };
```

# Development and administration for Finance and Operations apps

2/18/2021 • 3 minutes to read • [Edit Online](#)

## NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see [Power Automate Blog](#).
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see [Terminology updates](#).

This topic will be updated soon to reflect the latest terminology.

Development and administration for Finance and Operations apps includes:

- Administrator experience and Lifecycle Services
- Developer experience
- Intelligence
- Mobile apps
- Data management and data entities
- Office integration

## Developer experience

The developer experience is based on modern tooling using Visual Studio and .NET components.

- The development tools are decoupled from any running environment, which means that you develop against local, XML-based files, not the online database.
- Microsoft Visual Studio is the development environment. Finance and Operations customizes the Visual Studio environment to provide you with a smooth and familiar experience.
- The X++ compiler generates Common Intermediate Language (CIL) for all features. CIL is the same intermediate language used by other .NET-based (managed) languages, such as the C# programming language.
- You can leverage the browser-based client and design patterns for forms to provide an improved end-user experience.
- The Application Lifecycle Management (ALM) system supports build automation, test automation, and deployment of models to the cloud.

For more information, see [Develop and customize home page](#).

## Administrator experience and Lifecycle Services

Finance, Supply Chain Management, and Commerce are cloud-hosted. As an IT professional, you can use Dynamics Lifecycle Services (LCS) to monitor and tune your environments, deploy features, and stay up to date with recent hotfixes. Within your deployment, you can configure security, and manage when processes run. You can also use LCS when you are called on to support business intelligence and reporting, mobile apps, Office, and other integrations.

## BI & reporting

Finance and Operations provides five distinct reporting experiences. Specialized tools are provided to meet the complex and diverse reporting needs of various functions throughout the organization.

- Operational views – Designed to address the specific needs of a given business persona.
- Business documents – Static documents used to capture and exchange processed business data.
- Analytical tools and visualizations – Personalized presentations of logical calculations that allow the user to explore their data.
- Electronic reporting – Tool used to configure formats for electronic documents.
- Financial reporting – Designed to provide in-depth accounting management tools based on standard views of financial activities across legal entities.

## Mobile apps

The Finance and Operations mobile app empowers your organization to mobilize its business processes. After your IT admin enables the mobile workspaces feature for your organization, users can sign in to the app and immediately begin to run business processes from their mobile devices. The Dynamics 365 for Finance and Operations mobile app includes the following features that can help increase productivity:

- Users can view, edit, and act on business data, even if they have intermittent network connectivity or their mobile devices are offline. When a device reestablishes a network connection, offline data operations are automatically synchronized with Finance and Operations.
- IT admins or developers can build and publish mobile workspaces that have been tailored to their organization. The app uses your existing code assets, so you don't have to re-implement your validation procedures, business logic, or security configuration.
- IT admins or developers can easily design mobile workspaces by using the point-and-click workspace designer that is included with the Finance and Operations web client.
- IT admins or developers can optionally optimize the offline capabilities of workspaces by using the Business logic extensibility framework. Because data continues to be processed while a device is offline, your mobile scenarios remain rich and fluid, even if devices don't have constant network connectivity.

## Data management and data entities

Data from Finance and Operations can easily be integrated with Microsoft and non-Microsoft data sources using Dataverse, Power Apps, and Power BI. For more information, see [Data entities overview](#).

## Office integration

The Microsoft Office integration capabilities provide users with a productive environment that helps them get the job done by using Office products. For more information, see [Office integration overview](#).

## eLearning courses

For online courses and training, check out [Dynamics 365 Finance and Operations on Microsoft Learn](#).

# Finance home page

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic provides a list of the help topics and other resources for the financial management features in Microsoft Dynamics 365 Finance.

Select a feature area to learn more about it.

- [Accounts payable](#)
- [Accounts receivable](#)
- [Budgeting](#)
- [Cash and bank management](#)
- [Cost accounting](#)
  
- [Expense management](#)
- [Financial reporting](#)
- [Fixed assets](#)
- [General ledger and Financial reporting](#)
- [Project management and accounting](#)
- [Public sector](#)

## Additional resources

### Blogs

- [Microsoft Dynamics 365 blog](#)
- [Financials blog](#)
- [Microsoft Dynamics Operations Partner Community Blog](#)

### Task guides

Additional help is available as task guides inside Finance and Operations. To access task guides, click the Help button on any page.

### Videos

Check out the how-to videos that are now available on the [Microsoft Dynamics 365 YouTube Channel](#).

### Country/region functionality

Country/region regulations affect tax setup and other areas of financial management. Refer to the [Localization and regulatory features](#) section of our help content to learn about country/region-specific functionality.

### Additional content

Supply chain management functionality covers parts of the procure-to-pay process that includes requisitioning, ordering, receiving, invoicing and paying for the goods and services your organization purchases. Refer to the [Supply Chain Management home page](#) for information about the capabilities for managing purchases, inventory, and manufacturing.

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic provides a list of the help topics and other resources in Dynamics 365 Supply Chain Management.

## What's new and in development

Go to the [Dynamics 365 Roadmap](#) to see what new features are released and what new features are in development.

## Core concepts and tasks

Select a feature area to learn more about it.

- [Asset management](#)
- [Cost accounting](#)
- [Cost management](#)
- [Inventory management](#)
- [IoT Intelligence](#)
- [Master planning](#)
- [Procurement and sourcing](#)
- [Product information management](#)
- [Production control](#)
- [Sales and marketing](#)
- [Service management](#)
- [Transportation management](#)
- [Warehouse management](#)

## Dynamics 365 Finance

For information on Dynamics 365 Finance, go to the [Finance home page](#).

## Videos

This short video summarize the new supply chain management features added to Microsoft Dynamics 365 for Finance and Operations version 8.0 (April 2018).

- [Synchronize a work order between Field Service and Finance and Operations](#)

These short videos summarize the new supply chain management features added to Microsoft Dynamics 365 for Finance and Operations, Enterprise edition 7.3 (December 2017).

- [Prospect to cash integration](#)
- [Optimization advisor](#)
- [Use warehouse template to copy configuration](#)

These short videos summarize the new supply chain management features added to Microsoft Dynamics 365 for Finance and Operations, Enterprise edition (July 2017).

- [Get started with Cost accounting](#)

- [Cost control mobile workspace](#)
- [Use Excel for cost analysis](#)
- [Approve purchase orders on a mobile device](#)
- [Visual scheduling with Gantt chart for production and batch orders](#)

The following tech conference recordings discuss supply chain management functionality from previous versions of Finance and Operations. This functionality is now part of Dynamics 365 Supply Chain Management; the same concepts still apply, and the procedures are similar in the current version.

- **Cost management:**
  - [Overview of Cost management](#)
- **Master planning:**
  - [Extend the demand forecasting functionality](#)
  - [Master planning - tips and tricks for troubleshooting performance](#)
  - [Help! MRP is slow!](#)
- **Product information management:**
  - [Product configurator in Microsoft Dynamics AX](#)
- **Warehouse management:**
  - [Get the best out of your warehouse management system](#)
  - [Dynamics AX 2012 R3: Advanced warehouse management - A day in the life of process manufacturing](#)
- **Production control videos:**
  - [Subcontracting operations and activities in manufacturing](#)
- **Transportation management videos:**
  - [Transportation management \(TMS\) in the new Microsoft Dynamics AX](#)

## Blogs

There are many topics about manufacturing and supply chain management on the [Dynamics AX Manufacturing R&D Team Blog](#) and [Supply Chain Management in Dynamics AX R&D Team Blog](#). Most of these were written for the previous version, but the same concepts still apply, and the procedures are similar in the current version.
