Report results are stored in the **Inventory value** data entity. Therefore, you can filter and export the results to a format such as comma-separated values (CSV) or Microsoft Excel format.

The **Inventory value storage** report is helpful when the output contains many lines. For example, you have 50,000 items, and 300 stores have been created as warehouses. In this case, if you request inventory ending balances by item, site, and warehouse, the output will contain many lines.

NOTE

The report won't include subtotals that are defined in the report layout. It also won't include general ledger balances, even when they are defined in the report layout. Reconciliation to the general ledger must be done by using trial balances.

Turn on the Inventory value storage feature

Before you can generate an **Inventory value storage** report, you must turn on the feature in your system. Administrators can use the [feature management](#) settings to check the status of the feature and turn it on if it's required. In the **Feature management** workspace, the feature is listed in the following way:

- **Module** – Cost management
- **Feature name** – Inventory value storage

Generate an Inventory value storage report

Follow these steps to generate and store an **Inventory value storage** report.

1. Go to **Cost management > Inquiries and reports > Inventory value report storage**.
2. Select **New**.
3. In the **Inventory value** dialog box that appears, set the following values to define which records are included in your report:
 - On the **Parameters** FastTab, enter a unique name for the report, and use the fields in the **Date interval** section to define which records are included in the report. To define the date interval, you can either select a preset range (relative to the report generation date) in the **Date interval code** field, or select specific dates in the **From date** and **To date** fields.
 - On the **Records to include** FastTab, set up filters and constraints to define which data is included in the report.
 - On the **Run in the background** FastTab, specify how, when, and how often the report is generated.

NOTE

This report is always run as part of a batch job.

4. Select **OK** to apply your settings and close the dialog box.

After the batch job is completed, the report will be listed on the **Inventory value report storage** page. You might have to refresh the page to see the report.

Explore an Inventory value storage report

After you've generated a report, you can view and explore it at any time by following these steps.

1. Go to **Cost management > Inquiries and reports > Inventory value report storage**.
2. Select a report in the list.
3. Select **View details** to show the report content.
4. Explore the report by following any of these steps:
 - As for most standard pages in Supply Chain Management, you can select almost any column heading to sort or filter the grid by the values in that column.
 - Use the **Filter** field to filter the report by any value in any of several available columns.
 - Use the view menu (above the **Filter** field) to save and load your favorite combinations of sort and filter options.

Export an Inventory value storage report

Every report that you generate is stored in the **Inventory value** data entity. You can use the standard data management features of Supply Chain Management to export data from this entity to any supported data format, such as CSV or Excel format.

The following example shows how to export an **Inventory value report** report.

1. Go to **System administration > Workspaces > Data management**.
2. In the **Import / Export** section, select the **Export** tile.
3. On the **Export** page that appears, you will set up the export job. First enter a group name for the job.
4. In the **Selected entities** section, select **Add entity**.
5. In the dialog box that appears, set the following fields:
 - **Entity name** – Select **Inventory value**.
 - **Target data format** – Select the format to export data to.
6. Select **Add** to add the new row, and then select **Close** to close the dialog box.
7. Usually, you will export one report at a time. To export a single report, set up a filter for the row that you just added to the **Inquiry** dialog box. In this way, you can define which report from the **Inventory value** entity is included in your export. Follow these steps to set the following filter options to export a single report:
 - a. On the **Range** tab, select **Add** to add a row.
 - b. Set the **Table** field to **Inventory value**.
 - c. Set the **Derived table** field to **Inventory value**.

- d. Set the **Field** field to the field that you want to filter by. Usually, you will use the **Execution name** field and/or the **Execution time** field.
 - e. Set the **Criteria** field to the value that you want to look for in the selected field. (If you selected the **Execution name** field in the previous step, this value will be the name of the report. If you selected the **Execution time** field, it will be the time when the report was generated.)
 - f. Add more rows to the **Range** tab as you require, until you've uniquely identified the report that you're looking for.
8. Select **OK** to save your settings and close the dialog box.
 9. Select **Save** to save your export setup.
 10. On the **Export options** tab, select **Export now** to generate the export file.
 11. On the **Execution summary** page that appears, you can view the status of your export job and a list of the entities that were exported. In the **Entity processing status** section, select the **Inventory value** entity in the list, and then select **Download file** to download the data that was exported from that entity.

For more information about how to use data management to export data, see [Data import and export jobs overview](#).

Inventory aging report storage

2/18/2021 • 2 minutes to read • [Edit Online](#)

In Microsoft Dynamics 365 Supply Chain Management, you can run an **Inventory aging report storage** report and make the output available as a form and a chart. In the form, columns and aggregate balances are dynamically adjusted, depending on the layout that is configured. The chart provides a visual overview that supports filtering and lets you drill down into details. Additionally, a data entity that is named **Inventory aging report** lets you export the results of an **Inventory aging report storage** report run to a format such as a Microsoft Excel file or a PDF file.

This method of running an **Inventory aging report storage** report is helpful in cases where the output contains many lines. For example, the output will contain many lines if you have 50,000 items and 300 stores that are created as warehouses, and you request inventory aging by item, site, and warehouse.

Enable the Inventory value storage report feature

Before you can use this feature, you must enable it on your system. Administrators can use the [feature management](#) settings to check the feature status and enable it if needed. Here, the feature is listed as:

- **Module** - Cost management
- **Feature name** - Inventory aging report storage

Run an Inventory aging report storage

1. Go to **Cost management > Inquiries and reports > Inventory aging report storage**.
2. Select **New**.
3. In the **Process Identifier – Name** field, enter a unique name for the report.
4. Select the **Identification – ID** report, and filter it as you require.

Report execution is always done in a batch job.

5. After the batch job is completed, the output is shown on the **Inventory aging report storage** page.
6. To view the output as a form that has a traditional grid layout, select **View details**. To view the output as an aggregated chart, select **View chart**.

NOTE

The form won't include subtotals that are defined in the report layout.

The **Inventory aging report** data entity lets you export the output of an **Inventory aging report storage** report by applying a filter for the **Process Identifier – Name** field to any format that Data management supports.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Inventory aging report examples and logic

2/18/2021 • 4 minutes to read • [Edit Online](#)

This topic presents some examples that show how to interpret the results of an **Inventory aging** report. This report categorizes on-hand quantity and inventory values for a selected item or item group into several period buckets. This topic also shows the internal logic of the report.

The examples in this topic show results that are presented on a standard **Inventory aging** report. However, in general, we recommend that you use the [Inventory aging report storage](#) version of this report, especially when you have many items and warehouses that must be processed. Inventory aging report storage saves each report that you generate, shows the results as an interactive page and a chart, and lets you export any saved report.

Sample data that is used in these examples

The examples in this topic are based on the sample inventory transaction data that is described in this section.

Storage dimension setup

The example system contains the following setup of storage dimensions.

NAME	ACTIVE	PHYSICAL INVENTORY	FINANCIAL INVENTORY
Site	Yes	Yes	Yes
Warehouse	Yes	Yes	No

Inventory model

For the example system, the inventory model for the released products is *FIFO*, and the **Cost price** setting for the inventory model is *Include physical value*.

Inventory transactions

The example system contains the following inventory transactions for a released product that has the item number *1000*.

REFERENCE	SITE	WAREHOUSE	RECEIPT	ISSUE	PHYSICAL DATE	FINANCIAL DATE	QUANTITY	COST AMOUNT	PHYSICAL COST AMOUNT
Purchase order	1	11	Purchased		March 15	March 15	10	1,000	1,000
Purchase order	2	21	Purchased		March 15	March 15	10	2,000	2,000
Purchase order	1	11	Received		April 15		5		375
Transfer order	1	11		Sold	May 2	May 2	-5	-458.33	-458.33

REFERENCE	SITE	WAREHOUSE	RECEIPT	ISSUE	PHYSICAL DATE	FINANCIAL DATE	QUANTITY	COST AMOUNT	PHYSICAL COST AMOUNT
Transfer order	1	12	Purchased		May 2	May 2	5	458.33	458.33
Sales order	1	12		Sold	May 3	May 3	-1	-91.67	-91.67

How quantities and amounts in each period bucket are calculated

By using the sample data that is described in the previous sections, you can run an **Inventory aging** report that has the following settings:

- **As of date:** *May 9, 2020*
- **Site:** *View*
- **Warehouse:** *No*
- **Item number:** *Total*
- **Aging period:** Set this field to generate monthly buckets.

In this case, the content of the report that is generated will resemble the following example.

ITEM NUMBER	SITE	ON-HAND QUANTITY	ON-HAND VALUE	INVENTORY VALUE QUANTITY	INVENTORY VALUE	AVERAGE UNIT COST	5/8/2020 - 5/1/2020		4/30/2020 - 4/1/2020		3/31/2020 - 3/1/2020	
							P1:QUANTITY	P1:AMOUNT	P2:QUANTITY	P2:AMOUNT	P3:QUANTITY	P3:AMOUNT
1000	1	14	1,283.33	14	1,283.33	91.67			5.00	458.33	9.00	825.00
1000	2	10	2,000.00	10	2,000.00	200.00					10.00	2,000.00
1000 Total		24.00	3,283.33						5.00	458.33	19	2,825.00

Note the following details in this example report:

- The **Inventory value quantity**, **Inventory value**, and **Average unit cost** values that are shown on the report are values for the financial inventory dimension (**Site**, in this case).

For example, for site 1, the report shows the following information:

- The **Inventory value quantity** value is *14* (= 10 + 5 – 5 + 5 – 1).
 - The **Inventory value** value is *1,283.33* (= 1,000 + 375 – 458.33 + 458.33 – 91.67).
 - The **Average unit cost** value is *91.67*.
 - The **On-hand value** value and the **Amount** value in each period bucket are calculated by using the **Average unit cost** value.
- The report determines the on-hand quantity for each period bucket by summarizing the total received

inventory quantity for each period bucket. It then applies the first in, first out (FIFO) principle to deduct the total issued quantity, regardless of the inventory model that the items use.

If you run the same report again, but this time you set both the **Site** and **Warehouse** fields to *View*, the new report will resemble the following example.

ITEM NUMBER	SITE	WAREHOUSE	ON-HAND QUANTITY	ON-HAND VALUE	INVENTORY VALUE QUANTITY	INVENTORY VALUE	AVERAGE UNIT COST	5/8/2020 - 5/1/2020		4/30/2020 - 4/1/2020		3/31/2020 - 3/1/2020	
								P1:QUANTITY	P1:AMOUNT	P2:QUANTITY	P2:AMOUNT	P3:QUANTITY	P3:AMOUNT
1000	1	11	10	916.67	14	1,283.33	91.67			5.00	458.33	5.00	458.33
1000	1	12	4	366.67	14	1,283.33	91.67	4.00	366.67				
1000	2		10	2,000.00	10	2,000.00	200.00					10.00	2,000.00
1000 Totals			24.00	3,283.33				4.00	366.67	5.00	458.33	15	2,458.33

This time, site 1 is split into two rows, one for warehouse 11 and one for warehouse 12. However, the **Inventory value quantity**, **Inventory value**, and **Average unit cost** values are the same, because **Warehouse** isn't a financial inventory dimension.

Additionally, notice that the quantity distribution of site 1 is different. In the first report that you ran, the system ignored the transfer order that occurred in the same site and deducted the quantity of the sales invoice from the 3/31/2020 - 3/1/2020 period bucket in site 1. However, in the new report, the system deducts the quantity of the sales invoice from the 5/8/2020 - 5/1/2020 period bucket in warehouse 12.

Effects of inventory closing

If you run the inventory closing for May and then run the previous report again, but you set the **As of date** field to *May 31, 2020*, you will notice the following results:

- The **Inventory value** and **Average unit cost** values are updated.
- The **On-hand value** value and all the **Amount** values in every period bucket are updated accordingly.

The new report will resemble the following example.

ITEM NUMBER	SITE	WAREHOUSE	ON-HAND QUANTITY	ON-HAND VALUE	INVENTORY VALUE QUANTITY	INVENTORY VALUE	AVERAGE UNIT COST	5/31/2020 - 5/1/2020		4/30/2020 - 4/1/2020		3/31/2020 - 3/1/2020	
								P1:QUANTITY	P1:AMOUNT	P2:QUANTITY	P2:AMOUNT	P3:QUANTITY	P3:AMOUNT
1000 Totals			24.00	3,275.00				4.00	364.29	5.00	455.36	15	2,455.36

ITEM NUMBER	SITE	WAREHOUSE	ON-HAND QUANTITY	ON-HAND VALUE	INVENTORY VALUE	INVENTORY VALUE	AVERAGE UNIT COST	5/31/2020 - 5/1/2020		4/30/2020 - 4/1/2020		3/31/2020 - 3/1/2020	
								P1:QUANTITY	P1:AMOUNT	P2:QUANTITY	P2:AMOUNT	P3:QUANTITY	P3:AMOUNT
1000	1	11	10	910.70	14	1,275.00	91.07	0.00		5.00	455.36	5.00	455.36
1000	1	12	4	364.29	14	1,275.00	91.07	4.00	364.29				
1000	2		00	2.00	10	2,000.00	200.00					10.00	2.00
1000			24.00	3275.00				4.00	364.29	5.00	455.36	15.00	1,500.00
Totals				00									36

NOTE

BOM calculations

2/18/2021 • 9 minutes to read • [Edit Online](#)

The cost roll-up and sales price calculations are known as bill of materials (BOM) calculations, and you initiate them from the **Calculations** page. This topic provides information about BOM calculations.

The cost roll-up and sales price calculations are known as bill of materials (BOM) calculations, and you initiate them from the **Calculations** page. You use the **Calculations** page to perform the following tasks:

- Calculate the cost of a manufactured item, and generate an associated item cost record within a costing version.
- Calculate the sales price of a manufactured item, and generate an associated item sales price record within a costing version.

The way that you use the **Calculations** page varies slightly, depending on how you initiate the BOM calculations. The way that you use the **Calculations** page also depends on whether the BOM calculations involve a costing version for standard costs or planned costs, and on several policies that are defined in the costing version that is used in the BOM calculations. **Note:** A variation of the **Calculations** page is used in the context of a sales order, sales quotation, or service order line item. These calculations are known as order-specific BOM calculations. An order-specific BOM calculation doesn't generate an item cost record within a costing version. Instead, it generates a calculation record that appears on the **BOM calculation details** page. The calculation record includes a calculated cost and a calculated sales price. The **Calculations** page can be opened for a single manufactured item or for a costing version:

- To calculate costs for a single manufactured item, you initiate BOM calculations from the **Item price** page. The **Calculations** page inherits the item identifier. The costing version, BOM version, route version, calculation quantity, calculation date, and site must be specified.
 - By default, the BOM version and route version are set to the active versions for the item, site, date, and calculation quantity. However, you can override the default values with approved versions.
 - By default, the calculation quantity is set to the item's standard order quantity. However, you can override the default value.
 - The calculation date or site can be mandated by the costing version, or user-specified values can be set when the date or site isn't mandated in the costing version. A future calculation date determines how pending cost records are used. BOM calculations use a pending cost record that has the nearest from-date that is on or before the calculation date.
- To calculate costs for all manufactured items or selected items, or to update items on a where-used basis, you initiate BOM calculations from the **Costing version setup** page or the **Costing version maintenance** page. The **Calculations** page inherits the costing version.
 - For the calculations, it's assumed that the active BOM version and route version are used for a manufactured item (and for the related site, date, and quantity), unless a manufactured component has a specified sub-BOM or subroute.
 - For the calculations, it's assumed that the standard order quantity is used for manufactured items. The standard order quantity provides the basis for calculating component quantities, determining the relevant BOM versions and route versions (when you use quantity-sensitive BOMs and routes), and amortizing constant costs. However, when a manufactured component has a BOM line type of **Production** or **Vendor**, or when you use a make-to-order explosion mode for the BOM calculations, this assumption doesn't apply, because quantities reflect the specified calculation quantity.
 - The calculation date or site can be mandated by the costing version, or user-specified values can be set when the date or site isn't mandated in the costing version.

Other variations in BOM calculations reflect the costing type and restrictions of the costing version:

- BOM calculations that use standard costs must be restricted by costing version policies, because the restrictions help guarantee that standard costing principles are used. Standard costing principles require the enforcement of restrictions about the use of standard costs for purchased items, a single-level explosion mode, and the inclusion of miscellaneous charges in unit costs.
- BOM calculations that use planned costs don't have to follow standard costing principles. These BOM calculations can use different explosion modes, alternative sources of cost data for purchased items, and optional enforcement of restrictions within the costing version.

BOM calculations that use standard costs

Policies within the costing version (for standard costs) can mandate enforcement of five BOM calculation policies. The **Recording restriction** option in the costing version mandates one of these policies, where miscellaneous charges must be included in the unit price. Miscellaneous charges for purchased items can be entered manually, whereas miscellaneous charges for manufactured items reflect the calculated amortization of constant costs. The **Calculation restriction** option in the costing version mandates the other four BOM calculation policies:

- The source of cost contributions for purchased items must be based on standard costs. In other words, BOM calculations must use the item cost records within the specified costing version, or within the fallback that contains standard costs.
- To help guarantee accurate and consistent calculation of standard costs, the explosion mode must be single-level.
- To help guarantee consistent results when the sales price of the items is calculated, the profit setting must be mandated. The profit setting can be used, and the item sales price records can be generated, only if the costing version allows for content of sales prices.
- The fallback principle must be mandated, and can be set to **None**, **Active** (for active cost records), or **Costing version** (for a specified costing version).

BOM calculations that use planned costs

Policies within the costing version (for planned costs) can optionally mandate enforcement of five BOM calculation policies. Alternatively, the policies can just provide default values. The **Recording restriction** option in the costing version determines whether the BOM calculation policy about miscellaneous charges will be mandated or act as a default value. Miscellaneous charges can optionally be included in the unit price. The **Calculation restriction** option in the costing version determines whether the other four BOM calculation policies will be mandated or act as default values:

- The source of cost contributions for a purchased item can be the item cost records within a costing version. Alternatively, the source can be defined by the BOM calculation group that is assigned to the item. For example, the BOM calculation group can define purchase price trade agreements as the source of cost contribution data.
- The explosion mode can be single-level, multilevel, or make-to-order, or it can be based on the BOM line item. The explosion mode for the BOM line type replicates the cost calculation logic for production order estimates.
- The profit setting can be mandated, or it can be a default value. The profit setting can be used, and the item sales price records can be generated, only if the costing version allows for content of sales prices.
- The fallback principle can be mandated, or it can be a default value. The fallback principle can be set to **None**, **Active** (for active cost records), or **Costing version** (for a specified costing version).

BOM calculations generate warning messages and other types of messages. Several BOM calculation policies determine the types of messages. The warning conditions are defined in the BOM calculation group that is assigned to items. However, you can override these warning conditions when you initiate a BOM calculation. When the fallback principle is used, it's often helpful if the fallback is shown as an information message. When

you're trying to update calculated costs for items that have missing cost records, it's also helpful if the information message identifies items that weren't updated.

BOM calculations that use the fallback principle

The following situations illustrate two uses of the fallback principle:

- **Two-version approach to standard cost updates** - A costing version can contain the incremental changes to standard costs, such as pending cost records that represent new items or cost changes. In this situation, the fallback principle can identify the use of the active standard costs that are contained in other costing versions.
- **Simulation of the effect of cost changes by using planned costs** - A costing version for planned costs can contain incremental changes for simulation purposes. This costing version will include pending cost records that represent the simulated cost changes to items, cost categories, and calculation formulas for indirect cost. In this situation, the fallback principle can identify the use of the active standard costs that are contained in other costing versions.

BOM calculation of a suggested sales price

When you use a cost-plus-markup approach, the calculated sales price for an item reflects the set of profit-setting percentages that is specified for the BOM calculation, and the costs that are associated with the item's component items, routing operations, and applicable manufacturing overheads. The markup reflects profit-setting percentages that are assigned to cost groups, and the cost groups that are assigned to items, cost categories for routing operations, and the indirect cost calculation formulas for manufacturing overheads. The sets of profit-setting percentages are labeled **Standard**, **Profit 1**, **Profit 2**, and **Profit 3**. Within the Profit 1 set, for example, a profit-setting percentage of 50 percent can be defined for a cost group that is assigned to purchased material, and a profit-setting percentage of 80 percent can be defined for a cost group that is assigned to cost categories for routing operations. The context of the BOM calculation determines how the results of a calculated sales price are handled:

- **BOM calculation for an item and specified costing version** - The BOM calculation generates a pending sales price record within the costing version. This sales price record provides the starting point for viewing the calculation details (for example, on the **Calculate item cost** page). The sales price record acts mainly as reference information and isn't used as the basis for a sales price on sales orders.
- **Order-specific BOM calculation** - A variation of the **BOM calculation** page is used in the context of a sales order, sales quotation, or service order line item. An order-specific BOM calculation doesn't generate a record in the within a costing version. Instead, it generates a calculation record that appears on the **BOM calculation results** page. This calculation record provides the starting point for viewing the calculation details (for example, on the **Calculate item cost** page). Information about a selected calculation record can be transferred to the originating line item. For example, the calculated sales price can be transferred to a sales order line item.

Order-specific BOM calculations

An order-specific BOM calculation represents a variation of a BOM calculation for a manufactured item. The order-specific BOM calculation is performed in the context of a sales order, sales quotation, or service order line item. An order-specific BOM calculation generates a calculation record that appears on the **BOM calculation results** page. The calculation record includes a calculated weight, a calculated cost that is based on active cost records, and a calculated sales price. The calculation record that each order-specific BOM calculation for an item generates on the **BOM calculation results** page is uniquely identified by a calculation number. The results of a calculation record can be optionally transferred to the originating line item. An order-specific BOM calculation differs from a BOM calculation for a manufactured item in two ways:

- An order-specific BOM calculation doesn't generate an item cost record within a costing version. Therefore,

the BOM calculation policies aren't applied when an item cost record is created, or when a cost record is overwritten.

- An order-specific BOM calculation always uses the active cost records for components, cost categories, and indirect cost calculation formulas.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

BOM calculations groups

2/18/2021 • 8 minutes to read • [Edit Online](#)

This article provides information about calculation groups for bills of materials (BOMs) and how to set them up. To run a BOM calculation, you must either set up calculation groups and assign them to individual items, or set a default calculation group. The calculation settings from the calculation group are then used as default values on the BOM calculation page at the time of BOM calculation.

A default calculation group is required on the **Inventory and warehouse management parameters** page, or a product-specific calculation group is required on the **Released product details** page. The system first looks for the calculation group setup on the **Released product details** page. If it doesn't find a calculation group there, it looks on the **Inventory and warehouse management parameters** page. If the system can't find a calculation group, the user receives an error message during calculation. A calculation group contains policies for the cost price model, the sales price model, and the warnings checklist. The calculation settings from the calculation group are used as default values on the **BOM calculation** page at the time of BOM calculation.

Purposes of BOM calculation groups

You assign a BOM calculation group to items for several reasons:

- By setting the **Cost price model** field, you indicate the source of a purchased component's cost contribution data during the calculation of the planned cost of a manufactured item. Some manufacturers calculate planned costs by using the purchase price trade agreements for purchased components or another basis, such as the purchase price records in a costing version.
- By setting the **Sales price model** field, you indicate how the item's data is used to calculate a suggested sales price. You can specify either the item sales price or the cost group. Some manufacturers want to calculate a suggested sales price for manufactured items. The calculated sales price can reflect a rolled-price approach that is based on the component's sales price record. Alternatively, the calculated sales price can reflect a cost-plus-markup approach that is based on the component's cost and applicable profit percentage, which is associated with the item's cost group.
- By using the **Stop explosion** field, you indicate that a manufactured item should be treated as a purchased item for cost roll-up purposes during BOM calculation. Typical scenarios include a purchased item that is occasionally manufactured or a manufactured item that is now being purchased. The item is first designated as a manufactured item to define BOM and route information, and to support production orders for the item. However, the **Stop explosion** flag prevents cost calculations from using the item's BOM and route. Instead, the BOM calculation uses the item's specified costs.

Calculation groups

You define calculation groups under **Predetermined cost policies setup** in Cost management. Calculation groups that are assigned to items let you specify how the cost or sales price of components, as outlined by the calculation group, is sourced for the calculation. On the **Calculation groups** page, you can define a cost price model, an alternative cost price model, a sales price model, and warnings.

Cost price model

There are four options for the **Cost price model** field:

- **Item cost price** – The cost price from the **Released product** table is used, or the combination of item dimensions is used as the cost price.
- **Item purchase price** – The purchase price from the **Cost price** field on the **Purchase** tab of the **Released**

product list page is used.

- **Trade agreements** – You can configure trade agreements for specific combinations of items and vendors, or for specific sites. Then, when you select the **Trade agreements** option here, the trade agreement that you created for the purchase price together with the item and site will be used.
- **Inventory price** – The current inventory value for the item is used to calculate the unit cost in the BOM calculation. A unit cost price is calculated only if the posted quantity and the physical quantity are more than 0 (zero).

Alternative cost price

The **Alternate cost price** field has the same options as the **Cost price model** field. However, this field is used only when a price can't be found in the primary cost price model.

Sales price model

There are two options for the calculation of the **Sales prices** field:

- **Cost group** – When this option is selected, the sales price is calculated based on the cost price and the profit setting percentage from the cost group.
- **Item sales price** – When this option is selected, the sales price on the **Sell** FastTab from the Released product table is used.

Stop explosion

The **Stop explosion** check box is used to indicate when a manufactured item should be treated as a purchase item. Typically, you will leave the **Stop explosion** check box cleared. By selecting this check box, you indicate that a manufactured item must be treated as a purchase component instead of a manufactured component for the purpose of BOM calculation. Depending on the site, the item's cost can still be calculated by using BOM calculations. Explosion of planned purchase orders and production orders is stopped at the BOM whose components are associated with the calculation group that the **Stop explosion** check box is selected for. Master scheduling generates the planned orders on the BOM itself, not on the items that are included in the BOM. Basically, by selecting this check box, you specify that a cost won't be added into the BOM calculation for items that have this calculation group.

Warnings

On the **Warnings** FastTab, you select the options for any warning messages that users should receive when they do BOM calculations.

For example, if you select the **No BOM** check box, the user receives a warning if no active BOM version is found for one of the components or the parent item that the BOM calculation is run for. If you select the **No route** check box, the user receives a warning if no active route version is found. If you're using resources on your routes and operations, you can instruct the system to check for those resources. Then, if a resource isn't found on every line in the active route, the user receives a warning.

You can also verify and check for consumption. Consumption is the quantity in a particular route. Typically, it represents the amount of time that is required in order to perform a specific operation for a production process. You can check whether an item has no cost price. If there is no active cost price for an item, no cost is added into the BOM calculation.

You can also check and verify the age of the cost price. For example, enter **60** to indicate that the unit cost price must be reevaluated after 60 days. If this limit is reached, the system generates a warning. For example, a cost price was entered for an item in January of this year. If it's now August, which is more than 60 days after the cost price was entered, the user receives a warning when the BOM calculation is run. You can enter in a percentage in the **Minimum contribution margin** field. This value indicates the point at which the minimum contribution margin isn't being met. If the contribution margin for a particular component isn't met, the user receives a warning. Therefore, this field helps guarantee that you don't undercut the costs and the additional carrying costs that might be required for your items.

Default setup in Inventory and warehouse management parameters

Because calculation groups are required in order to run calculations, you must set up a default calculation group in the Inventory management parameters. This setup enables companies to have a standard cost group and profit setting for all items. Then, if a particular item has special calculation requirements, the user can assign a different calculation group to that item. Typically, you can set calculation groups on BOM component items instead of BOM items. However, when warning messages are shown, calculation groups can be applied. A calculation group that is assigned to items overrides the default value that is set up in the Inventory management parameters.

You can set up the default parameter at **Cost management > Inventory accounting policies setup > Parameters > Inventory accounting > Calculation group**. By setting up a default configuration group, you can also configure the warning conditions that prompt users during the BOM calculation process, if the selected components might cause calculation errors.

View warning messages on the Complete page

A BOM calculation generates warning messages. You can view the warnings about a selected item. For example, in Sales and marketing, create a new sales order for item D0001. Then, on the sales order line, on the **Update line** menu, click **Calculate Based on BOM/Formula** to view the calculation details and warnings. You can also view BOM calculation results on the **Complete** page. For the warning messages, only two warning conditions apply to manufactured items, whereas four warning conditions apply to any item:

- Identify when a manufactured item doesn't have an active BOM.
- Identify when a manufactured item doesn't have an active route.
- Identify when the item on a BOM line has a quantity of 0 (zero).
- Identify when the item on a BOM line has a cost of 0 (zero), or when it doesn't have a cost record.
- Identify when the item on a BOM line has an out-of-date cost. The warning reflects a comparison of the calculation date to the specified days for a maximum age of cost.
- Identify when the item on a BOM line has a profitability percentage that is less than you want.

You can define multiple BOM calculation groups, depending on your requirements for variations in warning messages. For example, one BOM calculation group that has warning conditions about an active BOM, a component quantity of 0 (zero), and component cost of 0 (zero) might be enough. When you start a BOM calculation, you can override the warning conditions that are associated with the BOM calculation group. You can also add or remove warning conditions. For example, if the current situation doesn't involve routing data, you can remove the warning condition about an active route. **Note:** Time and attendance includes a **Calculation groups** page, but that page has no relationship to BOM calculation groups. In Time and attendance, workers can be assigned to calculation groups that reflect the grouping of workers who are associated with the same supervisor or manager. Calculation of worker registrations can be done either automatically or manually by a supervisor or manager.

Cost calculation level

2/18/2021 • 2 minutes to read • [Edit Online](#)

The bill of materials (BOM) level that is named **Cost calculation level** excludes production orders and batch orders from its calculations. The system uses this level when it runs cost calculations in costing versions. In processes such as recalculation and inventory close, the system uses the **Costing level** BOM level instead.

The following simple scenario shows the differences between the **Cost calculation level** BOM level and the **Costing level** BOM level.

You have three products: A, B, and C. Product C is the component of product B, and product B is the component of product A.

- **Costing level** assigns the following BOM levels:
 - **Product A:** 0
 - **Product B:** 1
 - **Product C:** 2
- **Cost calculation level** assigns the following BOM levels:
 - **Product A:** 0
 - **Product B:** 1
 - **Product C:** 2

A production order for product C is then created, and product A is added to the production order BOM. After the order is estimated, BOM levels are updated in the following way:

- **Costing level** assigns the following BOM levels:
 - **Product B:** 1
 - **Product C:** 2
 - **Product A:** 3
- **Cost calculation level** assigns the following BOM levels:
 - **Product A:** 0
 - **Product B:** 1
 - **Product C:** 2

This behavior ensures that changes to production order BOMs don't affect subsequent cost calculations.

Backflush costing

2/18/2021 • 11 minutes to read • [Edit Online](#)

This topic introduces the concept of backflush costing that is used for Lean manufacturing.

Costing for Lean manufacturing enables the production flow to use the cost accumulation method that is known as backflush costing. In the backflush costing method, the direct materials that are consumed are accumulated in the production flow's work in progress (WIP) cost account. The standard cost inventory model group is used. The products that are received from the production flow are deducted from WIP at their standard cost. The main difference between backflush costing and standard cost is that, for backflush costing, variances aren't calculated per kanban or finished product. Instead, variances are calculated per production flow over a period. This method introduces a truly lean concept for reporting material consumption. Dedicated picked quantities of material aren't reported to a kanban or production order. Instead, full batches or handling units are staged to the production flow. After the batches or handling units are registered as empty, they are declared consumed. Advanced consumption might be used, depending on the [configuration of the production flow](#). Before advanced consumption can be used, organizations must allow themselves to make material vanish in the WIP of the production flow. The periodic backflush costing determines the effective value of WIP to the end of the period. This determination is based on the kanban handling units and the kanban job status. Deviations between the effective values and the actual WIP values per cost group and item are accounted and shown as variances.

Configuring backflush costing

To enable costing, you must complete the following setup:

- **Set up WIP accounts for the production group and production flow.** The WIP accounts for the production flow are specified in the production group. The backflush costing production flow calculates variances as the difference in the WIP value before and after backflush costing is run for each production flow. Therefore, we recommend that you create a WIP account for every production flow.
- **Assign a cost category to the resource group.** You must assign a cost category to the run-time category of the work cell. To determine variances by activity, you should create a cost category for every work cell. The cost categories for setup and quantity aren't considered in costing for lean manufacturing. The WIP accounts per resource group are ignored in backflush costing. For subcontracted activities, no cost category is required. The cost group that is assigned to the active service is used instead.
- **Assign cost groups.** To enable segmentation of the cost contribution in a production flow, you must assign cost groups by cost group type:
 - **Direct material cost group** - Direct material requires a cost group that identifies the material category for costing. This cost group enables an aggregated view of cost, WIP, and variances by direct material.
 - **Direct manufacturing cost group** - The direct manufacturing cost group captures the direct cost contribution of operational resources to the production flow. This cost group enables an aggregated view of cost, WIP, and variances by direct manufacturing cost.
 - **Indirect cost group** - The indirect cost group is required in order to calculate the indirect cost contribution to the production flow. This cost group enables an aggregated view of cost, WIP, and variances by indirect cost.
 - **Direct outsourcing cost group** - The cost group for the services enables an aggregated view of assigned cost and WIP, and determines the cost variances of the subcontracted services.
 - **Cost group for a finished product** - Finished products require a cost group that identifies the product category for costing. This cost group enables an aggregated view of cost, WIP, and variances by product category. The standard cost for products is calculated by using the cost calculation that is

based on the bill of materials (BOM), and either the production flow and kanban rules or the route.

Costing sheet

The costing sheet models the cost structure for the company and is built by the cost groups to classify the cost. The costing sheet has various forms. It shows cost information according to the structure that is designed in it. In the costing sheet, you also define the formula that is used to calculate the indirect cost. The calculation formula can be based on quantities, weight, volume, or value.

- **Define a costing version.** In the costing version, the company defines how the cost should be maintained. A costing version can contain a set of standard cost records or a set of planned cost records, depending on the costing type that is assigned to the costing version. The costing version that is used for costing for Lean manufacturing must be based on standard cost.
- **Assign an inventory model group for released products.** All products that are related to the production flow must be assigned to an inventory model group that uses the **Standard cost** inventory model group. Standard cost is maintained per site and activation date. For product masters, the inventory model group can be selected if the cost is maintained per variant or product master.
- **By definition, subcontracted services are non-inventoried services.** Subcontracted activities have no inventory model group. To cost a subcontracted activity correctly, you must make sure that the service activity belongs to an inventory model group where the inventory policy is set to **Stocked product = False**.

For output products, cost calculation that is based on the production flow requires that a standard cost be maintained for the services that are related to subcontracted activities. The cost group that is assigned to the services is used to determine the cost variances of the subcontracted activity.

Cost calculation for Lean manufacturing

For products that are supplied out of a production flow, the BOM calculation must be based on either a route version or a production flow. The BOM calculation calculates the cost of a product and the related breakdown to the resources and material that are required in order to build the product. The deduction from the WIP account for the production flow is done by using the breakdown of a product by item and cost group.

Calculation that is based on the production flow

Lean manufacturing for Dynamics 365 Supply Chain Management is independent of routes. The cost calculation for products that are supplied from a production flow can be based on the production flow itself. Before the calculation can be done, a kanban rule must be created that supplies the product out of the production flow. If a product can be supplied from multiple production flows at the same site on the calculation date, you can select the production flow for the BOM calculation. On the **Default production flow** page, you can configure a default production flow for each item. If multiple kanban rules exist for the same product in the same production flow that is active on the calculation date, the calculation selects the first kanban rule that is active for the calculation.

Calculation that is based on the route

Calculation that is based on a route is as valid as calculation that is based on a production flow. However, calculation that is based on a route doesn't use the costing for Lean manufacturing functionality. The route should use resource requirements for resource groups. To avoid systematic variances, it should also use the same work cells, or at least the same cost categories. Again, you should avoid cost categories for setup and quantity. They don't help calculate the cost in a more granular breakdown than Lean manufacturing cost backflushing. To determine which option (production flow or route) you should use to calculate the cost, consider the results of the cost breakdown. The version that comes closer to reality and produces fewer variances overall is the better option. In a Lean manufacturing environment where a product is supplied by a single production flow and a single kanban rule, the calculation that is based on the production flow is probably more accurate. For a product that can be supplied by Lean manufacturing and production orders on the same site, or that can have multiple production flows or multiple kanban rules in the same flow, a calculation might be

more accurate if it's based on a route version that is built specifically for the cost calculation, not for the production. The production flow calculation must be used to calculate products that involve subcontracting. The cost models for subcontracting via production orders and subcontracting in Lean manufacturing are using two different approaches. Lean manufacturing introduces a new cost group type, **Direct outsourcing**, to calculate subcontracted services.

Material consumption

When material is consumed from inventory to WIP, the cost of material is added to WIP at its actual standard cost for a cost group. This operation occurs under the following conditions:

- Kanban issues are posted for kanban picking lines that update inventory.
- Transfer jobs are completed that update inventory on pick but not receipt (Transfer of material from inventory to WIP).

Receiving products from the production flow

Products are received from the production flow under the following conditions:

- Process jobs are completed that have **Update inventory on receipt** set to **Yes**.
- Transfer jobs are completed that update inventory on receipt, but that have **Update inventory on pick** set to **No** (Transfer from WIP to inventory). This option lets you receive any products out of a production flow independently of the BOM and route configuration. The process just follows the physical flows. This option is especially suitable for receiving by-products, co-products, or scrap out of a production flow, and for correcting the cost balance of the production flow WIP accordingly.

Products that are received from the production flow are deducted from WIP.

Products in WIP

The WIP model of Lean manufacturing lets you use the kanban handling unit status to manage the material, semi-finished products, and finished products that are part of WIP.

- **Assigned** - The kanban can have consumed material that is accounted in WIP.
- **Received** - If the kanban refers to a last activity where **Update inventory on receipt** is set to **No**, it represents a full handling unit of a product or a semi-finished product that isn't registered to inventory.

Note that material in WIP isn't visible in inventory on-hand overviews. However, it's visible in the kanban quantity overviews.

Consuming products in WIP

Products in WIP are consumed when the corresponding kanban handling units are emptied. A kanban empty signal doesn't produce an active costing transaction but will take effect when the next backflush costing is run. Emptied kanban handling units are no longer accounted as on-hand and therefore calculated as consumed within the period.

Automatic empty registration

Scheduled or event kanbans can be set to automatic empty registration in the kanban rule:

- **When handling units are received** - By default, for scheduled kanbans, the material is declared as consumed when the last job of the kanban is completed. For fixed quantity kanbans, this option is recommended only for single-bin kanbans, because it returns the card to the source of demand whenever a kanban is received at the final destination.
- **When source requirement is registered** - This option is available only for event kanbans and is the

default option for them. In connection to WIP, this option is useful for keeping WIP clean, because kanbans for components in WIP are automatically emptied, and therefore consumed from WIP, when the parent kanban is prepared.

In conclusion, kanban handling units can be assigned (= in process), received (=full), or emptied. There is no partial emptying. Therefore, to enable accurate registration of consumption, it's important that you limit the product quantities of a kanban so that they are less than the consumption per period. Products that are moved to the shop floor in big batches that cover days or weeks of demand should not be consumed to WIP. Instead, these products should be kept in inventory.

Backflush costing

You should run backflush costing to periodically value the WIP and produce an end-of-period status that calculates the variances of material, labor, and indirect costs. The calculated variances are posted to the variance accounts. In the backflush costing process, all production flows of the legal entity are used in the same batch run. When backflush costing is run in a batch, the processing might be multi-threaded by production flow. The backflush period is defined by an end date. You can't post new transactions to a date when a backflush costing calculation has been run. You should never run backflush costing for the current date before the day is actually over. Backflush costing performs the following steps.

1. Determine the unused quantities in the production flow as of the period's end date. After the backflush costing is run, you can view the unused quantities on the date of the costing run in the **Unused quantities** dialog box.
2. Calculate the production flow's net realized usage over the period.
3. Clear the WIP from the realized resource consumption and products.
4. Calculate production variances to standard cost for the period. **For consumed components for the period:**
 - Financially update the net realized quantities of material that the production flow consumed over the period. The system processes in first in, first out (FIFO) order on the individual inventory transactions as to financially update the physically updated transactions for the production flow, until the net realized quantities for the period are reached.
 - Transactions are financially split to map the exact consumed quantities.
 - Unused quantities in the production flow WIP remain in physically updated status.

For production completed quantities of the period:

- Financially update the inventory transactions for the completed quantities for the period.

For the conversion cost:

- The applied conversion cost transactions (route transactions) that were recorded for the period are financially updated.
 - All direct manufacturing cost is financially updated. All kanban process jobs that are completed during the period are accumulated.
 - All indirect cost calculated for the consumed material within the period is calculated and deducted from WIP. The remaining indirect cost is posted as a variance.
5. Calculate the production variances to standard cost. The variance is calculated per cost group.

Common sources of production variances

2/18/2021 • 2 minutes to read • [Edit Online](#)

This article explains various typical sources of each type of production variance.

Here are some typical sources of a **lot size** variance:

- The good quantity for a production order differs from the calculation quantity that is used in the standard cost calculation. The quantity provides the basis for amortizing constant costs.
- The value of constant costs on the production order differs from the constant costs that are used in the standard cost calculation. The constant costs on the production order can differ for several reasons. For example, the constant costs might reflect the following factors:
 - Manual changes to the production bill of materials (BOM) or route
 - The selection of a different BOM version or route version when you create the production order
 - Planned engineering changes to the BOM version or route version that is assigned to the item

Here are some typical sources of a **production price** variance:

- The cost category (and cost category price) for the reported consumption of a routing operation differs from the cost category that is used in standard cost calculation.
- The active cost for the cost category price differs from the cost category price that is used in standard cost calculation.

Here are some typical sources of a **production quantity** variance:

- You over-issue or under-issue a material component.
- You over-report or under-report the time for a routing operation.
- You over-receive or under-receive the good quantity of the parent item, relative to the order quantity. However, you issue components and report operations completely, based on the order quantity for the production order.

Here are some typical sources of a **production substitution** variance:

- You issue a material component that isn't on the production BOM.
- You manually add a component to the production BOM and report that component as consumed.
- You report an item as consumed but don't manually add it to the production BOM.
- You manually add an operation to the production route and report that operation as consumed.
- When you create the production order, you select a BOM version that differs from the BOM version that is used in the standard cost calculation.
- When you create the production order, you select a route version that differs from the route version that is used in the standard cost calculation.

NOTE

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Cost categories used in production routing

2/18/2021 • 3 minutes to read • [Edit Online](#)

This article provides information about cost categories that apply to manufacturing environments that use routing.

Cost categories apply to manufacturing environments that use routing. They are assigned to operations resources and routing operations to define hourly costs and to segment cost contributions in a manufactured item's calculated costs. The cost groups that are assigned to cost categories classify manufacturing cost contributions, based on the operation resources and the type of activity, such as setup time and run time. The specificity of cost group assignments enables manufacturing overhead to be calculated based on routing information.

Note: In manufacturing environments, cost categories are known by several other names, such as labor rate codes or machine rate codes.

Each cost category has associated cost records and an assigned cost group. Different cost categories are required for different production purposes.

- Assign different hourly costs, depending on the operations resource. For example, the costs can differ for various types of labor skills, machines, or manufacturing cells.
- Assign different hourly costs for the setup time or run time that is associated with a routing operation.
- Assign operations resource costs based on the output quantity instead of hourly costs, such as the piece rates for paying labor.
- Provide cost group segmentation of cost contributions to a manufactured item's calculated cost. For example, you can segment of labor and machine costs.
- Provide the cost group basis for overhead calculation formulas, such as formulas for labor-related and machine-related overhead, or overhead that is related to setup and run time.

A cost category can be assigned to the setup time, the process time, and the quantity for a routing operation. When, for example, costs or cost group segmentation differs between the setup time and the process time, different cost categories should be defined and assigned to the setup time and the process time. The selective use of cost categories for setup time, process time, and quantity is determined by the route group that is assigned to an operation. The assignment of cost categories to time and quantity can be mandated by company-wide policies that are defined on the **Production control parameters** page.

Each cost category has associated costs that are based on the definition of cost records in a costing version. Use the **Cost category price** page to define the cost records for a specified costing version and site. When the cost record for a cost category is first entered, it has a status of **Pending** and an intended effective date. When you activate the cost record, the status is updated to **Current active**, and the effective date is updated to the activation date. Different cost records might reflect different sites, effective dates, or statuses. Bills of materials (BOM) calculations for a future or historical date use cost records that have the relevant effective date. The current active cost record will be used to estimate production order costs and to value reported time against a production order.

The cost record for a cost category can be site-specific or company-wide. To make a cost record site-specific, assign a site to it. Otherwise, a blank value indicates that the cost record applies to all sites in the company. Because costs can differ between sites, for example, the cost records must be defined as site-specific.

A routing operation generally inherits the cost categories that are assigned to the operations resource or master operation. When a production order is created, the routing operations in the production route reflect the

selected route version. You can override the cost categories that are assigned to the operations in the production route.

Some types of production work can apply to project time estimates and reporting. In this case, a cost category is required for production and project purposes. You must define additional project-related information when a cost category is flagged for use in projects.

NOTE

Cost categories used in Production control and Project management accounting

2/18/2021 • 2 minutes to read • [Edit Online](#)

Some types of production work can apply to project time estimates and reporting. This article provides information about the cost categories that you must define for these types of production work for production and project purposes.

Some types of production work can apply to project time estimates and reporting. In this case, a cost category is required for production and project purposes. When a cost category is used in production and projects, additional project-related information must be defined. For example, the hourly costs that are associated with projects can differ from the hourly costs that are associated with production. You can use the **Cost categories** page to define a cost category that is used in Production control and Project management accounting.

Note: Cost accounting has a **Project categories** page, but this page has no relationship to the functionality that is described in this topic. When you use a cost category in projects, the **Cost categories** page has additional tabs that show additional project-related information. This information includes the category group, a line property, and ledger accounts that are assigned to the cost category.

- The cost category must be assigned to a category group that supports a transaction type of **Hours**.
- The line property indicates default information about how reported time can be charged to a project.
- Typically, the ledger accounts that are related to costs and sales are defined for the category group that is assigned to the cost category. However, specific accounts can be defined for an individual cost category.

Additional buttons on the **Cost categories** page let you access project-related information about a selected cost category. For example, you can view project-related transactions, define employees or projects, define hourly costs and sales prices, and view reports.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

Display charges for a manufactured item

2/18/2021 • 2 minutes to read • [Edit Online](#)

The constant costs of a manufactured item reflect the operation setup times and the components that have a constant quantity or a constant scrap amount.

The calculated amount of an item's charges can be displayed with the item's unit costs. However, the charges are sometimes displayed as separate fields, and they are not included in the item's unit costs. When the charges appear as separate fields, one field displays the total amount of charges, and another field displays the costing lot size that is used to amortize the amount. The Item price page, for example, displays the charges as two separate fields. However, the Complete page displays the item's total cost per unit, and the amortized costs are included in the unit costs.

The charges for a manufactured item are always included in the item's unit cost for standard cost purposes. They can optionally be included for planned cost purposes. A policy in the costing version enforces the inclusion of charges in the cost of a manufactured item. When you activate an item's cost record, you update the charges for the item's base cost information, which is displayed in the Item price page. The charges are displayed as two separate fields, and they are not included in the item's unit cost. Each activation updates the item's base cost information, even if the activation reflects different sites. Therefore, you should view the base cost information as reference information.

Production order cost analysis

2/18/2021 • 3 minutes to read • [Edit Online](#)

This article provides information about the cost analysis that you can do for completed and current production orders. You can analyze the estimated costs and actual costs by using the Price calculation page or the Cost estimates and costings report. You can view information about the estimated and actual costs (and quantity) for each component item, the routing operation, and the indirect cost.

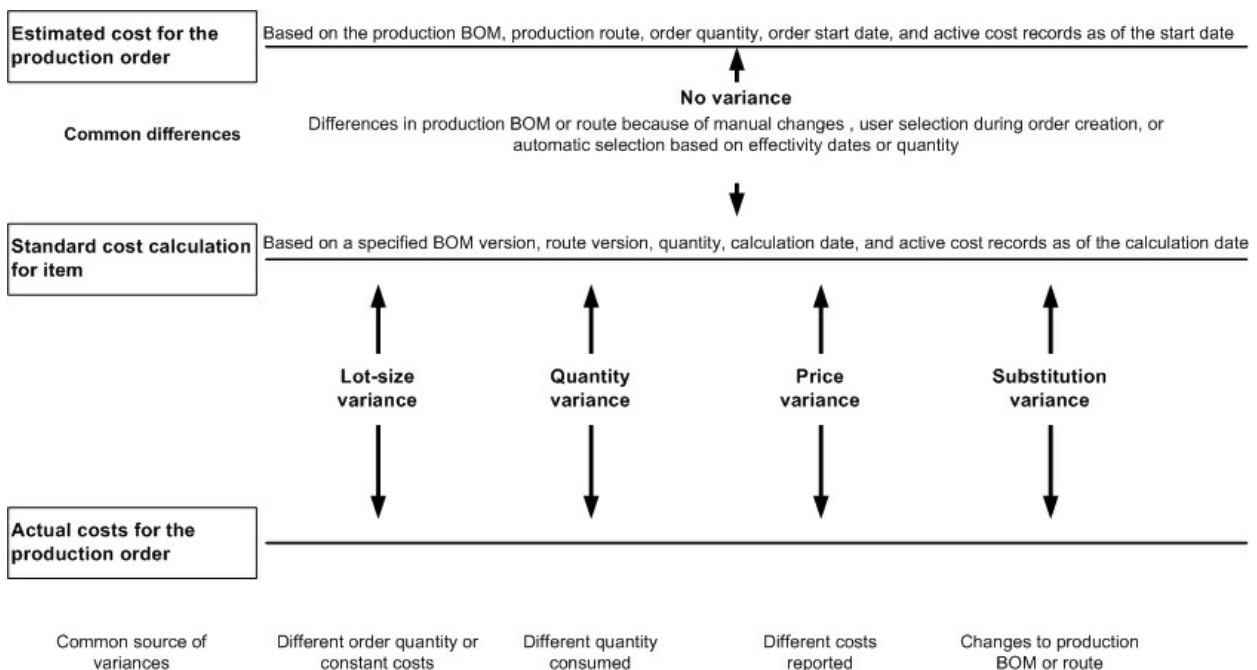

The actual costs for a production order are based on the reported consumption of material and routing operations. You can access detailed transactions about the reported consumption of material, routing operations, and indirect costs for a production order on the **Production posting** page.

Variance analysis for a completed production order

The variances reflect a comparison of the reported production activities and the calculation of standard costs for the production item. The variances don't reflect a comparison to the production order's estimated costs. The production activities that are reported include the consumption of material and routing operations, together with the associated indirect costs, and the quantity that is reported as finished. The following four types of variance are calculated:

- Lot size variance
- Production quantity variance
- Production price variance
- Production substitution variance

The following diagram shows the four variances that account for the difference between a production order's actual costs and the calculated costs within the item's cost record when the production order is ended.

You can analyze the production variances by using the **Variance** page or the **Production variance** report. Use the display options to view detailed variances by item and operations resource, or by cost group. The policy for cost breakdown in the inventory parameters determines whether the variances are tracked by cost group. You can also use the **single**, **multi**, and **total** display options to view summarized variances. The information about detailed variances can help you understand the source of each variance. To predict variances before you end a

production order, analyze the detailed information that is provided on the **Cost estimates and costings** report.

Cost analysis for current production orders

Separate reports provide information about each type of transaction. Use these reports to analyze costs for reported production activities. Information is displayed only for current production orders that have a status of **Started** or **Reported as finished**.

- **Materials in process** – This report lists the picking list transactions that are reported against the current production orders as of a specified transaction date. The report indicates the quantity of a component that was issued and the cost amount for each transaction. Use the selection criteria for a single component item. For example, you can print information about the component's issued quantity against applicable production orders. The issued quantity isn't updated by the quantities that are reported as finished for the parent item. Therefore, the actual quantity of raw materials in process might be overstated.
- **Work in process** – This report lists route transactions (or job transactions) that are reported against the current production orders as of a specified transaction date. The report indicates the hours, amount, and quantity (both good quantity and error quantity) that are reported for each transaction. It also includes information such as the operation number, operation ID, and operations resource. Additionally, this report shows the total time and amount for all transactions against the production order, and the quantity that is reported as finished.
- **Indirect costs in process** – This report lists the indirect costs that have been incurred against production orders. This data is based on reported consumption of routing operations and components as of a specified transaction date. The report indicates the type of indirect cost (surcharge or rate), the costing sheet code for the indirect cost, and the cost amount for each transaction. This report doesn't provide information about the route card or pick list transaction that generated the indirect cost.
- **In process production costing** – This report lists the combined consumption of material, routing operations, and indirect cost against the production orders as of a specified transaction date.
- **Finished items in process** – This report lists current production orders and the report-as-finished transactions as of a specified transaction date.

Production order cost estimation

2/18/2021 • 2 minutes to read • [Edit Online](#)

This article provides information about production cost estimation. Production cost estimation provides the projected material and capacity consumption costs of producing an item in the planned production order quantity.

After you create a production order, you must estimate production costs. The purpose is to estimate item and route consumption for the production process, because these estimates are used as the basis for subsequent scheduling and production processes.

Production cost estimation

Estimates of production costs are based on the following information:

- The quantity on the production order
- The components on the production bills of materials (BOMs)
- The routing operations in the production route
- The indirect costs that apply to the components and operations
- The active cost data as of the calculation date

If there is a phantom line item on the production BOMs, the calculations reflect the phantom's components and route operations. You can use the estimation task to recalculate estimated costs so that they reflect updated information. For example, the updated information might be changes to the quantity on the production order, the components on the production BOMs, the routing operations in the production route, the indirect costs that apply to these components and operations, or the active cost data as of the recalculation date. The calculations of estimated cost also suggest a sales price for the production item, based on a cost-plus-markup approach. The calculations of estimated cost can optionally apply to reference orders that reflect other production orders that are linked to the production order.

View the estimated costs

After you run estimation, you can view the results on the **Price calculation** page. The estimation calculates the following values:

- **Production cost** – The production cost is the top line of the estimate. It shows the complete cost of running the production order and the total sales price for the production. It's the sum of all the cost lines on the estimate.
- **Route or resource costs** – Route or resource costs are the costs for the production operations. They include the cost of elements such as setup time, run time, and overhead.
- **Material costs** – Material costs are the costs and prices of the BOM components that are required in order to produce the item. These costs have previously been established and entered into the system.

Other uses of cost estimation

A cost estimate also provides the following information:

- Meaningful price quotations
- Estimates of the profitability of the order
- Estimates of raw material usage

- Comparisons of cost information from previous productions
- Budget and forecasting information
- Estimates of the production size that is required in order to maintain a particular cost

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

View current WIP status on a production order

2/18/2021 • 2 minutes to read • [Edit Online](#)

This procedure shows how to view WIP statement on a production order. The demo data company used to create this procedure is USMF. This procedure is intended for the cost controller.

1. Click Cost administration.
2. Click Production orders.
3. Use the Quick Filter to filter on the Production field with a value of 'p000153'.
4. On the Action Pane, click Manage costs.
5. Click Production WIP statement.
6. In the From date field, set the date to '2012-12-01'.
7. In the To date field, set the date to '2012-12-31'.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Compare active, estimated, and realized costs on a production order

2/18/2021 • 2 minutes to read • [Edit Online](#)

This procedure shows how to view reasons for high production variance for a production order. The demo data company used to create this procedure is USMF. This procedure is intended for the cost controller.

1. Click Cost administration.
2. In the Date field, enter or select a value.
 - This procedure uses the fiscal year 2012. You can set From date to January 1, 2012 and To date to December 31, 2012.
3. Click the High production variances tab.
4. Click to follow the link in the Production field.
 - Click P000116 to follow the link in the Production field.
5. On the Action Pane, click Manage costs.
6. Click View cost comparison.
7. Click Close.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Production posting

2/18/2021 • 3 minutes to read • [Edit Online](#)

This article provides information about different types of postings in the production process.

Production posting activities follow production processes that are described in the sections below.

Material consumption

Materials are registered as consumed during production when the production picking list journal is posted. This process generates issue transactions that deduct the on-hand inventory. In the production parameters, you can specify whether the value of raw materials that are in progress (work in process [WIP]) should be posted in the ledger. The value of raw materials that are in progress (WIP) is then posted to a dedicated Picking list account and a dedicated Picking list offset account.

Time consumption

The time that workers spend on production jobs is recorded in the Route card journal or the Job card journal. When these journals are posted, ledger posting to a dedicated account for resources that are in progress (WIP) is processed. This posting represents the value of the time that is spent on the production order. After the production order is registered as ended, the WIP accounts are settled.

Reporting finished goods and error quantities

When a production order is reported as finished, the quantity of the finished goods that have been completed is updated in Inventory management through the Report as finished journal. If you're using WIP accounting, which can be set up in the production parameters, a ledger journal is made to reduce the WIP accounts and increase the inventory of the finished goods. The journal uses the standard cost that is defined for the product.

Ending the production order

Before a production order is ended, actual costs are calculated for the quantity that was produced. All estimated costs of material, labor, and overhead are reversed and replaced with actual costs. The overall cost of the finished item is debited from the inventory Receipt account and credited to the inventory Issues account. If you select the **End job** check box when you run the cost calculation, the status of the production order is changed to **Ended**. This status prevents any additional costs from being unintentionally posted to a completed production order. You can specify that the value of error quantities that are reported during reporting as finished should be allocated to the good quantities that are reported as finished. Alternatively, you can specify that the value of error quantities should be posted to a dedicated scrap account.

Controlling the level of ledger posting

In the **Production control parameters**, you can use the **Ledger posting** field to set the level of ledger posting for production processes. The following values are available:

- **Item and resource** – Use the ledger accounts that are set up on the item groups for raw materials and finished goods. WIP for time consumption is taken from resource or resource group from the route operations.
- **Item and category** – Use the ledger accounts that are set up on the item groups for raw materials and finished goods. WIP for time consumption is taken from the cost categories that are associated with the route

operations.

- **Production groups** – Use the ledger accounts that are set up on the production groups for both material and time consumption. The production groups are associated with the released products and copied to the production orders when those orders are created. The posting on the production orders will then follow the production groups that are associated with the production order.

Note: If the standard method for calculating the cost of the finished item was used, the final transactions reflect this fact. If actual costs and the costs that are calculated by using the standard method differ, the difference is posted to the account that shows profit or loss.

NOTE

Set up products that can be produced or procured

2/18/2021 • 2 minutes to read • [Edit Online](#)

Products can be sourced in various ways - they can be produced (manufactured) or procured (purchased). This article describes some typical points to consider when you configure products to support multi-sourcing.

Multi-sourcing is typically used for a purchased item that is occasionally manufactured, or when an item that was primarily a manufactured item is changed so that it's now primarily a purchased item. The item is first designated as a manufactured item, so that bill of materials (BOM) and route information can be defined, and to support production orders for the item. The production type should be set to **BOM** (or, for process manufacturing, **Formula** or **Co-Product**).

When you use standard cost, the item cost record can be calculated for the manufactured item. However, the item cost record might not match the standard cost that you want for purchasing purposes. In this case, the standard cost must be manually entered and activated for the item cost record. For the cost calculation, consider using a special BOM and route that represent the supply mix of the product over the course of a fiscal period, to minimize the variances over time. Additionally, a manufactured item at one site can be transferred to another site. Therefore, the item's cost must be manually entered and activated for the site that the item is transferred to. When you use the manufactured item as a component in higher-level products, the component's costs should be treated as a purchased item. This guideline applies, regardless of whether the component's costs were calculated or manually entered. In other words, a BOM calculation should treat the item's costs as a purchased component instead of using the item's BOM and route information to calculate costs.

To prevent the calculation from occurring, select the **Stop explosion** flag that is embedded in the BOM calculation group that is assigned to the item. To prevent master scheduling calculations from exploding requirements through the item, set the explosion fence to 0 (zero) days in item coverage or in the coverage group. The master scheduling calculation will then treat the item as a purchased item and won't perform more calculations for the item's BOM and route information.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Total cost allocation method

2/18/2021 • 4 minutes to read • [Edit Online](#)

Total cost allocation (TCA) is a method of calculating the cost between the main formula item for a batch order and the co-products that are defined for the formula. This method is dynamic. It calculates the cost as a weighted average between the quantities that are reported as finished for the formula item and the co-products. When TCA is used, you don't have to review cost allocations for every batch order. If TCA isn't used, the formula calculation uses existing functionality.

Using TCA for coproducts

Here are some of the guidelines for using TCA for co-products:

- If you set the **Total Cost Allocation** slider to **Yes** for a formula version, co-products must have a cost price that is more than 0 (zero). The value can be retrieved from the active cost version for the same site, or for the first site for a formula that isn't site-specific. This condition is validated when the formula is approved.
 - You don't need to manually enter cost allocation percentages for co-products. Instead, the system automatically creates the cost allocation percentage as the average of active cost prices of co-products.
 - You don't need to enter standard cost for non-standard cost items that are co-products. There are two types of costing versions in the system: standard cost and planned cost
 - If an item isn't valued by the standard cost valuation method, we recommend you use an active cost price in the planned cost version. This price is used for cost estimation, for example, BOM calculation, production cost estimation, and fallback price in the inventory valuation process.
- If you set the **Total Cost Allocation** slider to **Yes** for the formula version and the following conditions are true, the method of cost allocation is **TCA**, and the percentage of cost allocation is unchanged:
 - You added co-products.
 - You used a different method of cost allocation for the co-products.
- If you set the **Total Cost Allocation** slider to **No** for the formula version and the following conditions are true, the method of cost allocation is changed to **Manual**, and the percentage of cost allocation is unchanged:
 - You added co-products.
 - The percentage of cost allocation is more than 0 (zero).
- Before you can successfully perform a formula calculation, you must estimate the percentages of cost allocation. You can complete this step either manually or by using the **Estimate cost** option on the **Co-products** page. **Note:** The **Estimate cost** option is available only when the **Total Cost Allocation** slider is set to **Yes** for the formula version. You can view the expected allocation if the batch order quantities that are reported as finished match quantities that appear on the formula.
- When a batch order is created manually or a planned batch order is firmed, the value of the **Total Cost Allocation** slider for the formula version is copied to the batch order. However, you can change this setting on the batch order. If the **Total Cost Allocation** slider is set to **No** for the formula version and then changed to **Yes** for the batch order, the method of cost allocation for each line that was set to **Manual** is changed to **TCA**. A cost allocation of **None** is unchanged. If the **Total Cost Allocation** slider is set to **Yes** for the formula version and then changed to **No** for the batch order, the method of cost allocation for each co-product of the **Production** type is changed to **Manual**. Any estimated percentage

of cost allocation is unchanged.

- The **Co-product cost allocation** page shows the calculated cost allocation percentage. You can open this page from the **Batch order** page. This information is useful when the products and quantities that are reported differ from the scheduled or started quantities on the batch order. When the cost is complete, these new percentage allocations from TCA are shown on the **Co-product cost allocation** page.

Calculating the burden for byproducts

The **By-product cost allocation** field on the **Co-products** page is an enumerator field that is used only for by-products. For co-products, the value of this field is always **None**. For by-product lines, this field determines how the cost amount for the by-product line is added to the total cost of the production. The following options are available:

- **None** — No amount is added to the total cost of the production for this by-product line.
- **Percent** — The cost amount is calculated as a percentage of the total cost of raw materials that are consumed in the production. The percentage that is used for the calculation is entered in the field.
- **Per series** — The cost amount is calculated as an amount per standard batch size of the production order. This amount is independent of the reported quantity in the production. The amount that is used for the calculation is entered in the field.
- **Per quantity** — The cost amount is calculated as an amount per reported quantity of the formula item in the production. The amount that is used for the calculation is entered in the field.

Amortize constant costs for a manufactured item

2/18/2021 • 2 minutes to read • [Edit Online](#)

A manufactured item's constant costs reflect the operation setup times and the components that have a constant quantity or a constant scrap amount.

The concept of a costing lot size is used to amortize these constant costs in the calculated cost of a manufactured item. This concept has several synonyms, one of which is accounting lot size. The concept of amortizing constant costs also has several synonyms, one of which is proportional constant costs.

The quantity of a costing lot size for a manufactured item is used in a bill of material (BOM) calculation. The quantity depends on how you initiate and perform the BOM calculation, as illustrated by the following:

- Default calculation quantity in an item's BOM calculation – The item's standard order quantity for inventory acts as the costing lot size, but the default value might be a greater quantity to reflect the item's order quantity multiple. The item's standard order quantity and multiple can be defined within its default order settings or site-specific order settings.
- Specified calculation quantity in an item's BOM calculation – The specified calculation quantity acts as the costing lot size for the item. The calculation quantity initially uses the item's standard order quantity, but the default value can be manually overridden. The specified calculation quantity represents the costing lot size for the specified item, and for manufactured components that have a BOM line type of production. This is because it is assumed that the component will be produced to the exact quantity. The costing lot size for other manufactured components that have a BOM line type of item will reflect their standard order quantity.
- Specified make-to-order calculation quantity in an item's BOM calculation – The specified calculation quantity acts as the costing lot size for the item and its manufactured components when BOM calculations use a make-to-order explosion mode. It is assumed that the manufactured components will be produced to the exact quantity, just like a manufactured component that has a BOM line type of production.
- Specified calculation quantity in an order-specific BOM calculation – An order-specific BOM calculation can be performed for a line item on a sales order, sales quotation, or service order. The specified calculation quantity uses the quantity on the originating line item, but the default quantity can be overridden. You can select whether the order-specific BOM calculation uses a make-to-order or multilevel explosion mode.

The calculated amount of a manufactured item's amortized constant costs is termed charges.

Cost management Power BI content

2/18/2021 • 5 minutes to read • [Edit Online](#)

Overview

The **Cost management** Microsoft Power BI content is intended for inventory accountants or individuals in the organization who are responsible for or interested in the status of inventory or work in progress (WIP), or who are responsible for or interested in analyzing standard cost variances.

NOTE

The **Cost management** Power BI content described in this this topic applies to Dynamics 365 Finance and Operations 8.0.

The **Cost management** Power BI content pack, available on the AppSource site, has been deprecated. For more information about that deprecation, see [Removed or deprecated features for Finance and Operations](#).

This Power BI content provides a categorized format that helps you monitor the performance of inventories and visualize how cost flows through them. You can gain managerial insights such as the turnover ratio, number of days that inventory is on hand, accuracy, and "ABC classification" at your preferred aggregated level (company, item, item group, or site). The information that is made available can also be used as a detailed supplement to the financial statement.

The Power BI content is built on the **CostObjectStatementCacheMonthly** aggregated measurement, which has the **CostObjectStatementCache** table as its primary data source. This table is managed by the Data set cache framework. By default, the table is updated every 24 hours, but you can change the update frequency or enable manual updates in the configuration of the data set cache. Manual updates can be run in either the **Cost administration** workspace or the **Cost analysis** workspace.

After every update of the **CostObjectStatementCache** table, the **CostObjectStatementCacheMonthly** aggregated measurement must updated before data in the Power BI visualizations is updated.

Accessing the Power BI content

The **Cost management** Power BI content is shown in the **Cost administration** and **Cost analysis** workspaces.

The **Cost administration** workspace contains the following tabs:

- **Overview** – This tab shows application data.
- **Inventory accounting status** – This tab shows Power BI content.
- **Manufacturing accounting status** – This tab shows Power BI content.

The **Cost analysis** workspace contains the following tabs:

- **Overview** – This tab shows application data.
- **Inventory accounting analysis** – This tab shows Power BI content.
- **Manufacturing accounting analysis** – This tab shows Power BI content.
- **Std. cost variance analysis** – This tab shows Power BI content.

Report pages that are included in the Power BI content

The **Cost management** Power BI content includes a set of report pages that consist of a set of metrics. These metrics are visualized as charts, tiles, and tables.

The following tables provide an overview of the visualizations in the **Cost management** Power BI content.

Inventory accounting status

REPORT PAGE	VISUALIZATION

	Top 10 resources by favorable production variance

Understanding the data model and entities

Data from the application is used to fill the report pages in the **Cost management** Power BI content. This data is represented as aggregate measurements that are staged in the entity store, which is a Microsoft SQL Server database that is optimized for analytics. For more information, see [Power BI integration with Entity store](#).

The key aggregate measurements of the following objects are used as the basis of the Power BI content.

OBJECT	KEY AGGREGATE MEASUREMENTS	DATA SOURCE FOR FINANCE AND OPERATIONS	FIELD
CostObjectStatementCache Monthly	Amount	CostObjectStatementCache	Amount
CostObjectStatementCache Monthly	Quantity	CostObjectStatementCache	Qty
CostInventoryAccountingKPIGoal	AnnualInventoryTurn	CostInventoryAccountingKPIGoal	AnnualInventoryTurn
CostInventoryAccountingKPIGoal	InventoryAccuracy	CostInventoryAccountingKPIGoal	InventoryAccuracy

The following table shows the key calculated measurements in the Power BI content.

MEASURE	CALCULATION
Beginning balance	Beginning balance = [Ending balance]-[Net change]
Beginning balance qty.	Beginning balance qty. = [Ending balance qty.]-[Net change qty.]
Ending balance	Ending balance = (CALCULATE(SUM([Amount]), FILTER(ALL(FiscalCalendar) ,FiscalCalendar[MONTHSTARTDATE] <= MAX(FiscalCalendar[MONTHSTARTDATE])))
Ending balance qty.	Ending balance qty. = CALCULATE(SUM([QTY]), FILTER(ALL(FiscalCalendar),FiscalCalendar[MONTHSTARTDATE] <= MAX(FiscalCalendar[MONTHSTARTDATE])))
Net change	Net change = SUM([AMOUNT])
Net change qty.	Net change qty. = SUM([QTY])
Inventory turnover ratio by amount	Inventory turnover ratio by amount = if(OR([Inventory average balance] <= 0, [Inventory sold or consumed issues] >= 0), 0, ABS([Inventory sold or consumed issues])/[Inventory average balance])
Inventory average balance	Inventory average balance = (([Ending balance] + [Beginning balance]) / 2)
Days inventory on-hand	Days inventory onhand = 365 / CostObjectStatementEntries[Inventory turnover ratio by amount]
Inventory accuracy	Inventory accuracy by amount = IF([Ending balance] <= 0, IF(OR([Inventory counted amount] <> 0, [Ending balance] < 0), 0, 1), MAX(0, ([Ending balance] - ABS([Inventory counted amount]))/[Ending balance]))

The following key dimensions are used as filters to slice the aggregate measurements, so that you can achieve greater granularity and gain deeper analytical insights.

ENTITY	EXAMPLES OF ATTRIBUTES
Products	Product number, Product name, Unit, Item groups
Category hierarchies (Assigned to role Cost management)	Category hierarchy, Category level
Legal entities	Legal entity names
Fiscal calendars	Fiscal calendar, Year, Quarter, Period, Month
Site	ID, Name, Address, State, Country

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Troubleshoot cost management

2/18/2021 • 5 minutes to read • [Edit Online](#)

This topic describes how to fix issues that you might encounter while working with cost management.

Functional gaps between the inventory value/aging reports and their storage versions

The [Inventory aging report storage](#) and [Inventory value storage report](#) features enable Supply Chain Management to display large volumes of inventory transactions. In each case, the report results are saved for browsing and exporting, unlike with the non-storage versions of these reports. However, some functionality that exists in the non-storage versions of these reports doesn't exist in the storage versions. The following subsections summarize the differences and provide workarounds.

Storage reports don't include subtotals, even if they are enabled in the report layout

Subtotals can cause issues when the result is exported, especially if users change the record sequence.

To check the subtotals, you can export the result into Microsoft Excel. Alternatively, if you want to check subtotals within Supply Chain Management, use [Feature management](#) to enable the *New grid control* and *(Preview) Grouping in grids* features, which provide a much more flexible way to see the subtotal for any group by column. For more information, see [Grid capabilities](#).

Inventory value storage report doesn't support ledger account information

You can run the trial balance to get the inventory accounts balance and compare that to the **Inventory value storage** report.

Warnings or errors are shown when changing a ledger period status without closing inventory

Microsoft introduced the following validations to prevent issues caused by an incorrect period-end process around costing. If you encounter any of the following error messages, refer to [KB 4561987](#) for more information about how to resolve these issues.

- You are about to execute a Recalculation with a date %1 (10-02-2019). The last registered Recalculation was executed in a previous period with a date %2 (20-01-2019). No execution of an inventory close with a date %3 (31-01-2019) matching period end has been registered. Please remember to execute an inventory close as of %3 (31-01-2019) matching the period end. The valuation of inventories, cost of goods sold, and variances may not be correct in subledger or general ledger until this has been executed.
- You are about to change the status of ledger period %1 to %2. No execution of inventory close with a date %3 matching period end has been registered. Please execute an inventory close as of %3 matching the period end before changing the status. The valuation of inventories, cost of goods sold, and variances may not be correct in subledger or general ledger until this has been executed. Reported from legal entity %4. For now, it is informational, but you will be required to perform such action in future.
- The Account structure %1 has been changed. One or more main accounts %2 no longer exist. These Main accounts are required by the %3 with a date %4. Please add these Main accounts to the Account structure %1 before you can resume the %3 job. For now, it is informational, but you will be required to perform such action in future.
- You are about to execute an inventory close with a date %1 (31-01-2019). No execution of backflush

costing calculation with a date %2 (31-01-2019) matching period end has been registered. Please remember to execute a backflush costing calculation with a date of %3 (31-01-2019) matching period end. The valuation of inventories, cost of goods sold, and variances may not be correct in subledger or general ledger until this has been executed.

- You are about to execute a backflush costing calculation with a date %1 (28-02-2019). The last registered backflush costing calculation was executed in a previous period with a date %2 (31-01-2019). No execution of an inventory close with a date %3 (31-01-2019) matching a period end has been registered. Please remember to execute an inventory close as of %3 (31-01-2019) matching a period end. The valuation of inventories, cost of goods sold and variances may not be correct in subledger or general ledger until the inventory close has been executed.

Inventory aging report discrepancies

The **Inventory aging report** shows different values when viewed at different storage dimensions (such as site or warehouse). For more information about the reporting logic, see [Inventory aging report examples and logic](#).

An update conflict occurs when the inventory valuation method is either Standard cost or Moving average

When you post documents such as inventory journals, purchase order invoices, or sales order invoices in parallel for scalability and performance, you might receive an error message about an update conflict, and some of the documents might not be posted. This issue can occur when the inventory valuation method is either *Standard cost* or *Moving average*. Both these methods are perpetual costing methods. In other words, the final cost is determined at the time of posting.

If you're using the *Moving average* method, the error message resembles this example:

```
Inventory value xx.xx is not expected after the proportional expense calculation
```

If you're using the *Standard cost* method, the error message resembles this example:

```
The standard cost does not match with the financial inventory value after the update. Value = xx.xx, Qty = yy.yy, Standard cost = zz.zz
```

Until Microsoft releases a solution to fix the issue, consider using the following workarounds to help avoid or reduce these errors:

- Repost the failed documents.
- Create documents that have fewer lines.
- Avoid decimal values in the standard cost. Try to define the standard cost so that the **Price quantity** field is set to *1*. If you must specify a **Price quantity** value that is more than *1*, try to minimize the number of decimal places in the unit standard cost. (Ideally, there should be fewer than two decimal places.) For example, avoid defining standard cost settings such as **Price** = *10* and **Price quantity** = *3*, because they will produce a unit standard cost of 3.333333 (where the decimal value repeats).
- In a majority of documents, avoid having multiple lines that hold the same combination of product and financial inventory dimensions.
- Reduce the degree of parallelization. (In this case, your system might become faster, because fewer update conflicts and retries occur.)

NOTE

Business documents and printing

Reporting solutions are often used to capture and communicate the details of business transactions. Therefore, a reporting solution must be able to produce physical manifestations of business data by using existing devices, such as network printers. Examples of business documents include sales invoices, customer statements, and checks.

The image shows a configuration window for a 'Customer account statement' on the left, which is linked by a blue arrow to a sample 'Microsoft' sales invoice on the right. The configuration window includes sections for 'Parameters', 'Criteria', 'Maturity Distribution', and 'Destination'. The sales invoice displays the Microsoft logo, address, invoice number (CIV-000576), date (30 November 2012), and total amount (\$315,479.00). It features a table of items with columns for Item, Description, Quantity, Sales Price, Discount, and Amount. The invoice also includes a 'METHODS OF PAYMENT' section and 'OTHER INFORMATION'.

Information access and reporting

2/18/2021 • 11 minutes to read • [Edit Online](#)

This topic explains the various reporting options available as part of the platform.

Why information access is important

Information access is an essential part of an ERP solution and represents a significant portion of the user engagement with the system. Consider the numerous methods of capturing information related to daily activities and the level of investments required to manage the data. Employees depend on logical interpretations of massive amounts of data to stay on top of their daily tasks. Out of the box the platform provides a collection of reporting solutions to address the various information access needs of an ERP solution. In an increasingly competitive environment, mergers and acquisitions seem to occur as often as the change in seasons. More than ever before, businesses today are finding ways to expand their global reach to attract more customers. To be successful, they must adapt legacy solutions used to communicate with customers and prepare for the enforcement of regional regulatory requirements associated with new markets. Beyond the primitive functions provided by Microsoft Azure – compute, networking, storage, and authentication – the platform provides tools to manage resources for organizations that span in size from small businesses to global enterprise conglomerates. These tools are designed with flexibility in mind, to accommodate a dynamic world of business.

What is a "report" in the application?

A *report* can be defined simply as a structured presentation of data. Under ideal circumstances, reports materialize data in such a way that it allows the user to make informed decisions. The application supports a broad spectrum of information access scenarios: cross company all-up financial reporting; analytical dashboards and tiles; electronically transferable funds; customer sales invoices; checks and tax documents; and many more. Examples of integrated report scenarios that involve the consumption of business data include:

- **Native controls** including list pages, grid controls, and chart visualizations.
- **Dashboards and workspaces** containing predefined and personalized views.
- **Financial reporting** providing all-up views across legal entities.
- **Structured documents** distributed internally to employees or externally to customers and vendors.

Although each of these scenarios at its core involves the presentation of structured business data, the process of accessing these reports and how the results are subsequently consumed varies greatly. Flexibility in the user tooling is essential for scenarios that involve data exploration. By contrast, layout precision is required for compliance with most regulatory documents. Given the diversity of information access scenarios it's understandable that not all reports are created equal. This topic is intended to help familiarize you with the various reporting options available as part of the platform.

Common myths of reporting

To become a proficient *report maker*, it's often useful to let go of past inhibitions. The following section seeks to rebuke three common myths about reporting.

- **Myth #1: Operational reports require "real-time" data** To the contrary, there are relatively few reporting scenarios that require *real-time* results. And, in the grand scheme of things, taking a critical stance on a request for *real-time* views is recommended given the high development costs and potential heavy burden these solutions may incur on production environments.
- **Myth #2: The best tool is the one the developer is most comfortable using** Consider a customer

request for a report that allows them to monitor company's assets. In the past, a developer would build a static report displaying a list of inventory items with complex calculations relying entirely on the user to provide filters to sufficiently reduce the result set. This solution may function perfectly in developer environments with a reduced data set. However, this approach is prone to unnecessarily consume significant amounts of compute resources when utilized in production.

- **Myth #3: Developers are good at creating visually compelling designs** In reality, developers are the often the worst offenders when it comes to producing elegant design layouts that will appeal to the customer's aesthetic preferences. When it comes to analytical reports you're better off empowering users to both explore the data directly and share personalized views.

Understanding report requirements

The best reporting solutions are designed with the expertise, daily functions, and information access needs of the target user in mind. The platform offers several tools designed to meet the functional requirements which are common across various reporting experiences. Without question, selecting the right tool that most effectively addresses the *need* requires a clear understanding of the customer experience. You can drastically increase your chances of delivering a complete and robust solution that fully satisfies customer requirements by simply asking the right questions. Here are some leading questions to ask when evaluating customer requirements for reporting solutions:

- **Get to know the user**
 - What is the proficiency of the target persona? Are they familiar with analytical tools like Microsoft Excel?
 - Does the user require a guided parameter experience to refine the dataset?
 - How frequently will the report be accessed?
- **Familiarize yourself with the data**
 - Are they looking for transactional, analytical, and/or predictive information?
 - Does the shape of the data change and if so, how often?
 - Will the report include data from external sources?
- **Determine how the results will be used**
 - Are you going to explore the data to gain insights?
 - How will the results be shared with others?
 - Is there a fixed document structure for the target output?

It's understandable that customers *want* a solution that aligns with the existing processes they are comfortable using. However, there's a lot you can learn through these leading questions used to discover what the customer actually *needs* to be successful in their task. Delight your customers by providing them with solutions that empower them to be more productive.

Reporting experiences

Information access scenarios supported in applications can be broken down into five distinct reporting experiences. Specialized tools are provided to meet the complex and diverse reporting needs of various functions throughout the organization.

- **Operational views** – Designed to address the specific needs of a given business persona.
- **Business documents** – Static documents used to capture and exchange processed business data.
- **Analytical tools and visualizations** – Personalized presentations of logical calculations that allow the user to explore their data.
- **Electronic reporting** – Tool used to configure formats for electronic documents.

- **Financial reporting** – Designed to provide in-depth accounting management tools based on standard views of financial activities across legal entities.

Scorecard

The following table can be used as a guide when choosing the right tool for the reporting solution.

MAKER	OPERATIONAL VIEWS	BUSINESS DOCUMENTS	ANALYTICAL TOOLS & VISUALIZATIONS	ELECTRONIC REPORTING	FINANCIAL REPORTING
Persona	Developer	Developer	Power user	Power user	Power user
Authoring tool	Visual Studio	Visual Studio	PowerBI.com PowerBI app	Excel	Management Reporter Designer
Time to market	Weeks	Weeks	Hours	Hours	Hours
Data sources	Entity DB OLTP	OLTP	Entity DB Azure Catalog	OLTP	OLTP
Effort	Days	Days	Minutes	Hours	Hours
VIEWER	OPERATIONAL VIEWS	BUSINESS DOCUMENTS	ANALYTICAL TOOLS & VISUALIZATIONS	ELECTRONIC REPORTING	FINANCIAL REPORTING
Target	Organization	Back Office	Power user	Power user	Finance officers
Data accuracy	Near real-time	Real-time	Near real-time	Real-time	Cached views
Personalization	Medium-Modeled	None	High - Free form designer	Low - Expressions	Medium - Modeled
Sharing	None	PDF export O365 export Email	Dashboards Reports Tiles	Excel export	Excel export
Printing	Screen captures	Local printer Network devices	Screen captures	Excel	Local printer
Automation	Auto-refresh	Batch integration	Scheduled refresh	Batch jobs	None
Scenarios	Monitoring	Transactions	Exploratory	Transactions	Accounting

NOTE

"Near real-time" denotes processed data that is slightly slower than real-time.

Operational views

Operational views represent an essential part of the average employee's daily life. As important as a brush is to a painter, operational views are used to empower people to be productive. These views contain logical presentations of data to help the user discover patterns, highlight anomalies, and act on the most important

tasks. Targeted experiences are used to satisfy the unique information access requirements for a given persona. These views provide actionable controls that help to maximize efficiency for common user actions. Learn more about constructing custom operational workspaces in [Build operational workspaces](#). Example applications of operational views include controller operations, production floor management, and customer collections monitoring.

What are the characteristics and capabilities?

- A fully-integrated experience with responsive visualizations fully-aware of user context and selections.
- Views can be personalized to a large extent, to meet the unique desires of the user that are prone to change.
- Actionable controls allow the user to efficiently transact and monitor activities.
- Combination of analytical data to help answer general questions and transactional views to access record details.

What distinguishes "operational views" from other types of visualizations?

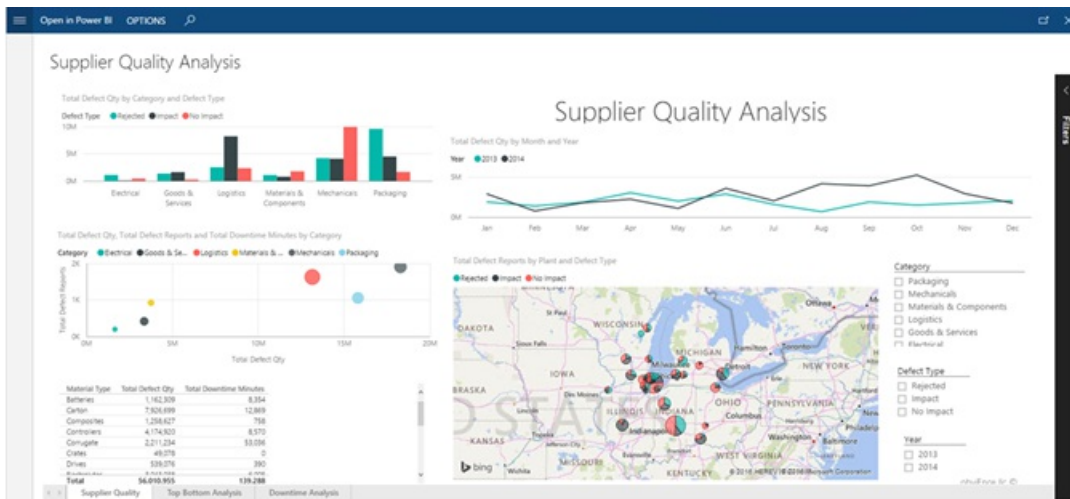

- General purpose tools designed to be utilized at all levels of the organization.
- Pre-defined views are provided based on common information access requirements associated with a specific role within the organization.
- Highly responsive to user interactions and changes made to the transactional database.

What's important to consider when selecting this tool for the job?

- The platform allows users to embed Power BI tiles and links to reports directly in workspaces.
- Users can introduce personalized workspaces to create their own custom operational views.
- Form data sources now support aggregate queries for analytical views using native controls.

Analytical tools and visualizations

Embedded visuals based on analytical data allow users to navigate between aggregate views down to the transactional details that affect them. Power BI service integration delivers world-class analytical tools with built-in support for accessing data. These tools empower "citizen developers" to author the reports they need and share the reports with others within the organization. Use the Power BI content packs available in Lifecycle Services to get started. Learn more about Power BI integration in [Features and services available through Power BI integration](#). Example applications of analytical tools and visualizations include customer sales per quarter, total revenue by region, and inventory turn-over.

What are the characteristics and capabilities?

- Near real-time results that provide macro level insights based on micro level activities.
- Common applications include charts, KPIs, and more complex visuals.
- Offer a deep exploratory experience with interactive controls that provide drill-thru navigations.

What distinguishes "analytical tools and visualizations" from other types of reports?

- Highly graphical in nature, these presentations are used to find the hidden meaning behind the data.
- Free form web designer that supports rich visualizations with built-in user interactions.
- Utilized by power users to explore data and gain insight through analysis.
- Personal in nature by allowing the user to choose which information to include.
- Built-in sharing capabilities and user controlled access management.

What's important to consider when selecting this tool for the job?

- Developers are responsible for publishing data entities that can be consumed by Power BI.
- Power users can produce mash-up views based on application data combined with external data sources.
- Visuals are highly-responsive to user interactions and provide near real-time results when using Direct Query access to the data source.

Business documents

These reporting solutions are often used to capture and communicate the details of business transactions. As such, this requires a reporting solution capable of producing physical manifestations of business data using existing devices like network printers. Learn more about the enhancements to the Document reporting service in [Document Reporting Services](#). Example applications of business documents include sales invoice, customer statements, and checks.

User parameters

Paginated document

What are the characteristics and capabilities?

- Paginated documents that are ultimately destined to be printed on paper or distributed via email.
- Heavily dependent on parameters to filter and produce the desired result set.
- Business documents capture a snap-shot of customer and vendor activity that can be archived for future reference.
- The complex solutions are developed in Visual Studio and deployed as part of the application.

What distinguishes "business documents" from other types of visualizations?

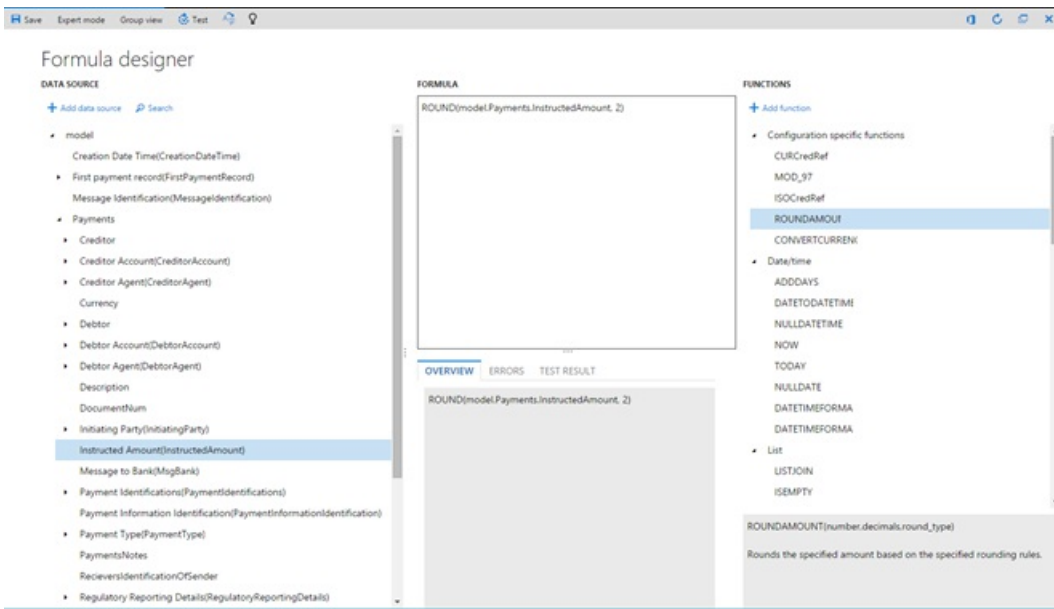

- Asynchronous data access and rendering solution designed to handle relatively large data sets.
- Dedicated reporting services offer distributed resource utilization.
- Ideal solution for automated processes that involve bulk generation of business documents.
- Includes built-in support for document archive and data extraction via file export to PDF in addition to Word, Excel, and CSV.

What's important to consider when selecting this tool for the job?

- Application suite reports are intended to be used as a starting point for custom solutions.
- Solutions are heavily dependent on metadata changes and do not offer personalization.
- Modifications to out-of-box solutions must be managed as a metadata change.

Electronic reporting

Electronic reporting (ER) is the tool to use to configure electronic document formats in accordance with the legal requirements of various countries/regions. For more information about the Electronic reporting tool, see [Electronic reporting \(ER\) overview](#). Example applications of electronic reporting include financial auditing, tax reporting, and electronic invoicing.

What are the characteristics and capabilities?

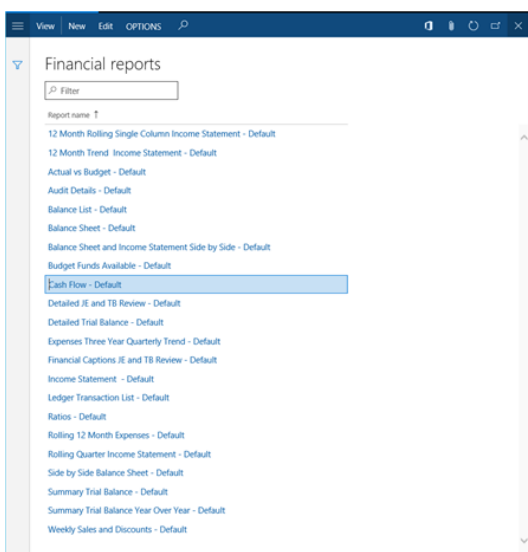

- Perfect tool for producing TEXT, XML, and OPENXML worksheet formats.
- Tooling is designed for business users familiar with Excel-based formulas.
- Highly adaptable to adhere to changes in regulatory requirements.
- Component versioning is available to manage draft definitions.

What distinguishes "electronic reports" from other types of visualizations?

- Designed for electronic submission to banks, governments, and other external entities.
- Use formulas to define data transformations into groups containing summary data and logical calculations.

Financial reporting

Standard financial reports are provided using the default main account categories. Use the report designer to create or modify traditional financial statements, such as Income statement and Balance sheet and share the results with other members of your organization. For detailed information about the Financial reporting tooling, see [General ledger and Financial reporting overview](#). Example applications of financial reporting include balance sheets, cash flow, and summary trial balance year over year.

	June	YTD
Net Income from Operations	16,510	1,912,447
Add Back Non-Cash Expenses:		
Depreciation and Amortization	17,600	105,600
Net Cash Flow from Operations	1,090	2,018,047
Sources (Uses) of Cash:		
Accounts Receivable	(1,090)	(35,819)
Liabilities	0	0
Inventory	0	(1,981,336)
Other Assets	0	0
Total Sources (Uses) of Cash	(1,090)	(2,017,155)
Net Cash Flow from Operating Activities	0	892
Cash flow from investing activities:		
Additions to Fixed Assets	17,600	(262,990)
	17,600	(262,990)
Cash flow from financing activities:		
Capital Stock	0	0
Paid-in Capital	0	0
Dividends Paid	0	0
Unrealized Currency Gain/Loss	0	0
Retained Earnings	0	0
Net Increase (Decrease) in Cash	17,600	(262,098)
Cash at Beginning of Period	(14,232)	0

Standard templates (GL > Inquiries > Financial reports)

Interactive financial reports

What are the characteristics and capabilities?

- Built-in flexible financial reporting solution designed to handle complex organizational structures.
- Fully-integrated with General ledger.
- Create custom financial reports using the default solutions as a starting point.
- Interactive reports with drill-down capabilities to navigate down to transaction details.

What distinguishes "financial reports" from other types of visualizations?

- User controls are tailored for the specialized needs of financial reporting.
- Create roll-up reports containing data across companies or business units.
- Utilizes a financial data mart for optimized performance.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Features available through the Power BI integration

2/18/2021 • 7 minutes to read • [Edit Online](#)

Microsoft Power BI is a suite of business analytics tools that let you analyze data and share insights. By using Power BI tools, you can explore data and quickly create rich reports and dashboards. You and your colleagues can then use the reports interactively on many devices. The application uses Power BI for data exploration.

Data exploration through Power BI

There are various types of reporting.

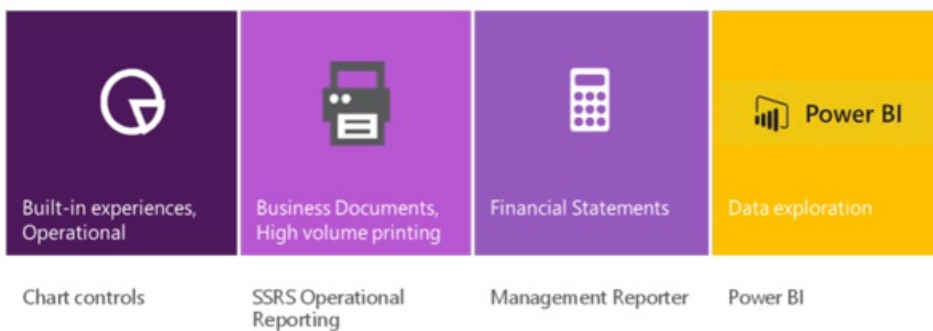

Chart controls are used to build embedded experiences that require visuals.

Microsoft SQL Server Reporting Services (SSRS) is an engine that is designed for pixel-perfect, formatted reports that often require printing. We use SSRS for document-style reports, such as invoices and purchase orders. Our investments in SSRS integration focus on document generation and printing scenarios.

For all non-document reports or reports that don't have to be printed, we want to embrace Power BI.

In the past, we have used the terms *self-service reports* and *ad-hoc reports* to refer to Power BI. We will now use the term *data exploration*. This change in terminology reflects a subtle shift in paradigms. Self-service reports were reports that the users themselves created. (Alternatively, a power user created the reports and shared them with other people. These people then continued to adjust the reports according to their requirements.) Often, users had to change the shape of a chart, add a new column, change the grouping, or just create a new view of data. Although we might think of the results as reports, users are just trying to understand the data by exploring it, pivoting it around columns, and changing the shape of charts. Technologies of the past didn't let users interactively explore large volumes of data. Therefore, users had to create "reports," or many views of the same data.

In Power BI, thanks to the in-memory database technologies in Microsoft SQL Server, a report is a just the starting point for interactive data exploration. Charts in a Power BI report invite users to click them, visuals change shape interactively, and data can easily be filtered. Users can easily adjust existing reports and create their own views of the data. The reports can be shared, and teams can collaborate over data.

Therefore, although you might use the term *report* to refer to Power BI artifacts, you should think about the larger scenario that is involved. Your users are exploring data! Power BI is the tool of choice when you must address data exploration and visualization requirements.

For a detailed discussion of reporting concepts, see [Information access and reporting](#).

Ready-made Power BI content

You can use ready-made Power BI reports right away. Two types of Power BI content are available:

- Power BI content that is available in Microsoft Dynamics Lifecycle Service (LCS)
- Power BI content packs that are distributed in the PowerBI.com marketplace

Depending on your version, you can use one of both types of content.

Power BI content that is available in LCS

LCS is a service that can manage your environments. LCS is operated by Microsoft. Power BI reports are developed by using Entity store and are then distributed in LCS as implementation assets. In LCS, you will find not only content that is developed by Microsoft, but also content that is developed by independent software vendors (ISVs) and partners.

We will continue to release Power BI content that is based on Entity store. For information, see the [Roadmap](#).

Power BI content packs that are distributed in the PowerBI.com marketplace

There are several Power BI content packs in the PowerBI.com marketplace. Although these content packs will continue to be supported until further notice, our future investments in content packs will be based on Entity store, and content will be released via LCS.

For more information about the content, see [Power BI content](#).

Extending, creating, and distributing Power BI reports

You should use the ready-made Power BI content as a first step. You can modify ready-made reports or extend them by using capabilities that are built into PowerBI.com. In addition to modifying ready-made reports, you can extend them using Power BI authoring tools such as Power BI desktop. You can also create new reports. You can use several approaches to create new Power BI reports.

Creating high-volume, near-real-time "operational Power BI reports" by using Entity store

Entity store is an operational data store that is built specifically for Power BI integration. To create high-volume, near-real-time Power BI reports that use Entity store, a business analyst or a developer can use Power BI desktop, which is the authoring tool for Power BI reports. Like other artifacts that developers create, these reports must be distributed to your users via LCS.

Reports that are created by using Entity store take advantage of DirectQuery technology. This technology enables reports to be created over large volumes of data. Reports that are created by using DirectQuery technology don't cache data in the PowerBI.com service. Instead, data is always stored in application.

For an overview of Power BI integration with Entity store, see [Power BI integration with Entity store](#).

If you're upgrading from Microsoft Dynamics AX 2012, you can upgrade cubes to aggregate measurements that use Entity store. You can then create Power BI reports by using Entity store. For more information, see [Migrate upgraded AX 2012 R3 sales cubes to the entity store](#).

Creating Power BI reports by using Excel

In addition to using the Power BI desktop authoring tool, you can use "Power tools" that are incorporated into Excel to create visualizations. Your organization might have many users who already use Excel every day. For a quick "one-off" report, Excel might be the best option for these users.

There are several scenarios where you can use Excel:

- Export data from a page in Dynamics 365 into Excel. You can then use the Power View add-in that is built into Excel to visualize the data. The Excel workbook can be used as a stand-alone visualization. In addition, you can import the report into the PowerBI.com service.
- Use the Power Query extension in Excel to combine the data in another worksheet (or data that is imported from OData endpoints) with external data. You can visualize the resulting data by using Power View.

- Use the PowerPivot extension in Excel to ingest a larger amount of data into Excel.

Consider using Export to Excel functionality for ad-hoc "one-off" reports. If the reports will be shared with a group of users, you should consider using Entity store to create them.

Sharing and using reports in PowerBI.com

PowerBI.com is a service that is offered by Microsoft. It lets you create dashboards and reports, and also enables collaboration with a group of users. Regardless of how you create your reports, you can share reports with users by uploading them into the PowerBI.com service. (This process is also known as *publishing*.)

After your reports are uploaded, your users can view, adjust, and explore them either on the web (when they are connected to the Internet at home or in the office) or by using apps on a device.

For more information about Power BI concepts, see the [Power BI documentation](#).

Pinning Power BI content to the client

PowerBI.com can be used on its own as a reporting and dashboard solution for your organization or business unit. However, users can also pin tiles and reports from their own PowerBI.com accounts to workspaces. Power BI content in Dynamics 365 provides contextual insights that are related to business operations.

You can pin two types of objects from PowerBI.com: tiles in PowerBI.com dashboards, and reports.

Before you can pin Power BI content, you must configure Power BI in your Dynamics 365 environment.

One-time configuration of PowerBI.com integration

Before you can pin tiles or reports, an administrator must configure integration with PowerBI.com in your environment. This configuration must be done only one time per environment. For instructions, see [Configure Power BI integration for workspaces](#).

Pinning PowerBI.com tiles

Power BI tiles that are pinned to the Dynamics 365 client provide insightful visuals at a glance. They also let users open PowerBI.com for interactive analysis. For more information, see [Configure Power BI integration for workspaces](#).

Pinning PowerBI.com reports to workspaces

As a power user, a business analyst, or a developer, you can use Power BI desktop to create reports that use Entity store. Not only are these reports rich and interactive, but your users can make changes without having to rely on another person.

Although the reports in PowerBI.com are powerful and interactive on their own, they can also be pinned into workspaces. Your users can pin reports to workspaces themselves. For more information about how to pin reports to workspaces, see [Pin Power BI reports to workspaces](#).

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Pin Power BI content

2/18/2021 • 3 minutes to read • [Edit Online](#)

Microsoft Dynamics 365 Finance uses Power BI for data exploration. This topic explains how you can pin full-page Power BI reports to workspaces to give your users an interactive data exploration experience.

This topic assumes that you're familiar with the feature that lets you pin Microsoft Power BI tiles to a workspace. For more information, see [Features and services available through Power BI integration](#). If you're a developer who is creating a workspace, to let users pin Power BI tiles to the workspace, embed the Power BI tile control.

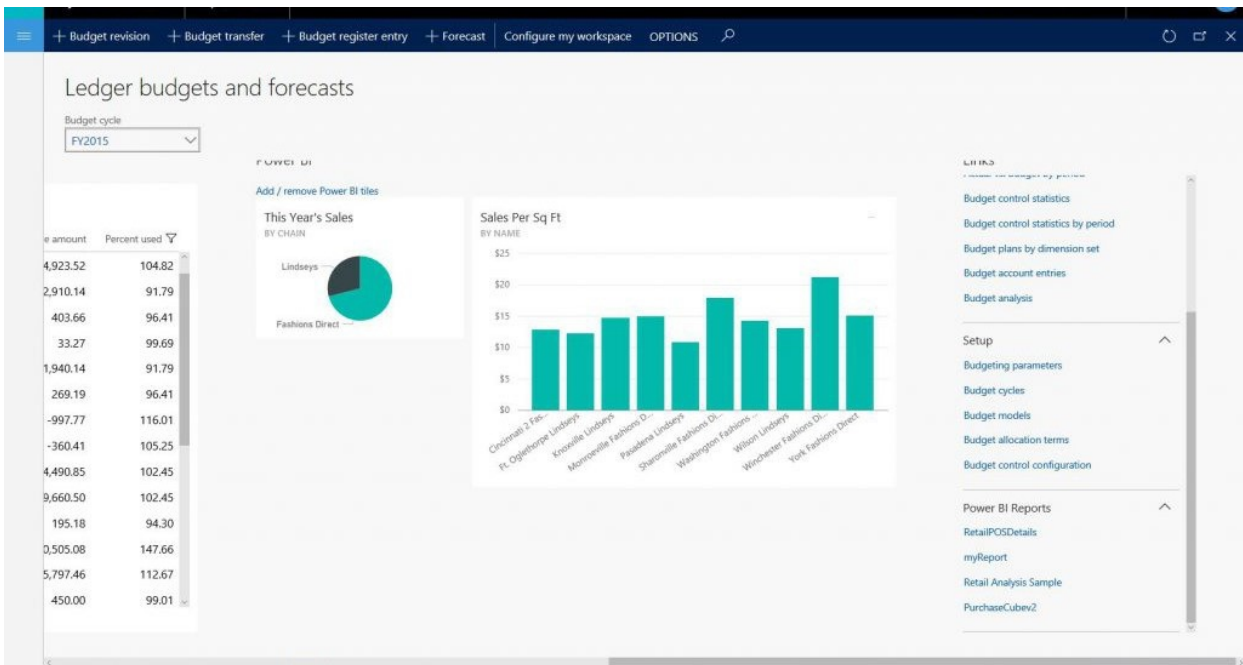

Pin Power BI reports to workspaces

Microsoft Dynamics AX platform update 1 (May 2016) introduced the capability to pin Power BI reports to workspaces. Power BI reports can be added to any workspace that contains a **Links** section. In other words, the reports can be added to most of the out-of-box workspaces that are included in the product. To enable Power BI reports and tiles, you must configure Power BI to work with the application. This one-time operation must be completed by an administrator of the environment. For instructions, see [Configure Power BI integration for workspaces](#). After you've configured Power BI to work with the application, open the **Ledger budgets and forecasts** workspace in the client. In the workspace, click the **Options** tab. Notice that this tab contains buttons to open the (Power BI) tile catalog and the (Power BI) report catalog. Click **Open report catalog**. A dialog box that contains a list of reports appears. The list of reports comes from the reports that you have in your Power BI account. If you open PowerBI.com in a browser, you will see that the same list of reports is used across your Power BI dashboards. Select some reports, as shown in the following illustration, and then click **OK** to continue.

The screenshot shows the 'Ledger budgets and forecasts' workspace in Dynamics 365 Finance. The 'Options' tab is active, and the 'Open report catalog' dialog box is open. The dialog box displays a list of reports with checkboxes for selection. The following table represents the data shown in the 'Open report catalog' dialog box:

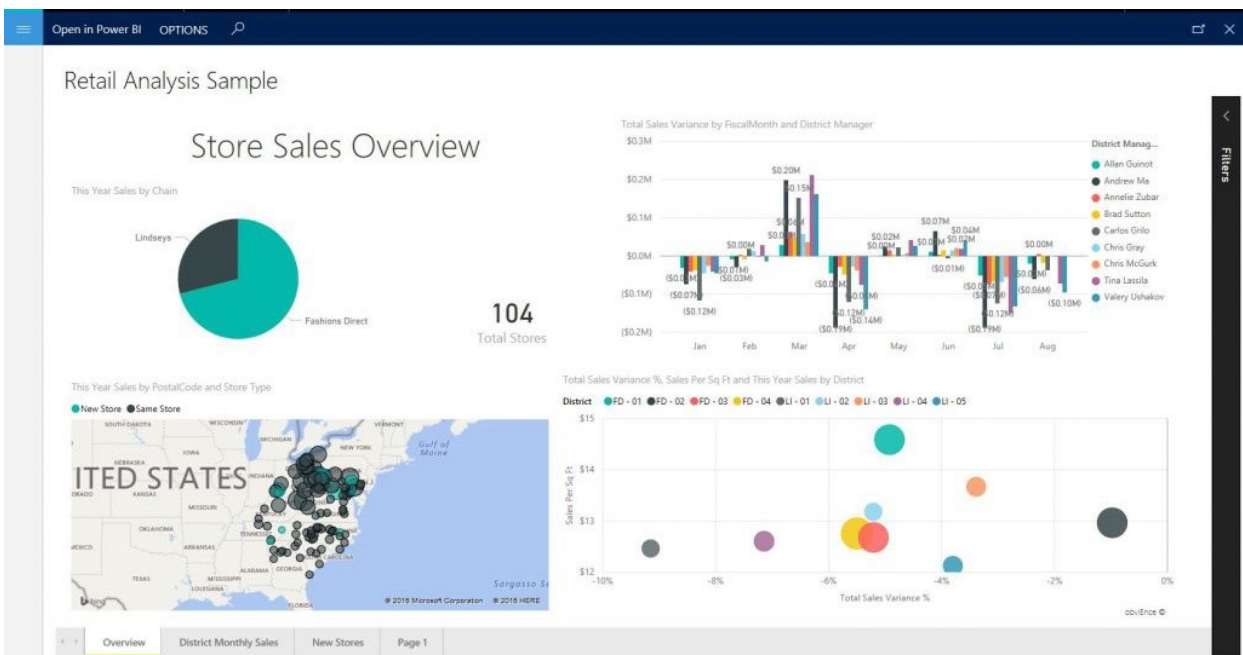

Report Name	Selected
Supplier Quality Analysis	<input type="checkbox"/>
Financial Performance Data Mo...	<input type="checkbox"/>
Retail Analysis Sample	<input checked="" type="checkbox"/>
myReport	<input checked="" type="checkbox"/>
RetailPOSDetails	<input checked="" type="checkbox"/>
RetailPOSDetails	<input type="checkbox"/>
CustomerReport	<input type="checkbox"/>
Retail Sales by Item	<input type="checkbox"/>
SalesInvoices-Import	<input type="checkbox"/>
Cost Management	<input type="checkbox"/>
Retail Channel Performance	<input type="checkbox"/>
VendorInvoices_PurchaseCubev...	<input type="checkbox"/>
Practice Manager BI Report - R1...	<input type="checkbox"/>
myLedgerReport	<input type="checkbox"/>
PurchaseCubev2	<input checked="" type="checkbox"/>
Workforce	<input type="checkbox"/>

Next, scroll to the bottom of the **Links** section in the workspace. Notice that a new section for Power BI reports has been added to your links.

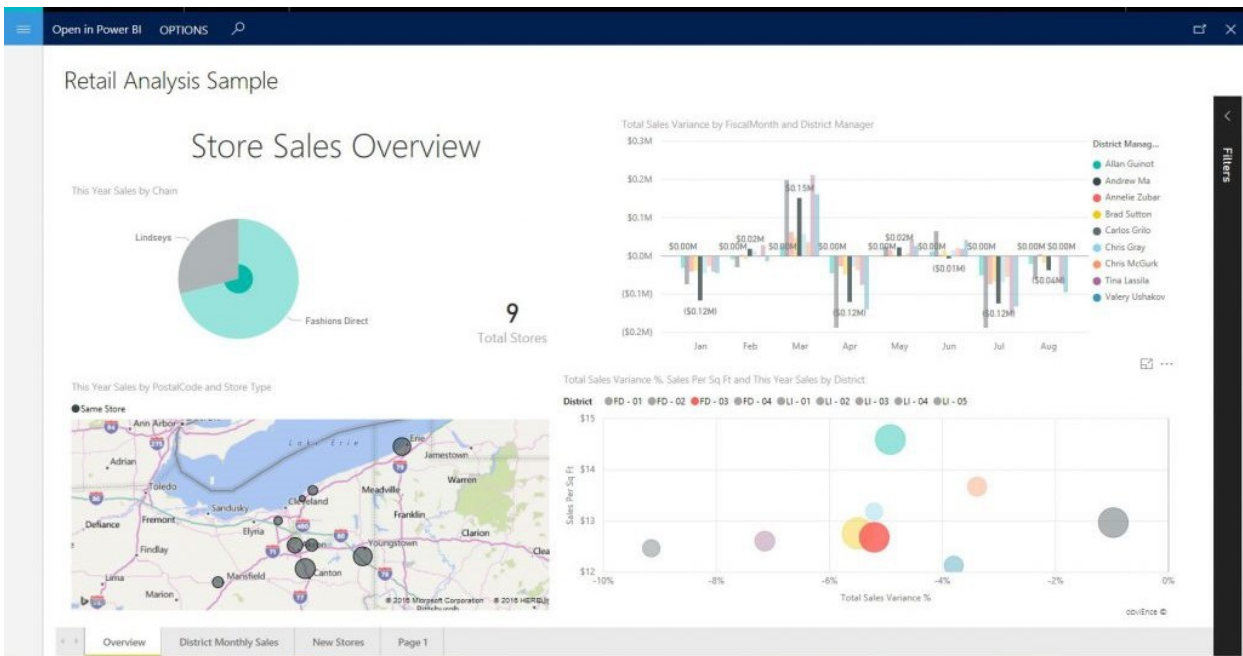

Full-page Power BI reports in the client

You can open and run Power BI reports in the client. The functionality resembles the functionality for running Microsoft SQL Server Reporting Services (SSRS) reports. To run a Power BI report, in the **Links** section, click the link for one of the Power BI reports. For this example, click the **Retail Analysis Sample** link. The Power BI report is opened in the client in a full-page view, as shown in the following illustration. This report is interactive. As you click regions of the report, the remaining visuals react to your selection.

You can filter the data on the report by using the filter pane. The following illustration shows the report after filters have been applied.

You can also open this report on PowerBI.com and make changes. You can then save the modified report as another copy that has a different name, and even pin the new report to the workspace.

Power BI in user-created workspaces

So far, we have described how to add Power BI tiles and reports to "developer-created" workspaces. Developer-created workspaces are workspaces that are created by Microsoft (that is, they are built into the product), by your independent software vendor (ISV) or partner, or by in-house developers. However, in Microsoft Dynamics AX platform update 1 (May 2016), users can create new workspaces by using the personalization capabilities of the client. To create a new workspace, on the home page (or the dashboard), right-click the tile for a workspace, and then click **Add a workspace**. A new workspace is created. New workspaces are named **My Workspace 1**, **My Workspace 2**, and so on. You can change the name later. Click the workspace that you just created. You can now add Power BI tiles and reports by using the same options that we discussed earlier. The following illustration shows an example.

Select analytical workspaces from Power BI

2/18/2021 • 3 minutes to read • [Edit Online](#)

Analytical workspaces

The analytical workspaces that are bundled with the application suite offer users relevant insights into their business data. However, in some cases, it might make sense to replace standard reports with custom reports that are designed specifically for the users in your organization.

The world-class tooling that PowerBI.com provides lets you produce analytical reports that contain mashup views that use data from external sources. In Platform update 26 for Finance and Operations, power users can replace the standard embedded reports with those that are hosted on PowerBI.com.

IMPORTANT

The functionality that this topic describes isn't a personalization. The customization of analytical workspaces applies to all users in the active legal entity.

Motivations for embedding PowerBI.com reports

Although standard reports deliver insights that are tailored for a given business persona, an organization might prefer a custom report in some cases. The application lets power users promote custom reports that are hosted on PowerBI.com and shared with members of the organization.

Here are some of the top motivations for selecting reports that are hosted on PowerBI.com:

- PowerBI.com reports support data mashups that use external data sources and can be accessed outside the application.
- The reports are appropriate for demonstrating custom solutions that are hosted on PowerBI.com and embedded in the application in one-box deployments.
- Organizations that have Microsoft Power BI Premium services want to augment the standard reports.

Embed a PowerBI.com report in an analytical workspace

The [How to embed PowerBI.com reports](#) video (shown above) is included in the [Finance and Operations playlist](#) available on YouTube.

To replace the standard reports, you must be a member of the System Report Editors security group. Members of this security group can access the options in application workspaces that let them customize the standard reports. This example shows how to replace the standard analytical report with a customized report that is hosted on PowerBI.com.

1. Sign in and open the application report that you want to customize. In this example, you will replace the standard analytical report that is embedded in the **Compensation management** workspace.

2. Select the **Analytics** tab to access the workspace's embedded analytical report.

By default, you will see the standard analytical workspace solution that is included with your application. The reports in this solution are automatically deployed and configured for your environment during the provisioning process.

NOTE

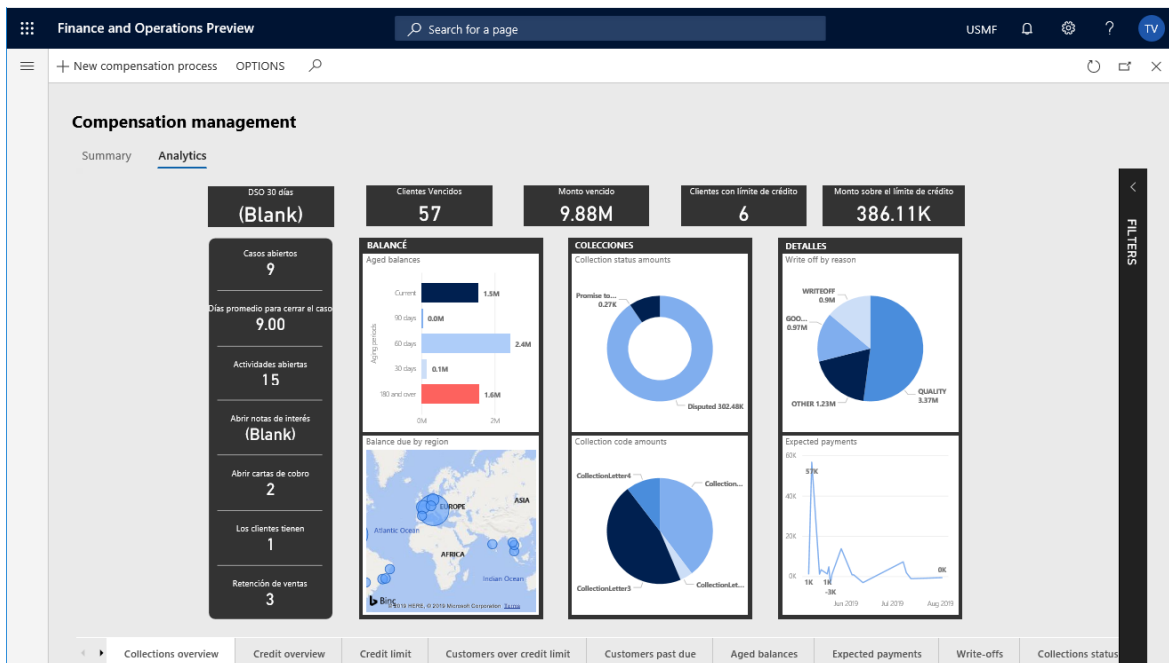

The analytical workspaces require a hosted Power BI service that is available only for dedicated environments. For more information, see the blog post, [Accessing Analytical Workspaces and Reports on 1-Box Environments](#).

3. On the Action Pane, on the **Options** tab, in the **Power BI** group, select **Select Analytics** to open the **Power BI Reports** dialog box.

This dialog box lets you select among the reports that have been shared on the PowerBI.com service. The reports are organized by workspace.

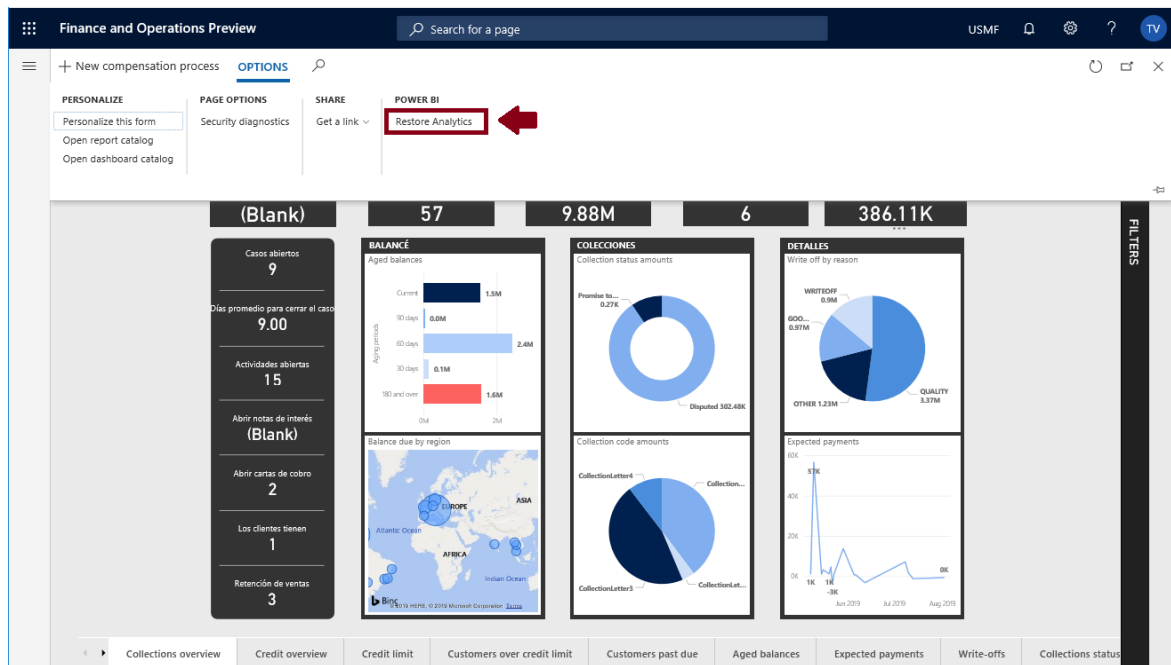

4. In the drop-down list, select the workspace that contains the report.
5. Select the report to embed in the application workspace, and then select **OK**.
6. To view the updates to the workspace, you must reload the page. Either move away from the workspace and then return, or refresh your browser.
7. In the **Compensation management** workspace, select the **Analytics** tab to access the PowerBI.com report that is now embedded in the analytical workspace.

Revert to the standard solution

After a PowerBI.com report has been embedded in an application workspace, updates to the report are reflected immediately for users. However, to replace the report with another PowerBI.com solution, a power user must first revert to the standard application solution. Follow these steps to revert to the standard application solution.

1. On the Action Pane, on the **Options** tab, in the **Power BI** group, select **Restore Analytics**.

2. To view the updates to the workspace, you must reload the page. Either move away from the workspace and then return, or refresh your browser.
3. In the **Compensation management** workspace, select the **Analytics** tab to access the standard solution that is now embedded in the analytical workspace.

NOTE

Cost management Power BI content

2/18/2021 • 5 minutes to read • [Edit Online](#)

Overview

The **Cost management** Microsoft Power BI content is intended for inventory accountants or individuals in the organization who are responsible for or interested in the status of inventory or work in progress (WIP), or who are responsible for or interested in analyzing standard cost variances.

NOTE

The **Cost management** Power BI content described in this topic applies to Dynamics 365 Finance and Operations 8.0.

The **Cost management** Power BI content pack, available on the AppSource site, has been deprecated. For more information about that deprecation, see [Removed or deprecated features for Finance and Operations](#).

This Power BI content provides a categorized format that helps you monitor the performance of inventories and visualize how cost flows through them. You can gain managerial insights such as the turnover ratio, number of days that inventory is on hand, accuracy, and "ABC classification" at your preferred aggregated level (company, item, item group, or site). The information that is made available can also be used as a detailed supplement to the financial statement.

The Power BI content is built on the **CostObjectStatementCacheMonthly** aggregated measurement, which has the **CostObjectStatementCache** table as its primary data source. This table is managed by the Data set cache framework. By default, the table is updated every 24 hours, but you can change the update frequency or enable manual updates in the configuration of the data set cache. Manual updates can be run in either the **Cost administration** workspace or the **Cost analysis** workspace.

After every update of the **CostObjectStatementCache** table, the **CostObjectStatementCacheMonthly** aggregated measurement must be updated before data in the Power BI visualizations is updated.

Accessing the Power BI content

The **Cost management** Power BI content is shown in the **Cost administration** and **Cost analysis** workspaces.

The **Cost administration** workspace contains the following tabs:

- **Overview** – This tab shows application data.
- **Inventory accounting status** – This tab shows Power BI content.
- **Manufacturing accounting status** – This tab shows Power BI content.

The **Cost analysis** workspace contains the following tabs:

- **Overview** – This tab shows application data.
- **Inventory accounting analysis** – This tab shows Power BI content.
- **Manufacturing accounting analysis** – This tab shows Power BI content.
- **Std. cost variance analysis** – This tab shows Power BI content.

Report pages that are included in the Power BI content

The **Cost management** Power BI content includes a set of report pages that consist of a set of metrics. These metrics are visualized as charts, tiles, and tables.

The following tables provide an overview of the visualizations in the **Cost management** Power BI content.

Inventory accounting status

REPORT PAGE	VISUALIZATION
Inventory overview	Beginning balance
	Net change
	Net change %
	Ending balance
	Inventory accuracy
	Inventory turnover ratio
	Days inventory on-hand
	Active product in period
	Active cost objects in period
	Balance by item group
	Balance by site
	Statement by category
	Net change by quarter
Inventory overview by site and item group	Inventory accuracy by site
	Inventory turnover ratio by site
	Inventory ending balance by site
	Inventory accuracy by item group
	Inventory turnover ratio by item group
Inventory overview by site and item group	Inventory ending balance by site and item group
Inventory statement	Inventory statement
Inventory statement by site	Inventory statement by site
Inventory statement by product hierarchy	Inventory statement
Inventory statement by product hierarchy	Inventory statement by site

	Variance by site
	Production variance by quarter
	Production variance by quarter and variance type
	Top 10 resources by unfavorable production variance
	Top 10 resources by favorable production variance

Understanding the data model and entities

Data from the application is used to fill the report pages in the **Cost management** Power BI content. This data is represented as aggregate measurements that are staged in the entity store, which is a Microsoft SQL Server database that is optimized for analytics. For more information, see [Power BI integration with Entity store](#).

The key aggregate measurements of the following objects are used as the basis of the Power BI content.

OBJECT	KEY AGGREGATE MEASUREMENTS	DATA SOURCE FOR FINANCE AND OPERATIONS	FIELD
CostObjectStatementCache Monthly	Amount	CostObjectStatementCache	Amount
CostObjectStatementCache Monthly	Quantity	CostObjectStatementCache	Qty
CostInventoryAccountingKPIGoal	AnnualInventoryTurn	CostInventoryAccountingKPIGoal	AnnualInventoryTurn
CostInventoryAccountingKPIGoal	InventoryAccuracy	CostInventoryAccountingKPIGoal	InventoryAccuracy

The following table shows the key calculated measurements in the Power BI content.

MEASURE	CALCULATION
Beginning balance	Beginning balance = [Ending balance]-[Net change]
Beginning balance qty.	Beginning balance qty. = [Ending balance qty.]-[Net change qty.]
Ending balance	Ending balance = (CALCULATE(SUM([Amount]), FILTER(ALL(FiscalCalendar) ,FiscalCalendar[MONTHSTARTDATE] <= MAX(FiscalCalendar[MONTHSTARTDATE]))))
Ending balance qty.	Ending balance qty. = CALCULATE(SUM([QTY]), FILTER(ALL(FiscalCalendar),FiscalCalendar[MONTHSTARTDATE] <= MAX(FiscalCalendar[MONTHSTARTDATE]))))
Net change	Net change = SUM([AMOUNT])
Net change qty.	Net change qty. = SUM([QTY])
Inventory turnover ratio by amount	Inventory turnover ratio by amount = if(OR([Inventory average balance] <= 0, [Inventory sold or consumed issues] >= 0), 0, ABS([Inventory sold or consumed issues])/[Inventory average balance])
Inventory average balance	Inventory average balance = (([Ending balance] + [Beginning balance]) / 2)
Days inventory on-hand	Days inventory onhand = 365 / CostObjectStatementEntries[Inventory turnover ratio by amount]
Inventory accuracy	Inventory accuracy by amount = IF([Ending balance] <= 0, IF(OR([Inventory counted amount] <> 0, [Ending balance] < 0), 0, 1), MAX(0, ([Ending balance] - ABS([Inventory counted amount]))/[Ending balance]))

The following key dimensions are used as filters to slice the aggregate measurements, so that you can achieve greater granularity and gain deeper analytical insights.

ENTITY	EXAMPLES OF ATTRIBUTES
Products	Product number, Product name, Unit, Item groups
Category hierarchies (Assigned to role Cost management)	Category hierarchy, Category level
Legal entities	Legal entity names
Fiscal calendars	Fiscal calendar, Year, Quarter, Period, Month
Site	ID, Name, Address, State, Country

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Learning Power BI content

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic describes the **Learning** Microsoft Power BI content.

Reports that are included in the Power BI content

The reports that are included in the **Learning** Power BI content have both charts and tables that contain additional information. The following table describes the reports.

REPORT	CONTENTS
Learning Overview	Summary of other reports
Course Analysis	Registration by location, attendee by status, courses by type per company, and course attendance by job
Registration Analysis	Registration list
Course Types	Course types by skill
Instructor Analysis	Ratio of courses to instructors, number of instructors, courses by instructor, courses per instructor, and course agenda by instructor
Courses Offered	List of courses
Courses Design	Course agenda

You can filter the charts and tiles on these reports, and pin the charts and tiles to the dashboard. For more information about how to filter and pin in Power BI, see [Create and Configure A Dashboard](#).

Understanding the data model and entities

The following data is used to fill the reports in the **Learning** Power BI content. This table shows the entities that the content was based on.

ENTITY	CONTENTS	RELATIONSHIPS WITH OTHER ENTITIES
Calendar Offset	Calendar offsets to slice reports	Course Agenda, Course Attendees
Company	Companies to filter reports by	Course Agenda, Course Attendees
Course	Course, description, instructor name, location, room, and status	Course Agenda, Course Attendees, Course Skill
Course Agenda	Agenda, course, and start and end times	Company, Calendar Offset, Date, Course

ENTITY	CONTENTS	RELATIONSHIPS WITH OTHER ENTITIES
Course Attendees	Name, status, job, and registration date	Company, Calendar Offset, Date, Course, Demographics, Employment, Course, Employee Name, Employee Title, Job, Position
Course Skill	Skill, skill type, and level	Course
Date	Days, weeks, months, and years	Course Agenda, Course Attendees
Demographics	Date of birth, gender, ethnic origin, and marital status	Course Agenda, Course Attendees
Employment	Start date, end date, and transition date	Course Agenda, Course Attendees
Job	Function, type, and title	Course Agenda, Course Attendees
Position	Position, title, and full-time equivalent (FTE)	Course Agenda, Course Attendees
Employee Name	First name, last name, and full name	Course Attendees
Employee Title	Title and seniority date	Course Attendees

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Organizational training Power BI content

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic describes the Finance and Operations - Organizational training Power BI content.

Reports that are included in the content pack

After you've connected the content pack to your data, the reports show your organization's data. If you've never used Microsoft Power BI before, you can learn more about it on the [Guided Learning page for Power BI](#). The reports that are included in the content pack have both charts and tables that contain additional information. The following table describes the reports.

REPORT	CONTENTS
Course Analysis	Registration by location, course attendees by status, and registration list
Course Types	Course types by skill

You can filter the charts and tiles on these reports, and pin the charts and tiles to the dashboard. For more information about how to filter and pin in Power BI, see [Create and Configure A Dashboard](#).

Understanding the data model and entities

Application data is used to populate the reports in the Organizational training content pack. The following table shows the entities that the content pack was based on.

ENTITY	CONTENTS	RELATIONSHIPS WITH OTHER ENTITIES
Training_CalendarOffset	Calendar offsets to slice reports	Training_CourseAgenda, Training_CourseAttendees
Training_Company	Companies to filter reports by	Training_CourseAgenda, Training_CourseAttendees
Training_Course	Course, description, instructor name, location, room, and status	Training_CourseAgenda, Training_CourseAttendees, Training_CourseSkill
Training_CourseAgenda	Agenda, course, and start and end times	Training_Company, Training_CalendarOffset, Training_Date, Training_Course
Training_CourseAttendees	Name, status, job, and registration date	Training_Company, Training_CalendarOffset, Training_Date, Training_Demographics, Training_Employment, Training_Course, Training_WorkerName, Training_WorkerTitle, Training_Job, Training_Position

ENTITY	CONTENTS	RELATIONSHIPS WITH OTHER ENTITIES
Training_CourseSkill	Skill, skill type, and level	Training_Course
Training_Date	Days, weeks, months, and years	Training_CourseAgenda, Training_CourseAttendees
Training_Demographics	Date of birth, gender, ethnic origin, and marital status	Training_CourseAgenda, Training_CourseAttendees
Training_Employment	Start date, end date, and transition date	Training_CourseAgenda, Training_CourseAttendees
Training_Job	Function, type, and title	Training_CourseAgenda, Training_CourseAttendees
Training_Position	Position, title, and full-time equivalent (FTE)	Training_CourseAgenda, Training_CourseAttendees
Training_WorkerName	First name, last name, and full name	Training_CourseAttendees
Training_WorkerTitle	Title and seniority date	Training_CourseAttendees

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Production performance Power BI content

2/18/2021 • 6 minutes to read • [Edit Online](#)

This topic describes what is included in the **Production performance** Microsoft Power BI content. It explains how to access the Power BI reports, and provides information about the data model and entities that were used to build the content.

Overview

The **Production performance** Power BI content is for production managers or individuals in the organization who are responsible for production control.

The reports that are included let you use Power BI to monitor the performance of manufacturing operations with regard to timely execution, quality, and cost. The reports use transactional data from production orders and batch orders, and provide both an aggregate view of company-wide production metrics and a breakdown of metrics by product and resource.

The Power BI content highlights the organization's ability to complete production on time and in full. Future performance is projected based on the production plans. Comprehensive reports provide detailed insights into product defects that are caused by production, and also the defect rates for resources and operations.

This Power BI content also lets you analyze production variances. Production variances are calculated as the difference between estimated cost and realized cost. Production variances are calculated when production orders or batch orders reach **Ended** status.

The **Production performance** Power BI content includes data that originates from production orders and batch orders. The reports don't include data that is related to kanban productions.

Accessing the Power BI content

The **Production performance** Power BI content is shown on the **Production performance** page (**Production control > Inquiries and reports > Production performance analysis > Production performance**).

Metrics that are included in the Power BI content

The **Production performance** Power BI content includes a set of report pages. Each page consists of a set of metrics that are visualized as charts, tiles, and tables.

The following table provides an overview of the visualizations that are included.

REPORT PAGE	CHARTS	TILES
Production performance	<ul style="list-style-type: none">• Number of production by date• Number of productions by product and item group• Number of planned productions by date• Bottom 10 products by on-time & in-full	<ul style="list-style-type: none">• Total orders• On-time & in full %• Incomplete %• Early %• Late %

REPORT PAGE	CHARTS	TILES
Defects by product	<ul style="list-style-type: none"> Defective rate (ppm) by date Defective rate (ppm) by product and item group Quantity produced by date Top 10 products by effective rate 	<ul style="list-style-type: none"> Defective rate (ppm) Defective quantity Total quantity
Defects trend by product	Defect rate (ppm) by quantity produced	Defect rate (ppm)
Defects by resource	<ul style="list-style-type: none"> Defect rate (ppm) by date Defect rate (ppm) by resource and Site Defect rate (ppm) by operation Top 10 resources by defect rate 	Defective quantity
Defects trend by resource	Defect rate (ppm) by quantity processed	
Production variances for job order costing	<ul style="list-style-type: none"> Production variance by date and cost group type Production variance by site and cost group type Top 10 products with unfavorable production variance Top 10 unfavorable production variance by resource 	<ul style="list-style-type: none"> Realized cost Production variance Production variance %

Understanding the data model and entities

The following data is used for the report pages in the **Production performance** Power BI content. This data is represented as aggregate measurements that are staged in the Entity store. The Entity store is a Microsoft SQL Server database that is optimized for analytics. To learn more about the entity store, see [Power BI integration with Entity store](#).

The following table shows the key aggregate measurements that are used as the basis of the Power BI content.

ENTITY	KEY AGGREGATE MEASUREMENTS	DATA SOURCE FOR FINANCE AND OPERATIONS APPS	FIELD
CostCalculation	CostAmount	ProdCalcTransExpanded	CostAmount
CostCalculation	CostMarkup	ProdCalcTransExpanded	CostMarkup
CostCalculation	ActualCostAmount	ProdCalcTransExpanded	RealCostAmount
CostCalculation	RealCostAdjustment	ProdCalcTransExpanded	RealCostAdjustment
RouteTransactions	ErrorQuantity	ProdRouteTransExpanded	QtyError

ENTITY	KEY AGGREGATE MEASUREMENTS	DATA SOURCE FOR FINANCE AND OPERATIONS APPS	FIELD
RouteTransactions	GoodQuantity	ProdRouteTransExpanded	QtyGood
ProductionOrder	DaysDelayed	ProdTableExpanded	DaysDelayed
ProductionOrder	LeadTime	ProdTableExpanded	LeadTime
ProductionOrder	PlannedLeadTime	ProdTableExpanded	PlannedLeadTime
ProductionOrder	ProductionOrderCount	ProdTableExpanded	
CoproductCostCalculation	CoproductCostAmount	PmfCoByProdCalcTransExpanded	CostAmount
CoproductCostCalculation	CoproductCostMarkup	PmfCoByProdCalcTransExpanded	CostMarkup
CoproductCostCalculation	CoproductRealCostAdjustment	PmfCoByProdCalcTransExpanded	RealCostAdjustment
CoproductCostCalculation	CoproductActualCostAmount	PmfCoByProdCalcTransExpanded	RealCostAmount

The following table shows how the key aggregate measurements are used to create several calculated measures in the content's dataset.

MEASURE	HOW THE MEASURE IS CALCULATED
Production variance, %	$\text{SUM}(\text{'Production variance' [Production variance]}) / \text{SUM}(\text{'Production variance' [Estimated cost]})$
All planned orders	$\text{COUNTROWS}(\text{'Planned production order'})$
Early	$\text{COUNTROWS}(\text{FILTER}(\text{'Planned production order'}, \text{'Planned production order' [Scheduled end date]} < \text{'Planned production order' [Requirement date]}))$
Late	$\text{COUNTROWS}(\text{FILTER}(\text{'Planned production order'}, \text{'Planned production order' [Scheduled end date]} > \text{'Planned production order' [Requirement date]}))$
On-time	$\text{COUNTROWS}(\text{FILTER}(\text{'Planned production order'}, \text{'Planned production order' [Scheduled end date]} = \text{'Planned production order' [Requirement date]}))$
On-time %	$\text{IF} (\text{'Planned production order' [On-time]} < > 0, \text{'Planned production order' [On-time]}, \text{IF} (\text{'Planned production order' [All planned orders]} < > 0, 0, \text{BLANK}())) / \text{'Planned production order' [All planned orders]}$
Completed	$\text{COUNTROWS}(\text{FILTER}(\text{'Production order'}, \text{'Production order' [Is RAF'ed]} = \text{TRUE}))$

MEASURE	HOW THE MEASURE IS CALCULATED
Defective rate (ppm)	IF('Production order'[Total quantity] = 0, BLANK(), (SUM('Production order'[Defective quantity]) / 'Production order'[Total quantity]) * 1000000)
Delayed production rate	'Production order'[Late #] / 'Production order'[Completed]
Early & in full	COUNTROWS(FILTER('Production order', 'Production order'[Is in full] = TRUE && 'Production order'[Is early] = TRUE))
Early #	COUNTROWS(FILTER('Production order', 'Production order'[Is early] = TRUE))
Early %	IFERROR(IF('Production order'[Early #] <> 0, 'Production order'[Early #], IF('Production order'[Total orders] = 0, BLANK(), 0)) / 'Production order'[Total orders], BLANK())
Incomplete	COUNTROWS(FILTER('Production order', 'Production order'[Is in full] = FALSE && 'Production order'[Is RAF'ed] = TRUE))
Incomplete %	IFERROR(IF('Production order'[Incomplete] <> 0, 'Production order'[Incomplete], IF('Production order'[Total orders] = 0, BLANK(), 0)) / 'Production order'[Total orders], BLANK())
Is delayed	'Production order'[Is RAF'ed] = TRUE && 'Production order'[Delayed value] = 1
Is early	'Production order'[Is RAF'ed] = TRUE && 'Production order'[Days delayed] < 0
Is in full	'Production order'[Good quantity] >= 'Production order'[Scheduled quantity]
Is RAF'ed	'Production order'[Production status value] = 5 'Production order'[Production status value] = 7
Late & in full	COUNTROWS(FILTER('Production order', 'Production order'[Is in full] = TRUE && 'Production order'[Is delayed] = TRUE))
Late #	COUNTROWS(FILTER('Production order', 'Production order'[Is delayed] = TRUE))
Late %	IFERROR(IF('Production order'[Late #] <> 0, 'Production order'[Late #], IF('Production order'[Total orders] = 0, BLANK(), 0)) / 'Production order'[Total orders], BLANK())
On-time & in full	COUNTROWS(FILTER('Production order', 'Production order'[Is in full] = TRUE && 'Production order'[Is delayed] = FALSE && 'Production order'[Is early] = FALSE))

MEASURE	HOW THE MEASURE IS CALCULATED
On-time & in full %	IFERROR(IF('Production order'[On-time & in full] <> 0, 'Production order'[On-time & in full], IF('Production order'[Completed] = 0, BLANK(), 0)) / 'Production order'[Completed], BLANK())
Total orders	COUNTROWS('Production order')
Total quantity	SUM('Production order'[Good quantity]) + SUM('Production order'[Defective quantity])
Defect rate (ppm)	IF('Route transactions'[Processed quantity] = 0, BLANK(), (SUM('Route transactions'[Defective quantity]) / 'Route transactions'[Processed quantity]) * 1000000)
Defect ratio mixed (ppm)	IF('Route transactions'[Total mixed quantity] = 0, BLANK(), (SUM('Route transactions'[Defective quantity]) / 'Route transactions'[Total mixed quantity]) * 1000000)
Processed quantity	SUM('Route transactions'[Good quantity]) + SUM('Route transactions'[Defective quantity])
Total mixed quantity	SUM('Production order'[Good quantity]) + SUM('Route transactions'[Defective quantity])

The following table shows the key dimensions that are used as filters to slice the aggregate measurements, so that you can achieve greater granularity and gain deeper analytical insights.

ENTITY	EXAMPLES OF ATTRIBUTES
Reported as finished date	Completion (RAF) date, Month, and Year offset
Ended date	Ended month offset and Month
Requirement date	Requirement date month offset and Requirement date
Route transaction date	Route transaction month offset and Date
Sites	Sites ID, Site name, State, and City
Entities	Id and Name
Resources	Resource ID, Resource name, Resource type, and Resource group
Products	Product number, Product name, Item ID, and Item group

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Warehouse performance Power BI content

2/18/2021 • 10 minutes to read • [Edit Online](#)

This topic describes what's included in the **Warehouse performance** Microsoft Power BI content. It explains how to access the Power BI reports, and provides information about the data model and entities that are used to build the content.

Overview

The **Warehouse performance** Power BI content was created so that warehouse and operations managers can monitor important inbound, outbound, and inventory metrics. It uses Warehouse management, product, and other transactional data from your system, and provides both an aggregate view of warehouse performance and a breakdown for vendors, product groups and products, and site and warehouses.

Warehouse managers can use the **Warehouse performance** Power BI content to measure the following three areas:

- **Inbound performance** – Measure how well a vendor is performing against customer requirements (in other words, measure delivery performance), and measure put-away performance, so that you can identify issues that involve workers or items over a period. It's important that you know whether vendors are delivering on time, early, or late, so that you can determine how vendor performance is affecting overall put-away performance. A vendor that delivers outside the dates that were agreed on can put extra pressure on the warehouse because of unexpected work, and can increase the average put-away time.
- **Shipping performance** – Measure whether your warehouse is shipping in full and on time to customers (in other words, measure outbound shipping and delivery performance), so that you can identify any issues that involve products, sites or warehouses, or dedicated customers. If you find that you're shipping late to specific areas or towns, you might have to pay more attention to transportation or account management.
- **Location inventory accuracy** – Inventory accuracy is important internal warehouse business intelligence (BI). It's very important that you determine how accurately you're counting in general. However, it's also important that you determine how accurate you are at storing items in the correct locations, and that you highlight discrepancy data, so that you can find better positions for items or initiate total counting on specific items. (Currently, the new item-based counting functionality is delivered as a hotfix.) If you're using this Power BI content to determine the correctness of on-hand inventory data per location, you can also identify theft in your shops. You can also determine whether any locations have on-hand quantities that differ from enterprise resource planning (ERP) data. Those locations might be too large, or they might be impossible to count. Alternatively, some of the physical positioning might be bad, so that it's difficult to keep a single type of item in sync with on-hand data.

Accessing the Power BI content pack

The **Warehouse performance** Power BI content is shown on the **Warehouse performance** page (**Warehouse management > Inquiries and reports > Warehouse performance analysis > Warehouse performance**).

Metrics that are included in the Power BI content

The **Warehouse performance** Power BI content includes a report. This report consists of a set of metrics that are visualized as charts, tiles, and tables. The following table provides an overview of the visualizations in the **Warehouse performance** Power BI content.

REPORT PAGE	CHARTS	DESCRIPTION
Inbound Performance	Total put aways	The number of put-away work lines that are processed during a given time.
Inbound Performance	Put away average time	The average time, in hours, for all purchase order put-away lines that are processed, from registration of the items until the last put is processed.
Inbound Performance	Received early	The number of purchase order lines that are received early.
Inbound Performance	Received on time	The number of purchase order lines that are received on time.
Inbound Performance	Received late	The number of purchase order lines that are received late.
Inbound Performance	On time by vendor	A view of the percentage of purchase order lines that are received from a vendor or vendor group early, on time, and late.
Inbound Performance	Dock to stock average put away (hours)	The average dock-to-stock put-away time in hours over time.
Inbound Performance	Average put away by worker	The average time, in hours, that a worker has been taking for put-away processing of purchase order lines.
Inbound Performance	Average put away hour by vendor	The average put-away time in hours by vendor or vendor group.
Inbound Performance	Average put away hour by product	The average put-away time in hours by item or item group.
Location inventory accuracy	Total count	The number of counting work lines that are processed for a given period.
Location inventory accuracy	Discrepancy rate	The total discrepancy rate as a percentage of all lines that are counted for a given period.
Location inventory accuracy	Count without discrepancy	Of the total number of counting work lines that are processed, the number of lines that are processed without any discrepancy.
Location inventory accuracy	Items counted over time	The percentage of items that are counted with and without discrepancy over time.

REPORT PAGE	CHARTS	DESCRIPTION
Location inventory accuracy	Item quantity discrepancy greater than %	A table view of counting lines that have discrepancies that exceed a specified percentage. The table includes information about locations, items, the average discrepancy, the total counting work lines that are counted, the number of counting lines that have discrepancies for the location, the average quantity that is counted, the expected total quantity that will be counted, and the actual item quantity that is counted.
Location inventory accuracy	Item count by worker	The counting performance of workers. Performance is expressed as a percentage of counting work lines that have and don't have discrepancies.
Location inventory accuracy	Item count by site / warehouse	Counting performance by the number of processed counting work lines by site or warehouse that have and don't have discrepancies.
Location inventory accuracy	Discrepancy rate by product	The discrepancy rate for counting performance. The rate is expressed as a percentage of processed counting work lines by item or item group.
Shipping performance	Lines shipped	The total number of shipment lines that are shipped over a given period.
Shipping performance	Early	The percentage of shipment lines that are shipped early.
Shipping performance	On time	The percentage of shipment lines that are shipped on time.
Shipping performance	Late	The percentage of shipment lines that are shipped late.
Shipping performance	Shipments over time	The percentage of shipment lines that are shipped on time, early, or late over a given period. A trend line shows the trend for lines that are shipped on time.
Shipping performance	Shipped late by city	A map visualization of cities and areas that are affected by late shipments.
Shipping performance	Shipped by product	The percentage that is shipped early, on time, or late by item or item group.
Shipping performance	Shipped by customer	The percentage that is shipped early, on time, or late by customer or customer group.

REPORT PAGE	CHARTS	DESCRIPTION
Shipping performance	Shipped by site / warehouse	The percentage that is shipped early, on time, or late by site or warehouse.

Understanding the data model and calculations

The following data is used to fill the report pages in the **Warehouse performance** Power BI content. This data is represented as aggregate measurements that are staged in the Entity store. The Entity store is a Microsoft SQL Server database that is optimized for analytics. For more information, see [Power BI integration with Entity store](#).

The following key aggregate measurements are used as the basis of the content.

REPORT PAGE	CHARTS	TABLES	CALCULATION DESCRIPTIONS
Inbound Performance	Total put aways	WHSWorkLine	The count of work lines where the work type is put .
Inbound Performance	Put away average time	WHSWorkLine	The sum of work lines max. time divided by the count of work lines max. time, where work lines max. time is the maximum gap between the work created date and the closed date.
Inbound Performance	Received early	WHSWorkLine	The count of work lines where the work created date is earlier than the delivery date that is used. If the delivery confirmed date isn't set, use the default delivery date.
Inbound Performance	Received on time	WHSWorkLine	The count of work lines where the work created date is equal to the delivery date that is used. If the delivery confirmed date isn't set, use the default delivery date.
Inbound Performance	Received late	WHSWorkLine	The count of work lines where the work created date is later than the delivery date that is used. If the delivery confirmed date isn't set, use the default delivery date.
Inbound Performance	On time by vendor	WHSWorkLine	Received early, Received on time, and Received late (see the descriptions earlier in this table).

REPORT PAGE	CHARTS	TABLES	CALCULATION DESCRIPTIONS
Inbound Performance	Dock to stock average put away (hours)	WHSWorkLine	Put away average time (see the description earlier in this table).
Inbound Performance	Average put away by worker	WHSWorkLine	Put away average time (see the description earlier in this table).
Inbound Performance	Average put away hour by vendor	WHSWorkLine	Put away average time (see the description earlier in this table).
Inbound Performance	Average put away hour by product	WHSWorkLine	Put away average time (see the description earlier in this table).
Location inventory accuracy	Total count	WHSWorkLineCycleCount	Cycle counts where the absolute discrepancy quantity is equal to or more than 0 (zero).
Location inventory accuracy	Discrepancy rate	WHSWorkLineCycleCount	Cycle counts that have discrepancies, divided by the total count. A cycle count is considered to have discrepancies if the absolute discrepancy quantity is more than 0 (zero).
Location inventory accuracy	Count without discrepancy	WHSWorkLineCycleCount	Cycle counts where the absolute discrepancy quantity is more than 0 (zero).
Location inventory accuracy	Count with discrepancy	WHSWorkLineCycleCount	Cycle counts where the absolute discrepancy quantity is equal to 0 (zero).
Location inventory accuracy	Items counted over time	WHSWorkLineCycleCount	Count without discrepancy and Count with discrepancy (See the descriptions earlier in this table.)

REPORT PAGE	CHARTS	TABLES	CALCULATION DESCRIPTIONS
Location inventory accuracy	Item quantity discrepancy greater than %	WHSWorkLineCycleCount	The average discrepancy is the absolute discrepancy quantity divided by the expected quantity where the absolute discrepancy quantity is more than 0 (zero). The average discrepancy quantity is the average absolute discrepancy quantity where the absolute discrepancy quantity is more than 0 (zero). Count with discrepancy, Total count, Expected quantity, and Counted quantity where the whole quantity is grouped by item and location (see the descriptions earlier in this table).
Location inventory accuracy	Item count by worker	WHSWorkLineCycleCount	Count without discrepancy and Count with discrepancy (see the descriptions earlier in this table).
Location inventory accuracy	Item count by site / warehouse	WHSWorkLineCycleCount	Count without discrepancy and Count with discrepancy (see the descriptions earlier in this table).
Location inventory accuracy	Discrepancy rate by product	WHSWorkLineCycleCount	Discrepancy rate (see the description earlier in this table).
Shipping performance	Lines shipped	SalesLine	The count of sales lines where sales lines are shipped.
Shipping performance	Early	CustPackingSlipOnTimeStat us	Sales lines where the ship date status is 1 (Early) . Early means that the ship date of the packing slip is earlier than the confirmed ship date of the sales line. If the confirmed ship date isn't set, use the requested ship date.

REPORT PAGE	CHARTS	TABLES	CALCULATION DESCRIPTIONS
Shipping performance	On time	CustPackingSlipOnTimeStat us	Sales lines where the ship date status is 2 (On time) . On time means that the ship date of the packing slip is equal to the confirmed ship date of the sales line. If the confirmed ship date isn't set, use the requested ship date.
Shipping performance	Late	CustPackingSlipOnTimeStat us	Sales lines where the ship date status is 3 (Late) . Late means that the ship date of the packing slip is later than the confirmed ship date of the sales line. If the confirmed ship date isn't set, use the requested ship date.
Shipping performance	Shipments over time	SalesLine CustPackingSlipOnTimeStat us	Orders that are fully shipped, where the whole quantity of the sales line is shipped, plus Early, On time, and Late (see the descriptions earlier in this table).
Shipping performance	Shipped late by city	CustPackingSlipOnTimeStat us	Late (see the descriptions earlier in this table).
Shipping performance	Shipped by product	CustPackingSlipOnTimeStat us	Early, On time, and Late (see the descriptions earlier in this table).
Shipping performance	Shipped by customer	CustPackingSlipOnTimeStat us	Early, On time, and Late (see the descriptions earlier in this table).
Shipping performance	Shipped by site / warehouse	CustPackingSlipOnTimeStat us	Early, On time, and Late (see the descriptions earlier in this table).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Analytical Workspaces (using Power BI Embedded)

2/18/2021 • 2 minutes to read • [Edit Online](#)

Dynamics Finance and Operations apps now deliver rich, interactive reports seamlessly integrated into application workspaces. By using graphics and visuals supported by Power BI, workspaces can provide a highly-visual, yet interactive experiences for users.

Overview

Workspaces in the application provide an overview of business processes or business units. With rich workspaces, users can get a bird's-eye view of the state of business before diving into details and taking action. Workspaces contain visuals, count tiles, and KPIs as well as quick links to reports and pages. Within a workspace, all controls are tightly integrated to provide a highly-productive and engaging work environment to the user. Power BI Embedded is a Microsoft Azure service that enables ISVs and app developers to surface Power BI data experiences within their applications. With Power BI Embedded, developers can deliver always-up-to-date views with Direct Query. To learn more about how the Power BI Embedded service integrates with the application, see [Power BI Embedded integration](#).

Power BI in workspaces

The application now delivers interactive reports that seamlessly integrate into application workspaces. By using rich infographics and visuals supported by Power BI (including the large number of controls provided by third parties), workspaces can provide a highly-visual, yet interactive experience for users. Using infographics in the overview page, users can get a quick glance of the state of the business. They can interact with data by simply clicking or touching visuals on the page. They can see the cause and effect, perform simple what-if operations without leaving the workspace. Thanks to stunning yet interactive visuals, your users will have fun exploring data and discovering hidden trends.

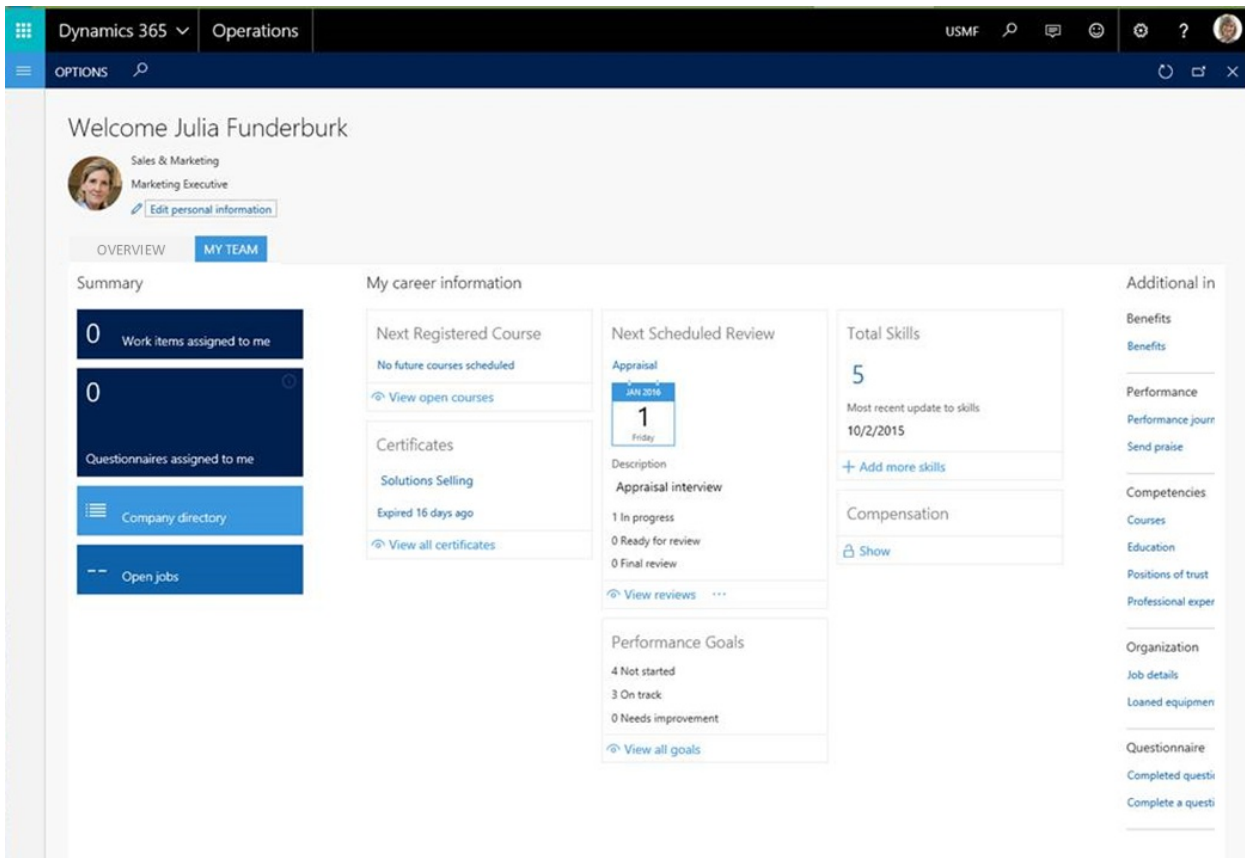

The following screenshot shows Power BI in a workspace.

Power BI vs operational workspaces

Power BI workspaces complement operational views with analytical insights based on near real-time information. The following offers a visual comparison of a Power BI workspace and an operational workspace.

The following screenshot shows an operational workspace.

Edit embedded reports in analytical workspaces

The [How to edit an embedded report in an analytical workspace](#) video (shown above) is included in the [Playlist](#) available on YouTube.

What's next?

Going forward, new cloud deployments will come bundled with the Power BI Embedded service. Additional documentation describing the Developer ALM process will be made available to help partners and ISVs create new solutions that take advantage of the Power BI Embedded service integration options that are available.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Power BI Embedded integration

2/18/2021 • 5 minutes to read • [Edit Online](#)

Microsoft Power BI content that partners and independent software vendors (ISVs) developed can be embedded directly into the Microsoft Dynamics 365 Finance. This topic describes some of the ways that you can use the Microsoft Power BI Embedded integration.

Overview

The integration of the application and [Power BI](#) enables data mash-up scenarios that require access to external data sources that are supported through Microsoft Power Query for Excel. Users can personalize workspaces by embedding tiles that are hosted on PowerBI.com. Users can also add direct links to reports that are hosted on PowerBI.com. In this way, users can access and interact with the reports without leaving the application. Power BI content (PBIX files) that partners and ISVs develop can be embedded directly into the application. PBIX files that are associated with a model file are automatically published in Power BI Embedded as part of the application deployment process. Additionally, you can add X++ extensions for embedded reporting scenarios that require the following functionality:

- Drill-down navigation into detailed pages in response to user interactions
- Report filters that are based on user and session context information, such as company or date range
- The ability to navigate directly to a specific tab on a Power BI report via menu items

For more information about customizations that use extensions, see [Customize through extension and overlaying](#).

Advantages of Power BI Embedded

- **Deliver Power BI workspaces and reports in the application.** If you're a power user or a business analyst, you can tweak ready-made reports or create new reports by using Power BI tools. As a developer, you can use the reports that your users create to provide rich navigation experiences in the product through workspaces. If you're in the partner and ISV community, you can build rich workspaces that include Power BI experiences, and then release those workspaces as part of your solution.
- **The Power BI Embedded service license is bundled with the application.** If you're an ISV or a systems integrator, you can package workspaces that are enabled for Power BI (and navigational experiences that those workspaces provide) as part of a Microsoft Dynamics Lifecycle Services (LCS) solution. Your customers get the same experience without having to have a PowerBI.com subscription. The workspaces just work with Finance and Operations applications.
- **Enable drill-down into detailed pages from Power BI.** The visuals are the starting point for action. Your users can drill down to business processes and pages to act immediately on issues that they uncover. The visuals let users filter data and uncover trends. Action pages reflect just the set of data that requires attention.
- **Help secure access to Power BI reports by using menu items.** As a developer, you can use familiar programming concepts that are available in Finance and Operations apps, because we have extended the same concepts to workspaces that are based on Power BI. You can create new workspaces or extend existing workspaces by adding an overview page that is driven by Power BI. Developers can associate menu items with Power BI reports and include them as links in workspaces. The role-based and task-based security in Finance and Operations apps can be used to help secure these menu items.
- **Filter reports based on application context.** You can build navigation experiences by passing one or more filters to Power BI reports. For example, depending on a user's actions or context, you can filter the Power BI report to reflect data from one business unit or a specific product. The user doesn't have to filter the

data. You can define drill-through links to Finance and Operations pages, so that users can go directly to the transactional details pages.

For more information about the Power BI Embedded service, see the [Power BI FAQ](#).

Service availability

The Power BI Embedded service is automatically deployed and configured for all cloud-hosted, multi-box deployments. Because the service relies on Microsoft Azure services, application analytical workspaces and reports are unavailable in one-box environments. The Power BI Embedded service is already available in most Azure datacenters. You can check the latest availability on the [Azure status](#) page.

Frequently asked questions

Can I customize the Power BI embedded reports?

Yes. To customize the Power BI embedded reports, just install Power BI Desktop in a one-box environment, and follow the steps in [Create analytical reports by using Power BI Desktop](#).

Do customers have to purchase a separate Power BI license to use the new embedded analytics?

No, customers don't have to purchase a separate Power BI license to use the new embedded analytics. However, a Power BI Pro license is required in order to connect to Entity Store from PowerBI.com by using DirectQuery.

Can I do data mash-ups by using external data in the embedded reports?

No, you can't currently do data mash-ups by using external data in the embedded reports.

Can I help secure data to only those companies that I have access to?

Yes, the single company view prevents users from accessing data from companies that they don't have access to. For more information about how to help secure custom solutions, see [Help secure analytical workspaces and reports by using Power BI Embedded](#).

How is currency shown across multiple companies?

Currency is shown as a system currency. The system currency is defined on the [System parameters](#) page.

Can I drill from summary balances back into Finance and Operations?

Yes, you can drill into the details on a Power BI report. However, there is limited support for drill-down into Finance and Operations apps.

What languages are currently supported?

Currently, only English is supported. However, the Power BI team plans to add support for other languages.

Can I access analytical workspaces and reports in the on-premises version of Finance and Operations?

No, you can't currently access analytical workspaces and reports in Dynamics 365 Finance + Operations (on-premises). Systems of Intelligence functions rely on cloud-hosted solutions.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Customize embedded reports in analytical workspaces

2/18/2021 • 4 minutes to read • [Edit Online](#)

Analytical workspaces

Analytical workspaces are bundled with the application suite. Through reporting, they offer users insights into data that is based on standard business operations. The reports are generic reports that are defined by business professionals. They include metrics that are considered interesting to a wide range of users from any industry.

However, in some cases, the standard reports include data that isn't relevant to all customers. More often, customers might want to access data points or calculations that are left out of the standard reports.

Power users can use web-friendly design tools to customize the analytical reports that are embedded in the application. By using the free-form canvas designer, users who are familiar with the relevant business insights that are required can help make the organization successful.

IMPORTANT

Customizations that are made to the embedded analytical reports are automatically deployed by the service and made available to other users of the system.

Edit embedded reports in analytical workspaces

The [How to edit an embedded report in an analytical workspace](#) video (shown above) is included in the [Playlist](#) available on YouTube.

Important points about embedded analytical reports

Although the standard reports deliver insights that are tailored to a given business persona, customizations can often maximize the value of these standard reports.

Here are some important points to note about this service capability:

- Customizations are limited to the report design canvas. Users can't change the definitions of report data sets.
- Report customizations that are made to the analytical workspace apply to all users in the environment.
- The service automatically preserves report customizations during product upgrades.
- The service doesn't support the export of customizations that are made to analytical workspaces.

Customize an analytical workspace

To customize the embedded application solutions, a user must be a member of the System Report Editors security group. Members of this security group can do customizations by using the buttons on the **Options** tab on the Action Pane of the application workspaces. This example shows how to customize one of the standard analytical workspaces that are bundled with the application suite.

1. Sign in and open the application workspace that you want to customize. In this example, you will replace the standard analytical report that is embedded in the **Compensation management** workspace.

2. Select the **Analytics** tab to access the workspace's embedded analytical report.

By default, you see the standard analytical workspace solution that is packaged with your application. The reports in this solution are automatically deployed and configured for your environment during the provisioning process.

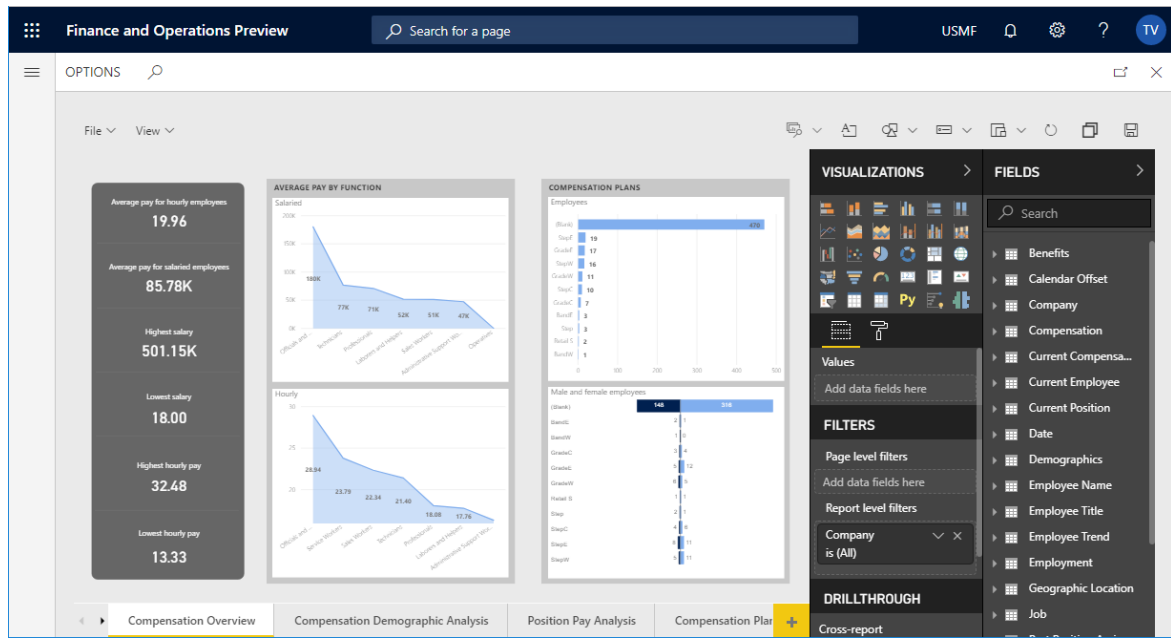

NOTE

The analytical workspaces require a hosted Microsoft Power BI service that is available only for dedicated environments. For more information, see [Accessing Analytical Workspaces and Reports on 1Box environment](#).

3. On the Action Pane, on the **Options** tab, in the **Power BI** group, select **Edit Analytics**.

The analytical workspace is opened in edit mode, and you have direct access to the Power BI web designer tools.

4. Use the Power BI web designer tools to customize the report canvas. The intuitive web controls let you perform typical actions such as adding and removing visuals, changing visual types, and formatting the content. You can also inspect the source of the report visualizations to make sure that decisions are based on the most relevant data that is available in the system. For more information, see [Add visualizations to a Power BI report](#).
5. After you've completed your report customizations, select the **Save** button to promote the report edits. Customizations to the report are reflected immediately in the service. Therefore, users in your organization have access to the latest innovations.

NOTE

Customizations made in the web editor are not saved back to the underlying PBIX report and are not retrievable if the PBIX report is later customized on a development environment.

Restore the standard application solution

Follow these steps to restore the analytical workspaces that are bundled with the application solution.

1. In the analytical workspace, on the Action Pane, on the **Options** tab, in the **Power BI** group, select **Restore Analytics**.
2. To view the updates to the workspace, reload the page. Either move away from the workspace and then return, or refresh your browser.
3. In the **Compensation management** workspace, select the **Analytics** tab to access the original analytical workspace that was packaged with the application.

Troubleshooting

Follow these steps to address common issues encountered while attempting to use analytical workspaces.

Error message: *Please log into Power BI to access its resource*

The Power BI service requires explicit permission from the user to allow access to hosted content. Use the following steps to ensure the current user is able to connect to reports hosted on PowerBI.com from the application suite.

1. Open any application workspace containing a section titled **Link**. For example, "Bank management".
2. Select **Options**, and then select **Open report catalog** on the top left.
3. Follow the steps in the dialog box to **Authorize to Power BI** to access Finance and Operations apps for the current user.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Document Reporting Services

2/18/2021 • 3 minutes to read • [Edit Online](#)

This article describes the integrated reporting solution that are available. This solution simplifies service administration, increases developer productivity, and provides an enhanced report viewing experience for users.

Document Reporting Services

Document Reporting Services are based on Microsoft SQL Server Reporting Services (SSRS). In the current version of the application, these services are hosted in the Microsoft Azure compute service. If you're developing in a one-box environment, the services also run locally in the Azure compute emulator.

Service deployment – Local vs. cloud

In a one-box environment, developers can create, modify, and preview reports, from end to end, by using Microsoft Visual Studio. A separate process isn't required in order to add reports to the application's metadata store. Changes to reports are packaged together with other solution updates and then deployed to the cloud after development is completed in the local environment.

Viewing reports

The enhanced report viewing experience that provides for end users is the same as the report preview experience in Microsoft Visual Studio. You no longer use a separate design preview in Visual Studio. Instead, just press Ctrl+F5 to build and preview the report in an Internet Explorer window. The report appears exactly as it would appear in the client. Even the user's parameter experience is the same. The following screen shot shows an example of a report preview that is opened from Visual Studio.

The screenshot shows a web browser window with the URL `https://usnconeboxa...` and a tab titled 'Customer list -- Microsoft ...'. The page header includes 'Admin (DAT) Company accou...' and navigation icons. The main content area is titled 'Customer list' and features a 'Fleet Management' section with a car icon and the text 'FABRIKAM Fleet Management'. Below this, there is an address: '123 Second Street, City, St. 99909 USA', and phone/fax numbers: 'P: 0123456789, F: 0123456780'. A prominent orange box displays 'Customer details report' dated '11/13/2014 9:31:03 PM' and '6 active customers'. The page is divided into three sections for member groups:

- Members of our Non-Member group:** A table with columns 'FIRST', 'LAST', and 'LICENSE'. It lists three members: Adrian Lannin (license 5688-8944-8185), Andreas Dziegiel (license V347-3489-2984), and Tony Smith (license B923-2381-9954). Below the table, it states 'We have 3 members of this group'.
- Members of our Advantage Member group:** A table with columns 'FIRST', 'LAST', and 'LICENSE'. It lists two members: Josh Bailey (license B889-1128-6699) and Phil Spencer (license S468-3184-6541). Below the table, it states 'We have 2 members of this group'.
- Members of our Executive Member group:** A table with columns 'FIRST', 'LAST', and 'LICENSE'. It lists one member: Mirina Natarajan (license S615-3939-2354). Below the table, it states 'We have 1 members of this group'.

The page footer indicates 'Page 1 of 1'.

Service administration prerequisites

The following table compares the service administration prerequisites for Microsoft Dynamics AX 2012 and the current version of the application.

AX 2012	THE CURRENT VERSION OF THE APPLICATION
<p>A report development environment has the following prerequisites:</p> <ul style="list-style-type: none"> • SSRS must be installed. • SSRS must be configured by using Reporting Services Configuration Manager. • SSRS extensions for the application must be installed. 	<p>Reporting services run in the Azure compute emulator, together with the application server. Therefore, there are no SSRS service administration prerequisites. After reports have been deployed to the local reporting services, they can be accessed from the client.</p>

Developing application reports

The process for developing a report in the current version is easier than it is in AX 2012, because you can create and validate a reporting solution entirely in Visual Studio. The following table describes how the application simplifies the basic procedure for adding an automatic design report that is based on a query.

AX 2012	THE CURRENT VERSION OF THE APPLICATION
<ol style="list-style-type: none"> 1. In the application, create a query in the Application Object Tree (AOT). 2. In Visual Studio, create a reporting project, and add the query to it. 3. Edit the report in the Visual Studio model editor. 4. Preview the report design in Visual Studio by using the model editor toolbar. 5. Use Visual Studio to add the report to the AOT. 6. Use the AOT in the client to create a menu item for the report, and add the menu item to a menu. 7. Use the AOT to deploy the report to the report server. 8. Verify the report in the client. 	<ol style="list-style-type: none"> 1. In Visual Studio, create a reporting project and the query. 2. Edit the report in Visual Studio. 3. In Visual Studio, add the report to a menu item, and set the menu item as a startup object. 4. Use the AOT to deploy the report to the report server. 5. Press Ctrl+F5 to verify the report in the application. <div style="border: 1px solid gray; padding: 5px; margin: 10px 0;"> <p>[!NOTE] There is no longer a separate preview of the report design from the model editor.</p> </div> <ol style="list-style-type: none"> 6. When the whole solution is completed, deploy it to the cloud in one package.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Supported fonts

2/18/2021 • 13 minutes to read • [Edit Online](#)

Finance and Operations apps include access to hundreds of standard, business-ready fonts available for documents rendered by the cloud-hosted service.

This portfolio will continue to grow as the service expands into new regions and industries. However, the service no longer supports the installation of custom fonts in customer environments. Requests to expand the collection of fonts supported by the service will be considered on a case-by-case basis.

The following list captures the portfolio of font families available for documents produced using SQL Server Reporting Services (SSRS) services in Finance and Operations apps.

Supported fonts for application version 8.3 with Platform update 32 or later

Configure SQL Server Reporting Services for on-premises deployments

2/18/2021 • 2 minutes to read • [Edit Online](#)

Use the steps in this topic to configure SQL Server Reporting Services (SSRS) for your Microsoft Dynamics 365 Finance + Operations (on-premises) deployment.

1. Open the Reporting Services Configuration Manager application.
2. Leave the default **Server name**, which should be the name of the current machine, and the **Report Server Instance**, **MSSQLSERVER**.
3. Click **Connect**.

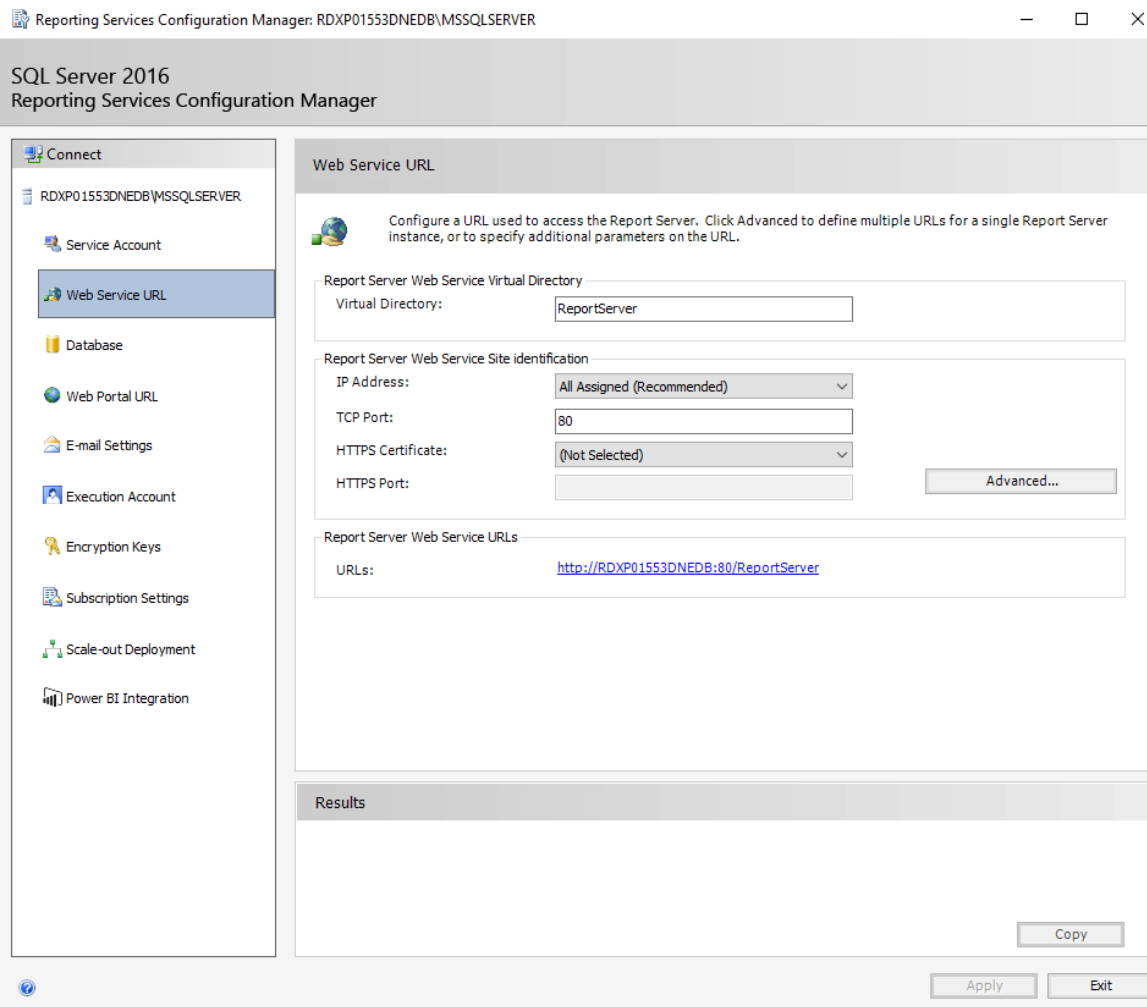

4. Click the **Service Account** tab and verify that the settings match the following graphic.

SQL Server 2016
Reporting Services Configuration Manager

The screenshot shows the 'Service Account' configuration window in the Reporting Services Configuration Manager. The left-hand navigation pane is visible, with the 'Service Account' tab selected. The main area is titled 'Service Account' and contains the following text: 'Specify a built-in account or Windows domain user account to run the report server service.' Below this, there is a section titled 'Report Server Service Account' with the instruction 'Choose an option to set the service account and then click Apply.' There are two radio button options: 'Use built-in account:' which is selected and has a dropdown menu showing 'Local System'; and 'Use another account:' which is unselected and has two text input fields labeled 'Account (Domain\user):' and 'Password:'. At the bottom right of the main area is a 'Copy' button. Below the main area is a 'Results' section, which is currently empty. At the very bottom of the window are 'Apply' and 'Exit' buttons.

5. Click the **Web Service URL** tab and verify that the settings match the following graphic.

6. Click the **Database** tab and verify that the **Database Name** and **Credential settings** match the following graphic.

NOTE

You will need to create a new database. To do this, click **Change Database**, and then verify that the new database name is: **DynamicsAxReportServer**.

SQL Server 2016
Reporting Services Configuration Manager

Connect

- Connect
- RDXP01553DNEDB\MSSQLSERVER
- Service Account
- Web Service URL
- Database**
- Web Portal URL
- E-mail Settings
- Execution Account
- Encryption Keys
- Subscription Settings
- Scale-out Deployment
- Power BI Integration

Report Server Database

Reporting Services stores all report server content and application data in a database. Use this page to create or change the report server database or update database connection credentials.

Current Report Server Database

Click: Change database to select a different database or create a new database in native or SharePoint integrated mode.

SQL Server Name:	rdxp01553Dnedb
Database Name:	DynamicsAxReportServer
Report Server Mode:	Native

Current Report Server Database Credential

The following credentials are used by the report server to connect to the report server database. Use the options below to choose a different account or update a password.

Credential:	Service Account
Login:	LocalSystem
Password:	*****

Results

7. Click the **Web Portal URL** tab and verify that the settings match the following graphic.

NOTE

You must click **Apply** to create and properly configure the Portal.

SQL Server 2016
Reporting Services Configuration Manager

The screenshot shows the 'Web Portal URL' configuration window in the Reporting Services Configuration Manager. The left-hand navigation pane is open to the 'Web Portal URL' tab. The main area contains the following elements:

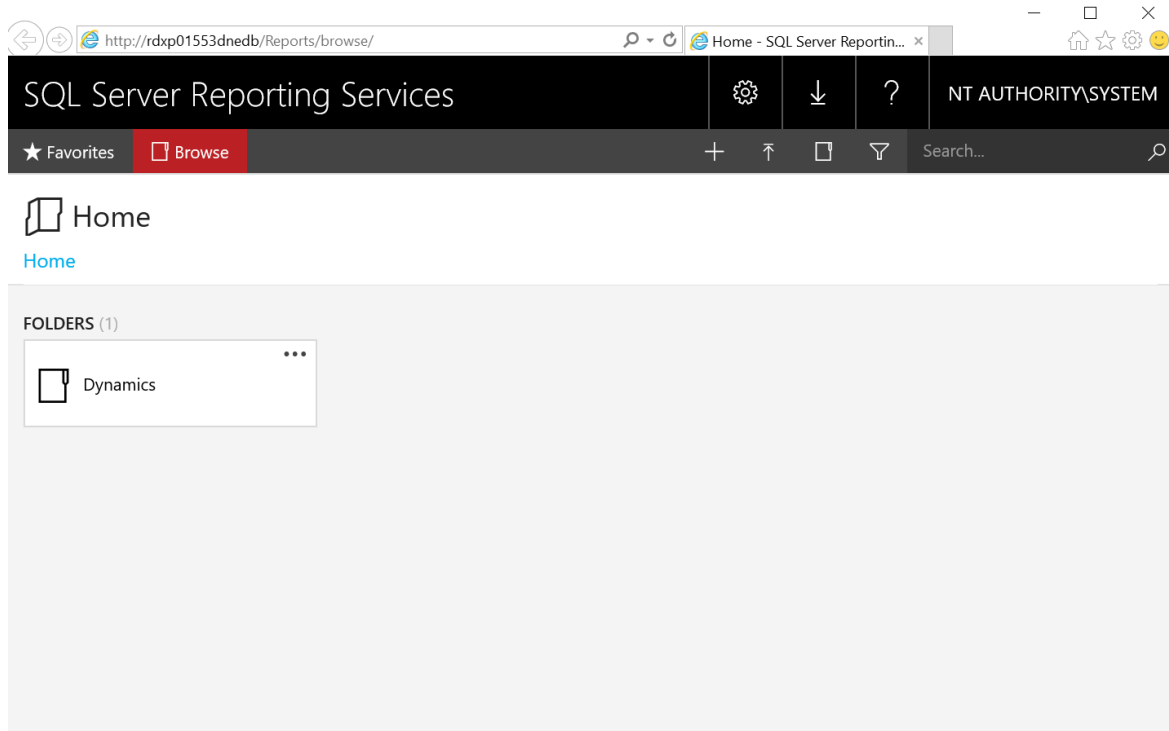

- Web Portal URL** header.
- Instructional text: "Configure a URL to access Web Portal. Click Advanced to define multiple URLs, or to specify additional parameters on the URL."
- Warning icon and text: "The Web Portal virtual directory name is not configured. To configure the directory, enter a name or use the default value that is provided, and then click Apply."
- Web Portal Site Identification** section with a scrollable area containing:
 - Virtual Directory:** A text box containing the value "Reports".
 - URLs:** A text box containing the value "http://RDXP01553DNEDB:80/Reports".
 - An **Advanced** button to the right of the URL text box.
- A horizontal scrollbar below the configuration area.
- Results** section, which is currently empty.
- A **Copy** button at the bottom right of the Results section.

At the bottom of the window, there are **Apply** and **Exit** buttons.

After the Portal is configured, the **Web Portal** tab will match the following graphic.

8. Click the reports URL to view the SQL Server Reporting Services web portal.
9. When you are in the portal, create a new folder named **Dynamics**.

10. In the **Reporting Services Configuration Manager**, click the **E-mail Settings** tab and verify that the settings match the following graphic.

SQL Server 2016
Reporting Services Configuration Manager

The screenshot shows the 'E-mail Settings' configuration window in the Reporting Services Configuration Manager. The left-hand navigation pane lists various configuration options, with 'E-mail Settings' currently selected. The main area is titled 'E-mail Settings' and contains a descriptive icon and text: 'To use report server e-mail, specify an existing SMTP server and an e-mail account that can send e-mail from that server.' Below this is a section for 'SMTP Settings' with the instruction: 'To edit, change the fields and click the Apply button.' The settings are as follows:

Field	Value
Sender Address:	<input type="text"/>
Current SMTP Delivery Method:	Use SMTP server
SMTP Server:	<input type="text"/>
Authentication:	No authentication

At the bottom of the window, there is a 'Results' section which is currently empty. A 'Copy' button is located in the bottom right corner of the main settings area. At the very bottom of the window, there are 'Apply' and 'Exit' buttons.

11. Click the **Execution Account** tab and verify that the settings match the following graphic.

SQL Server 2016
Reporting Services Configuration Manager

The screenshot shows the 'Execution Account' configuration window. On the left is a navigation pane with the following items: Connect, RDXP01553DNEDB\MSSQLSERVER, Service Account, Web Service URL, Database, Web Portal URL, E-mail Settings, Execution Account (selected), Encryption Keys, Subscription Settings, Scale-out Deployment, and Power BI Integration. The main area is titled 'Execution Account' and contains the following text: 'Specify this account to enable the use of report data sources that do not require credentials or to connect to remote servers that store external images used in reports. Be sure to specify a domain user account with minimal permissions for performing read-only operations. Avoid using an account that has more permissions than you actually need. The account you specify should be different from the service account to ensure you do not compromise security on your report server instance.' Below this is a section titled 'Execution Account' with the instruction 'Use the following options to set the account, then click Apply.' and a checkbox labeled 'Specify an execution account'. Underneath are three input fields: 'Account:', 'Password:', and 'Confirm Password:'. At the bottom right of the main area is a 'Copy' button. At the very bottom of the window are 'Apply' and 'Exit' buttons.

Execution Account

Specify this account to enable the use of report data sources that do not require credentials or to connect to remote servers that store external images used in reports. Be sure to specify a domain user account with minimal permissions for performing read-only operations. Avoid using an account that has more permissions than you actually need. The account you specify should be different from the service account to ensure you do not compromise security on your report server instance.

Execution Account

Use the following options to set the account, then click Apply.

Specify an execution account

Don't change the default settings on the **Encryption Keys** tab.

SQL Server 2016
Reporting Services Configuration Manager

The screenshot shows the Reporting Services Configuration Manager interface. On the left is a navigation pane with the following items: Connect, RDXP01553DNEDB\MSSQLSERVER, Service Account, Web Service URL, Database, Web Portal URL, E-mail Settings, Execution Account, Encryption Keys (highlighted), Subscription Settings, Scale-out Deployment, and Power BI Integration. The main area is titled 'Encryption Keys' and contains the following text: 'Reporting Services uses a symmetric key to encrypt credentials, connection strings, and other sensitive data that is stored in the report server database. You can manage this key by creating a backup. If you migrate or move the report server installation to another computer, you can restore the key to regain access to encrypted content.' Below this text are four sections, each with a button: 'Backup' (Backup the key to a password protected file for report server recovery in case of emergency. Backup), 'Restore' (To restore the encryption key, click the Restore button. You must know the password that was used to protect the encryption key file. Restore), 'Change' (This operation replaces the encryption key with a newer version. Change), and 'Delete Encrypted Content' (All stored connection strings, credentials, and encrypted values in a subscription will be deleted. After you delete this content, you must redefine all data source connections and subscriptions used on the report server. Delete). At the bottom right of the main area is a 'Copy' button. At the very bottom of the window are 'Apply' and 'Exit' buttons.

12. Click the **Subscription Settings** tab, and verify that the settings match the following graphic.

SQL Server 2016
Reporting Services Configuration Manager

Connect

- RDXP01553DNEDB\MSSQLSERVER
- Service Account
- Web Service URL
- Database
- Web Portal URL
- E-mail Settings
- Execution Account
- Encryption Keys
- Subscription Settings**
- Scale-out Deployment
- Power BI Integration

File Share Account

Configure an account to be used by subscriptions to access file shares. Use an account with as minimum permissions as possible and an account that is different from the account used for the Reporting Services service account.

File Share Account

Use the following options to set the account, then click Apply.

Specify a file share account

Don't change the default settings on the **Scale-out Deployment** tab.

SQL Server 2016
Reporting Services Configuration Manager

The screenshot shows the 'Scale-out Deployment' page in the Reporting Services Configuration Manager. The left-hand navigation pane includes options like 'Connect', 'Service Account', 'Web Service URL', 'Database', 'Web Portal URL', 'E-mail Settings', 'Execution Account', 'Encryption Keys', 'Subscription Settings', 'Scale-out Deployment' (which is selected), and 'Power BI Integration'. The main content area is titled 'Scale-out Deployment' and contains a descriptive paragraph, a 'Scale-out Deployment Status' section with key-value pairs, a table of server instances, and 'Add Server' and 'Remove Server' buttons. Below this is a 'Results' section with a 'Copy' button. At the bottom right, there are 'Apply' and 'Exit' buttons.

Scale-out Deployment

Use this page to view information about a scale-out deployment. Report Servers that are joined to the scale-out can store encrypted data in a common Report Server database. Servers that are waiting to join the scale-out deployment must be added by a Report Server instance that is already part of the deployment.

Scale-out Deployment Status

SQL Server Name: rdxp01553Dnedb
Database Name: DynamicsAxReportServer
Report Server Mode: Native

Server	Instance	Status

Apply Exit

Don't change the default settings on the **Power BI Integration** tab.

SQL Server 2016 Reporting Services Configuration Manager

The screenshot shows the Reporting Services Configuration Manager interface. On the left is a 'Connect' sidebar with various configuration options. The main area is titled 'Power BI Integration' and contains instructions for registering the report server with Power BI. A 'Register with Power BI' button is visible, and the status is 'Not Registered'. At the bottom right, there are 'Apply' and 'Exit' buttons.

Connect

- RDXP01553DNEDB\MSSQLSERVER
- Service Account
- Web Service URL
- Database
- Web Portal URL
- E-mail Settings
- Execution Account
- Encryption Keys
- Subscription Settings
- Scale-out Deployment
- Power BI Integration**

Power BI Integration

When the report server is registered with Power BI, users can pin report items to their Power BI dashboards. Use this page to register or unregister the report server with Power BI.

Power BI Registration

Click Register with Power BI to register the Report server with Power BI.

Power BI Registration: Not Registered

Results

13. Click Exit to close the Reporting Services Configuration Manager.

SQL Server 2016 Reporting Services Configuration Manager

The screenshot displays the Reporting Services Configuration Manager interface. On the left is a navigation pane with the following options: Connect, RDXP01553DNEDB\MSSQLSERVER (selected), Service Account, Web Service URL, Database, Web Portal URL, E-mail Settings, Execution Account, Encryption Keys, Subscription Settings, Scale-out Deployment, and Power BI Integration. The main area is titled 'Report Server Status' and contains a warning icon and text: 'Use the Reporting Services Configuration Manager tool to define or modify settings for the Report Server and Report Manager. If you installed Reporting Services in files-only mode, you must configure the Web service URL, the database, and the Report Manager URL.' Below this is a section for 'Current Report Server' with the following details:

SQL Server Instance:	MSSQLSERVER
Instance ID:	MSRS13.MSSQLSERVER
Edition:	ENTERPRISE EDITION
Product Version:	13.0.4422.0
Report Server Database Name:	DynamicsAxReportServer
Report Server Mode:	Native
Report Service Status:	Started

At the bottom of this section are 'Start' and 'Stop' buttons. Below the status information is a 'Results' section, which is currently empty. At the bottom right of the Results section is a 'Copy' button. At the very bottom of the window are 'Apply' and 'Exit' buttons.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Document printing overview

2/18/2021 • 3 minutes to read • [Edit Online](#)

You can print documents by using either a local printer or a network-connected device. This article provides an overview of how documents are printed.

Printing overview

The application provides integrated services and client applications that make it easy to generate, store, and distribute documents that support business activity. You can print documents by using either a local printer or a network-connected device. In addition, you can export pages and reports directly from the client, as PDF files or Microsoft Office documents. Finally, the distributed workload lets you print business documents directly from a mobile device by using network resources. Although printing requirements might vary, all industries typically must create hard copies of business documents by using the application. Printing documents on network devices from hosted applications presents a unique set of challenges. Here are some examples:

- Print drivers might not be available on the user's device.
- The user's device might not be connected to the corporate network.

By using a dedicated host and following a few easy steps, system administrators can configure deployments so that users can print directly from business applications on network devices.

Application printing scenarios

The following table describes the three primary printing scenarios.

SCENARIO	GOAL	SOLUTION
1. Printing what you see	Print what is currently shown in the browser.	A "print-friendly" version of the webpage is generated for the browser.
2. Interactive printing	Print a precision document on a locally connected device.	You can export a PDF version of the report and download it to the browser.
3. Printing on a network device	Send a precision document to a domain printer device.	A precision document is sent to a client application that runs on a server that is hosted in the customer's domain.

Because the solution varies, depending on the scenario, applications provide built-in services and tooling to help users accomplish their goals:

- **Scenario 1** is supported by the browser's rendering of the HTML5 client.
- **Scenario 2** uses client applications and Microsoft 365 services.
- **Scenario 3** requires support from client applications and from services that are hosted in Microsoft Azure.

In addition to the platform that is deployed to the Azure subscription, Finance and Operations applications provide customers with an integrated, first-party Azure application that helps them more easily use domain-hosted devices to print documents.

Service overview

While documents that are produced by the hosted applications are waiting to be printed on a network-

connected device, they are stored in Azure blob storage. The [Install the Document Routing Agent to enable network printing](#) uses Azure authentication to establish a secure channel to the Azure services.

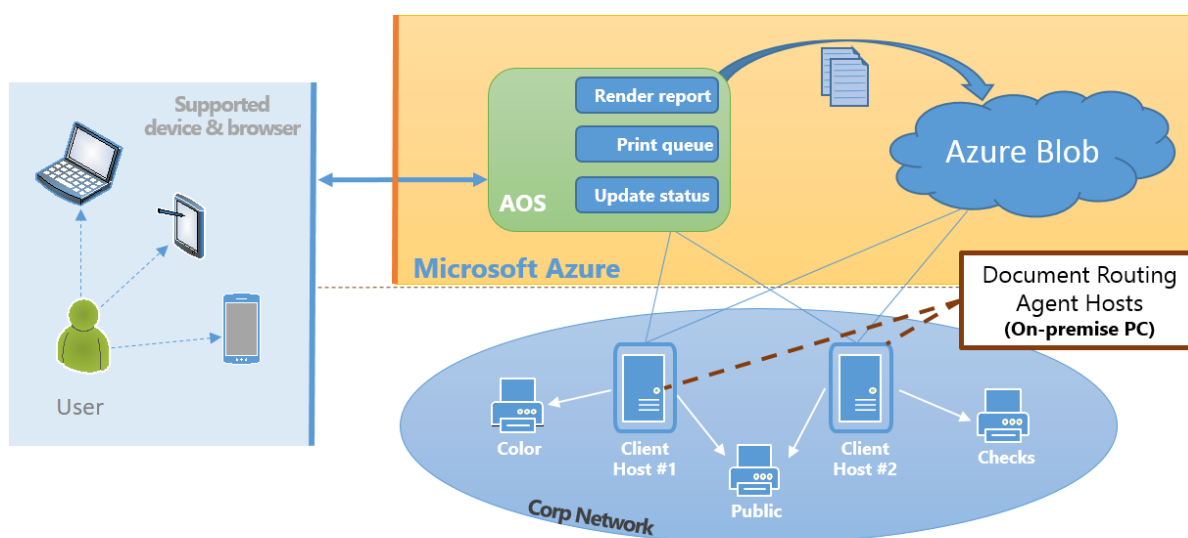

Execution sequence

1. The report is generated by Microsoft SQL Server Reporting Services (SSRS) and stored in Azure blob storage. Attached printer settings are stored together with the document.
2. The Document Routing Agent queries the Azure Service Bus queue for active jobs.
3. The document is downloaded by the Document Routing Agent and spooled to the network printer.

The client-based solution lets customers manage the scale of their printing needs. Customers who have heavy-volume printing workloads can install many Document Routing Agents to increase the number of concurrent printing operations. Alternatively, some customers require very few installations of the Document Routing Agent to handle their anticipated printing needs.

Service components for network printing

The following diagram shows the basic components that help support network printing operations.

Note that a single printer can be registered with multiple Document Routing Agents. To resolve the printer preferences, the hosted service uses the network path that uniquely identifies every network printer. As a result, even when a printer is registered by multiple clients, it appears as a single selection in the list of printers available in applications.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Install the Document Routing Agent to enable network printing

2/18/2021 • 5 minutes to read • [Edit Online](#)

This topic describes how to install and configure the Document Routing Agent (DRA). The DRA is a downloadable application that you can use to enable network printing scenarios. You can enable network printers for specific companies by using in-client administrative pages.

Preparing to install the Document Routing Agent

- Supported on Windows 8.1, Windows 10, Microsoft Windows Server 2012 R2, or Microsoft Windows Server 2016.
- Access to network printing resources requires Active Directory Domain Services (AD DS) authentication.
- When installing the DRA, make sure you are logged in as the Admin user.
- The Microsoft Azure Active Directory (Azure AD) account that is used to configure the DRA must share the same domain as the Azure tenant.
- The DRA requires .NET 4.62 or later and Adobe Acrobat Reader on the client.
- Configure Adobe client print settings to prevent document scaling.

Network printers that are registered for applications can be used by all legal entities (also known as companies) that are defined in the environment. Network printer settings are company-specific. Therefore, administrators can restrict access, based on the user's active company. For example, users in the active company might have access to all the network printers that are registered by the Document Routing Agent. However, users in another company won't have access to those printers until access is explicitly enabled for that company.

Key concepts

This topic will help you with the following tasks:

- Identify the key components that are involved in the support for network printing in applications.
- Learn about the function of the Document Routing Agent.
- Configure the Document Routing Agent to work against an existing application.
- Use administration pages to manage access to network printers.

Install the Document Routing Agent

Applications use the Document Routing Agent to manage the spooling of documents to network printer devices. You can obtain the client by using direct links that are embedded in the web application. Use the following procedure to download the application to your local computer. You will then be able to access both local and network printers that are connected to your computer, from a single deployment.

1. Open the **Manage network printers** page (**Organization administration > Setup > Network printers**).
2. On the **Options** tab, in the **Application** group, click **Download document routing agent installer**.

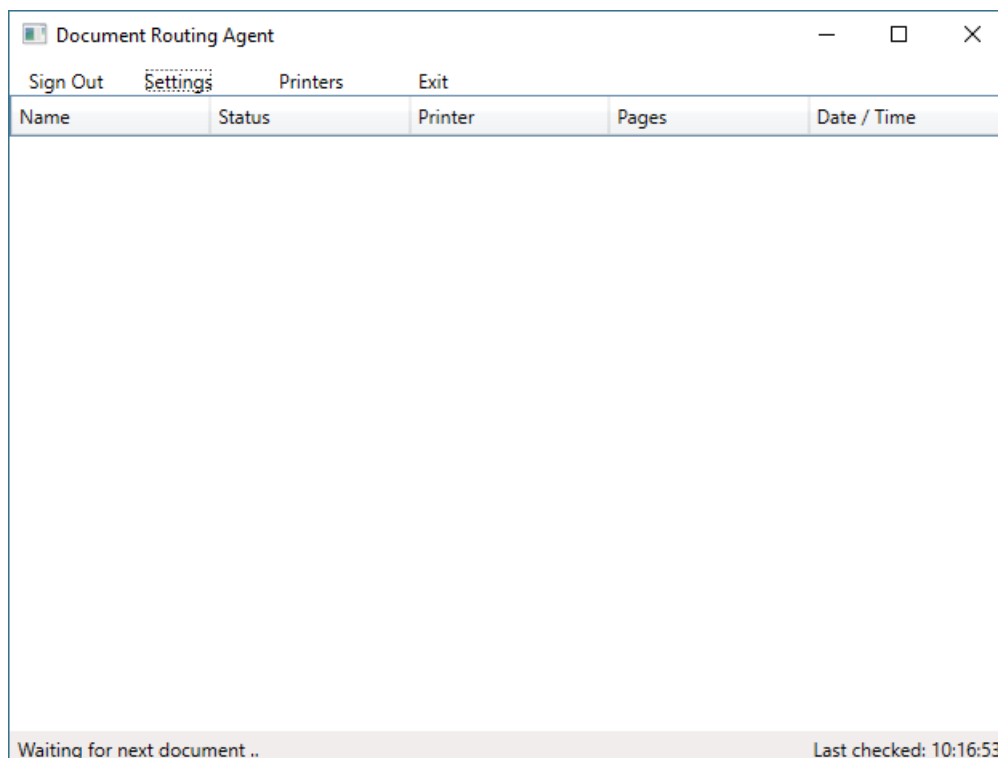

3. Run the downloaded file to begin the installation process.
4. Complete the setup process.

After the application is installed, you can begin to register local printers as network printers for the applications.

Configure the Document Routing Agent

Use the following procedure to configure the client application so that it can communicate with the Azure services that host the documents that are in-flight.

1. Close all browser instances that are running the application. This resets the local Azure authentication tokens.
2. On your desktop, run the Document Routing Agent.
3. On the toolbar, click **Settings**.

4. Add the following settings:
 - **Application ID** – The ID that is unique to the application and should be entered automatically.
 - **Finance and Operations URL** – The base URL of the application.
 - **Azure AD tenant** – The domain name of the Azure AD.

5. Click **OK**.
6. Click **Sign In** to sign in to your account.

NOTE

The account must share the same domain as the Azure AD that is associated with the application. The Document Routing Agent is now ready to process documents.

After you've successfully signed in, the **Printers** button becomes available on the toolbar.

Register network printers

Before you complete this procedure, make sure that you've installed all the network printers on the local host computer. All the printer devices that are installed will be available for service registration. Be sure to select only the printers that you want to expose in the applications.

1. On the toolbar, click **Printers**.
2. Select the printers to make available in the applications.

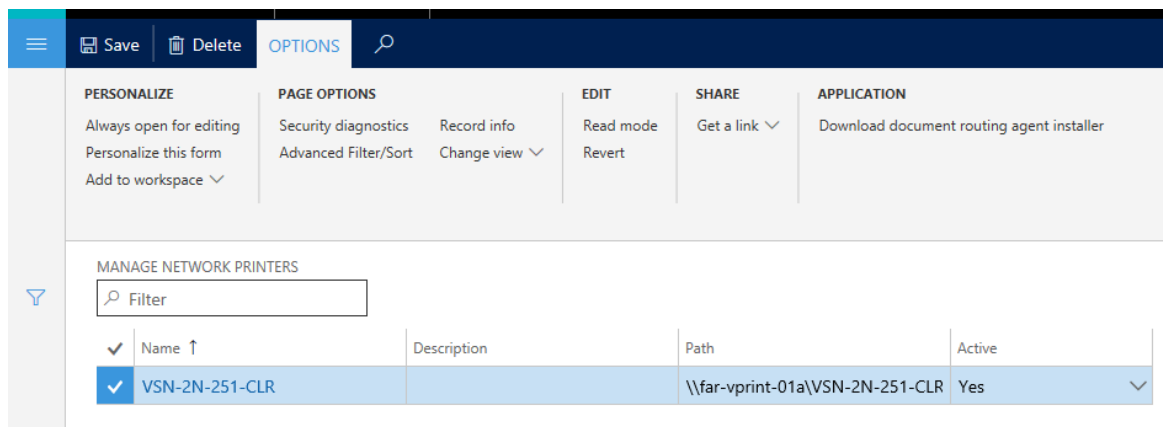

3. Specify a default name for the printer.
4. Click **OK**.

After you've completed this procedure, the selected printer devices are registered in the application's network printer catalog. System administrators can now enable the printers for access from within the application.

Administer network printers

Use client pages to manage access to the network printers that have been registered by one or more Document Routing Agents. Network printers are uniquely identified by their path. Therefore, printers are listed one time, even if they have been registered by more than one Document Routing Agent. Use the following procedure to activate the Application Object Server (AOS) network printers.

1. Open the **Manage network printers** page (**Organization administration > Setup > Network printers**).

2. Edit the existing entries that are mapped to each network printer. As part of your changes, edit the connection path.
3. To include a printer as an option in the **Print Destinations** field, set the **Active** field to **Yes**.

The network printers can now be used in the application.

Frequently asked questions

Does the Document Routing Agent have to be installed on each computer where a user connects by using a browser?

No. Client installations of the Document Routing Agent can be shared by individuals who access the provisioned environment. We recommend that you install agents on one or more Print Servers or other domain-hosted clients that have access to network printers.

If the Document Routing Agent belongs on a network Print Server, why doesn't the client run as a service?

The Document Routing Agent now supports running in the background as a service. You need to ensure that you have downloaded the latest version of the client. For more information, see [Run the Document Routing Agent as a Windows service](#).

Do I need to update credentials or refresh Azure authentication tokens on a recurring basis?

Yes. The Azure Active Directory token must be refreshed every 90 days. Failing to do so will prevent the DRA from being able to authenticate and retrieve printing instructions applications.

Is the Document Routing Agent supported on Microsoft Windows Server 2019?

Yes. The Document Routing Agent is supported on Microsoft Windows Server 2019.

NOTE

If the server is configured to prevent background service, the Document Routing Agent client will not be able to run as a service. For more information, see [Run the Document Routing Agent as a Windows service](#).

Will Microsoft add support for Microsoft Windows Server 2008 servers?

No, not at this time. There are several dependencies on Azure capabilities that are available only in Microsoft Windows Server 2012 R2 and Microsoft Windows Server 2016.

Does the user who installs the Document Routing Agent have to be part of a Finance and Operations apps security group?

Yes. To access the agent installation links, the user must be part of the **Document routing client** security role.

How many network printers can the Document Routing Agent support?

The number of supported network printers depends on the number of legal entities and the number of network printers deployed. If you have fifty printers and one legal entity, a single Document Routing Agent can handle

the load (although you'd want more than one to ensure high availability). If you have a large number of printers and legal entities, we recommend that you do some performance testing to determine the number of Document Routing Agents that you'll need.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Update the Document Routing Agent

2/18/2021 • 2 minutes to read • [Edit Online](#)

The solution for managing the print job queue is designed to allow customers to properly scale Dynamics 365 Finance and Operations apps to satisfy high-volume printing requirements. Although public service endpoints used to manage print jobs are backward-compatible, we strongly recommend that customers update **all** existing Document Routing Agent (DRA) clients.

If you don't update existing installations of the DRA the most current version, you might experience issues such as:

- Observable performance degradation in applications
- Document loss that is associated with orphaned print jobs
- Inconsistent handling of printed documents that have custom margins

IT administrators must perform the following procedures on each domain resource that is used to host a DRA.

NOTE

When you complete a DRA update, IT administrators should register any printers that are connected through the host server. For network printers that are identified by their network paths, if the paths have not changed, updates are not required.

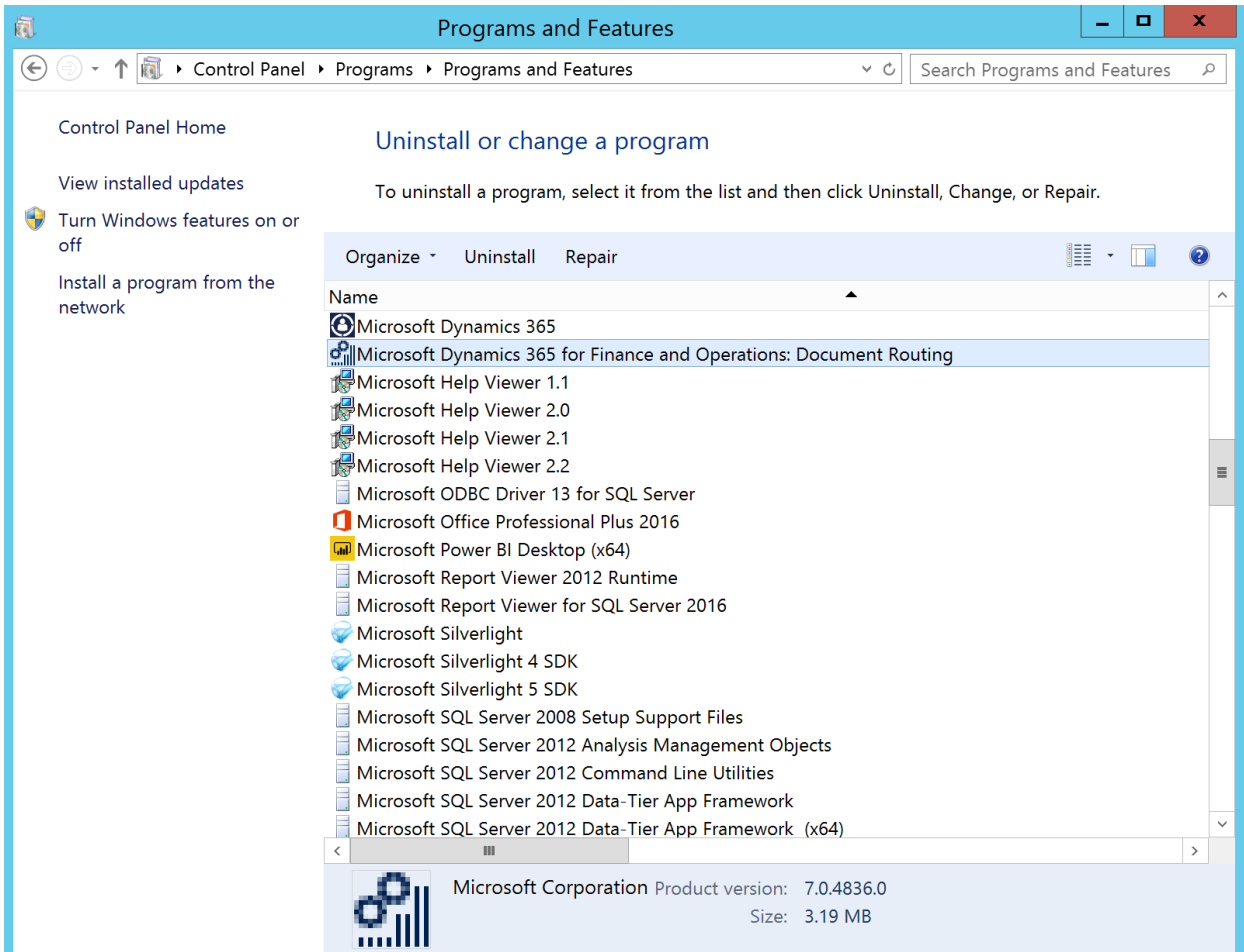

Get started

To continue to run the DRA as a Microsoft Windows service, you must have both the user name and the password of the domain account that is used to run the service. This information must be available after the update is completed. To find the information for the active service account, start the Microsoft Management Console (MMC) Services snap-in, and select **Microsoft Dynamics 365 Document Routing Service** in the list.

Uninstall an existing Document Routing Agent

Open **Programs and Features**, and then find and uninstall **Microsoft Dynamics 365 for Finance and Operations: Document Routing**.

During the uninstallation process, if you're prompted to close the Microsoft Dynamics 365 Document Routing Service application, select **Automatically close applications and attempt to restart them after setup is complete**.

Install the latest Document Routing Agent

For information about how to install the latest DRA that is available with your subscription, see [Install the Document Routing Agent to enable network printing](#).

NOTE

Be sure to open the DRA client after upgrading to refresh network user credentials.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Install network printer devices in on-premises environments

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic explains how to connect an on-premises deployment of Microsoft Dynamics 365 Finance + Operations (on-premises) to existing network printer devices. Network printing in the on-premises application is supported by the [Print and Document Services](#) feature in Microsoft Windows Server 2016. This feature lets you centralize tasks that are related to printer management. To install and configure Print and Document Services, you must have administrative access to the server that hosts the primary instance of Application Object Server (AOS).

Two roles are associated with the configuration of network printing services:

- **Service Administrator** – The person who has this role is responsible for installing and configuring components of the platform infrastructure. Traditionally, this role is an Active Directory account that has elevated domain privileges. It has enough privileges to install components of Microsoft Windows Server.
- **Organization Administrator** – The person who has this role manages application security privileges. This Active Directory account is assigned to the **System Administrator** role.

Before the organization administrator can begin to add network printers, the service administrator must install and configure Print and Document Services on the server that hosts the primary AOS instance. The organization administrator can then begin to use built-in tools to configure network printer devices.

Install and configure Print and Document Services

The environment administrator uses the information in this section to enable network printing services.

1. Install Print and Document Services by following the instructions in [Install Print and Document Services](#).
2. Configure Print and Document Services by following the instructions in [Configure Print and Document Services](#).
3. Follow these steps for each server that is used to host the AXService application:
 - a. On the local server, start the **Local Users and Groups** manager.
 - b. Select the **Groups** node.
 - c. Right-click **Print Operators**, and then select **Add to Group**.
 - d. Add the network Active Directory account that is used to run the AXService application to the group.
 - e. Install network printers by using the AXService user account. This step helps guarantee that the printer driver is available to the AXService user account.
 - f. Print a test page on the installed printers to make sure that all the connections are correctly configured.
 - g. Restart the AXService application to help guarantee that the user's profile is correctly loaded so that it can look up the printer driver.

Manage network printers

The system administrator uses the information in this section to define network printers.

1. Go to **Organization administration > Setup > Network printers**.

2. On the **Network printers** page, add new printers. For each printer, specify a name, description, path, and status. Make sure that the printer path matches the network path of the installed printer.

Items that are marked **Active** immediately become available to application users, so that they can begin to print document-style reports on network printer devices.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Document generation, publishing, and printing in on-premises deployments

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic describes the capabilities for generating, publishing, and printing documents in on-premises deployments of Microsoft Dynamics 365 Finance + Operations (on-premises). The application provides a fully integrated experience for enterprise document generation that is powered by Microsoft SQL Server Reporting Services (SSRS). From any supported device, users can produce standard industry documents that are linked to business processes. These documents include sales invoices, checks, and packing slips. Built-in tools let administrators configure the service so that users can securely connect to network printers.

You can upgrade solutions that are built on the Microsoft Dynamics AX 2012 SQL Reporting Services framework, or you can take advantage of the modern solutions that are available in [Microsoft Dynamics Lifecycle Services \(LCS\)](#).

Document publishing services: secure, reliable, and convenient

Employees spend lots of time on the go. Therefore, businesses depend on their employees' ability to stay productive while they work remotely. However, even today, documents remain critical for business transactions and record keeping.

From their mobile devices, users can print documents on network printers. Users can also automate the creation of business documents and use built-in tools to configure instructions for routing documents to multiple recipients.

The following options are available for document publishing:

- **Email** – Distribute mail via a server, and link reports as attachments.
- **Archive** – Store reports for future reference and regulatory compliance.
- **File** – Produce a PDF file that is downloaded directly to the browser for local printing.
- **Print** – Send documents directly to network printers from all supported platforms. These platforms include mobile devices.

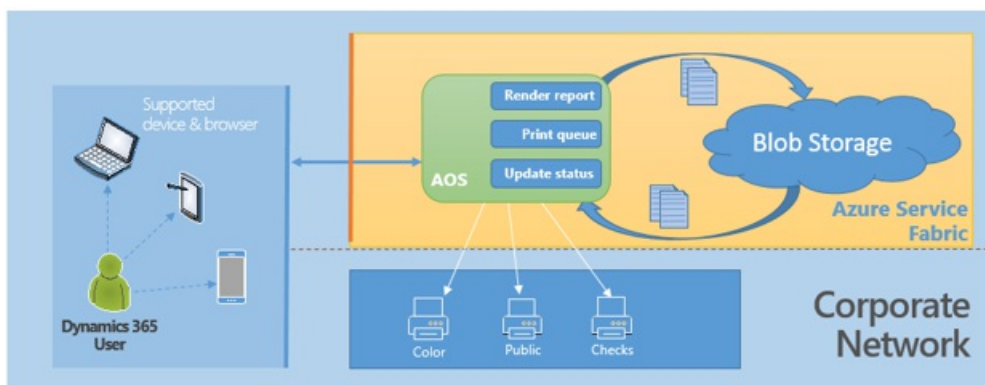

For a high-level summary of the options for information access that are available in the cloud-hosted solution, see [Document printing overview](#).

Comparing the cloud-hosted and on-premises services

Unlike the cloud-hosted service, the on-premises publishing service produces documents as PDF files that are automatically downloaded to the browser. Therefore, users can save documents or print hard copies by using local connected devices. Administrators can manage access to network printers directly from the application, by using built-in administrative pages. Users can interact with reports on demand, or they can schedule automatic jobs to securely generate and distribute documents on a recurring basis.

The following illustration shows the components that are involved in document printing.

For information about how to use extensions to manage availability of the embedded drill-through links in application reports, see the Appendix.

Managing access to network printers

Administrators can use built-in administrative pages to manage access to network printers. Network printers are secured per company and shared by users of the application. Documents are then printed by using a privileged domain account, based on settings that the user provides. In on-premises deployments, you don't have to install an adapter to connect to domain resources such as printers and fax machines.

The following illustration shows the page that is used to manage network printers.

Appendix

Turning on embedded links in business documents

Here is the code that you can use to make embedded drill-through links available in PDF documents.

```
class Controller extends SrsReportRunController
{
    protected void preRunModifyContract()
    {
        this.parmReportContract().parmRdlContract().parmEnableFileDrillThrough(true);
        super();
    }
    static void main(Args _args)
    {
        ...
    }
}
```

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Run the Document Routing Agent as a Windows service

2/18/2021 • 5 minutes to read • [Edit Online](#)

The Document Routing Agent includes an option that lets you select the mode of execution. The process can run as either a desktop application or a Microsoft Windows service. When the application runs as a Windows service, it can be started automatically after a computer restart. It can also be configured to run under the security context of a specific user account. This enhancement lets customers host the Document Routing Agent on secured domain resources such as network print servers.

This topic provides important information that will help you select the correct execution mode.

Service applications

An application is a program that a user interacts with on the desktop. A service is a process that runs in the background and doesn't have an active window. The Document Routing Agent now supports both execution modes. It's important that you understand why you might select one mode instead of the other and the steps that are involved in running the process as a service. For more information about Windows services, see [Introduction to Windows Service Applications](#). Here are some of the main benefits of running the Document Routing Agent as a background service:

- The service can be configured to start automatically after a computer restart. No user intervention is required.
- The service runs in the background. No active application runs in the notification area.
- The service routes documents without requiring that a user sign in by using cached credentials.

Although there are many benefits of running the Document Routing Agent as a Windows service, there are also limitations. The next section discusses an issue that affects the handling of document reports, such as checks, that require custom page margins.

Documents that require custom margins

When the Document Routing Agent runs as a Windows service, document reports, such as checks, that require custom margins can't be printed directly to network printers. Instead, the Document Routing Agent automatically routes those documents to a target folder. New configuration properties in the application's **Settings** dialog box let you define the target location for document reports that require custom margins.

When the Document Routing Agent runs as a desktop application, it continues to take advantage of Adobe Reader to spool the document to the shared printer device that is selected in Finance and Operations. To handle scenarios where documents that have custom margins must be printed, we recommend that you install the Document Routing Agent in multiple locations. Then install the printers that will handle those documents only on the Document Routing Agents that will run in desktop application mode. Alternatively, use a post-execution process to pick up the files in the target directory and direct them in the appropriate manner.

Install the latest build

1. Save a copy of the current Document Routing Agent configuration file. This file is located at C:\Users\\AppData\Local\Microsoft\Microsoft Dynamics 365 for Finance and Operations Document Routing\Microsoft.Dynamics.AX.Framework.DocumentRouting.config. In this path, <UserID> is the Active Directory Domain Services (AD DS) user name that the Document Routing Agent was installed under.

2. Uninstall the current version of the Document Routing Agent.
3. Install the latest version of the Document Routing Agent by following the instructions in [Install the Document Routing Agent to enable network printing](#).

NOTE

Although you install the application at this point, don't run it yet.

4. Copy the configuration file from step 1, and paste it into the following directory:
C:\ProgramData\Microsoft\Microsoft Dynamics 365 for Finance and Operations Document Routing. This step helps guarantee that all your previous configuration settings are used for the new version of the Document Routing Agent application.
5. Run the Document Routing Agent.
6. Sign in by using your Microsoft Azure Active Directory (Azure AD) or your credentials for your Finance and Operations apps.
7. View and verify your settings and printers by clicking the appropriate menu items.

The next section provides detailed instructions for selecting the Windows service execution mode.

Change the default execution mode

By default, the Document Routing Agent runs as a desktop application. To run the process as a Windows service, make sure that you're familiar with the process for [installing the Document Routing Agent to enable network printer devices](#). Then complete the following tasks.

Update the execution mode for the Document Routing Agent

1. Start the Document Routing Agent by using the desktop icon.
2. Select the **Sign In** option, and sign in by using your Azure AD credentials.
3. On the ribbon, select **Settings**.
4. Enable the **Run as a Windows Service** option.
5. Provide a target folder for PDF files that are produced for documents that have custom margins.
6. Select **OK**, and close the Document Routing Agent window.

Configure and start the Windows service

1. In Windows, start Service Manager.
2. In the list, select **Microsoft Dynamics 365 for Finance and Operations Document Routing Service**.
3. Right-click the name, and then select **Properties**.
4. On the **Log On** tab, select the **This account** option, and then supply the AD DS credentials that are used to run the service.

NOTE

The selected account must have access to the shared network devices. The windows domain account (or local machine account) used to run the windows service must be same as the account that starts the Document Routing Agent desktop app.

5. Select **OK**.

6. Start the service.

The Document Routing Agent is now running as a Windows service.

Troubleshooting tips

Verify the network printer connection

- Verify that the active account has enough access rights to the network printer.
- Verify that the user account can successfully print to the network device by using Notepad or another local application.

Verify security roles

- To access the application links that are used to install the Document Routing Agent, the user must be part of the **Document routing client** security role.

Review the service account's access rights

- Verify that the **DocumentRoutingService** service is running as a domain account that has access to the network devices.

Refresh the Azure service token

- Azure authentication tokens must be **refreshed every 90 days** while the Document Routing Agent is running as a Windows service. To refresh the service token, start the client, and then sign out and sign back in by using the menu items.

Disable shared printers for remote access

- When you connect to the host machine by using Microsoft Remote Desktop, make sure that you clear the **Printers** option in the **Local devices and resources** section on the **Local Resources** tab.

Review the event logs

1. On the host machine, start Event Viewer.
2. Review the logs at **Application and Services Logs > Microsoft > Dynamics > AX-DocumentRouting**.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

SQL Server Reporting Services (SSRS) reports that are available

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic points you to a report that lists the SQL Server Reporting Services (SSRS) reports available.

Reports can be defined simply as any visualization of a structured data set. This may include transactional data presented in a tabular layout and advanced graphical views of aggregate information. To account for this broad definition, the application offers several tools to produce reports to satisfy complex business requirements. One of these tools is SQL Server Reporting Services. SSRS reports provide the following advantages:

- Back office document management capabilities including email support, scheduled executions via batches, and print archive functionality.
- Parameterized views with drill-through navigation to application pages and other reports.
- Used to produce precision documents for compliance with local regulatory business practices.

For more information, see [Create reporting solutions](#).

To view the report

The **SQL Server Reporting Services Reports report**, included with the [Technical reference reports](#), lists each SSRS report that is available. The report indicates the data set used for each report, as well as the filters and fields available on each report.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Install modern report design templates

2/18/2021 • 5 minutes to read • [Edit Online](#)

This topic explains how to install the modern report design templates in the application suite. You can use these samples to create graphically rich business documents that have flexible branding in the header and footer.

Introduction

A new set of developer tools is available that takes the form of report designs for several core business documents in the application suite. These report designs have been re-imagined so that flexible branding appears in the header and footer of public-facing documents when transactions are generated in the application. The following illustration shows how an earlier design for a sales invoice differs from a modern sales invoice design.

The image shows two side-by-side sales invoice reports. The left report, titled 'LEGACY DESIGNS', is a 'SalesInvoice Report' for Contoso Entertainment Systems (West). It features a dense layout with multiple contact addresses, a detailed item list with columns for item number, description, quantity, unit, unit price, discount percent, discount, and amount, and a total amount of \$315,479.00. The right report is a modern Microsoft invoice for Owl Wholesale. It has a clean, professional layout with the Microsoft logo, a clear header with the invoice number (CIV-000676) and date (30 November 2012), and a table of items with columns for item, description, quantity, sales price, discount, and amount. The total amount is also \$315,479.00. The modern invoice includes a 'METHODS OF PAYMENT' section and 'OTHER INFORMATION' section.

After you complete the installation, you can use the built-in brand management tools to define brand settings that should be applied to the modern designs for application business documents. The brand management tools are available at [Organization administration > Setup > Document branding > Branding details](#).

Why aren't these designs the default designs for the application suite reports?

We are maintaining the legacy solutions for two primary reasons:

- **Modern designs don't include code.** Although the legacy solutions use embedded Microsoft Visual Basic (VB) code to recognize configuration keys and honor regulatory requirements that vary by region, the modern report designs offer much less flexibility. The benefit of a simple design that has minimal code behind it comes at the expense of reusability across regions.
- **Modern designs aren't available for all business documents.** There is a gap between the supported business documents and the availability of modern report designs. Although the legacy designs aren't as

aesthetically pleasing, they provide a sense of consistency.

IMPORTANT

The simple modern designs are **not** recommended for all types of deployments. They are intended for cases where the customer doesn't require runtime control over the layout of the document through existing application configuration settings.

Apply the modern designs

The modern report designs have been bundled into a model file and posted to Microsoft Dynamics Lifecycle Services (LCS). Therefore, you can easily access them from your existing subscription. Use the following procedure to obtain the modern report design solutions and install them in your local development environment. You must then apply some customizations to incorporate the modern report designs into the appropriate scenarios.

Follow these steps to install the modern report designs for the application suite.

1. Sign in to [LCS](#) to access the deployment dashboard. Then, on the **Shared asset library** page, select the **Model** asset type, and download the **ApplicationSuiteModernDesigns** model file. Save the model file to a location that is accessible from the development environment.

NOTE

Be sure to select the appropriate model file for the version of the application that you're using.

2. Import the model file into your local development environment. To install a model file in a development environment, use the ModelUtil.exe tool and the **-import** directive. Here is an example.

```
ModelUtil.exe -import -metadastorepath=[path of the metadata store] -file=[full path of the file to import]
```

3. Navigate to the `J:\AOSService\PackagesLocalDirectory\bin` folder.
4. Run the following command.

```
ModelUtil.exe -import -metadastorepath=J:\AOSService\PackagesLocalDirectory -file="E:\Test\AppSuiteModernDesigns.axmodel"
```

For more information about how to import model files, see [Export and import models](#). After you've imported the model file, start Microsoft Visual Studio. In Application Explorer, verify that the **Application Suite - Modern Designs** collection appears under the **AOT** node. For more information about how to use the Application Explorer, see [Development tools tutorial](#)

Now that you've successfully imported the Application Suite Modern Designs model, you must to rebuild the application suite to update the metadata elements.

Build the application suite

The Application Suite Modern Designs model is an extension of the Application Suite model. To help guarantee that all application references are updated so that they target the model extensions, you must build the Application Suite model by using Microsoft Visual Studio.

1. Start Visual Studio, or use the existing instance.

2. On the **Dynamics 365** menu, select **Build models**.
3. In the list, select the check box for the **ApplicationSuite** package.

NOTE

You will see that the Application Suite Modern Designs model is included in the package definition.

4. Select **Build** to do a full build of the application suite.

This process may take up to 20 minutes, depending on the size of your machine.

Deploy the modern designs (one-box environments)

After you've compiled the application suite that includes the modern report design templates, you should verify the changes locally. To verify the changes, you must deploy the new modern report design solutions to the instance of Microsoft SQL Server Reporting Services (SSRS) that is running locally.

Follow these steps to incorporate the modern report design into an existing application suite report.

1. Create a project that contains the application suite report. In Application Explorer, under the **Application Suite Modern Designs** model, expand the **Reports** node, and then expand the **Reports** subnode. Select all the items in the folder, right-click, and then select **Add to new project**.
2. Complete the **New Project** wizard. Accept all default values.
3. In Solution Explorer, select the project, right-click, and then select **Deploy reports** to deploy the build and deploy the reports locally.

When you add the modern report design to an existing report, you can reuse both the parameter handling and the data provider that the out-of-box solution uses.

Update Print management settings

At this point, you should be able to access the modern report designs from the application. Make sure that you do thorough test validations on the modern report design templates before you deploy them to production environments. To do test validations, you must activate the modern report designs for the application business process.

Follow these steps to update the Print management settings for customer sales orders by selecting the modern report design solution as the default report design.

1. Open the **Form setup** page for the module. For example, for Accounts receivable, select **Accounts receivable > Setup > Forms > Form Setup**.
2. Select **Print management** to open the **Print management setup** page.
3. Expand the tree, and find the settings for the **Sales order confirmation** document.
4. Select **Original <Default>** to begin to modify the default document routing.
5. In the **Report format** list, select **SalesConfirmModern.Report** to enable the modern report design solution.

Print management setup

The screenshot displays the 'Print management setup' interface. On the left, a tree view under 'Module - accounts receivable' shows 'Documents' expanded to 'Sales order confirmation', with 'Original <Default>' selected. The main panel shows the 'ORIGINAL OR COPY IDENTIFICATION' settings. A red box highlights the 'Report format' dropdown menu, which is currently set to 'All countries/regions'. The dropdown list shows 'SalesConfirm.Report' and 'SalesConfirmModern.Report'. The 'Original / copy' dropdown is set to 'Original'. The 'Name' field is 'Suspend printing for this document'. The 'Report format' and 'Default country/region' fields are visible below the dropdown.

6. Open another page. This step forces a save operation to occur.
7. Post a sales order to view the modern design in the application.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Power BI integration with Entity store

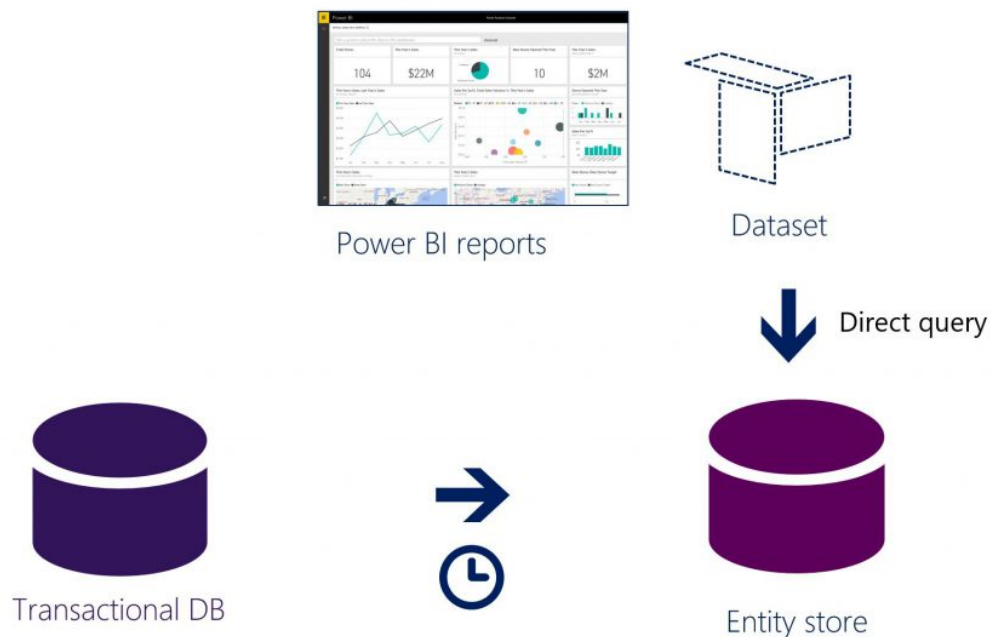

2/18/2021 • 4 minutes to read • [Edit Online](#)

Entity store is an operational data store that is included with Microsoft Dynamics 365 Finance. This topic describes how Entity store enables Power BI integration.

Entity store is an operational data store that is included with the application. The Entity store feature was introduced in the Microsoft Dynamics AX platform update 1 (May 2016) release. This feature lets an administrator or power user stage aggregate measurements in a dedicated data store for reporting and analytics. (Aggregate measurements are a star schema that is modeled by using entities.) We call this data store Entity store. It's a database that is optimized for reporting purposes. Entity store uses the in-memory, clustered columnstore index (CCI) functionality that is built into Microsoft SQL Server to optimize reporting and queries. Customers can use Microsoft Power BI DirectQuery models together with Entity store to enable high-volume, near-real-time analytical reporting over large volumes of data.

Power BI DirectQuery mode

In the February 2016 release of Microsoft Dynamics AX, you could create Power BI reports by using OData endpoints that are exposed via data entities (both aggregate data entities and detailed or regular data entities). Although this approach is still supported, Entity store also lets power users create Power BI DirectQuery reports.

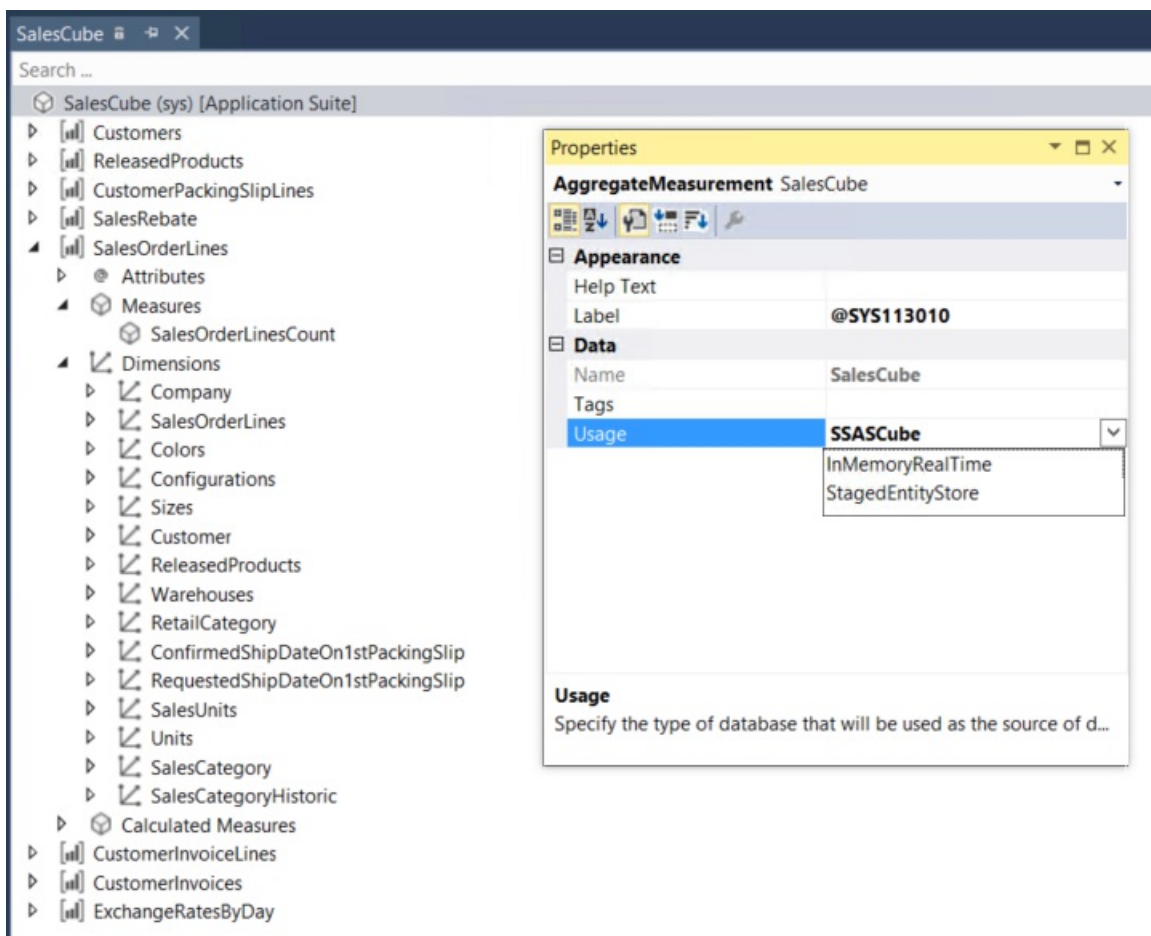

As the preceding illustration shows, DirectQuery is a reporting mode that runs reports directly on Entity store. In this reporting mode, data isn't staged in Power BI caches. This mode provides two immediate benefits:

- You can create Power BI reports over large data volumes.
- Reports don't have to be updated by using Power BI. When Entity store is updated, reports reflect the latest data.

Additionally, data doesn't leave your environment, because no data is cached in the Power BI service.

Stage aggregate measurements in Entity store

Aggregate measurements are a star schema that is modeled for analytical scenarios. In the February 2016 release, we enabled real-time, in-memory aggregate measurements. By using real-time aggregate measurements, you can enable embedded charts and key performance indicators (KPIs) that react to real-time operations on data. For information, see [Transition from Analysis Services cubes to aggregate models](#). Real-time aggregate measurements take advantage of the in-memory, non-clustered columnstore index (NCCI) technology. Visuals and aggregate calculations that are built over real-time aggregate measurements reflect transactions within seconds. In the platform update 1 (May 2016) release, we enabled aggregate measurements that can be staged in Entity store. Aggregate measurements that are staged in Entity store can be used for near-real-time analytical scenarios where large volumes of data must be explored by using Power BI. As a developer, you learned how to model an aggregate measurement for real-time analytics in [Model aggregate data](#). In the platform update 1 (May 2016) release, we also added the capability to model aggregate measurements that can be staged in Entity store. In Microsoft Visual Studio, you can specify **StagedEntityStore** as the usage property of an aggregate measurement. This new property was added in May 2016. Previously, **InMemoryRealTime** was available as the usage property.

However, you might wonder why you would model an aggregate measurement so that it can be staged? Why wouldn't you use in-memory real-time aggregate measurements all the time? There are several reasons for using the **StagedEntityStore** pattern:

- There might be large amounts of data that must be explored and analyzed.
- You might have Analysis projects (that is, cubes) that you migrated from Microsoft Dynamics AX 2012 R3 as part of the code upgrade process. Because of the complex views and joins that are present in the schema, query response times might not be acceptable for embedded visuals. However, you might not want to refactor the visuals to take advantage of NCCI technology immediately.
- Unlike the operational database schema, the schema in Entity store is modeled specifically for reporting. Therefore, it's much easier to build new reports from the schema in Entity store.
- Your scenario might not require that analytical data be updated within seconds of an operation. Most Power BI reports that are built to enable data exploration fall into this category. If data freshness of approximately

10 minutes is acceptable for your scenario, you might want to use the staged pattern.

If one of the preceding reasons covers your situation, you should stage your aggregate measurement in Entity store and it use for Power BI integration.

Update Entity store

Entity store refresh is automated and managed by the system. In the client, you can find the **Entity Store** page at **Systems administration > Setup > Entity Store**. For more information, see [Automated Entity store refresh](#).

Connecting to the Entity store database

For troubleshooting and diagnostics, you can connect to the Entity store database directly from a related sandbox environment. To connect:

1. Use Remote Desktop to access the sandbox. The RDP file can be downloaded from the **Environment Details** page after you have included your IP address in a safe list.
2. Open SQL Server Management Studio, and connect to the server specified on the **Environment Details** page.
 - Find the section titled **Database Accounts**. Locate the entry for the user with the name **axdwwadmin**.
 - The server name is the first portion of the **SQL Server\Database Name** field. This should be used in the format of **SQLServerName.database.windows.net** where **SQLServerName** is the value from **LCS**.
 - The authentication type should be changed from **Windows Authentication** to **SQL Server Authentication**.
 - The login will be **axdwwadmin** and the password will be the value from **LCS**.
3. Using the **Options** button or by browsing to the **Connection Properties** tab, change the **Connect to database** property from the default value to your **Database Name** value from **LCS**.
4. Click **Connect** to access the database.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Resolve issues after entity store maintenance

2/18/2021 • 2 minutes to read • [Edit Online](#)

When maintenance is performed on the entity store, it impacts the following components:

- Application analytical workspaces.
- Entity store-based reports that have been deployed to PowerBI.com.

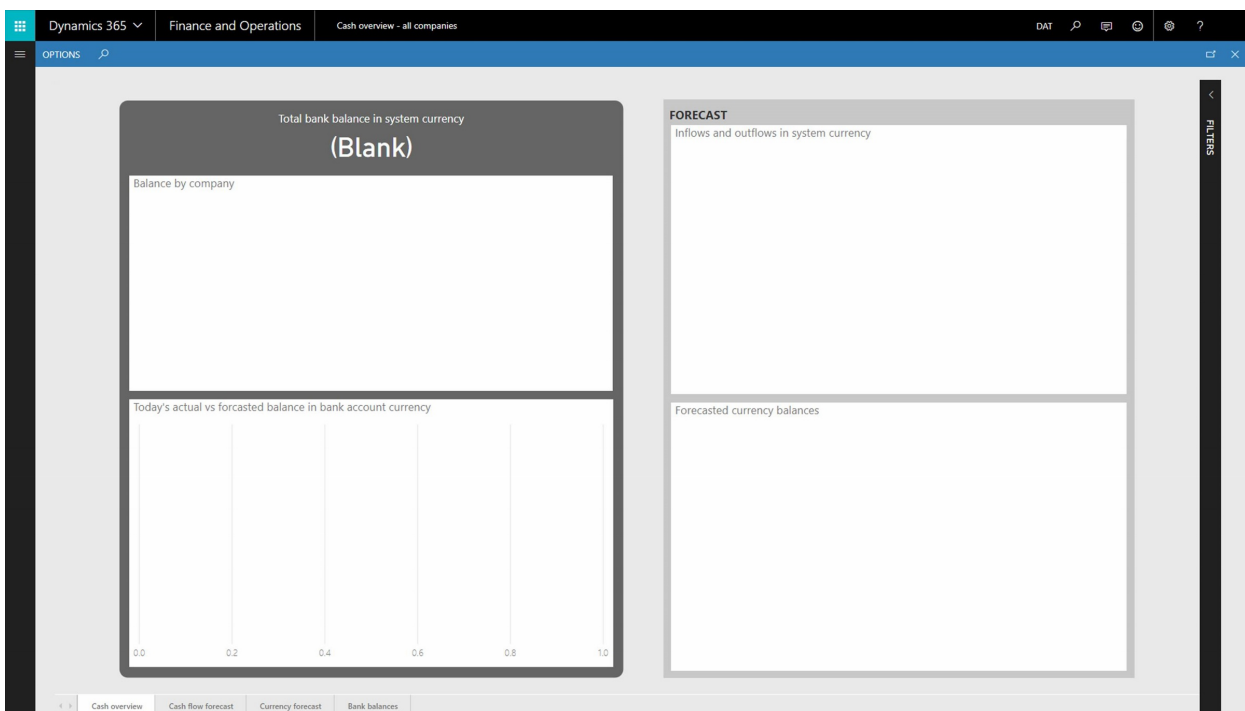

To resolve issues with these components, complete the procedures in this topic.

NOTE

There will be **no impact** to the normal operation of your application.

If you are using application analytical workspaces

Application analytical workspaces and reports may not render data after certain maintenance operations are completed. The following screenshot shows an example of this.

To resolve this issue:

1. Sign in to the application.
2. Go to the **Batch jobs** page (**System administration** > **Inquiries** > **Batch jobs**).
3. Delete all pending batch jobs associated with the entity store. These batch jobs:
 - Will have a status of **Waiting**.
 - Will typically have a description of **Deploy measurement**.

NOTE

The default description is **Deploy measurement**. If the description has been customized, you can verify whether a batch job is associated with the entity store by looking at the class name. Batch jobs associated with the entity store will have a class name of **BIMeasurementDeployManagementEntityBatchJob**.

4. Go to the **Entity store** page (**System Administration > Setup > Entity Store**).
5. Select all measurements that need to be refreshed.
6. Click **Refresh**, and then click **OK**.

After the refresh completes, the application analytical workspaces and reports will render data.

If you have deployed entity store-based reports to PowerBI.com and are using the reports within PowerBI.com

After refreshing the entity store (as described above), redeploy the reports using the **Deploy Power BI report files** page by selecting **System Administration > Setup > Deploy Power BI files**.

NOTE

Reports that were previously deployed to PowerBI.com may produce errors. If this occurs, you may need to delete and redeploy the report after the maintenance activity is completed.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Configure PowerBI.com integration

2/18/2021 • 5 minutes to read • [Edit Online](#)

Overview

Users can pin tiles, dashboards, and reports from their own PowerBI.com account to application workspace.

This functionality requires a one-time configuration of your environment. An administrator must do this step to enable Microsoft Power BI to communicate and authenticate correctly.

For a workspace to show a Power BI tile, the server must contact the Power BI service on behalf of a user and access the visualization. It must then redraw the visualization in the application workspace. The fact that the server contacts the Power BI service "on behalf of a user" is important. When a user, such as `D365User@contoso.com`, contacts the PowerBI.com service, Power BI should show only tiles and reports from the user's PowerBI.com subscription.

By completing this configuration step, you enable to contact the PowerBI.com service.

Things you must know before you start

- You must be a system administrator in the application. This option is available on the **System administration** menu.
- You must have a PowerBI.com account. You can create a trial account if you don't have an account. (A Pro license isn't required for this configuration step.)
- You must have at least one dashboard and one report in your Power BI account. Although the dashboard and report aren't required for this configuration step, you might not be able to validate the configuration if you don't have any content in your PowerBI.com account.
- You must be an administrator for your Microsoft Azure Active Directory (Azure AD) account. If you aren't the administrator, an administrative user must perform this configuration step for you.
- The Azure AD domain that is configured must be the same domain that you used for your PowerBI.com account. For example, if you provisioned the application in the Contoso.com domain, you must have Power BI accounts in that domain, such as `Tim@ContosoAX7.onmicrosoft.com`.
- Users navigating to these pinned tiles must have a valid Power BI.com license.

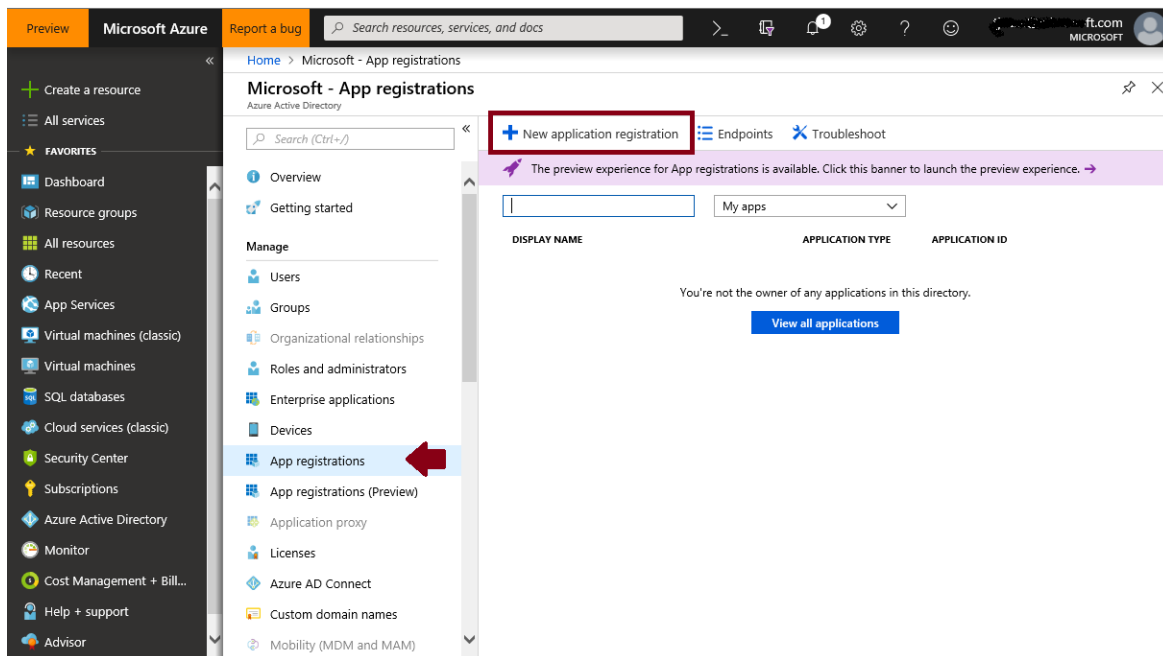

Registration process

1. Sign in to <https://portal.azure.com/> using an Azure tenant admin account.

NOTE

The user who completes this procedure must have Admin rights for the tenant to register applications.

2. Go to **Azure Active Directory > App registrations > New application registration**.

3. Enter the following values:

- **Name** - Your app name.
- **Application type** - Web app/API
- **Sign-on URL** - The base URL of your client. For example, `https://contosoax7.cloud.dynamics.com`.

NOTE

Depending on your version, you may need to add /oauth as a suffix to the URL, or use http instead of https as the protocol, such as: `https://contosoax7.cloud.dynamics.com/oauth` OR `http://contosoax7.cloud.dynamics.com/oauth`.

4. Click **Create**.
5. Copy the **Application ID**. This will be used to connect to the PowerBI.com service.
6. Click **Settings** > **Required permissions** > **Add** > **Select an API** > **Power BI Service (Power BI)**.
7. Click **Select**.
8. Enable Access and click **Select**.

Enable Access

<input type="checkbox"/>	APPLICATION PERMISSIONS	↑↓	REQUIRES ADMIN	↑↓
	View all content in tenant		✔ Yes	
<input checked="" type="checkbox"/>	DELEGATED PERMISSIONS	↑↓	REQUIRES ADMIN	↑↓
	View all datapools		✘ No	
	Read and write all datapools		✘ No	
	Read and Write all Reports		✘ No	
	View users Groups		✘ No	
<input checked="" type="checkbox"/>	View all Groups		✘ No	
<input checked="" type="checkbox"/>	View all Reports (preview)		✘ No	
<input checked="" type="checkbox"/>	Create content (preview)		✘ No	
<input checked="" type="checkbox"/>	View content properties (preview)		✘ No	
<input checked="" type="checkbox"/>	Read and Write all Datasets		✘ No	
<input checked="" type="checkbox"/>	View all Datasets		✘ No	
<input checked="" type="checkbox"/>	View all Dashboards (preview)		✘ No	
<input checked="" type="checkbox"/>	Add data to a user's dataset (preview)		✘ No	
	Read and Write all Dashboards		✘ No	
	View all content in tenant		✔ Yes	
	Read and write all workspaces		✘ No	
	View all workspaces		✘ No	

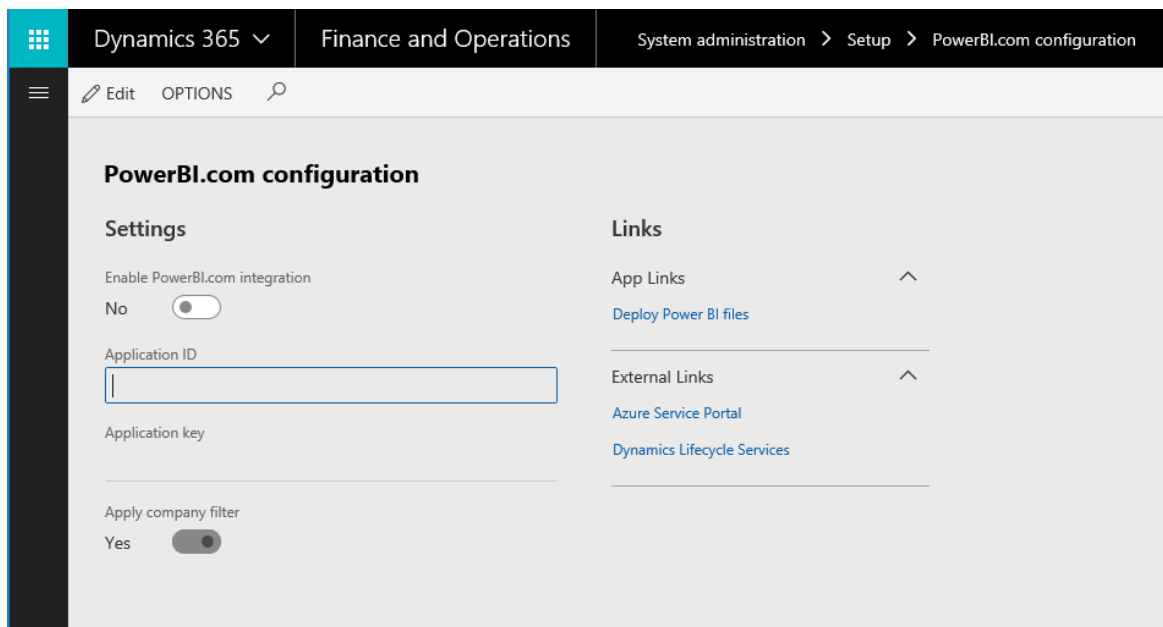

Select

9. Click **Done** and then click **Grant Permissions**.
10. Click **Settings > Keys**.
11. Enter a value for **Key description** and **Expires**, and then click **Save**.

Make a note of the **Application ID** and **Application Key**. You will use these values in the next procedure.

Specify Power BI settings in Finance and Operations

1. In the client, open the **Power BI configuration** page.

2. Select **Edit**.
3. Set the **Enabled** option to **Yes**.
4. In the **Application ID** field, enter the **Application ID** value that you got from Power BI in the previous procedure.
5. In the **Application Key** field, enter the **Application Key** value that you got from Power BI in the previous procedure.

You can apply the company filter only if your Power BI content has a table that is named **Company** and a column that is named **ID**. Ready-made Power BI content that is released uses this convention.

6. Click **Save**.

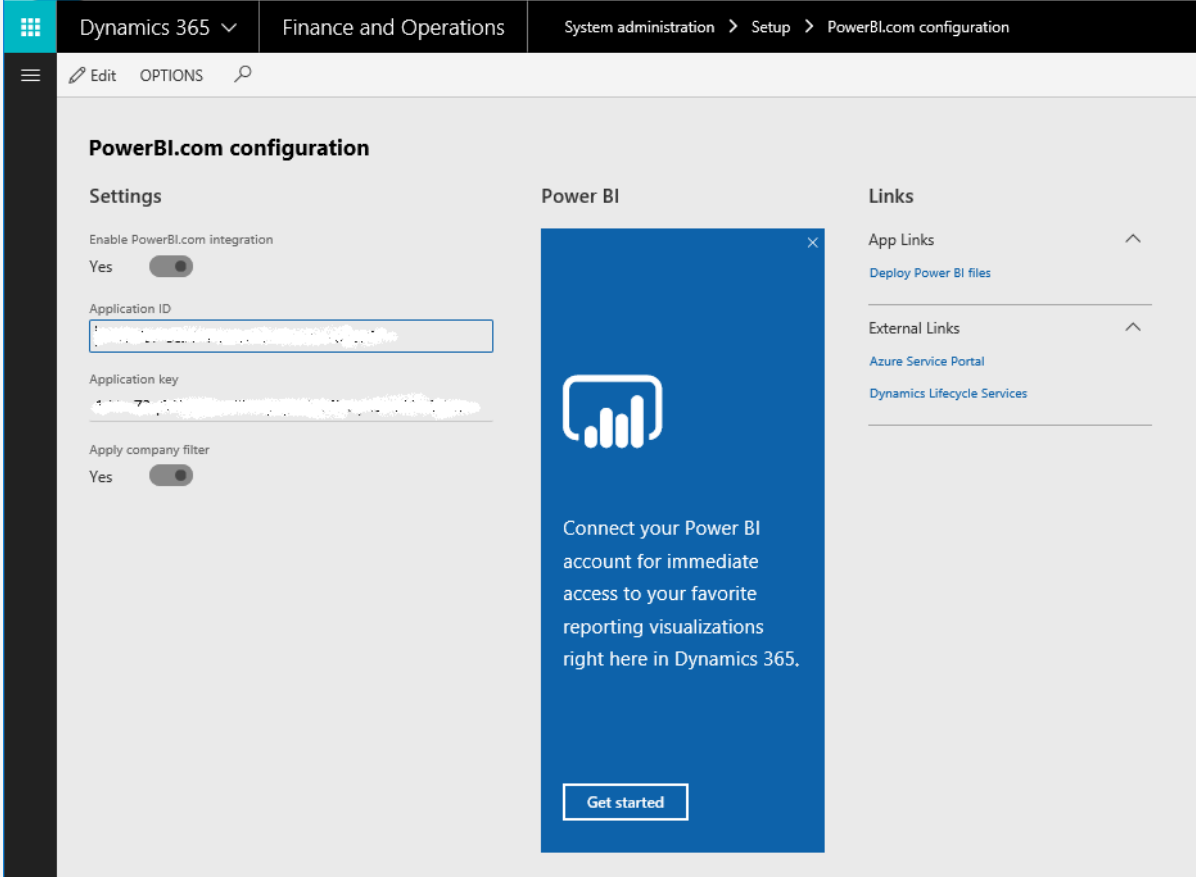

Complete the steps in the next section to verify the changes and enable PowerBI.com integrations.

Pin tiles to a workspace

1. To validate the PowerBI.com configuration, click **Get started**.

NOTE

You may need to refresh the browser to apply the changes.

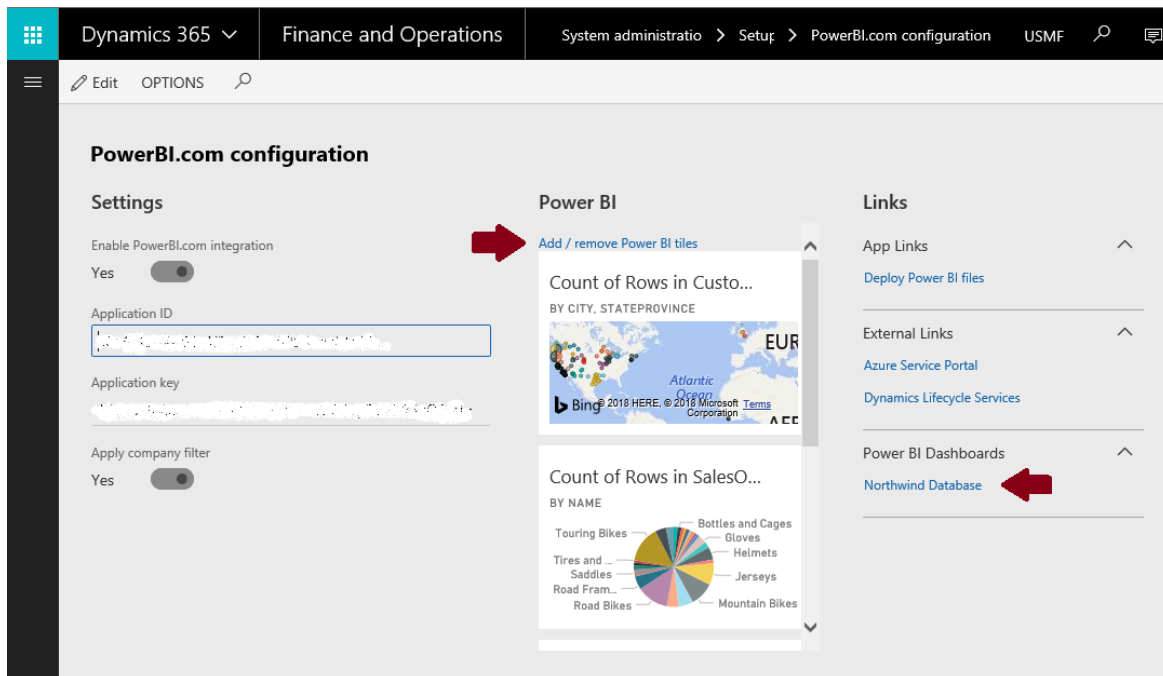

The screenshot displays the Dynamics 365 configuration interface for PowerBI.com. The breadcrumb trail at the top reads: Dynamics 365 > Finance and Operations > System administration > Setup > PowerBI.com configuration. The main content area is titled 'PowerBI.com configuration' and is divided into three sections:

- Settings:** Includes a toggle for 'Enable PowerBI.com integration' (set to 'Yes'), a text input for 'Application ID', a text input for 'Application key', and another toggle for 'Apply company filter' (set to 'Yes').
- Power BI:** A central blue panel with a bar chart icon. It contains the text: 'Connect your Power BI account for immediate access to your favorite reporting visualizations right here in Dynamics 365.' and a 'Get started' button.
- Links:** A sidebar on the right with two sections: 'App Links' containing 'Deploy Power BI files' and 'External Links' containing 'Azure Service Portal' and 'Dynamics Lifecycle Services'.

If you're starting Power BI from the application for the first time, you're prompted to authorize sign-in to Power BI from the client. Select **Click here to provide authorization to Power BI**.

Users must complete this step the first time they pin Power BI content.

2. The Azure AD consent page asks for your consent. User consent is required for the application to access PowerBI.com on behalf of the user. Select **Accept**.
3. Because you're already signed in to Azure AD, you don't have to enter your credentials again. A new tab appears, where you're prompted to authorize the connection between the application and Power BI. Authorize the connection, and then return to the original tab.
4. A list of tiles from your PowerBI.com account appears. Select one or more tiles to pin to the selected workspace.

Troubleshooting common errors

In the procedure above, after you click **Accept**, you might receive the following error message if the process is unsuccessful. Note that the details of the error appear at the bottom of the message. Additional technical information provides clues that can help you determine what went wrong.

Some common issues and the resolution steps

ERROR	RESOLUTION
The Power BI service is unavailable.	This issue doesn't occur very often, but the Power BI service might sometimes be unreachable. You don't have to re-register. Try to pin a tile to a workspace later.
You can't access the application.	You probably didn't select all the check boxes under Step 8 in the Registration process during the registration process. Start Power BI, and re-run the registration process.
The Power BI tiles page is empty (no content is shown).	Your PowerBI.com account might not have a dashboard or any tiles. Add a dashboard, such as a sample dashboard, and try to pin a tile again.
Error when authorizing Power BI	On the Azure Admin dashboard, under Users and Groups > User settings , make sure that the Users can consent to apps accessing company data on their behalf option is set to Yes .
Sorry, something went wrong. The authentication process was not successful. Please contact your system administrator.	This may occur in cases where service keys have expired. We recommend performing the registration process above, starting with step 3. When complete, be sure to update the PowerBI.com settings at AX client > System administration > Set up > PowerBI.com integration .

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Bring your own database (BYOD)

2/18/2021 • 13 minutes to read • [Edit Online](#)

This topic explains how administrators can export data entities from the application into their own Microsoft Azure SQL database. This feature is also known as *bring your own database* (BYOD). The BYOD feature was released in Microsoft Dynamics AX with platform update 2 (August 2016). Minor improvements and bug fixes have been included in subsequent platform updates.

The BYOD feature lets administrators configure their own database, and then export one or more data entities that are available in the application into the database. (Currently, more than 1,700 data entities are available.) Specifically, this feature lets you complete these tasks:

- Define one or more SQL databases that you can export entity data into.
- Export either all the records (*full push*) or only the records that have changed or been deleted (*incremental push*).
- Use the rich scheduling capabilities of the batch framework to enable periodic exports.
- Access the entity database by using Transact-SQL (T-SQL), and even extend the database by adding more tables.

Entity store or BYOD?

If you followed the series of [blog posts about Microsoft Power BI integration](#), you will be familiar with Entity store. Entity store is the operational data warehouse. Entity store provides built-in integration of operational reports with Power BI. Ready-made reports and analytical workspaces use Entity store. If you write Power BI reports by using data in your application environment, you should use Entity store.

However, the BYOD feature is recommended for the following scenarios:

- You must export data into your own data warehouse.
- You use analytical tools other than Power BI, and those tools require T-SQL access to data.
- You must perform batch integration with other systems.

NOTE

The application doesn't allow T-SQL connections to the production database. If you're upgrading from a previous version of Finance and Operations, and you have integration solutions that require direct T-SQL access to the database, BYOD is the recommended upgrade path.

You can use either Entity store or BYOD. The default operational reports that are available take advantage of embedded Power BI and Entity store. We recommend that you use our default operational reports as your first choice. You can also extend the ready-made operational reports to meet your requirements. You should consider BYOD a complementary option that you use as you require.

Creating a SQL database

Before you can configure the entity export option and use the BYOD feature, you must create a SQL database by using Azure portal.

For one-box development environments, you can create a database in the local Microsoft SQL Server database. However, this database should be used only for development and testing purposes. For production

environments, you must create an Azure SQL database.

You should also create a SQL user account for sign-in to the database. Write down the server name, database name, and the SQL user ID and password. You will use this information when you configure the entity export option in the next section.

If you're using the BYOD feature for integration with a business intelligence (BI) tool, you should consider using clustered columnstore indexes (CCIs). CCIs are in-memory indexes that improve the performance of read queries that are typical in analytical and reporting workloads.

NOTE

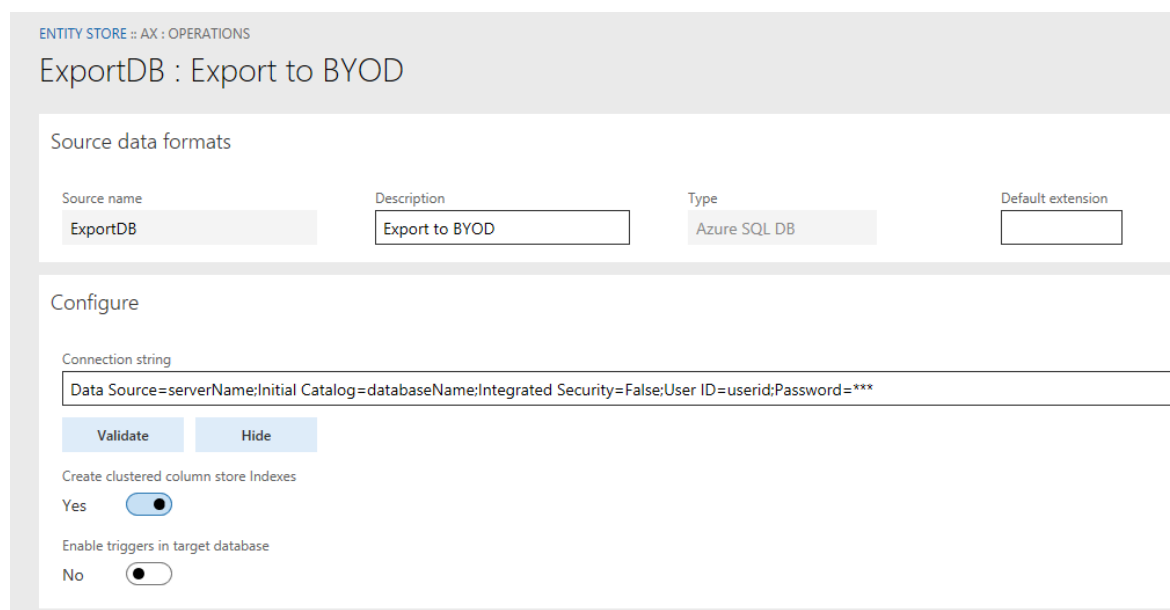

Your BYOD database must be accessible to Finance and Operations apps. If you encounter issues where you are unable access to access BYOD, you must ensure firewall rules in your BYOD are configured appropriately.

Configuring the entity export option

1. Start the client, and then, in the **Data management** workspace, select the **Configure Entity export to database** tile.
2. If you've configured any databases, a list is shown. Otherwise, you must configure a new database. In this case, select **New**, and then enter a unique name and a description for the new database. Note that you can export entities into multiple databases.
3. Enter the connection string in the following format:

```
Data Source=<logical server name>,1433; Initial Catalog=<your DB name>; Integrated Security=False; User ID=<SQL user ID>; Password=<password>
```

In this connection string, the logical server name should resemble **nnnn.database.windows.net**. You should be able to find the logical server name in Azure portal. The following illustration shows an example of a connection string.

Source name	Description	Type	Default extension
ExportDB	Export to BYOD	Azure SQL DB	

Configure

Connection string

Data Source=serverName;Initial Catalog=databaseName;Integrated Security=False;User ID=userid;Password=***

Validate Hide

Create clustered column store Indexes

Yes

Enable triggers in target database

No

NOTE

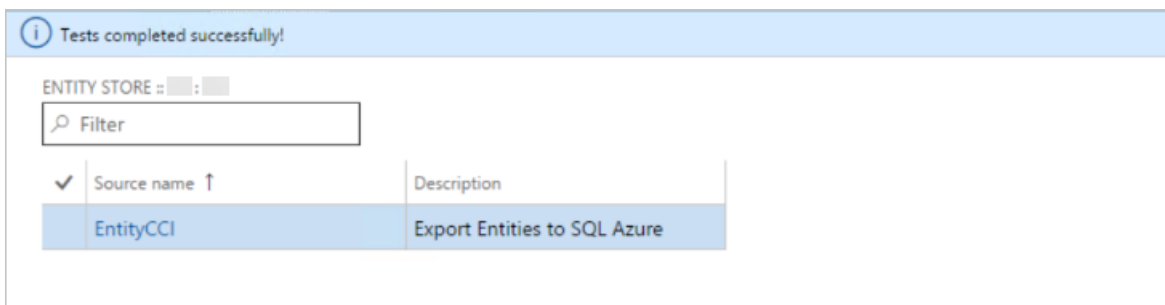

The default extension field shown in the image above does not apply to BYOD.

4. Select **Validate**, and make sure that the connection is successful.

- The **Create clustered column store indexes** option optimizes the destination database for selected queries by defining CCI for entities that are copied. However, CCI are currently supported only on SQL premium databases. Therefore, to enable this option, you must create a SQL premium database.
- The **Enable triggers in target database** option sets export jobs to enable SQL triggers in the target database. This option lets you hook downstream processes into the trigger to orchestrate actions that must be started after records have been inserted. One trigger is supported per bulk insert operation. The size of the bulk insert is determined by the **Maximum insert commit size** parameter in the Data management framework.

For scenarios in which reporting systems read data from BYOD, there is always the challenge of ensuring that the reporting systems get consistent data from BYOD while the sync is in progress. You can achieve this result by not having the reporting systems read directly from the staging tables created by the BYOD process. The staging tables hold the data while data is being synced from the instance and hence will be constantly changing. Use the SQL trigger feature to determine when the data sync has been completed, and then hydrate the downstream reporting systems.

When the validation is passed, the database that you configured for entity export appears in lists of databases, as shown in the following illustration.

You can now publish one or more entities to the new database by selecting the **Publish** option on the menu.

Publishing the entity schema to the database

The **Publish** page enables several scenarios:

- Publish new entities to the database.
- Delete previously published entities from the database. (For example, you might want to re-create the schema.)
- Compare published entities with the entity schema. (For example, if new fields are added later, you can compare the fields with your database schema.)
- Configure change tracking functionality that enables incremental updates of your data.

The following sections discuss each option.

Publish

The **Publish** option defines the entity database schema on the destination database. When you select one or more entities, and then select the **Publish** option, a batch job is started. This job creates the entities in the destination database. When the database definition job is completed, you receive a message, which you can access by using the bell symbol in the upper right.

The actual data update occurs when you export data. At this point, you're just creating the schema.

Drop entity

The **Drop entity** option deletes the data and the entity definition from the destination database.

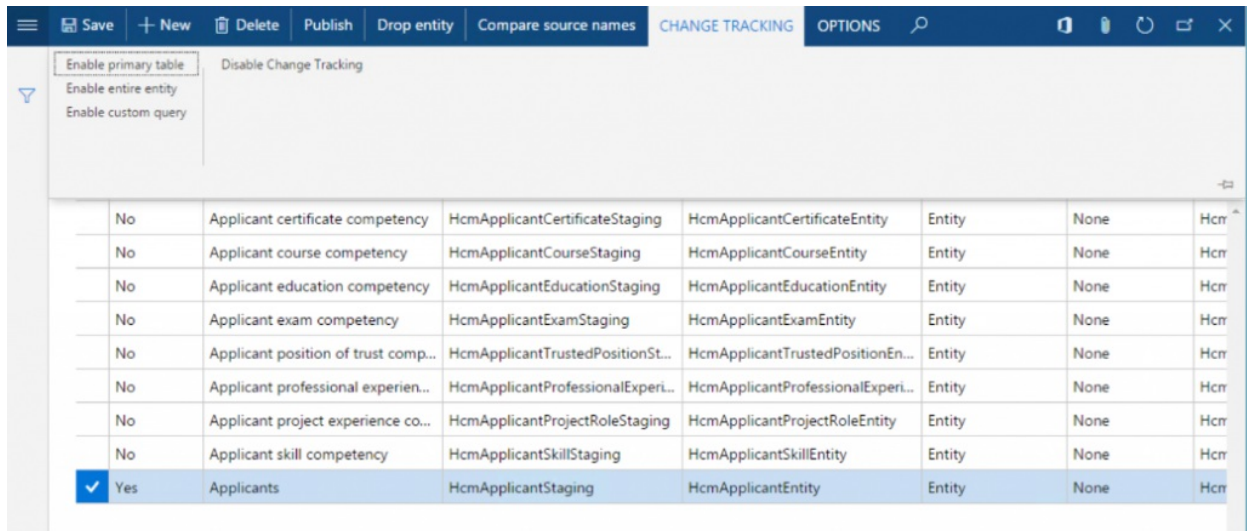

Compare source names

The **Compare source names** option lets you compare the entity schema in the destination with the entity schema in the application. This option is used for version management. You can also use this option to remove any unwanted columns from the destination table.

Configure change tracking

Change tracking is a feature that is provided in SQL Server and SQL Database. Change tracking enables the database to track changes including deletes that are made on tables. The system uses change tracking to identify changes that are made to tables as transactions. However, because the application must track changes at the data entity level, there is additional logic on top of SQL change tracking to make this functionality work. The steps to enable change tracking are explained later in this section.

The **Change tracking** option on the **Publish** page lets you configure how changes are tracked on the underlying entity.

Change Tracking	Entity Name	Staging Table	Entity Table	Type	Other	Other
No	Applicant certificate competency	HcmApplicantCertificateStaging	HcmApplicantCertificateEntity	Entity	None	Hcr
No	Applicant course competency	HcmApplicantCourseStaging	HcmApplicantCourseEntity	Entity	None	Hcr
No	Applicant education competency	HcmApplicantEducationStaging	HcmApplicantEducationEntity	Entity	None	Hcr
No	Applicant exam competency	HcmApplicantExamStaging	HcmApplicantExamEntity	Entity	None	Hcr
No	Applicant position of trust comp...	HcmApplicantTrustedPositionSt...	HcmApplicantTrustedPositionEn...	Entity	None	Hcr
No	Applicant professional experien...	HcmApplicantProfessionalExperi...	HcmApplicantProfessionalExperi...	Entity	None	Hcr
No	Applicant project experience co...	HcmApplicantProjectRoleStaging	HcmApplicantProjectRoleEntity	Entity	None	Hcr
No	Applicant skill competency	HcmApplicantSkillStaging	HcmApplicantSkillEntity	Entity	None	Hcr
<input checked="" type="checkbox"/>	Applicants	HcmApplicantStaging	HcmApplicantEntity	Entity	None	Hcr

The following table describes the change tracking options that are available.

OPTION	DESCRIPTION
Enable primary table	An entity consists of several tables. Select this option to track all changes that are made to the primary table of the entity. When changes are made to the primary table, the corresponding record is inserted into or updated in the destination database. Although data from the whole entity is written to the destination table, the system triggers the insert or update option only when the primary table is modified.
Enable entire entity	Select this option to track all changes to the entity. (These changes include changes to all the tables that make up the entity.) When changes are made to the entity, corresponding updates are made to the destination.
Enable custom query	This option lets a developer provide a custom query that the system runs to evaluate changes. This option is useful when you have a complex requirement to track changes from only a selected set of fields. You can also select this option when the entities that will be exported were built by using a hierarchy of nested views. For more information, see Enable change tracking for entities .

To use change tracking, you must enable the **Change tracking** option as shown above in data management. This action is available on the **Data entities** list page, by going to **Data management > Data entities**. You need to select an entity and select from one of the options listed above to enable change tracking on the data entity.

If you republish an entity that exists in the destination database, the system warns you that existing data will be

deleted because of the new operation.

When you confirm the publish operation, the system publishes the schema to the database, and you're notified when the operation is completed.

By selecting the **Show published only** option on the **Publish** page, you can show only the entities that were published to a given destination database. The Publish function creates the entity schema in the database. You can navigate to the database and see the table schemas that were created, together with corresponding indexes.

NOTE

Currently, you can't use BYOD to export composite entities into a database. You must export each entity in the composite entity.

Exporting data into your database

After entities are published to the destination database, you can use the Export function in the **Data management** workspace to move data. The Export function lets you define a Data movement job that contains one or more entities.

You can use the **Export** page to export data into many target data formats, such as a comma-separated values (CSV) file. This page also supports SQL databases as another destination.

Export

The screenshot shows the 'Export' configuration page. On the left, under 'JOB DETAILS', there are several settings: 'Name' is 'OneTimeExport'; 'Target data format' is 'EntityCCI'; 'Entity name' is empty; 'Use sample file' is 'No'; 'Skip staging' is 'Yes'; 'Default refresh type' is 'Incremental push only' (with a dropdown menu open showing 'Incremental push only' and 'Full push only'); and 'Generate data package' is 'No'. An 'Add entity' button is located below these settings. On the right, under 'SELECTED FILES AND ENTITIES', there is a search filter box, a trash icon, and up/down arrow icons. A blue card for 'Applicants' is shown with a checkmark and a 'View map' button.

You can create a data project that has multiple entities. You can schedule this data project to run by using the batch framework. You also schedule the data export job to run on a periodic basis by selecting the **Export in batch** option.

The same job can also be used to export data from all companies. In prior to Platform update 27, this feature can be enabled by enabling the flight `DMFEnableAllCompanyExport` as explained in [Data management overview](#). Starting in Platform update 27, this feature can be enabled in data management framework parameters. After the feature is enabled, a new option will appear when adding an entity to a data project. This option can be enabled to export data from all companies for the specific entity.

NOTE

Adding multiple entities to an export project for BYOD must be done carefully to ensure the overall reliability of the BYOD export is not compromised. Different parameters must be taken into consideration when deciding the number of entities that are added to the same project. Some of these parameters should be the degree of complexity of the entities, data volume per entity that is expected, and the overall time for export to complete at the job level. Adding hundreds of entities must be avoided, therefore creating multiple jobs with smaller number of entities is recommended.

Use of recurring exports in **Manage > Manage recurring data jobs** for BYOD is discouraged. You must use the **Export in batch** option.

Incremental export

When you add an entity for data export, you can select to do an incremental export (which is also known as incremental push) or a full push. For incremental push to work, you must enable the **Change tracking** option in the database and specify an appropriate change tracking option, as described earlier in this topic.

NOTE

A full push deletes all existing records from an entity and then inserts the current set of records from the selected entity.

If you select an incremental push, the first push is always going to be a full push. This is because SQL needs to know which records have been 'tracked' in order to be able to track subsequent changes. Whenever a new record is inserted, or a record is added or deleted, the corresponding change will be reflected in the destination entity.

Because the first push is always a full push, we do not recommend that you do an explicit full push before you enable change tracking.

We recommend that you first enable change tracking and schedule a export job with incremental push. This will take care of the first full push and the subsequent incremental exports.

Timeouts

The default timeouts for BYOD exports are set to ten minutes for truncation operations and one hour for actual bulk insert operations. When volumes are high, these timeout settings may not be sufficient and must be updated. Starting with the release of Platform update 18, you can update the timeout settings by navigating to **Data management > Framework parameters > Bring your own database**. These timeouts are company specific and must be set separately for each company.

Known limitations

The BYOD feature has the following limitations.

There should be no active locks on your database during synchronization

Because BYOD is your own database, you must ensure that there are no active locks on your Azure SQL database when data is being synced. Having active locks on your database during synchronization can result in slow writes or even failure to export to your Azure SQL database.

You can't export composite entities into your own database

Currently, composite entities aren't supported. You must export individual entities that make up the composite entity. However, you can export both the entities in the same data project.

Entities that don't have unique keys can't be exported by using incremental push

You might face this limitation especially when you try to incrementally export records from a few ready-made entities. Because these entities were designed to enable the import of data, they don't have a unique key. However, you can enable change tracking only for entities that have a unique key. Therefore, there is a limitation on incremental push. One workaround is to extend the required entity and define a unique key.

Troubleshooting

Incremental push not working correctly

Issue - When a full push occurs for some entity then a large set of records can be seen in BYOD using a select statement. However, an incremental push results in only a few records in BYOD. It seems as if the incremental push deleted all the records and added only the changed records in BYOD.

Solution - In cases like this it is recommended to disable and re-enable change tracking for the entity in question. The state of the SQL change tracking tables might not be in the expected state. Also verify that there are no other incremental exports that cover the same tables (DMF, MR, Retail).

SSIS Error Code DTS_E_OLEDBERROR. An OLE DB error has occurred. Error code: 0x80004005

Issue - Export to BYOD fails with an SSIS exception shown below.

```
An OLE DB error has occurred. Error code: 0x80004005.
```

```
An OLE DB record is available. Source: "Microsoft SQL Server Native Client 11.0" Hresult: 0x80004005  
Description: "Communication link failure".
```

```
An OLE DB record is available. Source: "Microsoft SQL Server Native Client 11.0" Hresult: 0x80004005  
Description: "TCP Provider: An existing connection was forcibly closed by the remote host."
```

```
Failed to open a fastload rowset for <entityStaging>. Check that the object exists in the database.
```

```
OLE DB Destination failed the pre-execute phase and returned error code 0xC0202040.
```

Solution - This can occur if the connection policy on the Azure SQL BYOD server is set to Proxy. This must be changed to 'Redirect' as explained in [SQL DB Connectivity Architecture](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Preview PDF documents using a PDF viewer

2/18/2021 • 2 minutes to read • [Edit Online](#)

Streamline application experiences that result in the production of business documents by taking advantage of the embedded PDF Preview option. Finance and Operations applications deliver a modern experience to preview business documents that are produced by the service. You can use the built-in toolbar to navigate and download the document or to print to locally connected devices.

The embedded viewer offers consistency between the screen presentation and the printed output. In addition, report viewing times are drastically reduced when compared to the legacy experience. The Preview option is available on all supported devices and does not require any additional third-party software. Documents can be easily downloaded and navigated by using the built-in viewer toolbar options.

The following illustration shows a preview of the experience with a modern business document.

Contoso Entertainment System USA
123 Coffee Street
Suite 300
Redmond, WA 98052
USA
Telephone

Ship to:
Contoso Retail San Diego
456 Peach Road
San Diego, CA 92114
USA

Confirmation 000783-1
17 August 2017
Sales order 000783

\$110.00

ITEM	DESCRIPTION	QUANTITY	SALES PRICE	DISCOUNT	AMOUNT

M0030	Professional speaker cable	2 ea	25.00	0.00	50.00
NET AMOUNT					110.00
SALES TAX					0.00
USD TOTAL					\$110.00

This text is from the Sales Order Confirmation form notes

PDF formatted document is presented to the user within hosted viewer control

The legacy HTML-based preview experience is being replaced by a true document preview experience. There are several key advantages in the modern PDF preview experience. These advantages include:

- A fidelity between the screen presentation and the printed output.
- A consistent document report preview experience across devices and platforms, including on-premises deployments.
- The server-side rendering improves the performance when producing the document.
- A built-in tooling that allows users to quickly navigate the contents of the business document.

Accessing the PDF preview experience (Platform update 36 or later)

The PDF preview experience is enabled by default in [Self-Service deployments](#) and in environments hosted on Platform update 39 or later. To use the PDF preview experience in cloud-hosted and Microsoft-managed environments running Platform updates 36 thru 38, use Feature Management to enable the **Report PDF viewer** feature.

Additional feature information

- Expandable/collapsible sections are available by default. These interactive operations do not function after the PDF document has been created.
- The printer drop-down menu allows users to choose from locally connected devices. This list does not include network printers connected through the service.
- Documents are downloaded to the local device using the built-in toolbar actions.
- Use the **Print destination** options to produce documents in formats other than PDF.

Feature limitations

The Embedded PDF viewer experience delivers a closed document that exactly matches the printed output of the document. These documents cannot be modified by the recipient making the format ideal for business operations. However, as a closed format, the documents are far less interactive on the screen when compared to HTML presentations. The following end-user capabilities are not supported when previewing documents using the embedded PDF viewer.

- By default, embedded drill-thru navigation links are only available while previewing PDF documents.
- PDF documents do not support expandable and collapsible sections.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Analytics, aggregate measurements, and KPI modeling

2/18/2021 • 6 minutes to read • [Edit Online](#)

This topic discusses the embedded business intelligence (BI), aggregate measurements, dimensions, and data entities, and aggregate programming model.

Embedded business intelligence

The term embedded business intelligence (BI) refers to experiences that use highly intuitive and fluid visualizations to provide insights that are relevant to a task, so that user is more informed and can make better choices. For example, a rental clerk in a car rental organization views the previous rental preferences of a customer when the customer makes a reservation. In this case, the clerk can see the vehicles and colors that the customer has selected in the past, and therefore can offer options that are likely to please the customer. Embedded BI is used throughout the user interface. At a technical level, building rich visualizations requires a powerful charting framework, and also an efficient way to access aggregated data that enables the display of fluid visualizations. Microsoft Dynamics 365 Finance and Operations meets both of these requirements, so that application developers can build rich and deep embedded BI-enabled scenarios.

Where are the perspectives?

Perspectives were a concept that was designed to present data from a reporting point of view. Perspectives have evolved over the past three releases for analytical scenarios.

VERSION	DESCRIPTION
Microsoft Dynamics AX 4.0	Perspectives provided the ability to model ad-hoc reporting models.
Microsoft Dynamics AX 2009	Perspectives added support for modeling analysis cubes.
Microsoft Dynamics AX 2012	Perspective modeling capabilities were improved through richer modeling support and deeper integration with the Application Object Tree (AOT).
Finance and Operations apps	Perspectives are a first-class citizen in the data access framework. They can be consumed via X++ or C# code, and also in a model-driven way.

Perspectives reside within the analytics collection in the Application Explorer. Perspectives have undergone a major upgrade and now incorporate the following improvements:

- You can model new aggregate models and customize existing aggregate models as a star schema within Application Explorer.
- Modeling for key performance indicators (KPIs) in Application Explorer is supported.
- You can model data entities by referencing aggregate models. Data entities can be exposed to external reporting tools, such as PowerBI, as OData endpoints. Data entities can also be consumed.
- You can consume aggregate models directly in the programming model by using X++ or C# code. You no longer have to write MDX code to consume aggregate data.

- Aggregate data is a first-class citizen within application data access. Its behavior is similar to the behavior of detailed data. For example, aggregate data can be enriched with extended data types (EDTs) and enumerations, and you can help secure them by using application security concepts.
- The aggregate data infrastructure is maintained completely within the environment. By default, aggregate measurements are real-time. As a system administrator, you can manage the latency of aggregate data and controls based on available resources and business needs, without having to deal with the complexity of scheduling and external tools.
- Developers can reuse existing business models, making the modeling process quicker and easier.

Projects that were generated by using perspectives from Dynamics AX 2012 and later can be upgraded to Finance and Operations metadata equivalents.

Aggregate measurements and aggregate dimensions

An aggregate measurement is a model that contains a collection of measures together with their corresponding dimensions. Measures are aggregate numbers, such as Total Sales or Number of Orders. Dimensions are slicers, such as Product, Vendor, or Customer, that help you analyze the measure. For example, the measure of Total Sales isn't useful unless it can be sliced by Product, Region, and Customer. Aggregate measurements are the evolution of AX 2012 analysis cubes. Whereas a cube was based on a multidimensional online analytical processing (OLAP) technology, an aggregate measurement abstracts the underlying technology. Therefore, you no longer have to know a lot about the underlying implementation technology. Additionally, the underlying technology infrastructure can take advantage of improvements in in-memory real-time technology without requiring the developer to rewrite the program. Aggregate dimensions are shared across an implementation. Aggregate measurements associate themselves with relevant aggregate dimensions. For example, Total Sales can be associated with Customer, Product, and Sales Region dimensions. However, Total Sales can't be associated with Vendor and Warehouse dimensions. Aggregate dimensions and aggregate measurements are modeled by using Visual Studio tools. The Upgrade tool lets customers and partners migrate existing Dynamics AX 2012 cubes to newer versions of the product.

Aggregate data entities

By using the model-driven approach, you can create data entities by directly referencing aggregate measurements and aggregate dimensions. These are known as aggregate data entities. Aggregate data entities are read-only data entities that are used for reporting purposes. To consume aggregate data when you build charts and other client controls, add the aggregate data to a form as a data source. You can also consume aggregate data entities programmatically in C# or X++ code.

Aggregate programming model

The Aggregate programming model lets a developer consume aggregate data programmatically by using either X++ or C# code. Data that you retrieve by using the Aggregate programming model can be used as a data source in forms and reports. A developer can add aggregate data that is modeled in perspectives to an **AXQuery** object. The developer can also use an existing aggregate data entity to create a query that can be extended by adding filters and additional columns that aren't present in the aggregate data entity. Bulk Move is a capability that is associated with the Aggregate programming model. When a query is run by the kernel, the developer can move all the records to a temporary or regular table without iterating row by row. Bulk Move provides a very efficient way to move data from aggregate models to temporary tables.

Method expressions

Method expressions are a programming model for constructing rich calculations that are used to define fields in a data entity. Method expressions enhance the computed column capability that was introduced in AX 2012 views. Method expressions let you build expressions by using the C# or X++ programming language. You can

also create calculations on aggregate data that was previously coded by using MDX. Method expressions can be shared across the program.

In-memory, near-real-time aggregate measurements

Aggregate measurements are deployed to Microsoft SQL Server non-clustered column store indexes (NCCI). Therefore, they can take advantage of the in-memory computing (IMC) engine that is built into Microsoft SQL Server 2016 as Azure DB. Aggregate measurements that have the IMC engine as their destination are referred to as in-memory, near-real-time (IM-NRT) aggregate measurements. These aggregate measurements don't require that a Microsoft SQL Server Analysis Services (SSAS) server be used. Because these models don't involve data updates, the queries that are sent to them reflect the latest state of data in the operational database. That is why it's referred to as near-real-time.

KPI modeling and customization

In AX 2012 and earlier versions, KPIs and business indicators had to be modeled by using native SQL Server development tools. Although users could pin a KPI or business indicator to a Role Center by using the **Business Overview** Web Part, they could not modify a KPI definition, such as the goal. Users can use a rich client form to modify a KPI definition that was built and shipped by a developer. Users can also define new KPIs by using the aggregate data that is contained in aggregate measurements. A developer can model a KPI definition in Microsoft Visual Studio and ship it to a customer, either as a project or together with an independent software vendor (ISV) solution. After a KPI is defined, users can customize it at run time.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Model aggregate data

2/18/2021 • 15 minutes to read • [Edit Online](#)

This tutorial will walk you through the process of modeling aggregate data.

Prerequisites

This tutorial requires you to access the environment using Remote Desktop, and be provisioned as an administrator. For more information, see the topic named [Deploy and access development environments](#).

Key concepts

- **Aggregate measurements**, similar to **perspectives** and **Cubes** from earlier versions, enable you to model and consume aggregate data.
- **Key Performance Indicators (KPIs)** are a form of analytic controls that track organizational performance against the current status. KPIs are represented as tiles in a **workspace** or the **dashboard**. In this tutorial, you will model a KPI in Visual Studio.
- KPIs that are modeled in Visual Studio can be modified in the client. A user also has the ability to model new KPIs using the client.
- A **workspace** is an overview page that is specific to a particular subject area. Workspaces are common to all users.
- The **dashboard** is the default home page for each user.
- **Tiles** are securable objects that can be pinned to a workspace or the dashboard. KPIs and aggregate data that are shown on the dashboard, or a workspace, can be secured by using menu items.
- Aggregate data can be consumed in building charts and other controls. Using the model driven approach, you have the ability to create data entities by directly referencing aggregate measurements and aggregate dimensions. These entities are referred to as **Aggregate data entities**. Aggregate data entities are read-only data entities used for reporting purposes.
- **The aggregate programming model** enables a developer to consume aggregate data programmatically using either X++ or C# code. Data retrieved using the aggregate programming model can be used as a data source in forms.
- **Method expressions** enable a developer to build rich expressions using aggregate data. Method expressions are an X++ class. KPIs can be modeled using method expressions, thereby eliminating the need to build MDX expressions.
- **Contextual BI** refers to providing required insights as part of the user experience such that the user has relevant insights to not only achieve the task at hand, but be highly-productive during the course of the day.
- **Embedded BI** refers to analytic content being embedded within the user experience. Contextual BI and embedded BI teams are closely related. Contextual BI implies the added notion that the context of analytic context revolves around the data or the task.
- **Self-service BI** refers to enabling a user to tweak existing and/or create new analytic content such as reports, KPIs, and dashboards.

Set up

If this is the first tutorial you are working on, make sure you have configured the administrator user if you are running on a local VM.

Import the tutorial project

If you have already imported the Fleet management tutorial project, skip to the next section. In Visual Studio, on the **Dynamics 365** menu, click **Import Project**.

1. Download the Fleet Management sample from <https://github.com/Microsoft/FMLab>, save it to c:\, and unzip it.
2. In the **Import Project** window, next to the **Filename** text box, click the ellipsis button.
3. In the **Select the file to import** window, browse to the location of the **FMLab** folder, click **FMTutorialDataModel.axpp**, and then click **Open**.
4. In the **Project file location** text box, enter **C:\FMLab**.
5. Select the **Overwrite Elements** check box, and then click **OK**.

Open the tutorial project

1. In Visual Studio, open the **FMTutorial** project. On the **File** menu, point to **Open**, and then click **Project/Solution**.
2. In the **Open Project** dialog box, browse to **C:\FMLab\FMTutorial**, and then click **FMTutorial**. Click **Open**. The **FMTutorial** project appears in **Solution Explorer**.
3. Use the **FMTDataHelper** class to load data for the Fleet Management tutorial. In **Solution Explorer**, in the **FMTutorial** project, expand **Classes**. Right-click **FMTDataHelper**, and then click **Set as Startup Object**.
4. On the **Build** menu, click **Rebuild Solution**. You use the rebuild to update the timestamps of the imported artifacts. You can view the build progress in the **Output** window.
5. Press **Ctrl+F5** to run the project and load the data.

Model an aggregate measurement for rental charges

Often, when a user asks for additional information, you get a request for one or more new reports. Imagine that the manager of a rental car company has called and asked for a report. The manager is interested in finding out how the rental business is performing. The manager wants a report that shows rental revenue by month. You soon find out that the manager is interested in a breakdown of rental revenues. The manager wants to know whether the rental revenue is high in cases where they have sold additional services, for example, car seats, GPS, re-fueling, as opposed to the base rental charge. As it turns out, the manager suspects that specific customer groups are driving revenue up, and this is why the manager wanted the report in the first place. The manager insists on adding **Customer group** to the report. Because the revenue must be considered in relation to the number of rentals, the manager doesn't want a few large corporate rentals to skew her analysis. You both agree that the number of rentals needs to be shown along with revenue. We could represent this requirement as a set of business questions using a matrix. Rows indicate the **measures** (or numbers) and the columns indicate the **dimensions** (or slicers). An "X" in the intersection between a measure and a dimension indicates that the measure needs to be "grouped by" the dimension.

	RENTAL DATE	CUSTOMER GROUP	RENTAL CHARGE TYPE
Revenue	X	X	X
Number of rentals	X	X	X

Next, we will model an aggregate measurement to answer this business question.

Add a measure group for rental charges by using an existing view

In this section you will add a new measure group to an existing aggregate measurement.

1. In **Solution Explorer**, expand the **Analytics** folder of the project, and then double-click the aggregate measurement, **FMTAggregateMeasurement**. The aggregate measurement will be launched in the designer. Notice that the existing aggregate measurement contains two measure groups related to vehicle inventory and rental details. You will create a new measure group related to rental charges.

- In **Solution Explorer**, expand the **Views** folder of the project, and then select the **FMTRentalChargeExtendedView** view.
- Drag-and-drop the **FMTRentalChargeExtendedView** into the root node of the **FMTAggregateMeasurement** aggregate measurement in the designer. Notice that a new measure group is created and the values of properties have been applied as follows.

PROPERTY	VALUE
Name	FMRentalChargeExtendedView
Table	FMRentalChargeExtendedView

- In **Solution Explorer**, double-click the **FMRentalChargeExtendedView** view. When the designer form opens, expand the **Fields** node.
- Select the **ExtendedAmount** and **RentalID** fields, and then drag-and-drop the two fields onto the **Measures** node of the newly created **FMTAggregateMeasurement** measure group called **FMRentalChargeExtendedView**. As you drag the fields, hover your cursor over the **FMTAggregateMeasurement** tab to access the **Measures** node. By default, when you drag-and-drop the fields, the system assumes that you want counts of the measures. In this case, you need to modify default properties for the **ExtendedAmount** and **RentalId** measures as follows:

PROPERTY (EXTENDEDAMOUNT)	VALUE
Default Aggregate	Sum
Field	ExtendedAmount (no change required)
Name	Revenue

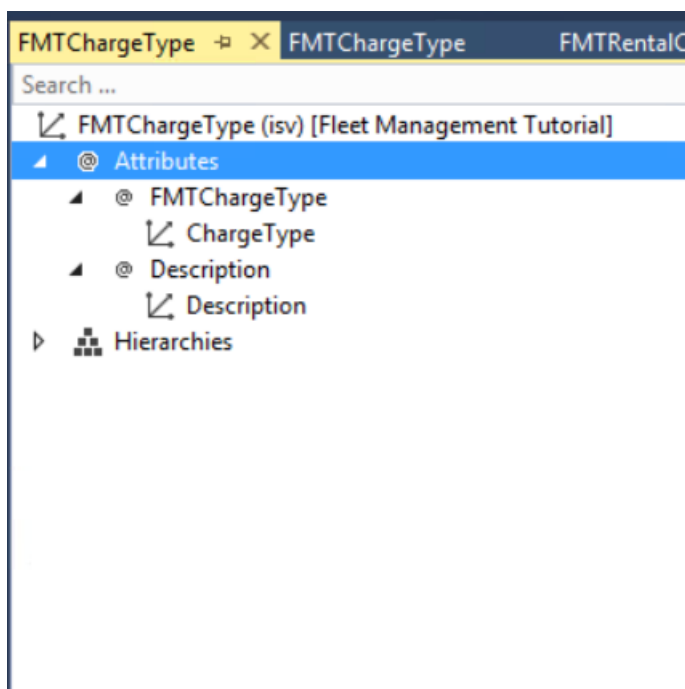

PROPERTY (RENTALID)	VALUE
Default Aggregate	DistinctCount
Field	RentalId (no change required)
Name	NumRentals

- Next let's create another measure which calculates **Revenue per Rental** by copying an existing measure. Select the **TotalRevenue** measure. Right-click and select **Copy** from the **Context** menu.
- Select the **FMRentals** measure group. Right-click and select paste. Rename the newly created measure to **RevenuePerRental**. Modify the aggregation function to **Average**.

Model an aggregate dimension charge type

To analyze rental revenue by the different charge types, you need to be able to slice revenue by the charge type. For this purpose, you will first model a charge type dimension.

- In **Solution Explorer**, under **FMTutorial**, right-click **Analytics**, point to **Add**, and then click **New Item**.
- Select **Dynamics 365 Artifacts > Analytics > Aggregate Dimension** from the list of items.
- In the **Name** property, enter **FMTChargeType**. This is the name of the aggregate dimension that will be created. This name must be unique. Click **Add**. The new dimension will appear in Visual Studio.
- In **Application Explorer**, expand the **AOT** and click **Data Model > Tables**. Drag-and-drop the **FMTChargeType** table from **Application Explorer** onto the root node of the newly created **FMTChargeType** dimension in the designer. Notice that dimension attributes and corresponding keys have been added using the AutoReport field group of the table.
- Expand the **Attributes** node of the new dimension. Notice that several attributes have been created for you by default. The system has also created a dimension key based on unique indexes of the table. You can add additional fields by dragging and dropping them into the **Fields** node.

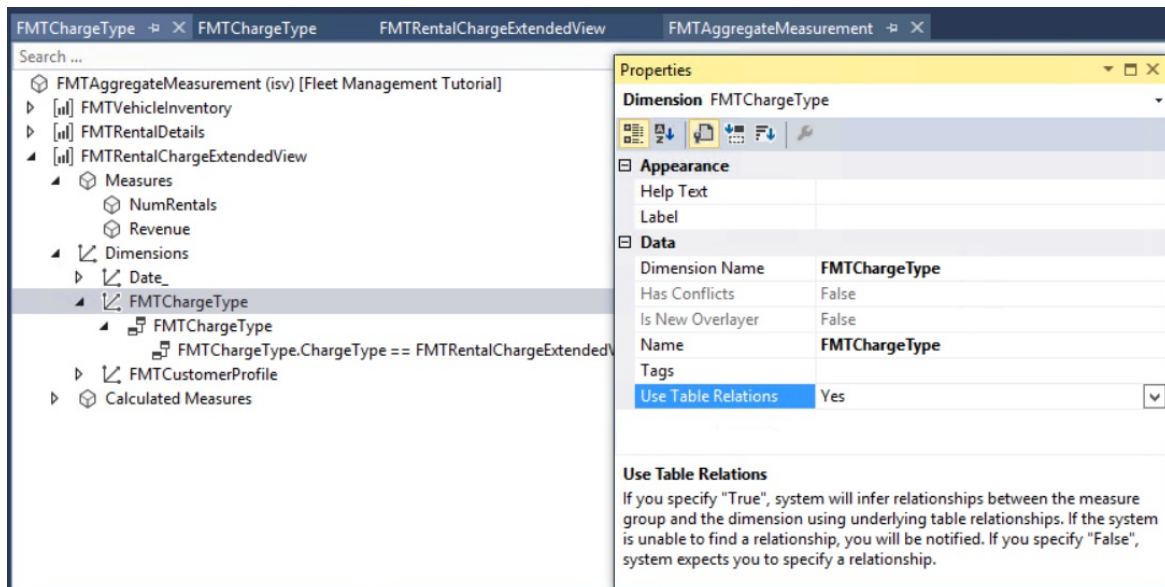

- Save the new dimension.
- You may get a warning asking you to rename the field name **Description** to avoid the MDX reserved word. Even though the aggregate dimension may not be deployed to SSAS in this aggregate

measurement, it's possible that this dimension may be used by an aggregate measurement deployed to SSAS in the future. To avoid potential issues in the future, rename the field name **Description** to **ChargeDescription**.

Model dimension references for customer profile and charge type dimensions

Next, create dimension references to new and existing dimensions so that revenue can be sliced by customer as well as charge type.

1. In **Solution Explorer**, double-click **FMTAggregateMeasurement** or, if you have it open, navigate to it in the designer.
2. In **Solution Explorer**, select the dimensions **FMTChargeType** and **FMTCustomerProfile**.
3. Drag-and-drop them into the **Dimensions** node of the **FMTRentalChargeExtendedView** measure group. Notice that dimension references have been created along with relations.
4. Save changes to **FMTAggregateMeasurement**. Review the property sheet for the dimension relation and notice that the **Use Table relations** property is set to **Yes**. Notice that the drag-and-drop operation created relationships between the measure group dimensions **FMTRentalChargeExtendedView** and **FMTChargeType**, **FMTCustomerProfile**. Review the property sheet for the dimension relation and notice that the **Use Table relations** property is set to **Yes**.

NOTE

In platform update 1611 and later, **UseTableRelations** property has been removed. When a new dimension reference is created, system will default existing relationships. You can continue to provide an explicit relationship by changing the relationship field that was defaulted. Providing an explicit relationship is equal to setting **UseTableRelationship** to **No**.

5. Expand the Dimension relations node for the **FMTCustomerProfile** dimension. Notice that the **UseTableRelations** property is set to **No**. In this case, the system has not been able to find a suitable relationship between the Measure group and dimension. You will need to specify one manually.
6. Expand the **FMTCustomerProfile** dimension reference if you have not done so already. Select the node **FMTCustomerExtendedView**. Right-click and see the property sheet.
7. Select **CustomerID** as the value for property **DimensionAttribute**. Select the relationship shown below. Select **Customer** for the property value **RelatedField**.
8. Save changes to **FMTAggregateMeasurement**.

9. In this scenario, we specified a relationship because the system was unable to find one. You could also specify a different relationship if you want to override the system choice by setting **Use Table Relations** property to **No**.

Model dimension references for the date dimension's rental start date and transaction date

Assume that for analysis purposes, you want to enable slicing by the start date of the rental; but for accounting purposes, you want to enable slicing by the transaction date for each of the charges. To do this, you need to associate the rental charges measure group with two date dimensions. In the BI world, this pattern is known as **Role Playing dimensions**. By default, a date dimension is added to the measure group. You can rename the default name appropriately and add new date dimensions as required.

1. Expand the **Dimensions** node of the **FMTRentalChargeExtendedView** measure group. Notice that the **Date_** dimension has already been included as dimension slicers.

NOTE

If the table or the view used to model the measure group is a Company-specific table, for example it contains DATAAREAID as part of the key), a **Company** dimension relation will be created by default. In this case, the view we used is not a company specific one.

2. Select the **Date** dimension and specify the following properties.

PROPERTY	VALUE
Name	RentalStartDate

PROPERTY	VALUE
Use Table Relations	No (This is the default – no need to change)

- Define the table relationship. Expand **RentalStartDate**, and then expand the **Date** node.
- Select the Relationship shown. Right-click and select the property sheet. Select **StartDate** for the value of **Related field** property.
- The relationship you defined should look like the following screenshot.

- Next, enable slicing of measures by the TransactionDate dimension. TransactionDate is also a date dimension, so you will add another reference to the date dimension and associate that with the corresponding field that contains the transaction date. When more than one date dimension is used as a slicer, each date dimension is known as a **Role playing date dimension**.
- Under the **FMTRentalChargeExtendedView** measure group, right-click the **Dimensions** node, and then click **New Dimension**. A new dimension will be added to the list of dimension references.
- Specify the following properties for the new dimension reference.

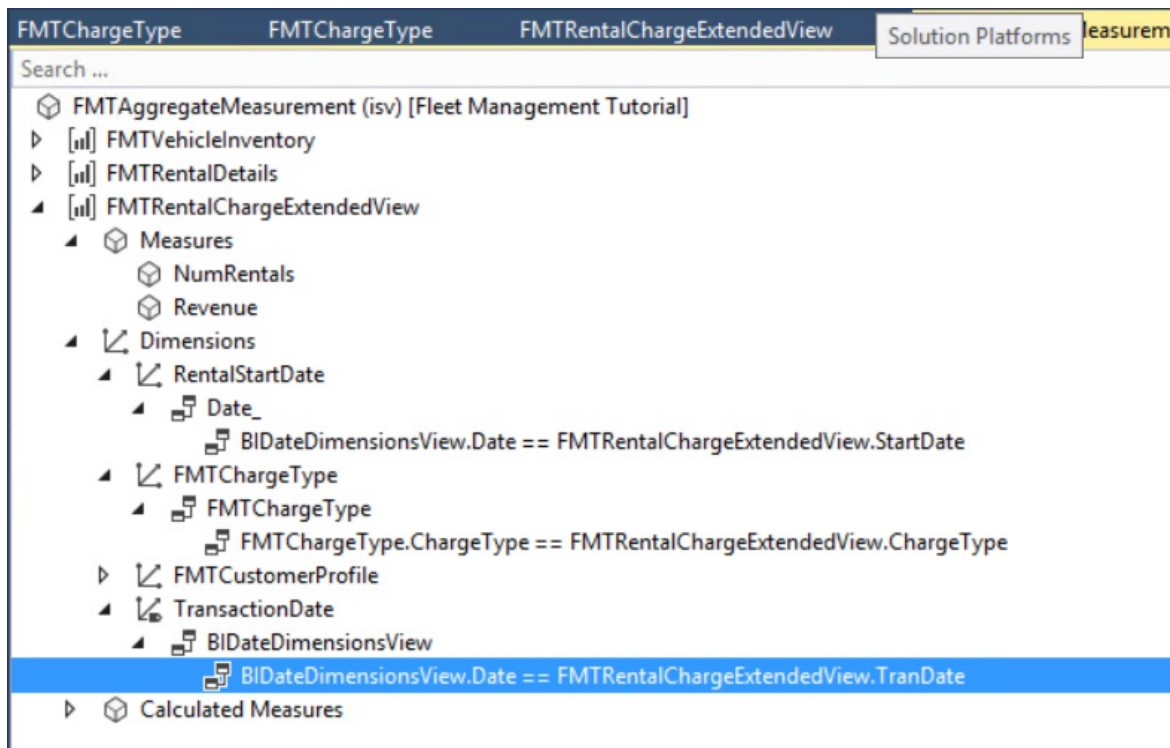

PROPERTY	VALUE
Dimension Name	Date_ <div style="border: 1px solid gray; padding: 5px; margin-top: 5px;"> <p>[!NOTE] If you select the Dimension Name in the wrong order, it will reset the other values you already set.</p> </div>
Name	TransactionDate
Use table relations	No
Tags	RolePlayingDate; Fleet

Notice the new property called **Tags**. This property enables the discovery of patterns within code and metadata from within the Visual studio environment. You can enter any number of tags and they can be searched using the hot keys or the **Dynamics 365** menu in Visual Studio.

9. Define the table relationship. Right-click **TransactionDate**, and then click **New Relation**. You do not need to specify any properties in the DimensionsRelation at this point.
10. Expand **BIDateDimensionValue**, and then select the **Relationship Constraint**. Right-click and select the property sheet.
11. Specify the following properties for the BIDateDimensionsView relation constraint.

PROPERTY	VALUE
Field	Date
Related Field	TranDate

The relationship you defined should look like the following screenshot.

12. Save the aggregate measurement.

Deploy the newly generated aggregate measurement

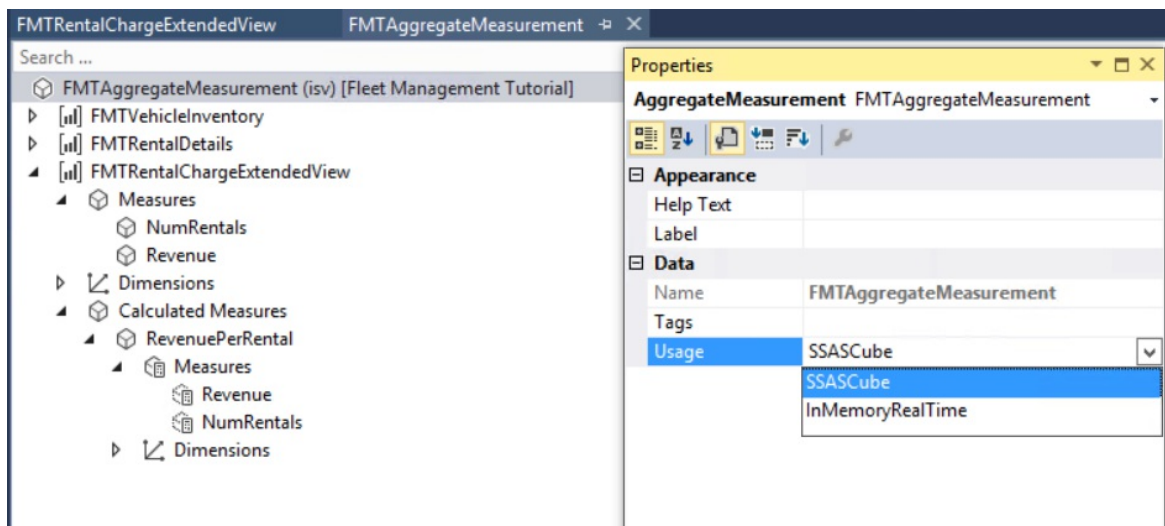

Now that you have completed modeling the aggregate measurement, you can deploy the aggregate measurement and continue with building KPIs and visualizations. You have 2 deployment choices as shown below.

OPTION	CONSIDERATIONS
In-memory real-time	This option will leverage the In-memory Column store indexes of SQL Server database to deploy Aggregate Measurements. This option is recommended when the Aggregate measurement is used for embedded analytics within the client where you need real-time analytics . For an overview of concepts on real-time analytics, see Analytics, aggregate measurements, and KPI modeling .

OPTION	CONSIDERATIONS
Stage in Entity Store	This option leverages Entity store, the operational data store that enables near real-time PowerBI reporting . If you choose this option, Aggregate measurement can be deployed to Entity store and you can schedule the data to be refreshed periodically. For an overview of this approach, refer to the blog post here: https://blogs.msdn.microsoft.com/dynamicsaxbi/2016/06/09/power-bi-integration-with-entity-store-in-dynamics-ax-7-may-update/

NOTE
 SSAS Cube option is no longer supported when modeling aggregate measurements.

1. Select the **FMTAggregateMeasurement** node. Right-click and select **Properties**. Select **InMemoryRealTime** as the value for the property **Usage**.

2. InMemoryRealTime aggregate models are deployed to SQL Server using Non-Clustered Column Store Index (NCCI) technology. NCCIs is an in-memory technology that enables analytical and operational workloads to be served from SQL server database. NCCI indexes can be defined on tables similar to any other index. While NCCI indexes can be defined manually, framework has the ability to analyze index requirements and add them to underlying tables where necessary.
3. Right-click **FMAggregateMeasurement** in Solution Explorer, and then click **Add Column store indices option**. You will notice several new indexes being added by the system.
4. Save and build the project.
5. InMemoryRealTime aggregate models do not require data processing as the models are queried real-time. If you have not enabled database synchronization along with the build, manually synchronize the database.

Model a KPI to show revenue per rental

Model a KPI in Visual Studio

Model a KPI definition in Visual Studio by using the aggregate measurement you defined above.

1. In **Solution Explorer**, right-click **FMTutorial**, point to **Add**, and then click **New Item**.

- Select **Dynamics 365 Artifacts > Analytics > Key Performance Indicator**. Enter **FMTRevenuePerRental** as the name of the KPI, and then click **Add**. The name must be unique across KPIs. The KPI is created.
- Select **FMTRevenuePerRental**, and specify the **Measurement**. Leave the default values for the other properties.

PROPERTY	VALUE
Measurement	FMTAggregateMeasurement
Bad Threshold	0
Good Threshold	0
Scoring Pattern	MoreIsBetter
Show Goal	Yes
Show Status and Trend	Yes
Threshold Type	Value

- Define the expression for the KPI value. Under **FMTRevenuePerRental**, select **Value**, and specify the following properties.

NOTE

The values must be entered in the order they appear in the table:

PROPERTY	VALUE
Value Type	BasedOnMeasure
Measure Group	FMTRentalChargeExtendedView
Measure	RevenuePerRental

- Define the expression for the KPI Goal. Select **Goal**, and specify the following properties.

PROPERTY	VALUE
Goal Type	BasedOnValue
Value	250

NOTE

You could have defined a goal based on an aggregate measure as well. In this case, we will define a number as the goal.

- Save the KPI definition.

Preview KPI in client

Next you will preview the KPI definition in the client.

1. Right-click **FMTutorial**, and then click **Re-Build**. On completion of the build, select the **Synchronize ... database** option.
2. Open Internet Explorer, and navigate to your Rainier instance base URL.
3. Navigate to the **Reservation Management workspace** under **App links > Fleet Management > Workspaces > Reservation Management**.
4. Select the KPI tile **Total Revenue**. KPI details page for **Total Revenue** KPI will be displayed.
5. To navigate to the newly defined KPI, select the **Show list** icon on top left. From the list of KPIs shown, select **FMTRevenuePerRental**.

Notice that the KPI details page for the new KPI, **FMTRevenuePerRental** is shown. Even though we did not define trend charts, the system created a set of charts based on the limited metadata defined by the developer. Users have the ability to modify KPI definitions and create new ones in the client. Next, you will modify the newly defined KPI.

6. To demonstrate this capability, you can change the KPI Goal. Click the **Edit** button on top left, and enter 900 as the Goal Value.
7. Modify the threshold properties as follows:

PROPERTY	VALUE
Threshold Type	Percentage
Red if less than	90
Green if more than	110

8. Click **Save** on the bottom left to save changes. Notice that the KPI status color has changed in the KPI tile shown.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Add financial dimensions to aggregate measurements

2/18/2021 • 6 minutes to read • [Edit Online](#)

This feature lets power users include financial dimensions in ready-made Microsoft Power BI reports. Power users can also create new Power BI reports that use financial dimensions.

Financial dimensions are user-defined configuration data that enables the ledger chart of accounts to retain additional information. By adding financial dimensions, a user can configure additional data fields that will be included with the chart of accounts and financial reports. Therefore, the ledger chart of accounts can be sliced and diced based on those fields. This feature provides powerful financial reporting. For example, you can explore ledger data by using the new financial dimensions that you've added. Because no financial dimensions are included in the ready-made Power BI reports when they are released, you must include these additional fields to the ready-made reports.

After financial dimension fields are included in the report, you can share the report with other users. Those other users can modify existing visuals, such as charts, by including all or some of the financial dimension fields.

NOTE

This feature is available in Microsoft Dynamics 365 for Finance and Operations, Enterprise edition (July 2017). Platform update 8 or later is also required.

How does this feature work?

The Entity store is an operational data warehouse that lets power users create reports. Whenever the Entity store is updated, all available financial dimensions are included in it. We will look at an example from the **Ledger Activity** aggregate measurement that contains General ledger journal-level details.

The following list shows some of the tables are filled in the Entity store when it's updated. Tables that have changed are bold.

- LedgerActivityMeasure_LedgerActivityMeasureGroup
- LedgerActivityMeasure_TransactionDate
- LedgerActivityMeasure_Currency
- LedgerActivityMeasure_FiscalPeriodDateAggregateDimension
- LedgerActivityMeasure_LedgerFactDimension
- LedgerActivityMeasure_FiscalYearOffsetDimension
- LedgerActivityMeasure_MainAccount
- **LedgerActivityMeasure_DimensionCombination**
- LedgerActivityMeasure_Ledger
- LedgerActivityMeasure_MainAccountCategory
- LedgerActivityMeasure_Company
- LedgerActivityMeasure_MainAccountLegalEntity
- **LedgerActivityMeasure_Agreement**
- **LedgerActivityMeasure_BankAccount**
- **LedgerActivityMeasure_BusinessUnit**

- LedgerActivityMeasure_Campaign
- LedgerActivityMeasure_Cargo
- LedgerActivityMeasure_Cargo_CN

Notice that, for each financial dimension that is defined in your system, you might see a corresponding table in the Entity store.

If you examine the LedgerActivityMeasure_DimensionCombination table, you will notice that the list of fields has been expanded and now includes additional fields. Each new field corresponds to a financial dimension. For an example, here are some of the additional fields:

- Agreement_FK
- Agreement_Description
- Agreement_Value
- BankAccount_FK
- BankAccount_Description
- BankAccount_Value
- BusinessUnit_FK
- BusinessUnit_Description
- BusinessUnit_Value

If a user defines a new financial dimension that is named **vendor**, when the Entity store is updated, a new table is added that is named LedgerActivityMeasure_Vendor.

The LedgerActivityMeasure_DimensionCombination table will also contain the following new set of fields:

- Vendor_FK
- Vendor_Description
- Vendor_Value

How a Power BI report author can create reports that use financial dimensions

A business user can create a new report that uses financial dimensions by using Power BI desktop. Existing reports that use financial dimensions can be updated so that they include additional fields.

In this example, we will use Power BI desktop to create a report that uses the Ledger Activity measure group.

1. In a development environment, connect to the Entity store database by using Power BI desktop.
2. Select the following tables:
 - LedgerActivityMeasure_LedgerActivityMeasureGroup
 - LedgerActivityMeasure_FiscalPeriodDateAggregateDimension
 - LedgerActivityMeasure_DimensionCombination
3. Use the **Manage relationships** option in Power BI desktop to define the following relationships between table fields:
 - Define a join between **LedgerActivityMeasure_LedgerActivityMeasureGroup.LEDGERDIMENSION** and **LedgerActivityMeasure_DimensionCombination.DIMENSIONCOMBINATIONRECID**.
 - Define a join between **LedgerActivityMeasure_LedgerActivityMeasureGroup.LEDGERGREGORIANDATEID** and **LedgerActivityMeasure_FiscalPeriodDateAggregateDimension.LEDGERPERIODGREGORIANDATEID**.

4. Create a matrix report that uses the **Sales** and **YearName** fields. The report should resemble the following example.

YEARNAME	SALES
2015	355,958,240.86
2016	478,064,122.48
2017	10,712,838.30
Total	844,735,201.64

Next, we will add financial dimension values.

5. In the list of fields in Power BI desktop, expand the **LedgerActivityMeasure_DimensionCombination** table. You will see that the list of dimension fields is expanded into table fields, as shown here.

6. Include the **BusinessUnit_Description** field in the report. Your report should now show sales by business unit, as shown in the following example.

YEARNAME	Electronics	Home	IT Consulting Practice	Management Consulting Practice	Sporting	Total
2015	7,362,985.20	152,524,507.23	100,045,909.46	699,928.66	7,937,635.30	355,958,240.86
2016	6,374,315.40	167,483,885.95	115,009,475.39	769,787.36	7,622,420.20	478,064,122.48
2017	100,000.00	10,390,021.77	0.00	26,571.26		10,712,838.30
Total	13,837,300.60	330,398,414.95	215,055,384.85	1,496,287.28	15,560,055.50	844,735,201.64

Notice that you have the **BusinessUnit_description** field and the **BusinessUnit_Value** field. The value field lets you to get a numerical value that can be used to sort columns.

7. Define a new financial dimension, and update the Entity store.
8. When the update is completed, right-click the **LedgerActivityMeasure_DimensionCombination** table, and then select **Refresh data**. Notice that the new financial dimension that you defined is reflected in the list of fields that are available for reporting.

9. You can include the new financial dimension fields in the report.

Creating reports that use expanded Financial dimension tables

As we discussed earlier, new tables were created in the Entity store. Each financial dimension field is also added to a new table. The new tables contain individual fields for the name, value, and description.

Notice that the new tables contain a key that can be used to join them with the LedgerActivityMeasure_DimensionCombination table that is used to create the report. If you want to use fields from these additional tables, just include them in the report and relate them by using the keys.

1. Open the report that you created earlier.

We will now add a financial dimension table to the report.

2. In Power BI desktop, click **Recent Sources** on the menu, and then select the **AXDW** data connection.

Table navigator is shown.

3. Select the **LedgerActivityMeasure_LegalEntity** table for the report.

NOTE

If you're using a development or demo environment, you see this table because **LegalEntity** is a financial dimension that is defined in demo data. If you're working with your own data, the tables that you see will correspond to financial dimensions that you've defined.

We will now relate the selected table to existing tables in the report.

4. In the report, open the **Manage relationships** dialog box.

5. Join **LedgerActivityMeasure_DimensionCombination.LegalEntity_FK** to **LedgerActivityMeasure_LegalEntity.KEY_**.

If you select a different dimension table in step 3, you must relate the corresponding **FieldName_FK** field from the combination table to the **KEY_** field in the dimension table.

How a developer can enable financial dimensions

Before users can see expanded financial dimensions in the Entity store, a developer must enable the use of financial dimensions in aggregate measurements. As a best practice, financial dimensions should be included when you model any aggregate measurement that involves financial data. To include financial dimensions, create an aggregate dimension that is based on "financial dimension tables." As we saw earlier, an aggregate dimension that you create by using financial dimension tables will be expanded at runtime.

What are financial dimension tables?

Financial dimension tables are base tables that contain financial dimension data. Examples include `DimensionAttributeValueCombination` and `DimensionAttributeValueSet`.

If you use a table, a view, or an entity that is based on those two tables, the fields of the aggregate dimension will be expanded at runtime.

Consider the following example from the `LedgerActivityMeasure` aggregate measurement.

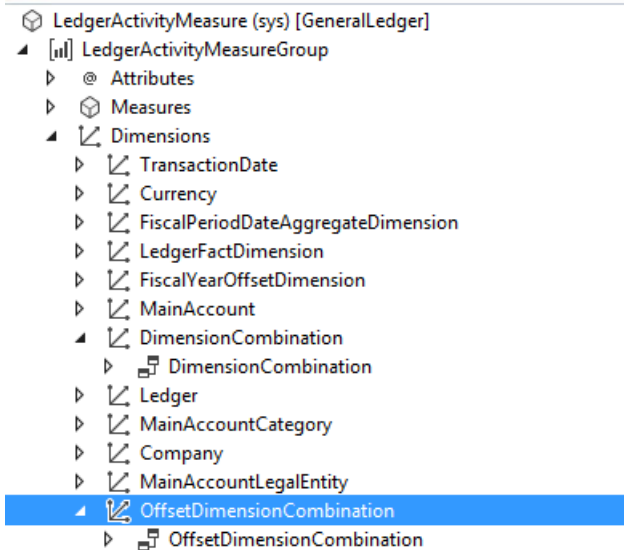

`DimensionCombination` is an aggregate dimension that is modeled by using the `DimensionAttributeValueCombination` base table. In this case, the developer has referenced the aggregate dimension by using the `LedgerActivityMeasureGroup` measure group.

At runtime, new dimension fields are added (that is, the `DimensionCombination` table is expanded) as new financial dimensions are defined in the system.

Creating role-playing financial dimensions

When you report by using ledger data, you might require reporting on primary accounts and offset accounts. For an example, if a ledger transaction involves the transfer of an amount from one account to another account, the primary account is the "from" account, whereas the offset account is the "to" account. This pattern is known as the *role-playing dimensions* pattern.

Both primary accounts and offset accounts must be associated with transaction data. Therefore, you must expand financial dimension fields of both primary accounts and offset accounts. We will now see how you can meet this requirement. Consider the following example.

We have modeled two dimension references for LedgerActivityMeaureGroup. The first reference, DimensionCombination, is joined by using the **LedgerDimension** field. We saw this pattern earlier in this topic.

The second reference, OffsetDimensionCombination, is another reference to the same dimension. We have reused the DimensionCombination aggregate dimension and given it a new name. In the second case, we can join by using the **OffsetLedgerDimension** field.

At runtime, the system will expand both these dimensions with additional fields. Therefore, you can report on primary and offset dimension fields.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Create analytical reports by using Power BI Desktop

2/18/2021 • 4 minutes to read • [Edit Online](#)

If you're a power user or a business analyst, you probably create many reports for your organization. You might create these reports in Microsoft Excel by formatting and relating data before you share it with other people. People in your organization might even come to you when they require modifications to the report. This solution offers an easy way to create rich, interactive reports. As a report writer, you can use Microsoft Power BI Desktop as the reporting tool. The reports that you create can then be published to PowerBI.com. For more information about Power BI Desktop, see [Create stunning reports and visualizations with Power BI Desktop](#).

Accessing the local Entity Store by using DirectQuery

You can create Microsoft Power BI reports by using Open Data Protocol (OData) endpoints that are exposed via data entities. Despite the limitations of this approach, the Entity Store still supports it for legacy solutions. However, DirectQuery is now the preferred method for sourcing data for analytical solutions. For more information about the benefits and limitations of DirectQuery, see [Use DirectQuery in Power BI Desktop](#).

When you use Power BI Desktop, you can create a report in your development or test environment by connecting directly to the local Entity Store database. When you're satisfied with the report, your administrator can help you migrate it to your production environment. The rest of this section walks you through this process.

NOTE

To develop or extend analytical workspaces and reports in the application suite, customers must use a development environment running in their own subscription or on local machines. You won't be able to develop or extend embedded analytical reports in Microsoft-provided Tier-1 environments. You need administrator rights to install Power BI Desktop.

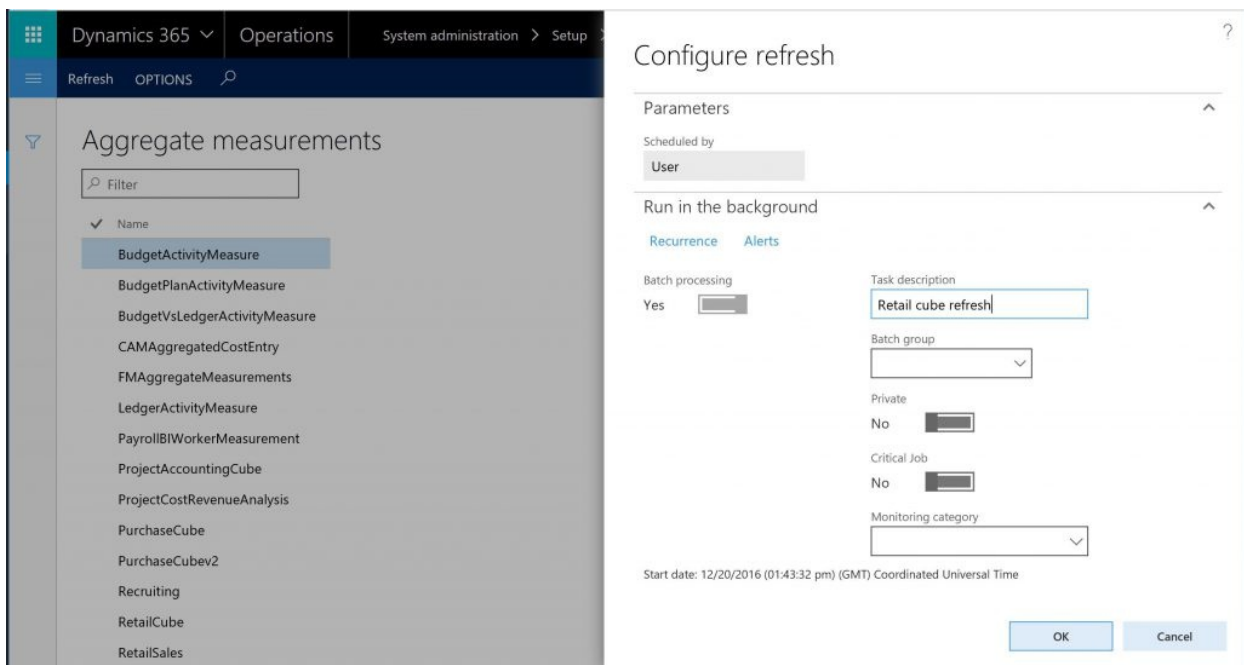

Tier-1 environments now include a service compatible version of Power BI Desktop. To develop or extend analytical workspaces and reports in the application suite, customers can use the Power BI Desktop application pre-installed on the development environment. Alternatively, you can use the latest compatible release of Power BI Desktop with Preview features turned off to author analytical reports for Finance and Operations apps. Download the August 2020 Update of Power BI Desktop at [Previous monthly updates to Power BI Desktop](#).

Step 1: Populate the local Entity Store database

For this example, we will stage the aggregate models that the Commerce analytical solution consumes in the local Entity Store. The models that the application uses are defined in the RetailCube aggregate measurement.

1. In the client, open the **Entity Store** page. (Select **System administration** > **Setup** > **Entity Store**.)
2. Select the **RetailCube** aggregate measurement, and then select **Refresh**.
3. Enter a name for the job that will be run in the background, and then select **OK**.

The following illustration shows the administrator dialog box that is used to configure the frequency of updates for the aggregate model.

To monitor the progress of the job that stages the data, you can use the batch job monitoring page. (Select **System administration** > **Database** > **Batch jobs**.) If you're using demo data, the job should take about a minute. After the data is in the Entity Store, you can write reports.

Step 2: Connect to the local Entity Store database

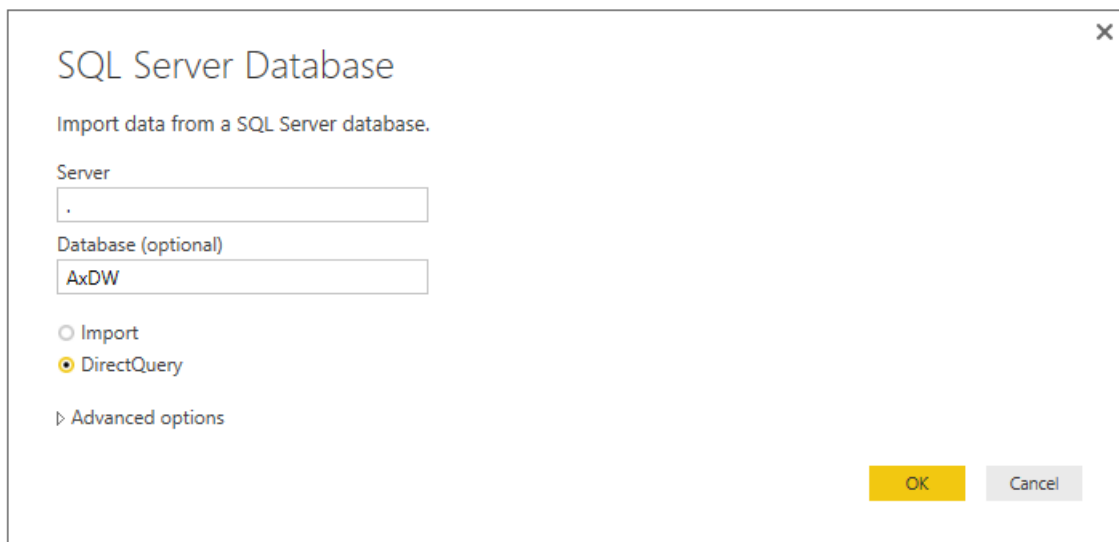

1. Start Power BI Desktop. If any updates are available for Power BI Desktop, you might have to download and apply them.
2. On the Power BI **Welcome** page, select **Get data**.

Alternatively, when Power BI Desktop starts, you can select **Get Data** > **SQL Server**.

3. In the **SQL Server Database** dialog box, enter . as the server name and **AxDW** as the database name. Then select the **DirectQuery** option.

The following illustration shows the settings that enable Power BI Desktop to access the local Entity Store database.

NOTE

The **Import** option isn't currently supported.

4. Select **OK**.

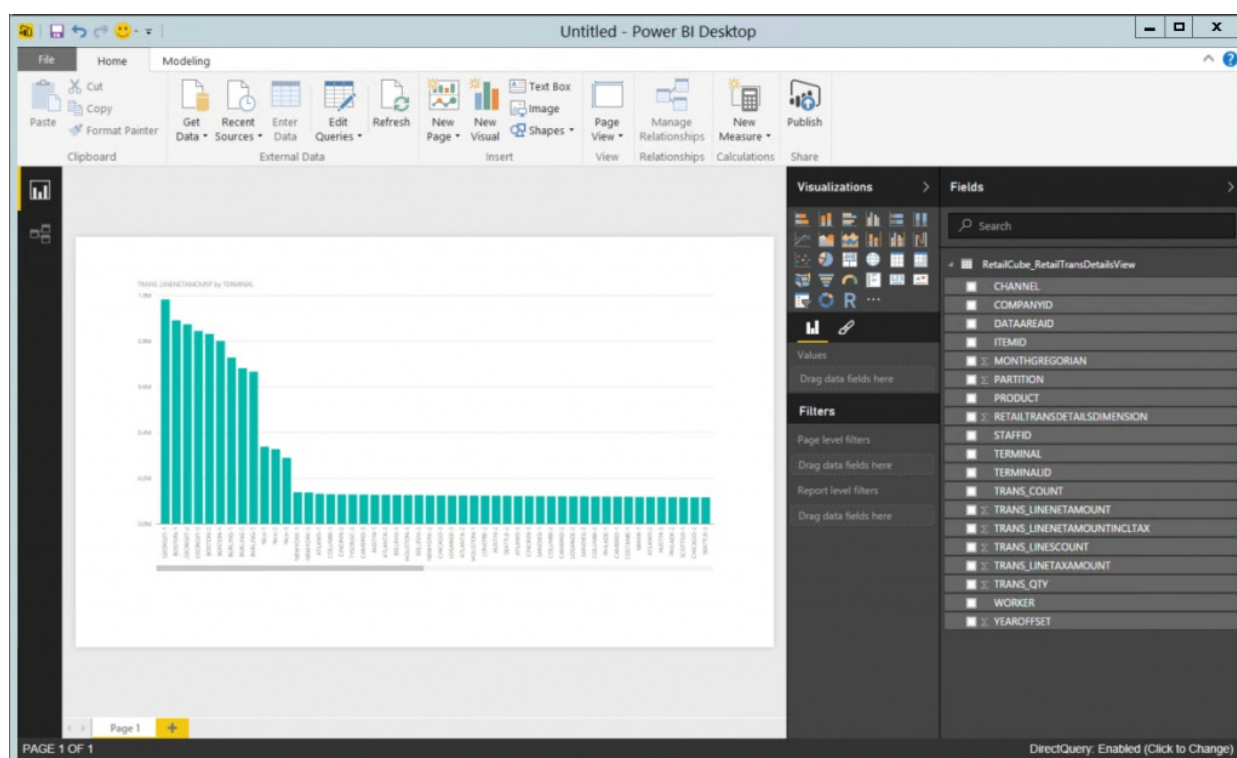

The **Navigator** dialog box appears. You use this dialog box to select which tables and views from the Entity Store you want to report on.

5. In the search box, enter **Retail** to filter for entities that are related to the RetailCube aggregate measurement.

6. Select the **RetailCube_RetailTransDetailsView** table that is shown in the navigator, and then select **Load**.

You can now create a report. You can drag measures and fields to the canvas, and can explore data and trends interactively.

The following illustration shows a basic report that uses the local Entity Store database as its source.

Power BI Desktop also supports the creation of calculations and lets you combine data from multiple aggregate measurements. Within minutes, you can create analytical reports by using data in the local development environment. When you're satisfied with the report, you can migrate it to the production environment, so that users can use the report to interact with production data.

Validating reports in a demo environment

The report shows the demo or test data in your developer environment. If you want to integrate the report into a demo environment, you can continue to publish this report to your PowerBI.com account and pin it to the client.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Add analytics to workspaces by using Power BI Embedded

2/18/2021 • 5 minutes to read • [Edit Online](#)

NOTE

This feature is supported in Finance and Operations (version 7.2 and later).

Introduction

This topic shows how to embed a Microsoft Power BI report on the **Analytics** tab of a workspace. For the example that is given here, we will extend the **Reservation management** workspace in the Fleet Management application to embed an analytical workspace on an **Analytics** tab.

Prerequisites

- Access to a developer environment that runs Platform update 8 or later.
- An analytical report (.pbix file) that was created by using Microsoft Power BI Desktop, and that has a data model that is sourced from the Entity store database.

Overview

Whether you extend an existing application workspace or introduce a new workspace of your own, you can use embedded analytical views to deliver insightful and interactive views of your business data. The process for adding an analytical workspace tab has four steps.

1. Add a .pbix file as a Dynamics 365 resource.
2. Define an analytical workspace tab.
3. Embed the .pbix resource on the workspace tab.
4. Optional: Add extensions to customize the view.

NOTE

For more information about how to create analytical reports, see [Getting started with Power BI Desktop](#). This page is a great source for insights that can help you create compelling analytical reporting solutions.

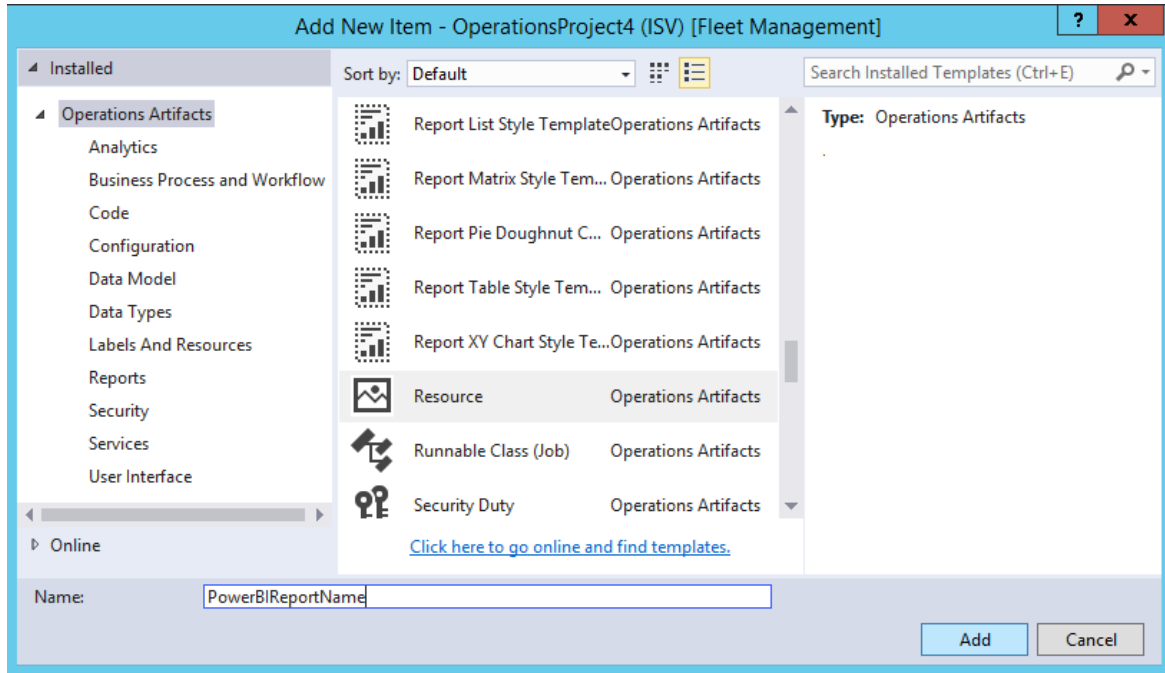

Add a .pbix file as a resource

Before you begin, you must create or obtain the Power BI report that you will embed in the workspace. For more information about how to create analytical reports, see [Getting started with Power BI Desktop](#).

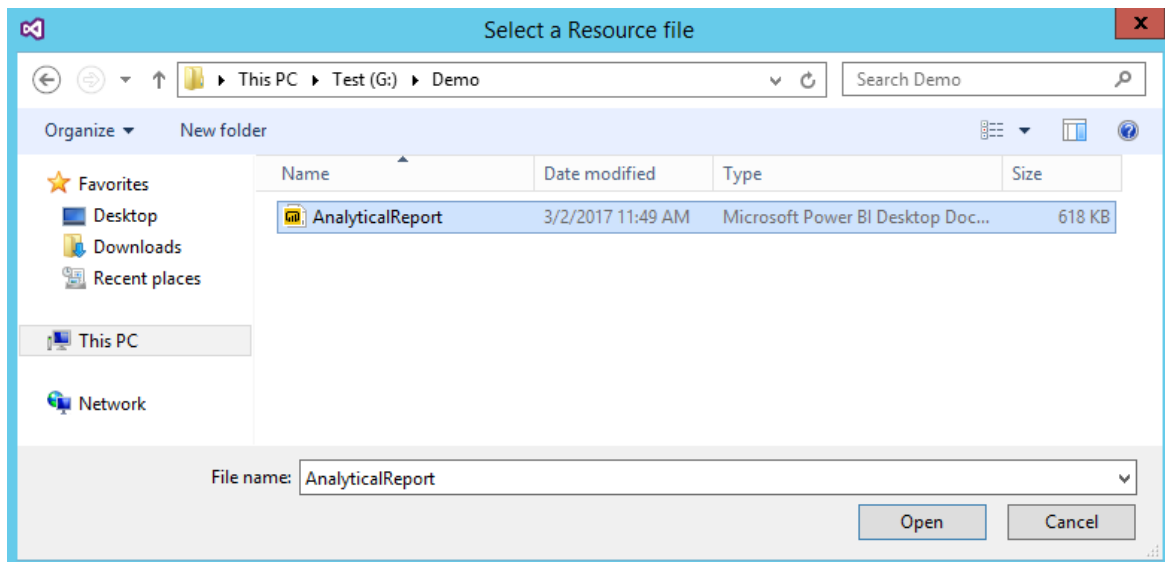

Follow these steps to add a .pbix file as a Visual Studio project artifact.

1. Create a new project in the appropriate model.
2. In Solution Explorer, select the project, right-click, and then select **Add > New Item**.
3. In the **Add New Item** dialog box, under **Operations Artifacts**, select the **Resource** template.

4. Enter a name that will be used to reference the report in X++ metadata, and then click **Add**.

5. Find the .pbix file that contains the definition of the analytical report, and then click **Open**.

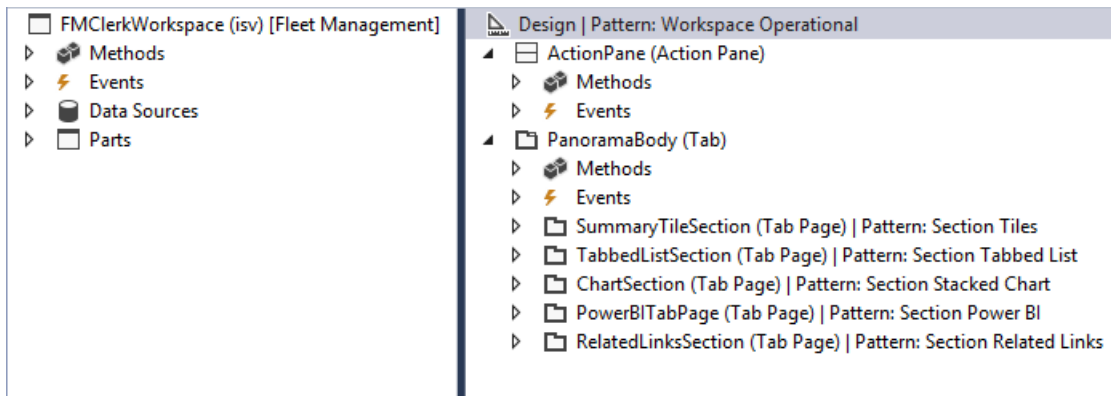

Now that you've added the .pbix file as a Dynamics 365 resource, you can embed the reports in workspaces and add direct links by using menu items.

Add a tab control to an application workspace

In this example, we will extend the **Reservation management** workspace in the Fleet Management model by adding the **Analytics** tab to the definition of the **FM ClerkWorkspace** form.

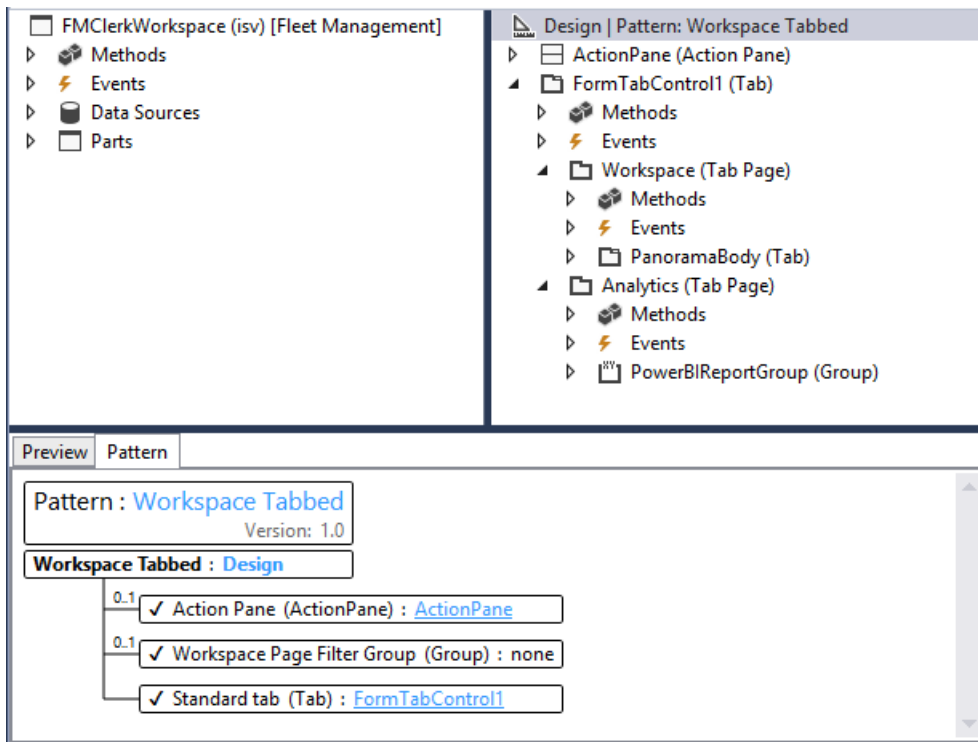

The following illustration shows what the **FM ClerkWorkspace** form looks like in the designer in Microsoft Visual Studio.

Follow these steps to extend the form definition for the **Reservation management** workspace.

1. Open the form designer to extend the design definition.
2. In the design definition, select the top element that is labeled **Design | Pattern: Workspace Operational**.
3. Right-click, and then select **New > Tab** to add a new control that is named **FormTabControl1**.
4. In the form designer, select **FormTabControl1**.
5. Right-click, and then select **New Tab Page** to add a new tab page.
6. Rename the tab page to something meaningful, such as **Workspace**.
7. In the form designer, select **FormTabControl1**.
8. Right-click, and then select **New Tab Page**.
9. Rename the tab page to something meaningful, such as **Analytics**.
10. In the form designer, select **Analytics (Tab Page)**.
11. Set the **Caption** property to **Analytics**, and set the **Auto Declaration** property to **Yes**.
12. Right-click the control, and then select **New > Group** to add a new form group control.
13. Rename the form group to something meaningful, such as **powerBIReportGroup**.
14. In the form designer, select **PanoramaBody (Tab)**, and then drag the control onto the **Workspace** tab.
15. In the design definition, select the top element that is labeled **Design | Pattern: Workspace Operational**.
16. Right-click, and then select **Remove pattern**.
17. Right-click again, and then select **Add pattern > Workspace Tabbed**.
18. Perform a build to verify your changes.

The following illustration shows what the design looks like after these changes are applied.

Now that you've added the form controls that will be used to embed the workspace report, you must define the size of the parent control so that it accommodates the layout. By default, both the **Filters Pane** page and the **Tab** page will be visible on the report. However, you can change the visibility of these controls as appropriate for the target consumer of the report.

NOTE

For embedded workspaces, we recommend that you use extensions to hide both the **Filters Pane** and **Tab** pages, for consistency.

You've now completed the task of extending the application form definition. For more information about how to use extensions to do customizations, see [Customize through extension and overlayering](#).

Add X++ business logic to embed a viewer control

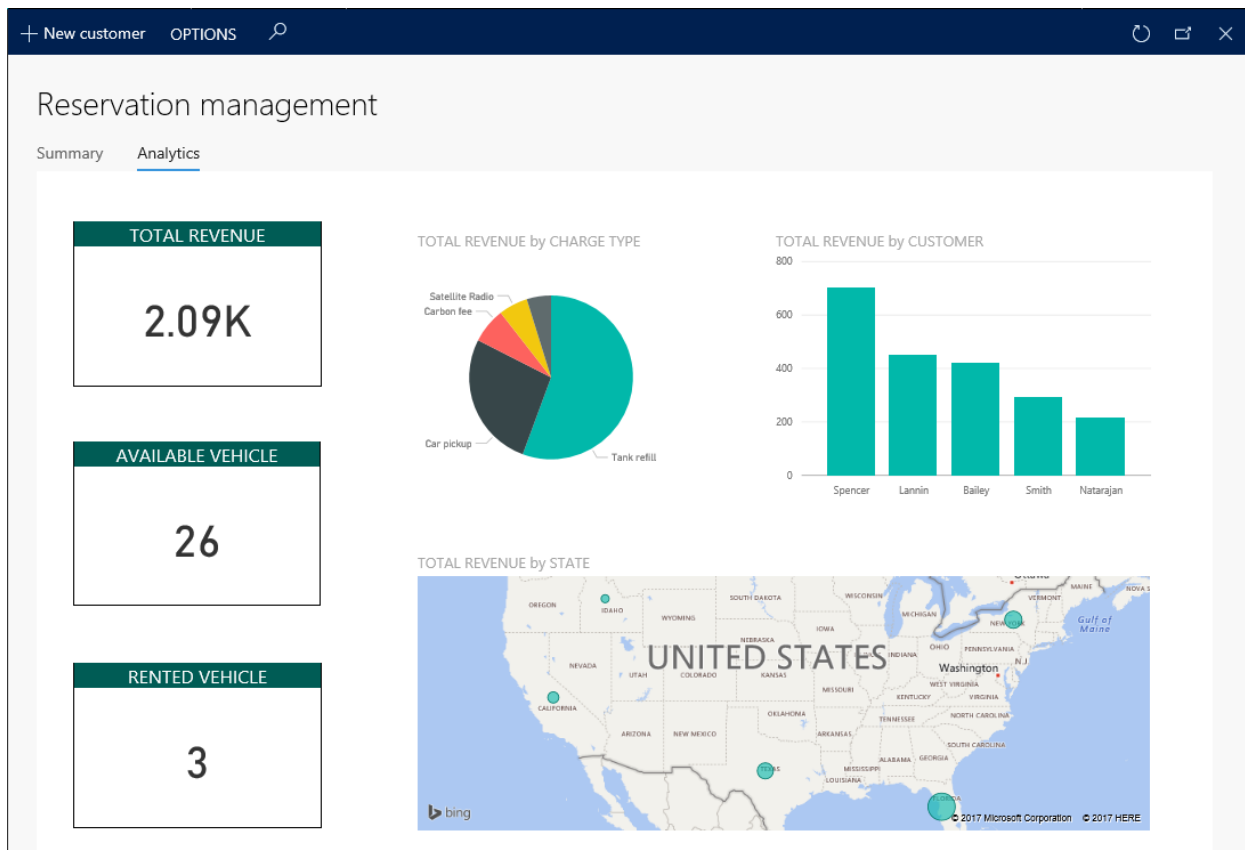

Follow these steps to add business logic that initializes the report viewer control that is embedded in the **Reservation management** workspace.

1. Open the **FM ClerkWorkspace** form designer to extend the design definition.
2. Press F7 to access the code behind the code definition.
3. Add the following X++ code.

```
[Form]
public class FMCLerkWorkspace extends FormRun
{
    private boolean initReportControl = true;
    protected void initAnalyticalReport()
    {
        if (!initReportControl)
        {
            return;
        }
        // Note: secure entry point into the Workspace's Analytics report
        if (Global::hasMenuItemAccess(menuItemDisplayStr(FMCLerkWorkspace), MenuItemType::Display))
        {
            // initialize the PBI report control using shared helper
            PBIReportHelper::initializeReportControl('FMPBIWorkspaces', powerBIReportGroup);
        }
        initReportControl = false;
    }
    /// <summary>
    /// Initializes the form.
    /// </summary>
    public void init()
    {
        super();
        this.initAnalyticalReport();
    }
}
}
```

4. Perform a build to verify your changes.

You've now completed the task of adding business logic to initialize the embedded report viewer control. The following illustration shows what the workspace looks like after these changes are applied.

NOTE

You can access the existing operational view by using the workspace tabs below the page title.

Reference

PBIReportHelper.initializeReportControl method

This section provides information about the helper class that is used to embed a Power BI report (.pbix resource) in a form group control.

Syntax

```
public static void initializeReportControl(  
    str                _resourceName,  
    FormGroupControl  _formGroupControl,  
    str                _defaultPageName = '',  
    boolean            _showFilterPane = false,  
    boolean            _showNavPane = false,  
    List               _defaultFilters = new List(Types::Class))
```

Parameters

NAME	DESCRIPTION
resourceName	The name of the .pbix resource.
formGroupControl	The form group control to apply the Power BI report control to.
defaultPageName	The default page name.
showFilterPane	A Boolean value that indicates whether the filter pane should be shown (true) or hidden (false).
showNavPane	A Boolean value that indicates whether the navigation pane should be shown (true) or hidden (false).
defaultFilters	The default filters for the Power BI report.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Help secure analytical workspaces and reports by using Power BI Embedded

2/18/2021 • 5 minutes to read • [Edit Online](#)

NOTE

This feature is supported in Microsoft Dynamics 365 for Finance and Operations, Enterprise edition (July 2017) (version 7.2) and later releases.

Introduction

This topic provides a walk-through for application developers who want to help secure analytical workspaces and reports that are delivered by using Microsoft Power BI Embedded. It describes the recommended strategies for securing access to both the reports and the data set, based on viewer access rights. By using the techniques that are described in this topic, you can hide reports from users and filter reports to show the data set that is appropriate for a specific user, based on the active company context.

Prerequisites

- Access to a developer environment that runs Platform update 8 or later
- An analytical report (.pbix file) that was created by using Microsoft Power BI Desktop, and that has a data model that is sourced from the Entity store database

Overview

Whether you're extending an existing application workspace or adding your own workspace, you can use embedded analytical views to deliver insightful and interactive views of your business data. Before you add new analytical workspaces and reports, it's important that you establish a strategy to help secure the content.

There are several considerations that you should be aware of when you develop analytical solutions by using Power BI Embedded. Analytical reports are secured by using menu items. After they have access to a report, all viewers can access the underlying data model that is defined in the report. Although service options are available that automatically hide the fields that back a report data set, all viewers of the report have effective access to the fields in the data model. Additionally, X++ extensions are available that influence the way that the report is presented in the client. Both the **Filter** pane and the **Report** tabs can be hidden. However, Microsoft Power BI filters can be modified by using client-side script injections.

Recommendation

Create scenario-specific .pbix files to deliver analytical views:

- Area overviews that are delivered by using workspaces
- Subject matter-specific analytical reports

NOTE

These analytical reports are often used to deliver reports that contain medium-business-impact and high-business-impact data.

For more information about how to create analytical reports, see [Getting started with Power BI Desktop](#). This page is a great source for insights that can help you create compelling analytical reporting solutions.

Help secure analytical views that are provided through embedded Power BI reports

Power BI report filters and the **Filter** pane serve as a mechanism for passing session context into the report that is embedded on the **Analytics** tab. The capability to turn the visibility of the **Filter** pane on and off isn't a security feature. Power BI report filters and the capability to hide and show the **Filter** pane are user experience (UX) decisions that the application designer makes.

Row-level security that is defined isn't inherited by Power BI reports. Instead, application developers can help secure the workspace or the report.

Help secure analytical workspaces on the Analytics tab

Analytical workspaces are embedded Power BI reports that are shown in a form control. Unless you complete the following procedure, anyone who has access to the workspace can see the **Analytics** tab and access the Power BI reports.

1. Add a menu item for the analytical workspace.
2. Verify that the form initialization uses the **hasMenuItemAccess** application programming interface (API) to verify that the user has access to the menu item.

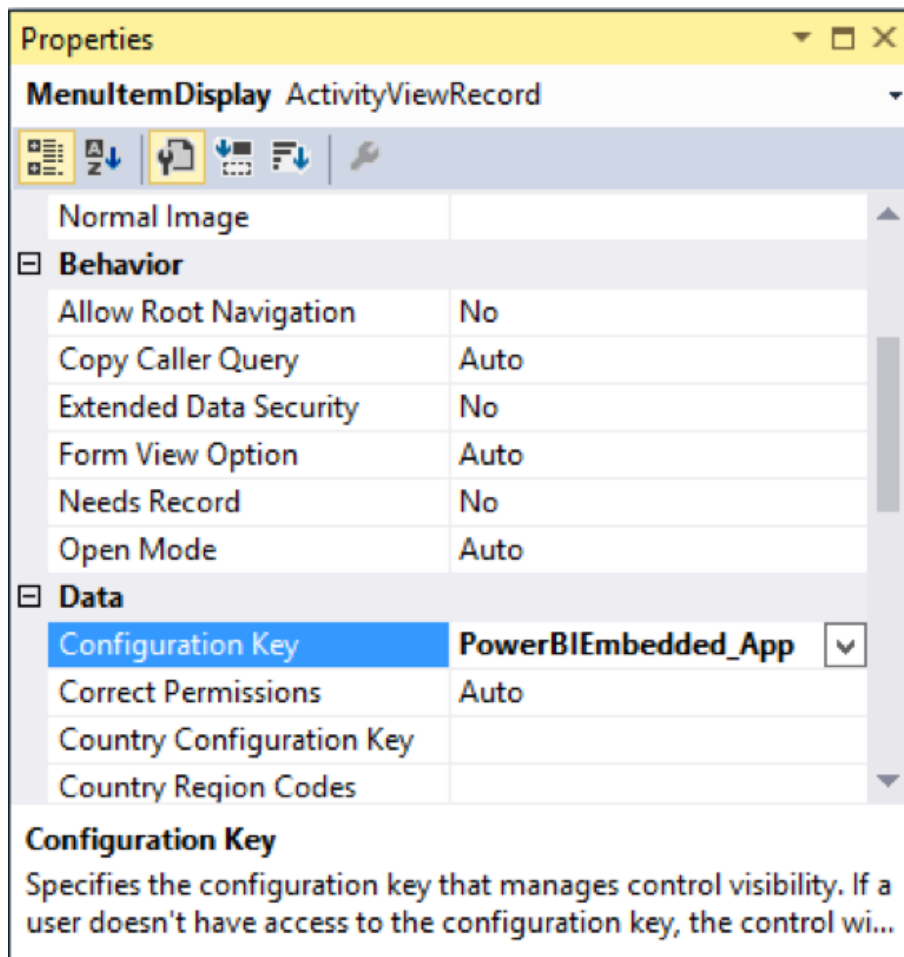

```
// Note: secure entry point into the Workspace's Analytics report
if (Global::hasMenuItemAccess(menuItemDisplayStr(FMClerkWorkspace), MenuItemType::Display))
{
    FMPBIWorkspaceController controller = new FMPBIWorkspaceController();
    PBIReportHelper::initializeReportControl('FMPBIWorkspaces', powerBIReportGroup);
}
```

The preceding logic will prevent the Power BI Viewer control from being initialized. Therefore, an empty tab will appear on the page. By default, the framework automatically hides empty tabs. Therefore, the **Analytics** tab is hidden and can't be access if the user doesn't have access to the menu item that is associated with the analytical workspace.

Help secure analytical reports

Embedded Power BI reports in the application are secured by using menu items. Users who try to access a Power BI report directly, by using a menu item in application, will receive an error. Follow these steps to help secure the analytical reports.

1. Add a menu item for the report or the appropriate tab. By default, the first tab of the report will be shown if no other tab is selected.
2. Link the menu item to the **PowerBIEmbedded_App** configuration key.

The menu item is now associated with the availability of the Power BI Embedded service. If the service is unavailable, the links for the menu items will be removed from the application.

Help secure analytical workspaces and reports by company

Power BI workspaces and reports can be secured by company (for example, `DataAreaID` value). Application solutions must apply the following steps for company-level security in analytical workspaces and reports.

In this scenario, the workspaces and reports that the sales manager from Contoso USA sees are limited to data that is related to Contoso USA. The report viewer must not have access to data that associated with any other company, unless the company context is changed.

1. Open the analytical report in Power BI Desktop by double-clicking the resource in a Microsoft Visual Studio project.
2. On the **Modeling** tab, click **Manage Roles**.
3. Create a new role against a column in the data model that contains the **Company** field. Name the new role **CompanyFilter**. A **COMPANY** field must be present in the data model to restrict access by company.

Roles

Tables

4. In the **Table filter DAX expression** field, enter `[COMPANY]=username()`.
5. To make sure that the rules work, on the **Modeling** tab, click **View as Roles**. In the dialog box, set the following fields:
 - a. Clear the **None** check box.
 - b. Select the **Other user** check box, and then enter **USMF** in the text box.
 - c. Select the **CompanyFilter** check box.

The reports will now show data as if you're running the USMF company.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Create reporting solutions

2/18/2021 • 10 minutes to read • [Edit Online](#)

This tutorial shows how to export data and create a report, expand predefined views and add navigation to charts, use the free-form report designer, and customize the parameter experience.

Prerequisites

For this tutorial, you must access the application environment, and you must be provisioned as an administrator on the instance.

Key concepts

- Describe the various ways reports can be created and consumed
- Add interactivity to embedded aggregate reports in forms and workspaces
- Use framework extensions to customize the parameter experience for SSRS based business documents
- Export List Page data to create reports with external tools including Microsoft Excel
- Author modern report designs using enhanced developer tooling in Visual Studio

What's new in Reporting?

- Embedded report drill-through navigations to AX forms and reports
- Navigate between reports using embedded report drill-through links
- Several Document Routing Service enhancements including support for custom print settings
- Introduced Document Brand Management administrative tools
- Additional visualizations available through the Embedded Charting Control
- Dates and Amounts in the report body are formatted based on the "Date, time, and number format" user setting
- Network Print monitoring form
- Table extensions need to be supported through the VS Query picker

What is a report in Dynamics 365 Finance and Operations apps?

Reports can be defined simply as any visualization of a structured data set. This may include transactional data presented in a tabular layout and advanced graphical views of aggregate information. To account for this broad definition, the application offers several tools to produce reports to satisfy complex business requirements. Some common applications of reports in an ERP include:

- Creating and archiving transactional documents as part of a posting process
- Producing packing slips for tracking orders from Manufacturing to Warehousing to Sales
- Monitoring key performance metrics and surfacing trends in data
- Navigating the client through filtered searches
- Distributing heavily branded documents to customers and employees
- Extracting data in such a way that it articulates the health of a business

The most difficult task for developers is selecting the *right* Business Intelligence visualization tool for the job, given a customer's requirements. To accomplish this, it's important to understand the capabilities offered through the tools that are available for creating reports. We offer tooling to support the following basic

reporting requirements:

- **Excel Integration** – Allows data management and analysis using Microsoft Excel
- **Embedded Analytics** – Add aggregate data to a Workspaces using native controls like charts and grids
- **Reporting Services** – Create business documents that require precision using SSRS-based solutions
- **Power BI Integration** – Author and share reports that can be accessed anywhere
- **Management Reporter** – Designed to help users create financial reports

The following table can be used to compare the basic characteristics of these reporting tools:

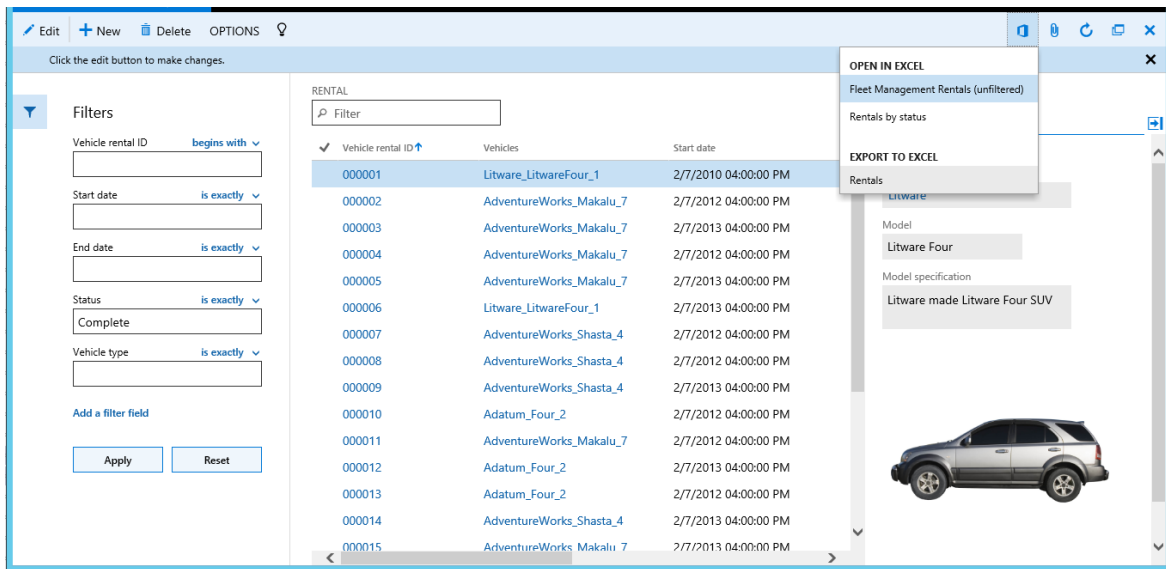

TOOL	AUTHOR	TARGET	DATA	CONSUMPTION	DESIGNER
Excel	Power User	Power User	Transactional	External	Free form
Embedded BI	Developer	All users	Aggregates	Internal	Modeled
SSRS Report	Developer	All users	Transactional and Aggregates	Internal/External	Free form
Power BI	Power User	All users	Aggregates	Internal/External	Free form
Management Reporter	Power User	Power User	Transactional	External	Modeled

Create a report using List Pages

In this section, we'll walk you through the process of exporting data displayed in an entity details form. Here we'll demonstrate how every form in can be viewed as a source of data for management and analysis using the power of Excel.

Create an analysis report based on all rentals in Fleet Management that are marked as complete

1. Open Internet Explorer, and navigate to your instance base URL and sign in.
 - a. On the cloud environment, the base URL is obtained from LCS
 - b. On a local VM, the base URL is `https://usnconeboxax1aos.cloud.onebox.dynamics.com`.
2. On the Dashboard, scroll to the far right, and click the **Reservation management** tile.
3. Under the **Summary** section, click on the **All rentals** tile.
4. Expand the **Filters** pane by clicking on the Filters icon next to the main grid.
5. Click **Add a filter field**, and then select **Status** in the drop-down list.
6. Enter **Complete** in the Status filter field, and then click **Apply**.
7. Expand the page action bar, click **Open in Office**, and then select **Rentals**.

After the data has been exported, you can use the power and flexibility of the Excel tools to create reports for presentation or additional analysis. The following is an example of a self-service report authored with Excel.

8. Close the browser session and the exported Excel file.

Advantages of List Pages

- Flexible source for accessing transactional business data using external reporting and analytical tools like Excel
- Allows end-users to model the data sets they need without requiring a developer
- Direct access to real-time business information

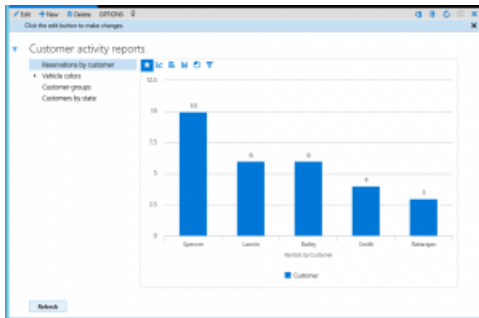

Expand predefined views and add navigation to charts

Business Intelligence can be useful at every level of an organization. Use embedded controls to elevate the most

relevant information based on the target persona. Native controls offer users an intuitive and convenient way of interacting with aggregate data allowing for informed decision making.

Create development project

1. On the Desktop, right-click the **Visual Studio** shortcut, and select **Run as administrator** to open the development environment.
2. On the toolbar, click **View**, and then select **Application Explorer**
3. Use the **Application Explorer** to search for the **FMReservationsReport** form in the **Fleet Management** module.
4. In the **Application Explorer's** search results, right-click **FMReservationsReport** form, and then select **Add to new project**.
5. Select the **Finance and Operations Project** template, and then click **OK** to create the project.
6. In **Solution Explorer**, right-click **FMReservationsReport** menu item, and then select **Set as startup object**.
7. Press **Ctrl+Shift+B** to save and build the project.
8. Press **Ctrl+F5** to load the form containing the report.

At this point, you have a collection of pre-defined chart visualizations of Aggregate data. The controls offer basic interactive features like hover text, series filtering, and touch expansion. However, it is often appropriate that a greater degree of user interactivity is required.

Change the default chart type for the visualization

1. Close the browser session and return to the Visual Studio project.
2. Open the **Application Explorer**, locate the **FMReservationsByCustPart** form, right-click, and then select **Add to project**.
3. Open the **FMReservationsByCustPart** form designer.
4. Access the **Series** collection in the **ReservationsByCust** chart definition.
5. Select the **SysBuildChatMeasure1** series definition
6. Locate the **Appearance** section in the **Properties** window.
7. Update the **Chart type** value and select **Pie**
8. Press **Ctrl+Shift+B** to save and rebuild the project.
9. Press **Ctrl+F5** to run the report.

The **Reservations by customer** view now visualizes the aggregate data set using a Pie chart to simplify the task of comparing rental activity across customers.

Additional functions include:

- Define contextual drill-through navigations using modeled properties
- Manage drill-through links using X++ form logic

Advantages of embedded aggregate visualizations

- Designed to be simple and intuitive to promote informed decisions at every level of the organization
- Pre-defined views tailored to meet the needs of the consumer
- Augments the user's ability to recognize key performance trends in the data

Using the freeform report designer

SSRS continues to be the platform for producing advanced Business Document solutions for your ERP application. The hosted service is designed for high volume and heavily transactional reports with an integrated parameter experience. Backed by the Document Printing & Distribution Services, these solutions are ideal for producing precision documents which are intended for email, printing, archive, and bulk distribution.

Open the Precision Designer

1. Close the browser session and return to the Visual Studio project.
2. Click **File > Close Solution**, to close the active project.
3. Use the **Application Explorer** to search for objects with **FMRentalsByCust** in the name
4. In the **Application Explorer's** search results, select all **Classes**, the **Output Menu Item**, and the **FMRentalsByCustomer** report
5. Right-click and then select **Add to new project**.
6. Select the **Dynamics 365** template, and then click **OK** to create the project.
7. In **Solution Explorer**, double-click on the **FMRentalsByCustomer** report to open the designer.
8. Expand the **Designs** collection in the designer to view the list of design definitions
9. Double-click on the **Report** design to view the report definition using the Precision Designer

The above is a screen-shot of the FMRentalsByCustomer report design definition as viewed using the Visual Studio Precision Designer. The Precision Designer offers a free-form design surface with built-in tools that allow you to customize the content and layout of the report. You can also take advantage of embedded VB code to create run-time design manipulations and support user interactions. As an integrated tool, developers are able to reference AX labels and public APIs to format data in the report body based on AX EDTs. MSDN offers a rich collection of developer documentation related to SSRS formatting capabilities. See the article [Reporting Services Reports \(SSRS\)](#) on for a good primer on designing effective SSRS reports.

Customizing the parameter experience

The Reporting Framework offers flexibility through service extensions to facilitate advanced solutions with requirements that cannot be addressed using a modeled solution. Use the VS designer to add basic parameter formatting, grouping, and input validation. X++ based data contract validation is available for more advanced scenarios. Consider adding User Interface (UI) Builder Classes to customize the parameter pane used to prompt for session inputs before running a report. These custom extensions are effective for addressing the following functions:

- Overriding dialog field events
- Validating report parameters inline
- Adding customized lookups to dialog fields
- Changing the layout of the dialog controls
- Adding custom controls including images

Defining parameters defaulting using code

1. In **Solution Explorer**, double-click on the **FMRentalsByCustUIBuilder** class to open the designer.
2. Locate the class **build** method and update the initialization code as follows

```

public void build()
{
    Dialog dialogLocal = this.dialog();
    contract = this.dataContractObject() as FMRentalsByCustContract;// associate dialog field with
data contract method
    this.addDialogField(methodStr(FMRentalsByCustContract, parmCustGroupId),
contract);dialogLocal.addGroup("@SYS41297");
    fromDateField = this.addDialogField(methodStr(FMRentalsByCustContract, parmFromDate), contract);
    toDateField = this.addDialogField(methodStr(FMRentalsByCustContract, parmToDate), contract);//
set the default date range values
    fromDateField.value(today() - 365);
    toDateField.value(today());
}

```

3. Press Ctrl+Shift+B to save and rebuild the project.

4. Press Ctrl+F5 to run the report.

The parameter initialization code above sets the default values of the report execution relative to today's date. Use the classes `UIBuilder` to override the framework's default handling of report parameters. Additional extension scenarios supported:

- Automatically set query ranges based on session context using `Controller` classes
- Select report designs at runtime using a shared menu item
- Modify report data contract values using business logic

NOTE

This example demonstrates a `UIBuilder` extension with an RDP-based based report. For a Query based example that includes a `UIBuilder` extension, view the `FMCustomerList` report.

Using VB code to manage running balances

The Reporting Framework offers flexibility through service extensions to facilitate advanced solutions with requirements that cannot be addressed using a modeled solution. Use the VS designer to add basic parameter formatting, grouping, and input validation. X++ based data contract validation is available for more advanced

scenarios. Consider adding User Interface (UI) Builder Classes to customize the parameter pane used to prompt for session inputs before running a report. These custom extensions are effective for addressing the following functions:

- Overriding dialog field events
- Validating report parameters inline
- Adding customized lookups to dialog fields
- Changing the layout of the dialog controls
- Adding custom controls including images

Import the section resources

1. Close the browser session and return to the Visual Studio project.
2. On the toolbar, click **DYNAMICS AX**, and then select **Import Project...**
3. In the File name window, browse to C:\FmLab\Lab10-3, select **FMrentalDetailsReport.axpp**, and then click **Open**.
4. In the Project file location text box, enter C:\FmLab\Lab10-3.
5. Select the **Current solution** radio button.
6. Click **OK** to close. Wait for the project to be imported and opened.
7. In the **Solution Explorer**, select the new project, right-click, and then select **Set as startup project**.
8. In the **Solution Explorer**, right-click **FMrentalDetails** menu item, and then select **Set as startup object**.
9. Select the Project in Solution Explorer, right-click, and then select **Deploy Reports**
10. Press **Ctrl+F5** to view the report.

Rental Details

Previous: \$1,575.00

Tony Smith

Counter	RentalID	Type	Description	Amount	Running balance
1	000005	Car pickup	2014 Adventure Works Makalu	\$35.00	\$1,610.00
2	000005	Child Seat	2014 Adventure Works Makalu	\$10.00	\$1,620.00
3	000005	Tank refill	2014 Adventure Works Makalu	\$40.00	\$1,660.00
4	000005	Carbon fee	2014 Adventure Works Makalu	\$5.00	\$1,665.00
5	000012	Tank refill	2014 Adatum Four	\$40.00	\$1,705.00
6	000012	Carbon fee	2014 Adatum Four	\$5.00	\$1,710.00
7	000026	Carbon fee	2014 Litware Four	\$5.00	\$1,715.00
8	000026	Tank refill	2014 Litware Four	\$40.00	\$1,755.00
9	000028	Car pickup	2014 Litware Four	\$35.00	\$1,790.00
10	000026	Car pickup	2014 Litware Four	\$35.00	\$1,825.00
11	000028	Carbon fee	2014 Litware Four	\$5.00	\$1,830.00
12	000028	Tank refill	2014 Litware Four	\$40.00	\$1,870.00

Total: \$295.00
Previous: \$1,575.00
Grand total: \$1,870.00

This report uses embedded VB script to keep track of running totals so that the balances from the previous page can be referenced on the active page. To inspect report's VB code, load the report design in the Precision Designer, access the **Report Properties**, and then select the **Code** section. Here you'll see several functions referenced by the report designs to surface running balances within the report headers and footers.

Advantages of SSRS reports

- Built-in back office document management capabilities including email support, scheduled executions via Batch, and Print Archive
- Parameterized views with drill-through navigations to forms and other reports
- Used to produce precision documents for compliance with local regulatory business practices

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Customize App Suite reports by using extensions

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic discusses a series of scenarios for customizing App Suite reports.

Finance and Operations offers an expanded set of tools to support custom solutions. Customizations to reporting solutions in the standard application are fully supported using a pure extension model. This topic contains guidance about how to add the most common customizations to standard application reports without overlayering Application Suite artifacts. Here are some of the key benefits of using an extension-based approach when customizing the application:

- It reduces the footprint of your application solutions by minimizing code duplication.
- Custom reports benefit from enhancements made to standard solutions including updates to business logic in Report Data Provider (RDP), data contracts, and UI Builder classes.
- Standard application solutions are unaffected and continue to be available in concert with custom reports.

Report extensions do not break or prevent access to standard application reports. Instead, the platform supports run-time selection of the target report allowing you to choose the appropriate report design based on the context of the user session. For more information about customizations using extensions, see [Customize through extension and overlayering](#)

Scenarios

There are four key scenarios which demonstrate the flexibility available. The first two scenarios involve extending existing RDP classes for custom reporting solutions.

- [Expand Application Suite report data sets](#) – Use table extensions and integrate custom business logic to add custom columns to an existing dataset.
- [Composing custom datasets](#) – Add more data to application reports by extending an existing RDP class to return a custom dataset.

The other two scenarios offer insights on how to use extensions to redirect application navigations to your custom solutions.

- [Extend report menu items to redirect user navigation](#) – Customize application menu items to redirect references to a custom report design.
- [Create custom designs for business documents](#) – Delegate handlers allow you to add custom report designs to an existing Print Management document instance.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Expand Application Suite report data sets

2/18/2021 • 5 minutes to read • [Edit Online](#)

This topic shows how to expand an existing report data set that is produced by using X++ business logic in a report data provider (RDP) class.

This topic focuses on the expansion of an existing report data set that is produced by using X++ business logic in a report data provider (RDP) class. You use custom delegate handlers and table extensions to include additional field data and/or calculations. You don't have to over-layer the Application Suite. You then create custom designs that replace the standard application solutions and present the data to users. The following illustration shows a typical application customization, as described in this topic.

What's important to know?

There are a few basic assumptions that you should be aware of before you apply this solution.

- **You can't directly extend RDP classes.** However, the platform provides extension points that enable data set expansion without duplicating business logic in the standard application.
- **There are two methods that can be used to expand report data sets.** Use the strategy that is appropriate for your solution:
 - **Data processing post-handler** – This method is called only one time, after the **ProcessReport** method is completed and before the data set is returned to the report server. Register for this post-handler to perform bulk updates on the temporary data set that is produced by the standard application solution.
 - **Temp table inserting event** – This method is called for each row that is added to the temporary table. It's more suitable for calculations and inline evaluations. Try to avoid expensive queries that have many joins and look-up operations.
- **Use event handlers to redirect menu items to your new report design.** You can customize all aspects of an application reporting solution by using event handlers. Add a **PostHandler** event for the controller class to reroute user navigations to a custom report design.

Expand a report data set

The following walkthrough shows the process of expanding an existing application data set by using a "pure" extension-based solution. The solution includes a custom **Rentals list** report for the Fleet Management application. The new report includes additional rental charge data in the rental details. The application customizations are defined in an extension model. The following illustrations show the standard design and the custom solution.

Before (standard design)

The screenshot shows the 'Rentals By Customer' report for Phil Spencer. It displays two rental records. The first record is for a 2014 Litware Four (Red, Standard fuel) with a total charge of \$480.00. The second record is for a 2012 Adventure Works Shasta (Gray). The report includes a table of charges for the first rental, such as Carbon fee, Tank refill, and Car pickup.

Date	Rental charge type	Extended amount
12/24/2010	Carbon fee	\$5.00
12/24/2010	Tank refill	\$40.00
	Car pickup	\$35.00

After (custom solution)

The screenshot shows the custom 'Rentals By Customer (CUSTOM)' report for Phil Spencer. It displays the same two rental records as the standard version. The first record is for a 2014 Litware Four (Red, Standard fuel) with a total charge of \$480.00. The second record is for a 2012 Adventure Works Shasta (Gray). The report includes a table of charges for the first rental, with a custom charge type 'We refill the gas tank' highlighted by a red arrow.

Date	Rental charge type	Extended amount
12/24/2010	Carbon fee	\$5.00
	Help offset carbon emissions.	
12/24/2010	Tank refill	\$40.00
	We refill the gas tank.	
	Car pickup	\$35.00
	We arrange pickup from another location.	

1. Create a new model for your application customizations. For more information about extension models, see [Customize through extension and overlaying](#). For this example, add a custom report to the

Fleet Management Extensions model.

2. Create a new project in Microsoft Visual Studio. Make sure that the project is associated with your extension model. The following illustration shows the project settings.

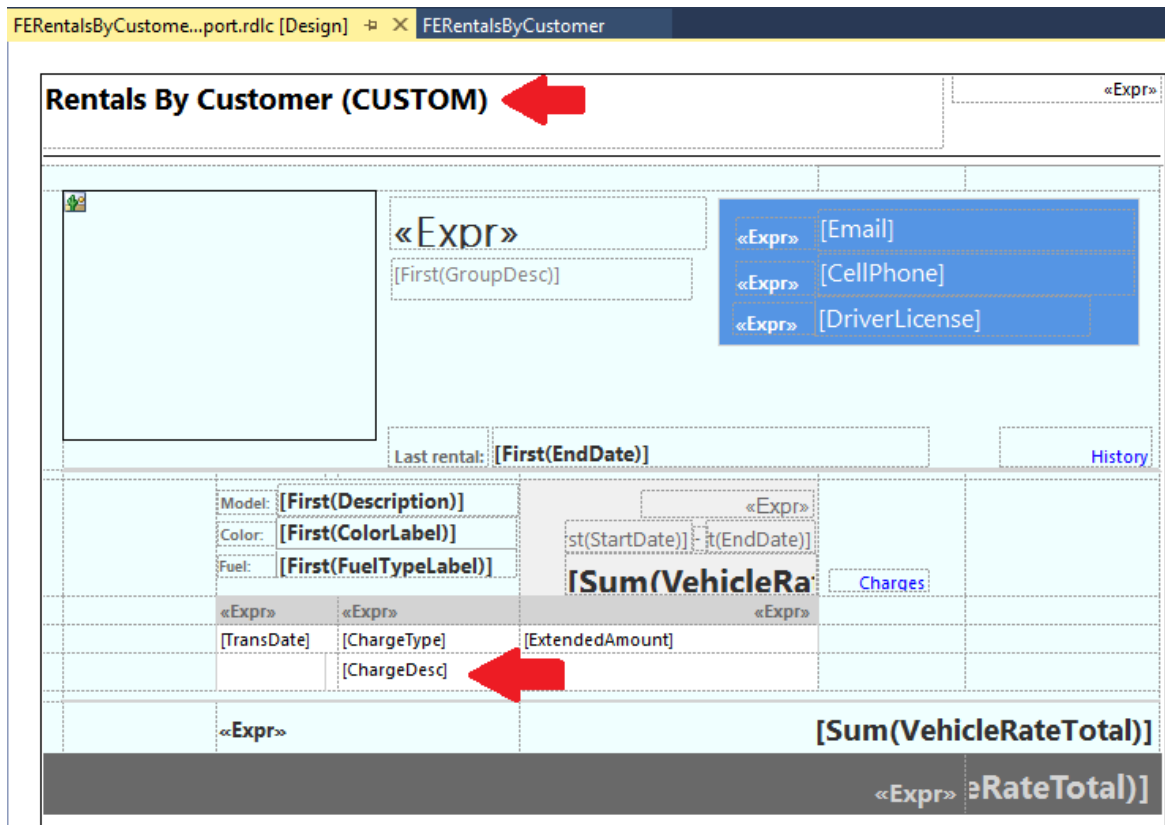

3. Add a table extension to store the custom report data. Find the temporary cache for the TmpFMRentalsByCust data set that is populated by the RDP class, and create an extension in your model. Define the fields that will be used to store the data for the report server, and then click **Save** to save your changes. The following illustration shows the table extension that is required for this example.

4. Add your custom report to the project. The custom design closely resembles the standard solution. Therefore, you can just duplicate the existing application report in the **Fleet Management Extension** model, and then update the report design so that it includes the custom title and additional text box in the Rental Charges container.
5. Rename the report so that it has a meaningful name. For this example, rename the custom report

FERentalsByCustomer to distinguish it from the standard solution.

6. **Restore the report data set references.** Open the report designer, expand the **Datasets** collection, right-click the data set that is named **FMRentalsByCustDS**, and then click **Restore**. The data set is expanded so that it includes the newly introduced columns. Therefore, these columns are now available in the report designer.
7. **Customize the report design.** The designer offers a free-form design surface that you can use to create the custom solution. The following illustration shows the custom design that is used for this example.

8. **Add a new report handler (X++) class to the project.** Give the class a name that appropriately describes that it's a handler for an existing application report. For this example, rename the class **FERentalsByCustomerHandler** to distinguish it from other report handlers.
9. **Add a PostHandler method to begin to use your custom report.** In this example, extend the controller class in the standard solution, **FMRentalsByCustController**, by using the following code.

```
class FERentalsByCustomerHandler
{
    [PostHandlerFor(classStr(FMRentalsByCustController), staticMethodStr(FMRentalsByCustController,
construct))]
    public static void ReportNamePostHandler(XppPrePostArgs arguments)
    {
        FMRentalsByCustController controller = arguments.getReturnValue();
        controller.parmReportName(ssrsreportstr(FERentalsByCustomer, Report));
    }
}
```

User navigations in the application will now be rerouted to the custom reporting solution. Take some time to deploy the custom report to the report server and verify that the application is using it. At this point, you just have to add the business logic that is used to populate the custom fields that you introduced in step 3. In the next step, you must select the method of data set expansion that is appropriate for your solution.

10. **Add X++ business logic to populate the custom field data.** Select the data processing technique that makes sense for the type of transformation that you require for the solution.

- **Option 1: Add a data processing post-handler.** Apply this technique for bulk insert operations that use a single pass over the result set of the standard solution. Here is the code that expands the data set by using a table lookup.

```
class FERentalsByCustomerHandler
{
    [PostHandlerFor(classStr(FMRentalsByCustDP), methodstr(FMRentalsByCustDP, processReport))]
    public static void TmpTablePostHandler(XppPrePostArgs arguments)
    {
        FMRentalsByCustDP dpInstance = arguments.getThis() as FMRentalsByCustDP;
        TmpFMRentalsByCust tmpTable = dpInstance.getTmpFMRentalsByCust();
        FMRentalCharge chargeTable;
        ttsbegin;
        while select forUpdate tmpTable
        {
            select * from chargeTable where chargeTable.RentalId == tmpTable.RentalId;
            tmpTable.ChargeDesc = chargeTable.Description;
            tmpTable.update();
        }
        ttscommit;
    }
}
```

- **Option 2: Add a temp table Inserting event.** Apply this technique for row-by-row calculations. Here is the code that expands the data set by using a table lookup.

```
class FERentalsByCustomerHandler
{
    [DataEventHandlerAttribute(tableStr(TmpFMRentalsByCust), DataEventType::Inserting)]
    public static void TmpFMRentalsByCustInsertEvent(Common c, DataEventArgs e)
    {
        TmpFMRentalsByCust tempTable = c;
        FMRentalCharge chargeTable;
        // update the value of the 'ChargeDesc' column during 'insert' operation
        select * from chargeTable where chargeTable.RentalId == tempTable.RentalId
        && chargeTable.ChargeType == tempTable.ChargeType;
        tempTable.ChargeDesc = chargeTable.Description;
    }
}
```

You've now finished expanding the report data set. After the application is compiled, it will begin to reroute user navigations to the new report design by using the custom X++ business logic that you defined in the report class handler that is defined in the extension model.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Extend report menu items to redirect user navigation

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic shows how to extend existing application menu items so that, after only minimal code changes, navigations are redirected to a custom reporting solution.

This topic focuses on the process of extending existing application menu items so that, after only minimal code changes, navigations are redirected to a custom reporting solution. By using this technique, you will avoid the inconvenience of tracking down and replacing all references to an existing application report. Just extend an existing application menu item to redirect application navigations to reports that are defined in an extension model. The following illustration shows a typical application customization.

What's important to know?

There are a few basic assumptions that you should be aware of before you apply this solution.

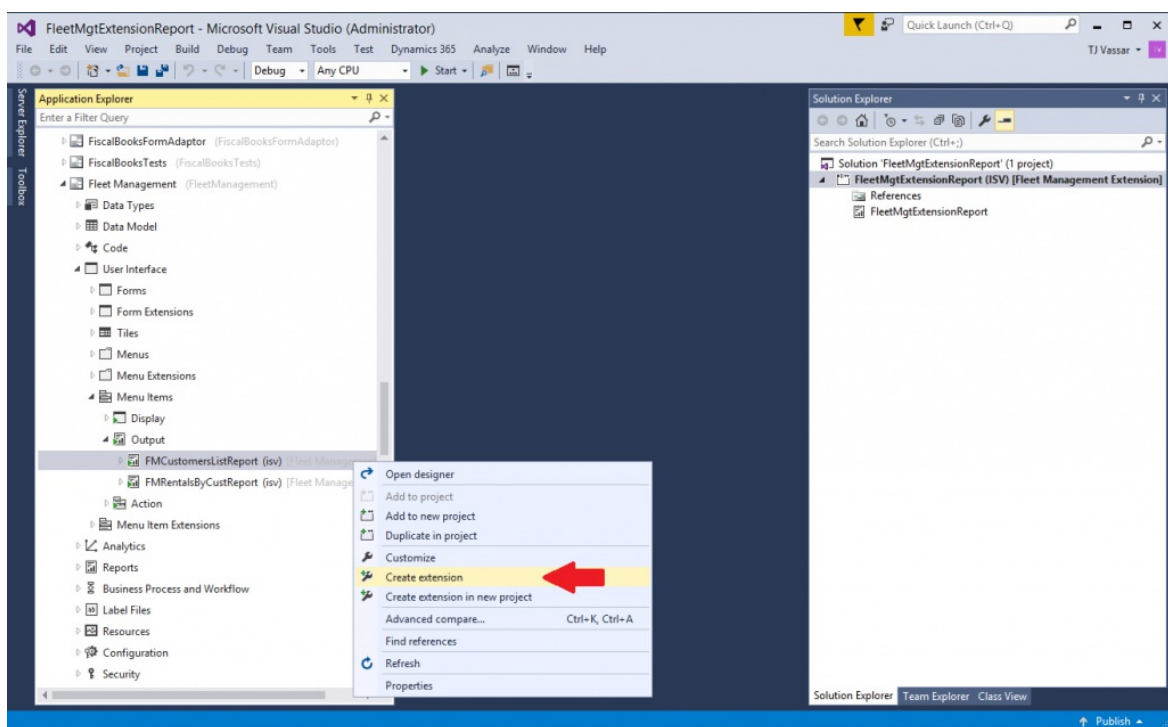

- Extended menu items let you override both the display string and the target.
- This technique can be used for all types of reports, from simple query-based reports to complex report data provider (RDP)-based reports.
- Extended menu items are available for direct references to reports and solutions that orchestrate the reporting session by using a controller class.

Extend report menu items

The following walkthrough shows how to use menu item extensions to redirect user navigations in the application to a custom solution. The solution includes a custom **Customer list** report for the Fleet Management application and defines all the application customizations in a pure extension model. The following illustration shows the menu item that you use to access the custom **Customer list** report.

1. Create a new model for your application customizations. For more information about extension models, see [Customize through extension and overlaying](#).
2. Create a new project in Microsoft Visual Studio, and add your custom report. Additionally, add all the solution artifacts. These artifacts include the RDP class or source query, the controller class, and UI builders, if they are present.
3. Create an extension of the menu item that is used to access the report. In this example, the output menu item is named `FMCustomerListReport`. Use the menu item structure to find the menu item name that is exposed in the application. The following illustration shows the action in Application Explorer.

4. Modify the properties of the menu item extension. Update the report design or controller reference in the menu item to direct navigations to your custom solution.

NOTE

The property changes that you can make on the object depend on the original application solution. If the application report manages the solution by using a controller, a controller class is required for the report.

5. Rebuild the solution, and deploy the custom report.

You've now finished extending the report menu item. Navigations to the standard menu item will now be redirected to your custom reporting solution.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

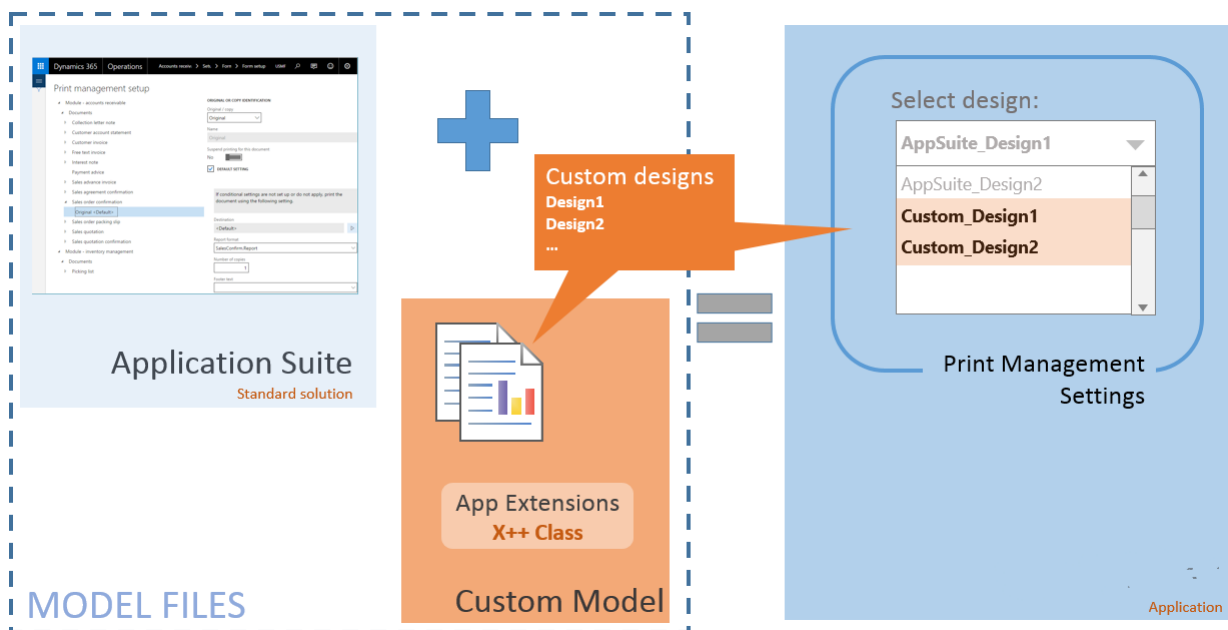

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Create custom designs for business documents

2/18/2021 • 4 minutes to read • [Edit Online](#)

This topic shows how to create a custom report design for an existing application business document by using a pure extension model.

Microsoft Dynamics 365 Finance includes an expanded set of tools to support custom solutions. This topic focuses on the steps for creating a custom report design for an existing application business document by using a pure extension model. Follow the steps later in this topic to associate a custom report design with an instance of an application document. When you've finished, users can configure Print management settings to select the custom design whenever it's appropriate, based on transaction details. The following illustration shows a typical application customization.

What's important to know?

Here are some important points that you should be aware of before you apply this solution:

- Print management settings are scoped to the active legal entity. Custom designs can be associated with one or more Print management settings.
- Standard report designs continue to be available alongside custom solutions. Use Print management settings to select the appropriate design, based on transaction details.
- If you introduce a business document for a custom business process, more work is required. For more information about how to create a custom business document solution, see the [Print Management Integration Guide](#).

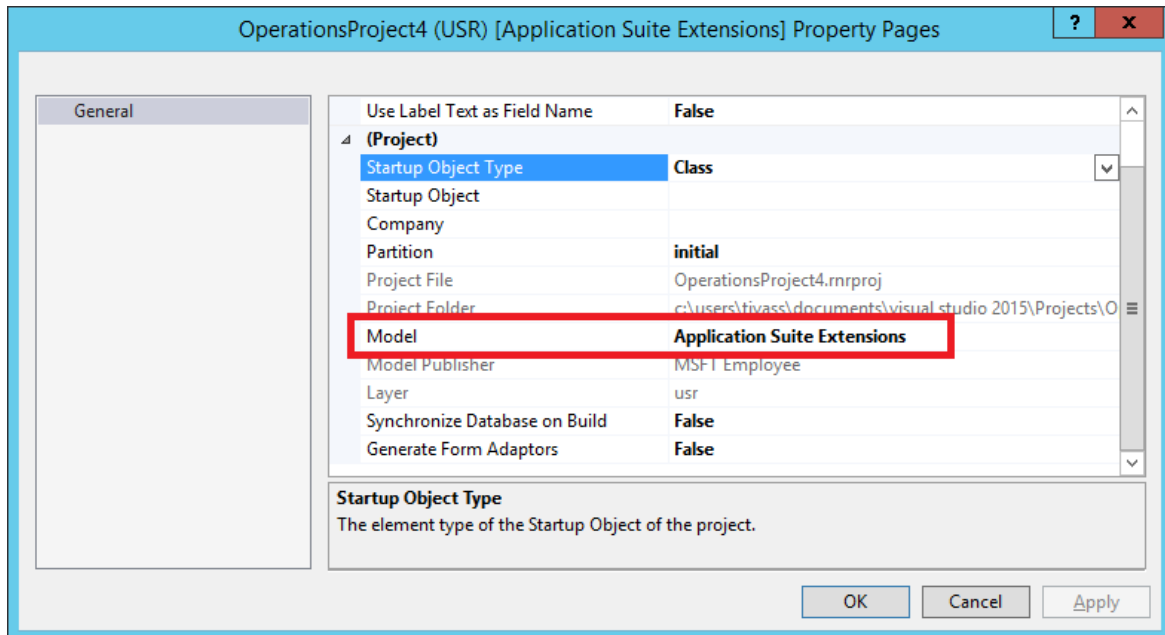

Customize a business document

The following walkthrough shows the process of introducing a custom report design for an existing application business document and then using Print management to select the new design. The solution includes a custom design definition for the **Sales confirmation** report that is provided in the standard application as part of the Application Suite model. The application customizations will be defined in an extension model.

1. **Create a new model for your application customizations.** For more information about extension

models, see [Customize through extension and overlaying](#). For this example, you add a model that is named **Application Suite Extensions**, and that references the Application Suite, Application Platform, and Application Foundation packages.

2. **Create a new project in Microsoft Visual Studio.** Make sure that the project is associated with your extension model. The following illustration shows the project settings.

3. **Create a custom report design for the business document.** You must make sure that your custom solution consumes the correct report data contract. Find the existing Application Suite report in Application Explorer. This report is named **SalesConfirm**. Right-click it, and then click **Duplicate in project** to create the custom solution.
4. **Rename the report so that it has a meaningful name.** For this example, name the custom report **SalesConfirmExt** to distinguish it from the standard solution. Compile the project, and deploy the report to verify that the changes have no errors.
5. **Use the free-form designer to customize the report design.** Select the report design that is named **Report**, right-click it, and open the precision designer. Customize the design to satisfy the organization's business requirements. The following illustration shows a custom design definition for the **Sales confirmation** report.

6. Add a new X++ class that extends the standard report controller. Give the class a name that appropriately describes that it's a handler for an existing application report. For this example, rename the class `SalesConfirmControllerExt` to distinguish it from other report controllers.
7. Use the extended class to load the custom design. Add a `main` method that refers to the custom report design. (You can just copy the `main` method from the standard solution and add references to the new `Controller` class.) Here is the code that extends the standard solution.

```

class SalesConfirmControllerExt extends SalesConfirmController
{
    public static SalesConfirmControllerExt construct()
    {
        return new SalesConfirmControllerExt();
    }
    public static void main(Args _args)
    {
        SrsReportRunController formLetterController = SalesConfirmControllerExt::construct();
        SalesConfirmControllerExt controller = formLetterController; controller.initArgs(_args,
        srsReportStr(SalesConfirmExt, Report));
        if (classIdGet(_args.caller()) == classNum(SalesConfirmJournalPrint))
        {
            formLetterController.renderingCompleted +=
            eventhandler(SalesConfirmJournalPrint::renderingCompleted);
        }
        formLetterController.startOperation();
    }
}

```

8. Add a new report handler (X++) class to the project. Give the class a name that appropriately describes that it's a handler for Print management–based documents. For this example, rename the class `PrintMgtDocTypeHandlerExt` to distinguish it from other object handlers.
9. Add a delegate handler method to start to use your custom report. In this example, extend the `getDefaultReportFormatDelegate` method in the `PrintMgtDocTypeHandlerExt` class by using the following code.

```

class PrintMgtDocTypeHandlersExt
{
    [SubscribesTo(classstr(PrintMgmtDocType), delegatestr(PrintMgmtDocType,
getDefaultReportFormatDelegate))]
    public static void getDefaultReportFormatDelegate(PrintMgmtDocumentType _docType,
EventHandlerResult _result)
    {
        switch (_docType)
        {
            case PrintMgmtDocumentType::SalesOrderConfirmation:
                _result.result(ssrsReportStr(SalesConfirmExt, Report));
                break;
        }
    }
}

```

10. **Extend the menu item for the application report.** Find the existing Application Suite menu item in Application Explorer. This menu item is named **SalesConfirmation**. Right-click it, and then click **Create extension**. Open the new extension object in the designer, and set the value of the **Object** property to **SalesConfirmControllerExt** to redirect user navigations to the extended solution.
11. **Update the Print management settings to use the custom business document.** For this example, go to **Accounts receivable > Setup > Forms > Form setup**. Click **Print Management**, find the document configuration settings, and then select the custom design. The following illustration shows the Print management settings after the changes have been compiled.

You've now finished customizing the business document. Users will now be presented with the custom report design for the business document when they process transactions in the application.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Help prevent long-running reports from timing out

2/18/2021 • 2 minutes to read • [Edit Online](#)

This article provides tips that can help you prevent reports that run for a long time from timing out.

Paginated reports and documents are generated by using Microsoft SQL Server Reporting Services. Reporting Services retrieves report data from Application Object Server (AOS) by using a custom extension that uses Windows Communication Foundation (WCF) to communicate with AOS. The size of the data set and the complexity of the report that is generated can affect the time that is required to display the report. Additionally, if various time-outs and other thresholds are reached, report generation might fail. Service time-outs in deployments are fixed and limit interactive connections to 10 minutes. Any data set generation process that exceeds this service time-out limit won't be completed. This article describes the extensions that support long-running reports. These extensions help guarantee that long-running reports can be generated even if the process exceeds the 10-minute service time-out limit.

Preprocess the data source

If the report uses the Report Data Provider (RDP) to retrieve data, the report should be modified to use a pre-processed RDP class as the data source. In this way, processing logic is invoked before a call is made to Reporting Services. For more information about RDP classes, see [Using Report Data Provider Classes to Access Report Data](#) and [Report Programming Guide](#).

When is this necessary?

SYMPTOMS

Reports are failing due to timeouts

"A connection attempt failed because the connected party did not properly respond after a period of time...."

CAUSE

Default timeout only **10 minutes**

RESOLUTION

Pre-process the report data sets

How do I migrate a regular RDP to a pre-process data access solution by using TempDB?

1. Change the RDP base class from `SRSReportDataProviderBase` to `SRSReportDataProviderPreProcessTempDB`.
2. Update the table type from `InMemory` to `TempDB`.
3. Rebuild the report's RDP class.
4. Restore the data source that is linked to the RDP class in the report designer.

5. Redeploy the report.
6. Introduce a **Controller** class to run the report.
7. Update the Output Menu Item so that it points to the **Controller** class instead of the report.

Use batch processing

To improve performance when you print statements or reports that include large amounts of data, use batch processing. When you use batch processing, you can run specific tasks as batch jobs and then schedule those batch jobs to run on a different computer (a batch server). By moving the processing of these tasks to a batch server, you can improve the report performance on the client computer. You can also apply range restrictions to limit the size of each batch.

To further improve performance, don't submit one large batch. Instead submit multiple smaller batches for processing at the same time on different servers. Many tasks can be run as part of batch jobs. For more information, see [Batch processing overview](#).

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Electronic reporting (ER) overview

2/18/2021 • 20 minutes to read • [Edit Online](#)

This topic provides an overview of the Electronic reporting (ER) tool. It includes information about key concepts, the scenarios that ER supports, and a list of formats that have been designed and released as part of the solution.

ER is a tool that you can use to configure formats for both incoming and outgoing electronic documents in accordance with the legal requirements of various countries/regions. ER lets you manage these formats during their lifecycle. For example, you can adopt new regulatory requirements, and generate business documents in the required format to electronically exchange information with government bodies, banks, and other parties.

The ER engine is targeted at business users instead of developers. Because you configure formats instead of code, the processes for creating and adjusting formats for electronic documents are faster and easier.

ER currently supports the TEXT, XML, Microsoft Word document, and OPENXML worksheet formats. However, an extension interface provides support for additional formats.

Capabilities

The ER engine has the following capabilities:

- It represents a single shared tool for electronic reporting in different domains and replaces more than 20 different engines that do some type of electronic reporting for Finance and Operations.
- It makes a report's format insulated from the current implementation. In other words, the format is applicable for different versions.
- It supports the creation of a custom format that is based on an original format. It also includes capabilities for automatically upgrading the customized format when the original format is changed because of localization/customization requirements.
- It becomes the primary standard tool to support localization requirements in electronic reporting, both for Microsoft and for Microsoft partners.
- It supports the ability to distribute formats to partners and customers through Microsoft Dynamics Lifecycle Services (LCS).

Key concepts

Components

ER supports two types of components: **Data model** and **Format**.

Data model and model mapping components

A data model component is an abstract representation of a data structure. It's used to describe a specific business domain area with enough detail to satisfy the reporting requirements for that domain. A data model component consists of the following parts:

- A data model, as a set of domain-specific business entities and a hierarchically structured definition of relations between those entities.
- A model mapping that links selected application data sources to individual elements of a data model that specifies, at run time, the data flow and rules of business data population to a data model component.

A business entity of a data model is represented as a container (record). Business entity properties are represented as data items (fields). Each data item has a unique name, label, description, and value. The value of

each data item can be designed so that it's recognized as a string, integer, real, date, enumeration, Boolean, and so on. Additionally, it can be another record or records list.

A single data model component can contain several hierarchies of domain-specific business entities. It can also contain model mappings that support a report-specific data flow at run time. The hierarchies are differentiated by a single record that has been selected as a root for model mapping. For example, the data model of the payment domain area might support the following mappings:

- Company > Vendor > Payment transactions of the AP domain
- Customer > Company > Payment transactions of the AR domain

Note that business entities such as company and payment transactions are designed one time. Different mappings then reuse them.

A model mapping that supports outgoing electronic documents has the following capabilities:

- It can use different data types as data sources for a data model. For example, it can use tables, data entities, methods, or enums.
- It supports user input parameters that can be defined as data sources for a data model when some data must be specified at run time.
- It supports the transformation of data into required groups. It also lets you filter, sort, and sum data, and append logical calculated fields that are designed through formulas that resemble Microsoft Excel formulas. For more information, see [Formula designer in Electronic reporting \(ER\)](#).

A model mapping that supports incoming electronic documents has the following capabilities:

- It can use different updatable data elements as targets. These data elements include tables, data entities, and views. The data can be updated by using the data from incoming electronic documents. Multiple targets can be used in a single model mapping.
- It supports user input parameters that can be defined as data sources for a data model when some data must be specified at run time.

A data model component is designed for each business domain that should be used as a unified data source for reporting that isolates reporting from the physical implementation of data sources. It represents domain-specific business concepts and functionalities in a form that makes a reporting format's initial design and further maintenance more efficient.

Format components for outgoing electronic documents

A format component is the scheme of the reporting output that will be generated at run time. A scheme consists of the following elements:

- A format that defines the structure and content of the outgoing electronic document that is generated at run time.
- Data sources, as a set of user input parameters and a domain-specific data model that uses a selected model mapping.
- A format mapping, as a set of bindings of format data sources that have individual elements of a format that specify, at run time, the data flow and rules for format output generation.
- A format validation, as a set of configurable rules that control report generation at run time, depending on the running context. For example, there might be a rule that stops output generation of a vendor's payments and throws an exception when specific attributes of the selected vendor are missing, such as the bank account number.

A format component supports the following functions:

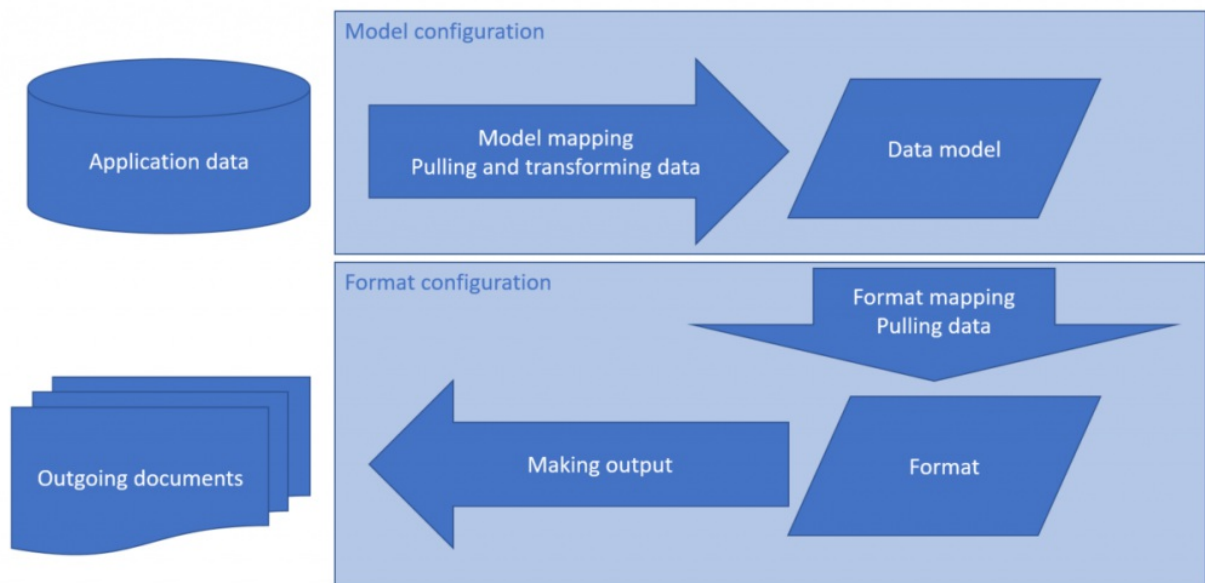

- Creation of reporting output as individual files in various formats, such as text, XML, Microsoft Word document, or worksheet.

- Creation of multiple files separately and encapsulation of those files into zip files.

A format component lets you attach specific files that can be used in the reporting output:

- Excel workbooks that contain a worksheet that can be used as a template for output in the OPENXML worksheet format
- Word files that contain a document that can be used as a template for output in the Microsoft Word document format
- Other files that can be incorporated into the format's output as predefined files

The following illustration shows how the data flows for these formats.

To run a single ER format configuration and generate an outgoing electronic document, you must identify the mapping of the format configuration.

Format components for incoming electronic documents

A format component is the scheme of the incoming document that is imported at run time. A scheme consists of the following elements:

- A format that defines the structure and content of the incoming electronic document that contains data that is imported at run time. A format component is used to parse an incoming document in various formats, such as text and XML.
- A format mapping that binds individual format elements to elements of a domain-specific data model. At run time, the elements in the data model specify the data flow and the rules for importing data from an incoming document, and then store the data in a data model.
- A format validation, as a set of configurable rules that control data import at run time, depending on the running context. For example, there might be a rule that stops data import of a bank statement that has a vendor's payments and throws an exception when a specific vendor's attributes are missing, such as the vendor identification code.

The following illustration shows how the data flows for these formats.

To run a single ER format configuration to import data from an incoming electronic document, you must identify the desired mapping of a format configuration, and also the integration point of a model mapping. You can use the same model mapping and destinations together with different formats for different type of incoming documents.

Component versioning

Versioning is supported for ER components. The following workflow is provided to manage changes in ER components:

1. The version that is originally created is marked as a **Draft** version. This version can be edited and is available for test runs.
2. The **Draft** version can be converted to a **Completed** version. This version can be used in local reporting processes.
3. The **Completed** version can be converted to a **Shared** version. This version is published on LCS and can be used in global reporting processes.
4. The **Shared** version can be converted to a **Discontinued** version. This version can then be deleted.

Versions that have either **Completed** or **Shared** status are available for other data interchange. The following actions can be performed on a component that has these statuses:

- The component can be serialized in XML format and exported as a file in XML format.
- The component can be reserialized from an XML file and imported into the application as a new version of an ER component.

Component date effectivity

ER component versions are date-effective. You can set the **Effective from** date for an ER component to specify the date that the component becomes effective for reporting processes. The application session date is used to define whether a component is valid for execution. If more than one version is valid for a particular date, the latest version is used for reporting processes.

Component access

Access to ER format components depends on the setting for the ISO country/region code. When this setting is blank for a selected version of a format configuration, a format component can be accessed from any company at run time. When this setting contains ISO country/region codes, a format component is available only from companies that have a primary address that is defined for one of a format component's ISO country/region codes.

Different versions of a data format component can have different settings for ISO country/region codes.

Configuration

An ER configuration is the wrapper of a particular ER component. That component can be either a data model component or a format component. A configuration can include different versions of an ER component. Each configuration is marked as owned by a specific configuration provider. The **Draft** version of a component of a configuration can be edited when the owner of the configuration has been selected as an active provider in the ER settings in the application.

Each model configuration contains a data model component. A new format configuration can be derived from a specific data model configuration. In the configuration tree, the format configuration that is created appears as a child of the original data model configuration.

The format configuration that is created contains a format component. The data model component of the original model configuration is automatically inserted into the format component of the child format configuration as a default data source.

An ER configuration is shared for application companies.

Provider

The ER provider is the party identifier that is used to indicate the author (owner) of each ER configuration. ER lets you manage the list of configuration providers. Format configurations that are released for electronic documents as part of the Finance and Operations solution are marked as owned by the **Microsoft** configuration provider.

To learn how to register a new ER provider, play the task guide, **ER Create a configuration provider and mark it as active** (part of the **7.5.4.3 Acquire/Develop IT service/solution components (10677)** business process).

Repository

An ER repository stores ER configurations. The following types of ER repositories are currently supported:

- LCS shared library
- LCS project
- File system
- RCS
- Operations resources
- Global repository

An **LCS shared library** repository provides access to the list of configurations within the Shared asset library in Lifecycle Services (LCS). This type of ER repository can only be registered for the Microsoft provider. From the LCS Shared asset library you can import the latest versions of ER configurations into the current instance.

An **LCS project** repository provides access to the list of configurations of a specific LCS project (LCS project assets library) that was selected when the repository was registered. ER lets you upload shared configurations from the current instance to a specific **LCS project** repository. You can also import configurations from an **LCS project** repository into the current instance of your Finance and Operations apps.

A **File system** repository provides access to the list of configurations that are located as xml files in the specific folder of the local file system of the machine where the AOS service is hosted. Required folder is selected at the repository registration stage. You can import configurations from a **File system** repository into the current instance.

Note that this repository type is accessible in the following environments:

- Cloud-hosted environments deployed for development purposes (containing test models of enclosed suites)
- Locally deployed environments (on-premises)

For more information, see [Import Electronic reporting \(ER\) configurations](#).

An RCS repository provides access to the list of configurations of a specific instance of [Configuration service \(RCS\)](#) that was selected at the repository registration stage. ER lets you import completed or shared configurations from the selected RCS instance into the current instance so you can use them for electronic reporting.

For more information, see [Import Electronic reporting \(ER\) configurations from RCS](#).

A **Global repository** repository provides access to the list of configurations within the global repository in the [Configuration service](#). This type of ER repository can only be registered for the Microsoft provider. From the global repository, you can import the latest versions of ER configurations into the current instance.

For more information, see [Import Electronic reporting \(ER\) configurations from Global repository of Configuration service](#).

An **Operations resources** repository provides access to the list of configurations that Microsoft, as an ER configuration provider, initially releases as part of the application solution. These configurations can be imported into the current instance and used for electronic reporting or playing sample task guides. They can also be used for additional localizations and customizations. Note that the latest versions provided by Microsoft ER configurations must be imported from the LCS Shared asset library by using corresponding the ER repository.

Required **LCS project**, **File system**, and **Regulatory Configuration Services (RCS)** repositories can be registered individually for each configuration provider of the current instance. Each repository can be dedicated to a specific configuration provider.

Supported scenarios

Building a data model

ER provides a model designer that you can use to build a data model for a particular business domain. All domain-specific business entities, and the relations between them, can be presented in a data model as a hierarchical structure.

To become familiar with the details of this scenario, play the **ER Design domain specific data model** task guide (part of the **7.5.4.3 Acquire/Develop IT service/solution components (10677)** business process).

Translating data model content

Data model content (labels and descriptions) can be translated into other languages that the applications support. You might want to translate data model content for the following reasons:

- At design time, to make the content more intelligible for format designers who speak other languages, and who will use the data model for data mapping of format components.
- At run time, to make the content more user-friendly by presenting prompts and help for run-time parameters, and configured validation messages (errors and warnings), in the language that the currently signed-in user prefers.

Configuring data model mappings for outgoing documents

ER provides a model mapping designer that lets users map data models that they have designed to specific application data sources. Based on the mapping, the data will be imported at run time from selected data sources into the data model. The data model is then used as an abstract data source of ER formats that generate outgoing electronic documents.

To become familiar with the details of this scenario, play the **ER Define model mapping and select data sources** and **ER Map data model to selected data sources** task guides (part of the **7.5.4.3 Acquire/Develop IT service/solution components (10677)** business process).

Configuring data model mappings for incoming documents

ER provides a model mapping designer that lets users map data models that they have designed to specific destinations. For example, data models can be mapped to the updatable data components (tables, data entities, and views). Based on the mapping, the data will be updated at run time by using the data from the data model. As abstract storage of the ER format, the data model is filled with data that is imported from an incoming electronic document.

Storing a designed model component as a model configuration

ER can store a designed data model, together with associated data mappings, as a model configuration of the current instance. The following illustration shows an example of this type of data model configuration (the payment model configuration).

To become familiar with the details of this scenario, play the **ER Map data model to selected data sources** task guide (part of the **7.5.4.3 Acquire/Develop IT service/solution components (10677)** business process).

Building a format that uses a data model as a base

ER supports a format designer that you can use to build the format of an electronic document for a selected business domain by selecting the model component as a base. The same ER format designer lets you map a format that you create to a selected domain's data model mapping as a data source.

To become familiar with the details of this scenario, play the **ER Design domain specific format** task guide (part of the **7.5.4.3 Acquire/Develop IT service/solution components (10677)** business process).

Building a configuration to generate electronic documents in OPENXML worksheet format

The ER format designer can be used to build an electronic document in OPENXML worksheet format.

To become familiar with the details of this scenario, play the **ER Create a configuration for reports in OPENXML format** task guide (part of the **7.5.4.3 Acquire/Develop IT service/solution components (10677)** business process). As part of the task guide step for importing a template, use the [Template of Payment Report \(SampleVendPaymWsReport.xlsx\)](#) Excel file as a template.

Building a configuration to generate electronic documents in a Word document format

The ER format designer can be used to build an electronic document in a Word document format. The following illustration shows an example of this type of format. Note that this format reuses the existing ER configuration that was originally designed to generate the report output in OPENXML format.

To become familiar with the details of this scenario, play the **ER Design a configuration for generating reports in Microsoft WORD format** task guide (part of the **7.5.4.3 Acquire/Develop IT service/solution components (10677)** business process). As part of the task guide step for importing a template, use the following Word files as templates for the ER format:

- [Template of Payment Report \(SampleVendPaymDocReport.docx\)](#)
- [Bounded template of Payment Report \(SampleVendPaymDocReportBounded.docx\)](#)

Building a configuration to import data from incoming electronic documents

The ER format designer can be used to describe an electronic document that is planned for data import in either XML or text format. The designed format is used to parse an incoming document. The ER format mapping designer can be used to define the binding of the elements of the designed format to the data model.

To become familiar with the details of this scenario, play the **Create required ER configurations to import data from an external file** task guide (part of the **7.5.4.3 Acquire/Develop IT service/solution components (10677)** business process). Use the following files to play this guide:

- [ER data model configuration \(1099model.xml\)](#)
- [ER format configuration \(1099format.xml\)](#)
- [Sample of the incoming document in XML format \(1099entries.xml\)](#)

- [Sample of the workbook to manage data of incoming document \(1099entries.xlsx\)](#)

Storing a designed format component in a format configuration

ER can store a designed format together with the configured data mappings as a format configuration of the current instance. The preceding illustration shows an example of this type of format configuration (**BACS (UK)**, which is a child of the **Payment model** configuration). To become familiar with the details of this scenario, play the **ER Design domain specific format task guide** (part of the **7.5.4.3 Acquire/Develop IT service/solution components (10677)** business process).

Configuring Finance to start to use a created format internally

The application can be configured to start to use a created format to generate electronic reports. The reference to the created format configuration should be defined in the settings of a specific domain. For example, to start to use an ER format configuration for electronic vendor payments in BACS format, the format configuration should be referenced in specific methods of payment.

To become familiar with the details of this scenario, play the **ER Use format to generate electronic document for payments task guide** (part of the **7.5.4.3 Acquire/Develop IT service/solution components (10677)** business process).

Handling ER components

Publishing an ER component in LCS to offer it externally (localization)

The owner of a component (model or format) that has been created can use ER to publish the completed version of the component to LCS. A repository of the **LCS project** type for the current ER configuration provider is required. When the status of the completed version of a component is changed from **COMPLETED** to **SHARED**, that version is published in LCS. When a component has been published to LCS, the owner of that component becomes a provider of the service to support the component. For example, if the format component is designed to generate an electronic document that is legally required (for example, in accordance with a localization scenario), it's assumed that the format will be kept compliant with legislative changes, and that the provider will issue new versions of the component whenever new legislative requirements arise. To become familiar with the details of this scenario, play the **ER Upload a configuration into Lifecycle Services task guide** (part of the **7.5.4.3 Acquire/Develop IT service/solution components (10677)** business process).

Importing an ER component from LCS to use it internally

ER lets you import ER components from LCS to the current instance. A repository of the **LCS project** type is required. When an ER component has been imported from LCS to the current instance, the owner of the instance becomes a consumer of the service that is provided by the owner (author) of the imported component. For example, if a format component is designed to generate a specific electronic document from the application in a country/region-specific format (localization scenario), it's assumed that the service consumer will be able to obtain any updates that are made to that format, to keep it compliant with legislative requirements. To become familiar with the details of this scenario, play the **ER Import a configuration from Lifecycle Services task guide** (part of the **7.5.4.3 Acquire/Develop IT service/solution components (10677)** business process).

Building a format selecting another format as a base (customization)

ER lets you create (derive) a new component from the current version of a component (base) that was imported from LCS. For example, a user wants to derive a new format to implement some special requirements for an electronic document (such as an additional field or an extensive description) to support a customization scenario. To become familiar with the details of this scenario, play the **ER Upgrade format by adoption of new base version of it task guide** (part of the **7.5.4.3 Acquire/Develop IT service/solution components (10677)** business process).

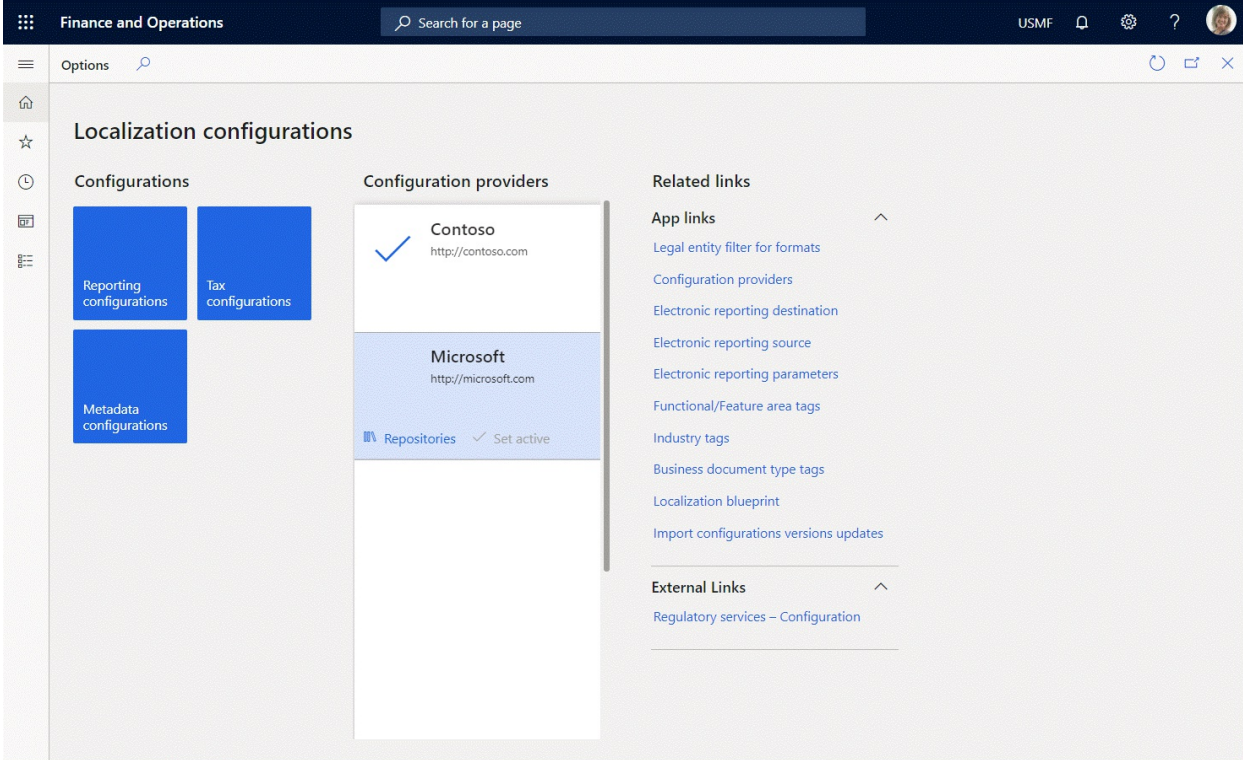

Upgrading a format selecting a new version of base format (rebase)

ER lets you automatically adopt changes of the latest version of the base component in the current draft version

of the derived component. This process is known as *rebasing*. For example, a new regulatory change that has been introduced in the latest version of the format that was imported from LCS can be automatically merged into the customized version of this format of the electronic document. Any changes that can't be merged automatically are considered conflicts. These conflicts are presented for manual resolution in the designer tool for the appropriate component. To become familiar with the details of this scenario, play the **ER Upgrade format by adoption of new base version of that format** task guide (part of the 7.5.5.3 Acquire/Develop changed IT service/solution component (10683) business process).

List of ER configurations that have been released in Finance

The list of ER configurations for Finance is constantly updated. Open the [Global repository](#) to review the list of ER configurations that are currently supported. On the **Discontinuation details** FastTab, you can review the information about configurations that have been discontinued or that are no longer being maintained.

The screenshot shows the 'Localization configurations' page in the Finance and Operations application. The page is divided into three main sections: 'Configurations', 'Configuration providers', and 'Related links'. The 'Configurations' section on the left contains three blue tiles: 'Reporting configurations', 'Tax configurations', and 'Metadata configurations'. The 'Configuration providers' section in the center lists two providers: 'Contoso' (http://contoso.com) and 'Microsoft' (http://microsoft.com). The 'Microsoft' provider is highlighted in blue and has a 'Repositories' button and a 'Set active' checkbox. The 'Related links' section on the right is divided into 'App links' and 'External Links'. The 'App links' section includes links for 'Legal entity filter for formats', 'Configuration providers', 'Electronic reporting destination', 'Electronic reporting source', 'Electronic reporting parameters', 'Functional/Feature area tags', 'Industry tags', 'Business document type tags', 'Localization blueprint', and 'Import configurations versions updates'. The 'External Links' section includes a link for 'Regulatory services - Configuration'.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Create Electronic reporting (ER) configurations

2/18/2021 • 13 minutes to read • [Edit Online](#)

As part of the requirements for LCS solutions for localization and translation, localization ISV solution providers must implement country/region-specific or solution-specific features by using the Electronic reporting tool. This article provides background information that will help you start to use Electronic reporting to create configurations. This article isn't meant to replace any available and upcoming Electronic reporting documentation, but is intended as a supplemental view from the perspective of localization requirements.

Electronic reporting

General electronic reporting (GER) is a new configurable tool that helps you create and maintain regulatory electronic reporting and payments, based on the following three concepts.

Configuration instead of coding

- Configuration can be done by a business user and doesn't require a developer.
- The data model is defined in business terms.
- Visual editors are used to author all components of the GER configuration.
- A Microsoft Excel-like formula language is used for data transformation.

One configuration for multiple Dynamics 365 Finance releases

- Manage one domain specific data model that is defined in business terms.
- Isolate application release specifics in release-dependent data model mappings.
- Maintain one format configuration for multiple releases of the current version, based on the data model.

Easy or automatic upgrade

- Versioning of GER configurations is supported.
- The Microsoft Dynamics Lifecycle Services (LCS) Assets library can be used as a repository for GER configurations for version exchange.
- Localizations that are based on origin GER configurations can be introduced as child versions.
- A GER configuration tree is provided as a tool that helps control dependencies for versions.
- Only differences in localization (delta configuration) are recorded to enable automatic upgrade to a new version of the origin GER configuration.
- It's easy to manually resolve conflicts that are discovered during automatic upgrade of localization versions.

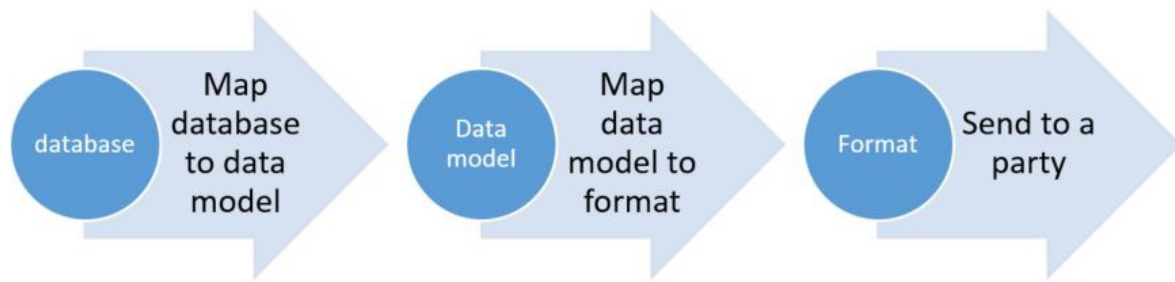

GER lets users define electronic format structures, and then describe how those structures should be filled by using data and algorithms. Users can use a formula language that is very similar to the Excel language for data transformation. To make the database-to-format mapping more manageable, reusable, and independent of format changes, an intermediate data model concept is introduced. This concept enables implementation details to be hidden from the format mapping and also enables a single data model to be reused for multiple format mappings.

What's new here

WHAT CAN YOU DO?	MICROSOFT DYNAMICS AX 2012	CURRENT VERSION OF FINANCE	WHY IS THIS IMPORTANT?
Configure and generate electronic documents to meet the legal requirements in various countries/regions.	Electronic documents are hard-coded in X++ or as Extensible Stylesheet Language Transformations (XSLTs).	GER is a new tool for configuring and generating electronic documents that target a business user instead of a developer.	GER simplifies the creation, maintenance, and upgrade of electronic document formats to meet legal requirements in various countries/regions.
Configure regulatory updates to formats.	Any format adjustments require development effort.	A business user can configure the formats, based on domain-specific data models (for example, for payments, Intrastat reports, or tax reports).	GER makes the process of creating or changing electronic document formats faster and easier. These changes can be made by business users instead of developers.
Separation of data and formats makes updates easier.	Access to data and access to formatting aren't isolated.	GER lets you set up data models that are domain-specific and independent of the database as data sources for document formats. Formats can be configured based on these domain-specific data models by using simple visual tools that are similar to Excel. Data models and formats support versioning, and formats can be date-effective.	GER makes it faster and easier for partners and customers to upgrade their format and customizations to new versions of formats that are released by Microsoft or other partners.
Distribute data models and formats.	An adjusted format deployment requires a new hotfix package that overrides the existing format.	Each data model or format version is stored in a separate configuration, and is distributed to partners and customers through LCS. By using LCS, partners can share their data model and format configurations with other partners and customers, who can customize and share them further.	GER provides one common way (through LCS) for Microsoft and partners to distribute electronic document configurations to other partners and customers. GER also makes it easier for partners and customers to customize, upgrade, and distribute electronic document formats for their specific business requirements.
Customization and upgrade are easier.	Custom modification of each format must be manually ported to the source code of a new hotfix package.	Partners and customers can customize Microsoft data models and formats, or create their own. GER saves partner and customer configuration changes as deltas to Microsoft configurations to simplify upgrades to new versions of Microsoft configurations. Delta customization and easy upgrade are supported through the whole customization chain.	GER provides one common way (through LCS) for Microsoft and partners to distribute electronic document configurations to other partners and customers. GER also makes it easier for partners and customers to customize, upgrade, and distribute electronic document formats for their specific business requirements.

Basic concepts

Main data flow

Data model configuration creation

It's a good idea to reuse and customize data models that are released by Microsoft whenever you can, or to create a business domain area-specific data model that will introduce the abstract model of required entities and their relations. In this way, you will be aligned with future updates that are released by Microsoft, or can at least reuse your model for the design and maintenance of multiple domain-specific electronic documents that have different formats that are required in different scenarios or countries/regions.

Design the data model of the created model configuration

A data model is designed to recognize and describe the required business entities and the relations between them in the selected domain. A data model consists of descriptors that express entities by using data containers (records). Properties of entities are expressed by using data items. A record definition is an entity that contains fields (the data items). Each data item has a unique name, label, description, and value. The value of each data item can be designed so that it's recognized as string, integer, real, date, enumerate type, and so on. Additionally, the value can be another record or record list. A single record definition can be selected as a root of the data model. (A root is the starting point of the entire model for data source mapping.) In this case, the model is used as a data source that delivers data according to the single predefined data flow. If no record definition was selected as a root of the data model, the data model contains record definitions that can be assigned as a root at the format mapping stage. The data flow of such a model can be defined as a data source in multiple ways, depending on the nature of the format. For example, a single data model can be designed for the payments domain area. This data model can include data record definitions for the company as a legal entity, for vendors and customers, and also for payments. However, according to the nature of the format, the data must be presented in the following way: payer > payee > payments. Therefore, a single data model can offer data according to the following alternative paths:

- Company > vendor > payment for the Accounts payable domain when the company record definition is selected as a root.
- Customer > company > payment for the Accounts receivable domain when the customer record definition is selected as a root.

Format configuration creation

You use the data model configuration that is created to hold abstract data for a new electronic format that you want to design. If you intend to consume a data model that was prepared earlier when you create a new format, make sure that you select the **Format based on data model** option for **Create configuration**. After you have a format configuration, you must define a format structure. The structure can be created manually or automatically by importing an example of an XML file or an Excel template. The data model of the parent configuration is automatically offered for format mapping, together with a proper root container. Nevertheless,

a format might require that data be represented in a specific way. Therefore, you can use formula designer to define expressions as virtual data items (calculated fields) for our data containers.

NOTE

Although GER allows for direct mapping of format components to database artifacts (tables or data entities), we don't recommend this approach, because it's likely that multiple formats will be maintained in some business domain areas that use the same data sources. Whenever the structure of such database artifacts is changed, the format mapping to the database artifacts must also be changed, and the cost of these changes will be multiplied by the number of maintained formats. Therefore, we recommend that you work through the data model as the abstract description of the domain-specific data structure, and that you use the direct binding of format elements to database components only for simplification and for coverage for specific customizations (for example, to refer to custom tables when these references are required in a limited number of maintained formats).

Version control

One of the principles behind the design of Electronic reporting is that it should be easy to distribute a data model and formats together with an enhanced maintenance model for their customizations. All the configurations are versioned, and an existing customization can be "cloned" to derive a new configuration for localization or customization implementation. For example, we represent a company that is named Proseware, Inc. We have subscribed to the service of a company that is named Litware Inc., which provides us with the Intrastat returns configuration and supports all legal requirements in it. We have already received specific configurations, from Litware Inc., together with data model and formats, and have deployed them. Our company is working in a district where, in addition to the federal requirements, we must support the following regional requirements:

- As part of Intrastat transactions details, our XML file must show the statistical procedure code that isn't required anywhere else.
- We must limit the length of the company name that is presented in the Intrastat returns header block to 200 characters.

To support these requirements and comply with local district authorities, we must implement this localization as a localized configuration. However, we must keep the link with the origin configuration, so that we can adopt any future changes that are introduced at the federal level as new versions of the origin configuration. Therefore, we import the Litware Inc. origin configuration from LCS, derive it as a new localized configuration, introduce the required changes, complete this work by introducing a first version of the localized format, and start to use it internally. Whenever Litware Inc. offers us a new version of the origin configuration, we import it from LCS, rebase our localized configuration to this version, adopt changes to support new federal requirements, complete this work by introducing a next version of the localized format, and continue to use it internally.

NOTE

The draft version of any configuration must be "completed" before it can become available locally for further action, such as the following:

- Make it available so that it can be referenced as a data source from a new format.
- Enable configuration exchange between companies or instances via configuration import/export, and so on.

Electronic reporting domain coverage

Several out-of-box configurations can be used to meet electronic reporting requirements for specific countries/regions. The following list show some examples of format configurations that are grouped into business domains. To get a complete, up-to-date list of available and supported configurations, open a

configuration repository setup to show the configurations that are available for import from either resources or an LCS Assets library.

- Audit file
 - FEC
 - GDPdU...
- Payments (ISO20022)
 - SEPA CT
 - SEPA DD
 - JBA
 - BACS...
- Statistical reports
 - EU Intrastat...
- Tax reports
 - CIS
 - BAS
 - ELSTER
 - EU Sales list...
- Customer e-Invoice
 - OIOUBL...

Your solution uptake

You can choose how to move your electronic reporting functionality into GER. However, you should consider the following high-level steps when you plan that move.

1. Review the electronic reporting functionality that your solution currently provides.
2. Identify domain areas that your solution covers, such as Payments and E-Invoices.
3. Review the configurations that are provided by Microsoft. It's likely that you'll find a configuration that you can use as a base. For example, if your solution customizes the SEPA CT payment format, you should extend the SEPA CT configuration.
4. Create new configurations that are based on either an existing model or format, or a new model or format.
5. Define input parameters that users must select when they run the report, and validations for the content of the report.
6. Define mappings with the model by using arithmetic, string, data, or other available Excel-like functions.
7. Define labels and translation to different languages, where applicable.
8. Define templates that have named ranges, and set links from the configuration for the Excel report, if applicable.

Terminology

TERM	DEFINITION
------	------------

TERM	DEFINITION
GER	Electronic reporting is an engine that simplifies the creation of electronic reports for information interchange with governments, banks, and other parties. Currently, Electronic reporting supports text, XML, and OpenXML spreadsheet formats, and provides an extension interface to support more formats.
Transformation	If you have a typical action that must be done on the source of data before it is sent as output to a format, you can introduce a transformation and attach it to format components. Transformation is a GER formula that takes one value as a parameter and returns another value. For example, you have many format fields that contain spaces, and the spaces should be replaced by spaces when the fields are exported. In this case, you can create a transformation that takes a string argument and uses the REPLACE function to do the job. You can then create string components and associate them with that transformation.
Data model	A data model provides a structure for data. This structure is used to abstractly describe certain business domain areas at sufficient detail to satisfy the reporting requirements in this domain.
Configuration	A container for either a data model or a format, together with its mappings to data sources, that can be maintained and executed, and that supports versioning. The configuration is the entity that will be imported or exported to organize electronic document format exchange between Finance and Operations instances.
Derive action	An operation that uses a configuration that already exists as a basis to create a new configuration.
Rebase action	An operation that updates a derived configuration with changes that were introduced in a new version of the base configuration. The version number is selected at the rebase initialization stage.
Update conflict	A conflict that is discovered during the rebase action, where the new base version contains adjustments of a format/mapping element (name, property, and so on) that has also been adjusted in the derived version.
Relocation conflict	A conflict that is discovered during the rebase action, where the new base version contains a new position (parent element) of a format element (name, property, and so on) that has also been relocated to a different position in the derived version.
Duplication conflict	A conflict that is discovered during the rebase action, where the new base version introduced a new format element that is the same as an element (in other word, it has the same name and child components) that has also been entered in the derived version.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

ER Design domain specific data model

2/18/2021 • 5 minutes to read • [Edit Online](#)

The following steps explain how a user in the System Administrator or Electronic Reporting Developer role can create a new Electronic reporting (ER) configuration that contains a data model for electronic payment documents. This data model will later be used as a data source when you create the format of the payment documents.

In this example, you will create a configuration for sample company, Litware, Inc. These steps can be performed in any company as ER configurations are shared among companies. To complete these steps, you must first complete the steps in the "Create a configuration provider and mark it as active" procedure.

1. Go to Organization administration > Workspaces > Electronic reporting.

Select the configuration provider for sample company, 'Litware, Inc.' If you don't see this configuration provider, you must first complete the steps in the "Create a configuration provider and mark it as active" procedure.

2. Click Reporting configurations.

You will create a configuration that contains a data model for electronic payment documents. This data model will be used later as a data source when you create the format for the payment documents.

Create a new data model configuration

1. Click Create configuration to open the drop dialog.
2. In the Name field, type 'Payments (simplified model)'.
3. In the Description field, type 'Payment model configuration'.

The active configuration provider is automatically entered here. This provider will be able to maintain this configuration. Other providers can use this configuration, but will not be able to maintain it.

4. Click 'Create configuration' button to complete the configuration creation task

Create a data model

You're creating a new data model for the selected configuration. This configuration version will have a status of Draft.

1. Click Designer.

Define the structure of a party participating in a payment process

1. Click New to open the drop dialog.
2. In the Name field, type 'Party'.
3. Click Add.
4. Click New to open the drop dialog.
5. In the Name field, type 'Name'.
6. In the Item type field, select 'String'.
7. Click Add.
8. In the Find field, type 'Party'.

9. Click Find previous.

Define the bank structure for this model

1. Click New to open the drop dialog.
2. In the Name field, type 'Agent'.
3. In the Item type field, select 'Record'.
4. Click Add.
5. In the Description field, enter 'Financial institution (for instance, a bank) servicing an account for the party (debtor/creditor).'

Financial institution (for instance, a bank) servicing an account for the party (debtor/creditor).

6. Click New to open the drop dialog.
7. In the Name field, type 'Name'.
8. In the Item type field, select 'String'.
9. Click Add.
10. Click New to open the drop dialog.
11. In the Name field, type 'SWIFT'.
12. Click Add.
13. In the Description field, enter 'Bank identification code'.
14. Click New to open the drop dialog.
15. In the Name field, type 'RoutingNumber'.
16. Click Add.
17. In the Description field, enter 'Routing number'.
18. Click Find previous.

Define the bank account structure for this model

1. Click New to open the drop dialog.
2. In the Name field, type 'Account'.
3. In the Item type field, select 'Record'.
4. Click Add.
5. In the Description field, enter 'Identification of an account of a party in a financial institution (for instance, a bank).'

Identification of an account of a party in a financial institution (for instance, a bank).

6. Click New to open the drop dialog.
7. In the Name field, type 'Currency'.
8. In the Item type field, select 'String'.

9. Click Add.
10. In the Description field, enter 'Currency code'.
11. Click New to open the drop dialog.
12. In the Name field, type 'Number'.
13. Click Add.
14. Click New to open the drop dialog.
15. In the Name field, type 'IBAN'.
16. Click Add.
17. In the Description field, enter 'International bank account number'.

Define the payment message structure for credit transfer payment type

1. Click New to open the drop dialog.
2. In the New node as a field, enter 'Model root'.
3. In the Name field, type 'CustomerCreditTransferInitiation'.
4. Click Add.
5. In the Find field, type 'CustomerCreditTransferInitiation'.
6. Click Find previous.
7. Click New to open the drop dialog.
8. In the Name field, type 'MessageIdentification'.
9. Click Add.
10. In the Description field, enter 'The point-to-point reference assigned by the instructing party (and sent to the next party) to identify a message.'.

The point-to-point reference assigned by the instructing party (and sent to the next party) to identify a message.

11. Click New to open the drop dialog.
12. In the Name field, type 'ProcessingDateTime'.
13. In the Item type field, select 'DateTime'.
14. Click Add.
15. In the Description field, enter 'Date and time at which the payment message was created.'.
16. Click New to open the drop dialog.

Define the payment transaction structure for this model.

17. In the Name field, type 'Payments'.
18. In the Item type field, select 'Record list'.
19. Click Add.

20. In the Description field, enter 'Payment lines of the current message'.
21. Click New to open the drop dialog.
22. In the Name field, type 'Creditor'.
23. In the Item type field, select 'Record'.
24. Click Add.
25. In the Description field, enter 'Party to which an amount of money is due.'.
26. Click Switch item reference.
27. In the Find field, type 'Party'.
28. Click Find next.
29. Click OK.
30. In the Find field, type 'Payments'.
31. Click Find next.
32. Click New to open the drop dialog.
33. In the Name field, type 'Debtor'.
34. Click Add.
35. In the Description field, enter 'Party that owes an amount of money to the (ultimate) creditor.'.
36. Click Switch item reference.
37. In the Find field, type 'Party'.
38. Click Find next.
39. Click OK.
40. Click Find next.
41. Click New to open the drop dialog.
42. In the Name field, type 'Description'.
43. In the Item type field, select 'String'.
44. Click Add.
45. Click New to open the drop dialog.
46. In the Name field, type 'Currency'.
47. Click Add.
48. In the Description field, enter 'Currency code'.
49. Click New to open the drop dialog.
50. In the Name field, type 'TransactionDate'.
51. In the Item type field, select 'Date'.
52. Click Add.

53. In the Description field, enter 'Transaction date'.
54. Click New to open the drop dialog.
55. In the Name field, type 'InstructedAmount'.
56. In the Item type field, select 'Real'.
57. Click Add.
58. In the Description field, enter 'The amount of money to be moved between the debtor and creditor, before deduction of charges. The amount should be expressed in the currency as ordered by the initiating party.'

The amount of money to be moved between the debtor and creditor, before deduction of charges. The amount should be expressed in the currency as ordered by the initiating party.
59. Click New to open the drop dialog.
60. In the Name field, type 'End2EndID'.
61. In the Item type field, select 'String'.
62. Click Add.
63. In the Description field, enter 'The unique identification assigned by the initiating party. This identification is passed on, unchanged, throughout the entire end-to-end chain.'
64. In the Name field, type 'PaymentModel'.

The PaymentModel name aligns with predefined interfaces of payment forms.
65. Click Save.
66. Close the page.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Prepare application metadata to be used in RCS

2/18/2021 • 2 minutes to read • [Edit Online](#)

The following steps explain how a user in the System Administrator or Electronic Reporting Developer role can create a new Electronic reporting (ER) configuration that contains application metadata for designing ER model mapping configurations in Regulatory configuration service (RCS). This configuration will be used for designing a sample ER model mapping configuration to access foreign trade transactions. In this example, you will create a configuration for sample company, Litware, Inc. These steps can be performed in any company. To complete these steps, you must first complete the steps in the topic, [Create configuration providers and mark them as active](#).

Prerequisites

1. Go to **Organization administration > Workspaces > Electronic reporting**.
2. Make sure that the configuration provider for the sample company, Litware, Inc., is available and marked as **Active**. If you don't see this configuration provider, complete the steps in the procedure [Create configuration providers and mark them as active](#).
3. Click **Metadata configurations**.
4. Assume that RCS will be used to design an ER solution for a Finance and Operation application that will generate electronic documents that contain information from foreign trade business domain. To specify the mapping between ER data model and sources of required data, in RCS we need to have access to metadata of the Finance and Operation application. Therefore, as part of designing ER solution we configure a new ER metadata configuration containing all metadata that is currently required for generation ER reports for selected business domain.

Add metadata configuration

1. Click **Create configuration** to open the drop dialog.
2. In the **Name** field, type 'Foreign trade metadata'.
3. Click **Create configuration**.
4. Click **Designer**.
5. Click **Add**.

NOTE

You can select all metadata for the entire application or selected models or selected modules. Be aware that in this case the following metadata will be automatically added: tables of records, enumerations, and extended data types. When additional types of metadata are needed, they must be added manually.

We have some foreign trade transactions related metadata by selecting metadata items manually.

6. Click **Add data source**.
7. Click **Table records**.
8. Use the Quick Filter to filter on the **Name** field with a value of 'Intrastat'.
9. Select the **Intrastat** table record.
10. Click **OK**.

We added metadata information about the Intrastat table of records.

11. In the tree, expand **Table records Intrastat>Relations**.
12. In the tree, select **Table records Intrastat>Relations\IntrastatCommodity (Table records EcoResCategory)**.
13. Click **Add metadata**.

NOTE

Metadata about required relations for selected table of records must be added manually.

16. Click **Add data source**.
17. Click **Enumeration**.
18. Use the Quick Filter to filter on the **Name** field with a value of 'IntrastatDirection'.
19. Select the **IntrastatDirection enumeration** record.
20. Click **OK**.
21. Click **Save**.
22. Close the page.

Complete the draft version of metadata configuration

1. Click **Change status**.
2. Click **Complete**.
3. Click **OK**.
4. Select the completed version 1.

Export the completed version of metadata configuration from application as XML file

1. Click **Exchange**.
2. Click **Export as XML file**.
3. Click **OK**.

The created ER metadata configuration has been saved as XML file that can be imported to RCS and used as the source of information about metadata for the foreign trade business domain. Based on this information, we can specify the mapping between application metadata and ER data model.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Access application metadata by using ER configuration

2/18/2021 • 3 minutes to read • [Edit Online](#)

The following steps explain how a Regulatory configuration service (RCS) user in the System Administrator or Electronic Reporting Developer role can design a new Electronic reporting (ER) model mapping by using the application metadata. Application metadata will be accessed by using an ER metadata configuration that contains a sample set of metadata to access foreign trade transactions. To complete these steps, in RCS you must first complete the steps in the topic, [Create configuration providers and mark them as active](#) procedure. Then complete the steps in the topic, [Prepare application metadata to be used in RCS](#).

Prerequisites

1. Go to **All workspaces > Electronic reporting**.
2. Make sure that the configuration provider for the sample company, Litware, Inc., is available and marked as **Active**. If you don't see this configuration provider, complete the steps in the procedure [Create configuration providers and mark them as active](#).

Import metadata configuration

1. Click **Metadata configurations**.
2. Import the ER metadata configuration that contains metadata that has been configured to generate electronic documents for foreign trade business. This ER metadata configuration has been exported as XML file while the steps in the [Prepare application metadata to be used in RCS](#) procedure have been completed.
3. Click **Exchange**.
4. Click **Load from XML file**.
5. Click **Browse** and select the 'Foreign trade metadata.xml' file.
6. Click **OK**.
7. Close the page.

Create data model configuration

1. Click **Reporting configurations**.
2. Click **Create configuration** to open the drop dialog.
3. In the **Name** field, type 'Foreign trade model'.
4. Click **Create configuration**.
5. Click **Designer**.
6. Click **New** to open the drop dialog.
7. In the **Name** field, type 'Root'.
8. Click **Add**.
9. Click **New** to open the drop dialog.
10. In the **Name** field, type 'Transaction'.
11. In the **Item type** field, select **Record list**.
12. Click **Add**.
13. Click **New** to open the drop dialog.
14. In the **Name** field, type 'Commodity code'.

15. In the **Item type** field, select **String**.
16. Click **Add**.
17. Click **New** to open the drop dialog.
18. In the **Name** field, type 'Invoiced amount'.
19. In the **Item type** field, select **Real**.
20. Click **Add**.
21. Click **New** to open the drop dialog.
22. In the **Name** field, type 'Date'.
23. In the **Item type** field, select **Date**.
24. Click **Add**.
25. Click **Root reference**.
26. Click **OK**.
27. Click **Save**.
28. Close the page.
29. Click **Change status**.
30. Click **Complete**.
31. Click **OK**.

Create model mapping configuration

1. Click **Create configuration** to open the drop dialog.
2. In the **New** field, enter 'Model Mapping based on data model Foreign trade model'.
3. In the **Name** field, type 'Foreign trade mapping'.
4. Click **Create configuration**.
5. Expand the **Prerequisites** section.
6. Click **Edit**.
7. Click **New**.
8. In the list, mark the selected row.
9. In the **Prerequisite component type** field, select **Configuration**.
10. Select **Foreign trade metadata** configuration.
11. Click **Save**.
12. We added the reference to the version 1 of the 'Foreign trade metadata' configuration. Application metadata from this configuration will be offered while this model mapping will be designed.
13. Close the page.
14. Click **Designer**.
15. Click **Designer**.
16. In the tree, select **Dynamics 365 for Operations\Table records**.
17. Click **Add root**.
18. In the **Name** field, type 'Intrastat'.
19. Select **Intrastat** table records.
20. Click **OK**.

NOTE

The only 2 tables were offered as the only 2 tables were added into the set of metadata which is currently in use.

21. Click **Bind**.
22. In the tree, expand **Intrastat**.

23. In the tree, select **Intrastat\AmountMST**.
24. In the tree, expand **Transaction = Intrastat**.
25. In the tree, select **Transaction = Intrastat\Invoiced amount**.
26. Click **Bind**.
27. In the tree, select **Intrastat\TransDate**.
28. In the tree, select **Transaction = Intrastat\Date**.
29. Click **Bind**.
30. In the tree, expand **Intrastat> Relations**.
31. In the tree, expand **Intrastat> Relations\IntrastatCommodity**.
32. In the tree, select **Intrastat> Relations\IntrastatCommodity\Code**.
33. In the tree, select **Transaction = Intrastat\Commodity code**.
34. Click **Bind**.
35. Click **Validate**.

NOTE

We have successfully bound elements of data model with items of data sources that are described by using details of application metadata from the referred ER metadata configuration. 36. Click **Save**. 37. Close the page. 38. Close the page. 39. When needed, you can extend the existing set of metadata and then export the new completed version of ER metadata configuration. You can then import it to RCS, and update the prerequisites of the configured model mapping configuration referring to a new version of imported metadata configuration.

NOTE

This way of getting information about application metadata is the only one available for locally deployed applications (when local business data (LBD), or on-premises, deployment model is used).

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Access application metadata by using connected applications

2/18/2021 • 3 minutes to read • [Edit Online](#)

The following steps explain how a Regulatory configuration service (RCS) user in the System Administrator or Electronic Reporting Developer role can design a new Electronic reporting (ER) model mapping by using metadata in Finance and Operations. Application metadata will be accessed online by using the RCS connected application. Sample ER model mapping will be configured to access foreign trade transactions. To complete these steps, in RCS you must first complete the steps in the topic, [Create configuration providers and mark them as active](#). If you have not completed the steps in the topic, [Access application metadata by using ER configuration](#), go to the [Electronic reporting examples page](#) to download and save the following ER configurations: Foreign trade metadata.xml; Foreign trade model.xml; Foreign trade mapping.xml, and then complete the steps in the procedure.

Prerequisites

1. Go to **All workspaces > Electronic reporting**.
2. Make sure that the configuration provider for the sample company, Litware, Inc., is available and marked as **Active**. If you don't see this configuration provider, complete the steps in the procedure [Create configuration providers and mark them as active](#).

Get required ER configurations

1. Click **Reporting configurations**.
2. If you already completed the steps in the [Access application metadata by using ER configuration](#) procedure, you already have all necessary ER configurations (foreign trade metadata, model and mapping configurations) in the current RCS instance. You can skip all the remaining steps of this sub-task.
3. Click **Exchange**.
4. Click **Load from XML file**.
5. Click **Browse** and select the **Foreign trade metadata.xml** file.
6. Click **OK**.
7. Click **Exchange**.
8. Click **Load from XML file**.
9. Click **Browse** and select the **Foreign trade model.xml** file.
10. Click **OK**.
11. Click **Exchange**.
12. Click **Load from XML file**.
13. Click **Browse** and select the **Foreign trade mapping.xml** file.
14. Click **OK**.

Register a connected application

1. Close the page.
2. Close the page.
3. Go to **All workspaces > Electronic reporting**.
4. Click **Connected applications**.

5. Make sure that the configured application is Azure based and accessible for the current RCS user. It is also required that the current RCS user has access to the selected application and has been registered as a user of this application playing a role giving them privileges to access application's metadata.
6. Click **New**.
7. In the **Name** field, type 'MyConnectedApp'.
8. In the **Application** field, type 'https:// mycompany.operations.dynamics.com'.
9. In the **Tenant** field, type 'mycompany.onmicrosoft.com'.
10. Click **Save**.
11. When you check connection to configured application, on the **Connect to remote application** page click **Click here to connect to selected remote application** link.
12. Click **Check connection**.
13. Click **Close**.
14. When the connection validation succeeded, version and tenant details will be updated for the configured application in the current grid.

Review existing model mapping configuration

1. Close the page.
2. Click **Reporting configurations**.
3. In the tree, expand **Foreign trade model**.
4. In the tree, select **Foreign trade model\Foreign trade mapping**.
5. Expand the **Prerequisites** section.

NOTE

Currently, this mapping refers to the metadata configuration. Application metadata from this configuration will be offered while this model mapping will be designed.

6. Click **Designer**.
7. Click **Designer**.
8. In the tree, select **Dynamics 365 for Operations\Table records**.
9. Click **Add root**.
10. In the **Table** field, enter or select a value.

NOTE

Currently, this mapping refers to the metadata configuration. Application metadata from this configuration will be offered while this model mapping will be designed.

11. Click **Cancel**.
12. Close the page.
13. Close the page.

Assign connected application to model mapping

1. Click **Edit**.
2. Select **MyConnectedApp** application.

NOTE

Currently, this mapping refers to the metadata of the selected connected application. When the same mapping refers to metadata configuration and connected application at the same time, metadata of the connected application will be used.

3. Click **Designer**.
4. Click **Designer**.
5. In the tree, select **Dynamics 365 for Operations\Table records**.
6. Click **Add root**.
7. In the **Table** field, enter or select a value.

NOTE

More than two application tables were offered now as this mapping uses all the metadata of the connected application that has been assigned for it.

8. Click **Cancel**.
9. Click **Validate**.

NOTE

We successfully bound elements of data model with items of data sources that are described by using details of metadata of the connected application that has been assigned for this mapping.

10. Close the page.
11. Close the page.

When you need to evaluate this model mapping by using metadata of a different version application, register another connected application, assign it to this model mapping and validate it against new metadata.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Define ER model mappings and select data sources for them

2/18/2021 • 4 minutes to read • [Edit Online](#)

The following steps explain how a user in the System Administrator or Electronic Reporting Developer role can select data sources for an Electronic reporting (ER) data model. The data sources will be bound to individual components of the selected data model at design time and populate business data to that data model at run-time. In this example, you will select data sources for an existing data model that has been created for sample company, Litware, Inc. To complete these steps, you must first complete the steps in the "Create a new data model" procedure.

Open the Electronic Reporting configurations tree

1. Go to Organization administration > Workspaces > Electronic reporting.
2. Click Reporting configurations.

Insert a new model mapping

1. In the tree, select 'Payments (simplified model)'.
2. Click Designer.
3. Click Map model to datasource.
4. Click New.
 - This will create a new record that will map the data model to data sources. In this example, you will map the data model to data sources for the desired payment type: credit transfer. It is possible to design more than one mapping for a particular data model. For example, you could create a mapping for the different types of payments, such as for direct debit or for credit transfers. In this example, you will create a mapping for credit transfers.
5. In the Name field, type 'CT mapping'.
 - CT mapping
6. In the Description field, type 'Payment model mapping CT'.
 - Payment model mapping CT
7. In the Definition field, type 'CustomerCreditTransferInitiation'.
 - CustomerCreditTransferInitiation
8. ResolveChanges the Definition.
9. Click Save.

Define required data sources for the current model mapping

1. Click Designer.
2. In the tree, select 'Dynamics 365 for Operations\Table records'.
3. Click Add root.
 - Enter this data source to access payment transactions.
4. In the Name field, type 'Transactions'.
 - Transactions
5. In the Label field, enter 'Transactions'.
 - Transactions

6. In the Help field, enter 'Ledger journal lines'.
 - Ledger journal lines
7. Select Yes in the Ask for query field.
 - Select Yes.
8. In the Table field, type 'LedgerJournalTrans'.
 - LedgerJournalTrans
9. Click OK.
 - Select the LedgerJournalTrans table as a data source for the current data model.
10. In the tree, select 'Functions\Calculated field'.
11. Click Add.
 - Click Add to add a new calculated field.
12. In the Name field, type '\$EndToEndID'.
 - \$EndToEndID
13. Click Edit formula.
14. In the tree, select 'String\CONCATENATE'.
15. Click Add function.
16. In the tree, expand 'Transactions'.
17. In the tree, select 'Transactions\Voucher'.
18. Click Add data source.
19. In the Formula field, enter 'CONCATENATE(Transactions.Voucher, "-", ' '.
 - Type [, "-",] at the end of the formula.
20. In the tree, select 'String\TEXT'.
21. Click Add function.
22. In the tree, select 'Transactions\Record-ID(ReclId)'.
23. Click Add data source.
24. In the Formula field, enter 'CONCATENATE(Transactions.Voucher, "-", TEXT(Transactions.ReclId))'.
 - Type [)])] at the end of the formula.
25. Click Save.
 - Make sure that no errors have been discovered for the created formula. See the ERRORS tab below the formula editor control.
26. Close the page.
27. Click OK.
 - Add the calculated field to this data source.
28. Click Add.
 - Click Add to add a new calculated field.
29. In the Name field, type '\$Amount'.
 - \$Amount
30. Click Edit formula.
31. In the tree, expand 'Transactions'.
32. In the tree, select 'Transactions\Debit(AmountCurDebit)'.
33. Click Add data source.
34. In the Formula field, enter 'Transactions.AmountCurDebit - '.
 - Type [-] at the end of the formula.
35. In the tree, select 'Transactions\Credit(AmountCurCredit)'.
36. Click Add data source.
37. Click Save.
38. Close the page.

39. Click OK.
 - This will add the \$Amount calculated field to the selected data source for the current data model.
40. In the tree, select 'Transactions\$Amount'.
41. In the tree, expand 'Transactions'.
42. In the tree, expand or collapse 'Transactions\$Amount'.
43. In the tree, expand or collapse 'Transactions'.
44. In the tree, select 'Dynamics 365 for Operations\Table records'.
45. Click Add root.
 - Enter this data source to access the company's bank account details.
46. In the Name field, type 'BankAccount'.
 - BankAccount
47. In the Label field, enter 'Bank Account'.
 - Bank Account
48. In the Help field, enter 'Bank Account'.
 - Bank Account
49. Select Yes in the Ask for query field.
 - Select Yes.
50. In the Table field, type 'BankAccountTable'.
 - BankAccountTable
51. Click OK.
 - Select the BankAccountTable table as a data source for the current data model.
52. Click Add root.
 - Enter this data source to access the company's requisites.
53. In the Name field, type 'Company'.
 - Company
54. In the Label field, type a value.
 - Company information
55. In the Help field, enter 'Company information'.
 - Company information
56. Select Yes in the Ask for query field.
 - Select Yes.
57. In the Table field, type 'CompanyInfo'.
 - CompanyInfo
58. Click OK.
 - Select the CompanyInfo table as a data source for the current data model.
59. In the tree, select 'Functions\Calculated field'.
60. Click Add root.
 - Insert a calculated field as a new data source.
61. In the Name field, type 'ProcessingDateTime'.
 - ProcessingDateTime
62. In the Label field, enter 'Processing date & time'.
 - Processing date & time
63. Click Edit formula.
64. In the tree, select 'Date/time\SESSIONNOW'.
65. Click Add function.
66. Click Save.

67. Close the page.

68. Click OK.

- Add the ProcessingDateTime calculated field as a data source for the current data model.

69. Click Save.

70. Close the page.

71. Close the page.

72. Close the page.

ER Map data model to selected data sources

2/18/2021 • 3 minutes to read • [Edit Online](#)

The following steps explain how a user in the System Administrator or Electronic Reporting Developer role can map an Electronic reporting (ER) data model to selected data sources. This model mapping will later be used as a data source in a format configuration that will be used to manage electronic payment documents. In this example, you map a data model for sample company, Litware, Inc. to data sources. To complete these steps, you must first complete the steps in the "Select data sources for model mapping" procedure.

Open ER configurations tree

1. Go to Organization administration > Workspaces > Electronic reporting.
2. Click Configurations.

Select created model mapping

1. In the tree, select 'Payments (simplified model)'.
 - Make sure that the model configuration "Payments (simplified model)" has been created in advance. Otherwise, stop now and return after completion of the task guide 'Create a new configuration with data model of the selected domain'.
2. Click Model designer.
3. Click Map model to datasource.
4. Select the 'CT mapping' record.
 - CT mapping

Bind created data sources to data model elements

1. Click Designer.
2. In the tree, select 'Processing date & time(ProcessingDateTime)'.
3. In the tree, select 'Processing date(ProcessingDateTime)'.
4. Click Bind.
5. In the tree, select 'Payment message identification(MessageIdentification)'.
6. In the tree, expand 'Transactions'.
7. In the tree, select 'Transactions\Journal batch number(JournalNum)'.
8. Click Bind.
9. In the tree, select 'Payments'.
10. In the tree, select 'Transactions'.
11. Click Bind.
12. In the tree, expand 'Payments= Transactions'.
13. In the tree, expand 'Payments= Transactions\Creditor'.
14. In the tree, expand 'Payments= Transactions\Creditor\Account'.
15. In the tree, select 'Payments= Transactions\Creditor\Account\Currency code(Currency)'.
16. In the tree, expand 'Transactions\vendBankAccountInTransactionCompany()'.
17. In the tree, select 'Transactions\vendBankAccountInTransactionCompany()\Currency(CurrencyCode)'.
18. Click Bind.
19. In the tree, select 'Payments= Transactions\Creditor\Account\IBAN code(IBAN)'.

20. In the tree, select 'Transactions\vendBankAccountInTransactionCompany()\IBAN(BankIBAN)'.
21. Click Bind.
22. In the tree, select 'Payments= Transactions\Creditor\Account\Number'.
23. In the tree, select 'Transactions\vendBankAccountInTransactionCompany()\Bank account number(AccountNum)'.
24. Click Bind.
25. In the tree, expand 'Payments= Transactions\Creditor\Agent'.
26. In the tree, select 'Payments= Transactions\Creditor\Agent\Name'.
27. In the tree, select 'Transactions\vendBankAccountInTransactionCompany()\Name'.
28. Click Bind.
29. In the tree, select 'Payments= Transactions\Creditor\Agent\Routing number(RoutingNumber)'.
30. In the tree, select 'Transactions\vendBankAccountInTransactionCompany()\Routing number(RegistrationNum)'.
31. Click Bind.
32. In the tree, select 'Payments= Transactions\Creditor\Agent\SWIFT code(SWIFT)'.
33. In the tree, select 'Transactions\vendBankAccountInTransactionCompany()\SWIFT code(SWIFTNo)'.
34. Click Bind.
35. In the tree, select 'Payments= Transactions\Creditor\Name'.
36. In the tree, expand 'Transactions\findVendTable()'.
37. In the tree, select 'Transactions\findVendTable()\name()'.
38. Click Bind.
39. In the tree, select 'Payments= Transactions\Currency code(Currency)'.
40. In the tree, expand 'Transactions>Relations'.
41. In the tree, expand 'Transactions>Relations\Currency table(Currency)'.
42. In the tree, select 'Transactions>Relations\Currency table(Currency)\Currency code(CurrencyCodeISO)'.
43. Click Bind.
44. In the tree, expand 'Payments= Transactions\Debtor'.
45. In the tree, expand 'Payments= Transactions\Debtor\Account'.
46. In the tree, select 'Payments= Transactions\Debtor\Account\Currency code(Currency)'.
47. In the tree, select 'Bank Account(BankAccount)'.
48. In the tree, expand 'Bank Account(BankAccount)'.
49. In the tree, select 'Bank Account(BankAccount)\Currency(CurrencyCode)'.
50. Click Bind.
51. In the tree, select 'Bank Account(BankAccount)\IBAN'.
52. In the tree, select 'Payments= Transactions\Debtor\Account\IBAN code(IBAN)'.
53. Click Bind.
54. In the tree, select 'Payments= Transactions\Debtor\Account\Number'.
55. In the tree, select 'Bank Account(BankAccount)\Bank account number(AccountNum)'.
56. Click Bind.
57. In the tree, expand 'Payments= Transactions\Debtor\Agent'.
58. In the tree, select 'Payments= Transactions\Debtor\Agent\Name'.
59. In the tree, select 'Bank Account(BankAccount)\Name'.
60. Click Bind.
61. In the tree, select 'Payments= Transactions\Debtor\Agent\Routing number(RoutingNumber)'.
62. In the tree, select 'Bank Account(BankAccount)\Routing number(RegistrationNum)'.
63. Click Bind.
64. In the tree, select 'Payments= Transactions\Debtor\Agent\SWIFT code(SWIFT)'.

65. In the tree, select 'Bank Account(BankAccount)\SWIFT code(SWIFTNo)'.
66. Click Bind.
67. In the tree, select 'Payments= Transactions\Debtor\Name'.
68. In the tree, select 'Company information(Company)'.
69. In the tree, expand 'Company information(Company)'.
70. In the tree, select 'Company information(Company)\Name'.
71. Click Bind.
72. In the tree, select 'Payments= Transactions\Description'.
73. In the tree, select 'Transactions\Description(Txt)'.
74. Click Bind.
75. In the tree, select 'Payments= Transactions\End to end identification code(End2EndID)'.
76. In the tree, select 'Transactions\$EndToEndID'.
77. Click Bind.
78. In the tree, select 'Payments= Transactions\Instructed amount(InstructedAmount)'.
79. In the tree, select 'Transactions\$Amount'.
80. Click Bind.
81. In the tree, select 'Payments= Transactions\Transaction date(TransactionDate)'.
82. In the tree, select 'Transactions\Date(TransDate)'.
83. Click Bind.

Validate created mapping

1. Click Validate.
 - Validate the new mapping to ensure that all bindings are okay.
2. Click the arrow to expand or collapse the Error List section.
3. Click Save.
4. Close the page.
5. Close the page.
6. Close the page.

Change the status of the current version of model configuration

1. Click Change status.
 - Change the status of designed model configuration – from Draft to Completed to make it available for payment format design.
2. Click Complete.
 - Select Complete.
3. In the Description field, type a value.
 - For example, 'version 1'.
4. Click OK.
5. Select the completed version of the current configuration.
 - Note that the created configuration is saved as completed version 1.

NOTE

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

ER Create a format configuration (November 2016)

2/18/2021 • 3 minutes to read • [Edit Online](#)

This topic explains how a user in the System Administrator or Electronic Reporting Developer role can create a format configuration for Electronic reporting (ER). This format configuration will define the format of electronic documents that are used for processing payments. In this example, you will create a format configuration for sample company, Litware, Inc. To complete these steps, you must first complete the steps in the "Map model to selected datasources" procedure.

Create a new format configuration

1. Go to **Organization administration > Workspaces > Electronic reporting**.
2. Click **Reporting configurations**.
3. In the tree, select **Payments (simplified model)**.
4. Click **Create configuration** to open the drop dialog.

NOTE

If you don't see **Create configuration**, you must enable design mode on the **Electronic reporting parameters** page.

5. In the **New** field, enter **Format based on data model PaymentModel**.
6. In the **Name** field, type **BACS (UK fictitious)**.
7. In the **Description** field, type **BACS vendor payment format (UK fictitious)**.
 - The active configuration provider is automatically entered here. This provider will be able to maintain this configuration. Other providers can use this configuration, but will not be able to maintain it.
 - A particular format of electronic document can be defined. Leave this field blank if you want to select a format at run-time.
8. In the **Data model definition** field, enter or select a value.
9. Click **Create configuration**. A new configuration has been created. The draft version can be used to store the design format for managing electronic documents.

Design the format of an electronic document

1. Click **Designer**.
2. Click **Add root** to open the drop dialog.
3. In the tree, select **Common\File**.
4. In the **Name** field, type **Xml**.
5. In the **Encoding** field, type **UTF-8**.
6. Click **OK**.
7. Click **Add**.
8. In the tree, select **XML\Element**.
9. In the **Name** field, type **Message**.
10. Click **OK**.
11. In the tree, select **Xml\Message**.
12. Click **Add Element**.
13. In the **Name** field, type **ProcessingDate**.

14. Click **OK**.
15. Click **Add Element**.
16. In the **Name** field, type **MessageId**.
17. Click **OK**.
18. Click **Add Element**.
19. In the **Name** field, type **Payments**.
20. Click **OK**.
21. In the tree, select **Xml\Message\Payments**.
22. Click **Add Element**.
23. In the **Name** field, type **Item**.
24. Click **OK**.
25. In the tree, select **Xml\Message\Payments\Item**.
26. Click **Add**.
27. In the tree, select **XML\Attribute**.
28. In the **Name** field, type **Id**.
29. Click **OK**.
30. Click **Add**.
31. In the tree, select **XML\Element**.
32. In the **Name** field, type **Vendor**.
33. Click **OK**.
34. In the tree, select **Xml\Message\Payments\Item\Vendor**.
35. Click **Add Element**.
36. In the **Name** field, type **Name**.
37. Click **OK**.
38. Click **Add Element**.
39. In the **Name** field, type **Bank**.
40. Click **OK**.
41. In the tree, select **Xml\Message\Payments\Item\Vendor\Bank**.
42. Click **Add Element**.
43. In the **Name** field, type **RoutingNumber**.
44. Click **OK**.
45. Click **Add Element**.
46. In the **Name** field, type **AccountNumber**.
47. Click **OK**.
48. In the tree, select **Xml\Message\Payments\Item\Vendor**.
49. Click **Copy**.
50. In the tree, select **Xml\Message\Payments\Item**.
51. Click **Paste**.
52. In the **Name** field, type **Payer**.
53. In the tree, select **Xml\Message\Payments\Item**.
54. Click **Add Element**.
55. In the **Name** field, type **Currency**.
56. Click **OK**.
57. Click **Add Element**.
58. In the **Name** field, type **Description**.
59. Click **OK**.

60. Click **Add Element**.
61. In the Name field, type **TransDate**.
62. Click **OK**.
63. Click **Add Element**.
64. In the Name field, type **Amount**.
65. Click **OK**.

Prepare format components for mapping to data model elements

1. In the tree, select **Xml\Message\ProcessingDate**.
2. Click **Add** to open the drop dialog.
3. In the tree, select **Text\DateTime**.
4. In the **Format** field, type **yyyy-MM-dd**.
5. Click **OK**.
6. In the tree, select **Xml\Message\Payments\Item\TransDate**.
7. Click **Add DateTime**.
8. In the **Format** field, type **yyyy-MM-dd**.
9. In the **DateTime** type field, select **Date**.
10. Click **OK**.
11. In the tree, select **Xml\Message\Messageld**.
12. Click **Add** to open the drop dialog.
13. In the tree, select **Text\String**.
14. Click **OK**.
15. In the tree, select **Xml\Message\Payments\Item\Vendor\Name**.
16. Click **Add String**.
17. Click **OK**.
18. In the tree, select **Xml\Message\Payments\Item\Vendor\Bank\RoutingNumber**.
19. Click **Add String**.
20. Click **OK**.
21. In the tree, select **Xml\Message\Payments\Item\Vendor\Bank\AccountNumber**.
22. Click **Add String**.
23. Click **OK**.
24. In the tree, select **Xml\Message\Payments\Item\Payer\Name**.
25. Click **Add String**.
26. Click **OK**.
27. In the tree, select **Xml\Message\Payments\Item\Payer\Bank\RoutingNumber**.
28. Click **Add String**.
29. Click **OK**.
30. In the tree, select **Xml\Message\Payments\Item\Payer\Bank\AccountNumber**.
31. Click **Add String**.
32. Click **OK**.
33. In the tree, select **Xml\Message\Payments\Item\Currency**.
34. Click **Add String**.
35. Click **OK**.
36. In the tree, select **Xml\Message\Payments\Item\Description**.
37. Click **Add String**.
38. Click **OK**.

39. In the tree, select **Xml\Message\Payments\Item\Amount**.
40. Click **Add String**.
41. Click **OK**.
42. Click **Save**.
43. Close the page.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

ER Map components of the created format to data model elements (November 2016)

2/18/2021 • 3 minutes to read • [Edit Online](#)

The following procedure shows how a user in either the System administrator or Electronic reporting developer role can map data model elements to components of the created Electronic reporting (ER) configuration, which defines an electronic document format for the payments business domain. This format will be used later to generate electronic documents for processing payments. In this example, you will create a format configuration for the sample company, 'Litware, Inc.'. These steps can be performed in any company as ER configurations are shared for all companies. To complete these steps, you must first complete the steps in the "Create a format configuration" task guide.

Select a format configuration

1. Go to Organization administration > Workspaces > Electronic reporting.
2. Click Reporting configurations.
3. In the tree, expand 'Payments (simplified model)'.
4. In the tree, select 'Payments (simplified model)\BACS (UK fictitious)'.
5. Click Designer.

Map format components to data model elements

1. Click Expand/collapse.
2. Click the Mapping tab.
3. In the tree, expand 'model'.
4. In the tree, select 'Xml\Message\ProcessingDate\DateTime'.
5. In the tree, select 'model\ProcessingDateTime'.
6. Click Bind.
7. In the tree, select 'Xml\Message\Messageld\String'.
8. In the tree, select 'model\Messageldentification'.
9. Click Bind.
10. In the tree, expand 'model\Payments'.
11. In the tree, select 'Xml\Message\Payments\Item\Amount\String'.
12. In the tree, select 'model\Payments\InstructedAmount'.
13. Click Bind.
14. In the tree, select 'Xml\Message\Payments\Item\TransDate\DateTime'.
15. In the tree, select 'model\Payments\TransactionDate'.
16. Click Bind.
17. In the tree, select 'Xml\Message\Payments\Item\Description\String'.
18. In the tree, select 'model\Payments\Description'.
19. Click Bind.
20. In the tree, select 'Xml\Message\Payments\Item\Currency\String'.
21. In the tree, select 'model\Payments\Currency'.
22. Click Bind.
23. In the tree, select 'Xml\Message\Payments\Item\ld'.

24. In the tree, select 'model\Payments\End2EndID'.
25. Click Bind.
26. In the tree, expand 'model\Payments\Creditor'.
27. In the tree, expand 'model\Payments\Creditor\Account'.
28. In the tree, expand 'model\Payments\Creditor\Agent'.
29. In the tree, select 'Xml\Message\Payments\Item\Vendor\Name\String'.
30. In the tree, select 'model\Payments\Creditor\Name'.
31. Click Bind.
32. In the tree, select 'Xml\Message\Payments\Item\Vendor\Bank\RoutingNumber\String'.
33. In the tree, select 'model\Payments\Creditor\Agent\RoutingNumber'.
34. Click Bind.
35. In the tree, select 'Xml\Message\Payments\Item\Vendor\Bank\AccountNumber\String'.
36. In the tree, select 'model\Payments\Creditor\Account\Number'.
37. Click Bind.
38. In the tree, select 'Xml\Message\Payments\Item\Payer\Name\String'.
39. In the tree, expand 'model\Payments\Debtor'.
40. In the tree, expand 'model\Payments\Debtor\Account'.
41. In the tree, expand 'model\Payments\Debtor\Agent'.
42. In the tree, select 'model\Payments\Debtor\Name'.
43. Click Bind.
44. In the tree, select 'Xml\Message\Payments\Item\Payer\Bank\RoutingNumber\String'.
45. In the tree, select 'model\Payments\Debtor\Agent\RoutingNumber'.
46. Click Bind.
47. In the tree, select 'Xml\Message\Payments\Item\Payer\Bank\AccountNumber\String'.
48. In the tree, select 'model\Payments\Debtor\Account\Number'.
49. Click Bind.
50. In the tree, select 'Xml\Message\Payments\Item'.
51. In the tree, select 'model\Payments'.
52. Click Bind.
53. Click Save.

Validate format mapping

1. Click Validate.
 - Validate the new mapping to ensure that all bindings are okay.
2. Close the page.

Change status of the current version of format configuration

In the next steps, you'll change the status of the format configuration from Draft to Completed to make it available for payment document generation.

1. Click Change status.
2. Click Complete.
3. In the Description field, type a value.
 - For example, 'version 1'.
4. Click OK.
5. Select completed version of the current configuration.

- Note that the configuration is saved as completed version 1.1: version 1 of the format based on the version 1 of the data model.

Define effective date for completed version of format

Each format version can be configured as available for usage starting from a certain date. When more than one format version is active on a certain date, the latest format (based on version number) will be selected for usage. The session date value is used for proper version selection.

Restrict access to created format from companies

1. Expand the ISO Country/region codes section.

- Each format access can be restricted by identifying particular countries/regions in which a format is applicable. When the list of countries/regions for particular format is empty, this format can be used in any company. When some ISO country/region codes are inserted in the list of countries/regions, the format can only be use in companies if the primary address is in the country/region.

NOTE

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

(ER) Import configurations from RCS

2/18/2021 • 2 minutes to read • [Edit Online](#)

The following steps explain how a user in the System Administrator or Electronic Reporting Developer role can import a new version of an Electronic reporting (ER) configuration from Microsoft Regulatory Configuration Services (RCS). In this example, you will select the version of the ER configuration that has been configured in an RCS instance and import it into the current instance for sample company, Litware, Inc. These steps can be performed in any company because ER configurations are shared among companies. To complete these steps, you must first complete the steps in the topic, [Create configuration providers and mark them as active](#). To complete these steps, you must also have access to an RCS instance containing at least one ER configuration in either **Completed** or **Shared** status.

1. Go to **Organization administration > Workspaces > Electronic reporting**.
2. Make sure that the configuration provider for the sample company, Litware, Inc., is available and marked as **Active**. If you don't see this configuration provider, complete the steps in the topic, [Create configuration providers and mark them as active](#).
3. If you have no RCS environment provisioned to your company, select **Regulatory services – Configuration** external link and follow the instructions to provision an RCS environment.
4. Select **Electronic reporting parameters**.
5. Select the **RCS** tab.
6. If RCS environment has been already provisioned to your company, use presented on the page URLs to access it.
7. Close the page.

Register a new ER repository.

1. In the list, mark the selected row.
2. Select Litware, Inc. provider.
3. Select Repositories.
4. Select Add to open the drop dialog.
5. In the Configuration repository type field, enter 'RCS'.
6. Select Create repository.
7. In the RCS environment display name field, enter or select a value.
8. Select the desired RCS instance. You can have several of them.
9. Select OK.

Import ER configurations from RCS-based repository

1. Select **Show filters**.
2. Enter a filter value of "RCS" on the **Name** field using the **begins with** filter operator.
3. When you open the selected repository, on the **Connect to Regulatory Configuration Services** page, select **Select here to connect to Regulatory Configuration Services** link.
4. Select **Open**.
5. Select **Close**.
6. Select the desired version of ER configuration and select **Import** to bring it in the current instance.

NOTE

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

ER Generate electronic documents for payments using a format configuration

2/18/2021 • 2 minutes to read • [Edit Online](#)

The following steps explain how a user in the System Administrator or Electronic Reporting Developer role can use a new Electronic reporting (ER) format configuration to generate electronic documents for processing payments. These steps can be performed in the GBSI sample company.

To complete these steps, you must first complete the steps in the "Create a configuration with format of payment document" procedure.

Change the configuration of the electronic payment method

1. Go to Accounts payable > Payment setup > Methods of payment.
2. Toggle the File format section to expand it, if needed.
3. Use the Quick Filter to find records. For example, filter on the Method of payment field with a value of 'Electronic'.
4. Click Edit.
5. Set the General electronic reporting field to Yes.
 - Select Yes to use the General electronic reporting pattern for payment files generation.
6. In the Name field, click the drop-down button to open the lookup.
7. Select BACS (UK fictitious) format configuration.
8. Click Save.
9. Close the page.

Test the format of generated payment files

1. Go to Accounts payable > Payments > Payment journal.
2. Click New.
3. In the list, mark the selected row.
4. In the Name field, click the drop-down button to open the lookup.
5. In the list, click the link in the selected row.
 - Select VendPay.
6. Click Save.
7. Click Lines.
8. In the Company field, type 'DEMF'.
 - DEMF
9. In the Account field, specify the values 'DE-01001'.
 - DE-01001
10. In the Description field, type 'Payment'.
 - Payment
11. In the Debit field, enter a number.
 - 1000
12. Click the Payment tab.
13. In the Method of payment field, click the drop-down button to open the lookup.

14. In the list, find and select the desired record.
 - Select the Electronic value.
15. In the list, click the link in the selected row.
16. Click Save.
17. Click Generate payments.
18. In the Method of payment field, click the drop-down button to open the lookup.
19. In the list, find and select the desired record.
 - Select the Electronic value.
20. In the list, click the link in the selected row.
 - Select the Electronic value.
21. In the File name field, type a value.
 - For example, type 'payments'.
22. In the Bank account field, click the drop-down button to open the lookup.
23. In the list, click the link in the selected row.
 - Select the value GBSI OPER.
24. Click OK.
25. Click OK.
 - Analyze the created payment file in XML format. Compare it with the designed document layout and defined payment transaction attributes.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

ER Upgrade your format by adopting a new, base version of that format

2/18/2021 • 9 minutes to read • [Edit Online](#)

The following steps explain how a user in the System Administrator or Electronic Reporting Developer role can maintain an Electronic reporting (ER) format configuration. This procedure explains how a custom version of a format can be created based on the format received from a configuration provider (CP). It also explains how to adopt a new, base version of that format.

To complete these steps, you must first complete the steps in the "Create a configuration provider and mark it as active" and "Use created format to generate electronic documents for payments" procedures. These steps can be performed in the GBSI company.

Select format configuration for customization

1. Go to Organization administration > Workspaces > Electronic reporting.

In this example, sample company Litware, Inc. (<https://www.litware.com>) will act as a configuration provider that supports format configurations for electronic payments for a particular country. Sample company Proseware, Inc. (<http://www.proseware.com>) will act as a consumer of the format configuration that Litware, Inc. provided. Proseware, Inc. uses formats in certain regions of that country.

2. Click Reporting configurations.
3. Click Show filters.
4. Apply the following filters: Enter a filter value of "BACS (UK fictitious)" on the "Name" field using the "begins with" filter operator.

The selected format configuration BACS (UK fictitious) is owned by provider Litware, Inc.

5. Click Show filters.
6. In the list, find and select the desired record.

The version of the format with the status of Completed will be used by Proseware, Inc. for customization.

Create a new configuration for your custom format of electronic document

Proseware, Inc. received version 1.1 of BACS (UK fictitious) configuration that contains the initial format to generate electronic payment documents from Litware, Inc. in accordance to their service subscription. Proseware, Inc. wants to start using this as a standard for their country but some customization is required to support specific regional requirements. Proseware, Inc. also wants to keep the ability to upgrade a custom format as soon as a new version of it (with changes to support new country-specific requirements) comes from Litware, Inc. and they want to perform this upgrade with the lowest cost.

To do this, Proseware, Inc. needs to create a configuration using the Litware, Inc. configuration BACS (UK fictitious) as a base.

1. Close the page.
2. Select Proseware, Inc. to make it an active provider.

3. Click Set active.
4. Click Reporting configurations.
5. In the tree, expand 'Payments (simplified model)'.
6. In the tree, select 'Payments (simplified model)\BACS (UK fictitious)'.

Select the BACS (UK fictitious) configuration from Litware, Inc. Proseware, Inc. will use version 1.1 as a base for the custom version.

7. Click Create configuration to open the drop dialog.

This lets you create a new configuration for a custom payment format.

8. In the New field, enter 'Derive from Name: BACS (UK fictitious), Litware, Inc.'.

Select the Derive option to confirm the usage of BACS (UK fictitious) as the base for creating the custom version.

9. In the Name field, type 'BACS (UK fictitious custom)'.

10. In the Description field, type 'BACS vendor payment (UK fictitious custom)'.

The active configuration provider (Proseware, Inc.) is automatically entered here. This provider will be able to maintain this configuration. Other providers can use this configuration, but will not be able to maintain it.

11. Click Create configuration.

Customize your format for the electronic document

1. Click Designer.
2. Click Expand/collapse.
3. Click Expand/collapse.
4. In the tree, select 'Xml\Message\Payments\Item\Vendor\Bank'.
5. Click Add to open the drop dialog.
6. In the tree, select 'XML\Element'.
7. In the Name field, type 'IBAN'.
8. Click OK.
9. In the tree, select 'Xml\Message\Payments\Item\Vendor\Bank\IBAN'.
10. Click Add to open the drop dialog.
11. In the tree, select 'Text\String'.
12. Click OK.
13. In the tree, select 'Xml\Message\Payments\Item\Vendor\Name\String'.
14. In the Maximum length field, enter '60'.
15. Click the Mapping tab.
16. In the tree, expand 'model'.
17. In the tree, expand 'model\Payments'.
18. In the tree, expand 'model\Payments\Creditor'.
19. In the tree, expand 'model\Payments\Creditor\Account'.
20. In the tree, select 'model\Payments\Creditor\Account\IBAN'.
21. In the tree, select 'Xml\Message\Payments\Item = model.Payments\Vendor\Bank\IBAN\String'.
22. Click Bind.
23. Click Save.

Validate the customized format

1. Click Validate.

Validate the customized format layout and data mapping changes to make sure that all bindings are okay.

2. Close the page.

Change the status of the current version of the custom format configuration

Change the status of the designed format configuration from Draft to Completed to make it available for payment document generation.

1. Click Change status.

Note that the current version of the selected configuration is in Draft status.

2. Click Complete.
3. In the Description field, type a value.
4. Click OK.
5. In the list, find and select the desired record.

Note that the created configuration is saved as completed version 1.1.1. This means it is version 1 of the custom BACS (UK fictitious custom) format, which is based on version 1 of the BACS (UK fictitious) format, which is based on version 1 of the Payments (simplified model) data model.

Test the customized format to generate payment files

Complete the steps in the "Use created format to generate electronic documents for payments" procedure in a parallel Finance and Operations session. Select the BACS (UK fictitious custom) format in electronic payment method parameters. Make sure that the created payment file contains the recently introduced XML node presenting IBAN code in accordance to regional requirements.

Update the existing country-specific configuration

Litware, Inc. needs to update the BACS (UK fictitious) configuration and adopt new country requirements for managing the format of the electronic document. Later, this will be enclosed in a new version of this configuration that will be offered for service subscribers, including Proseware, Inc.

In real service provision related processes, each new version of BACS (UK fictitious) can be imported by Proseware, Inc. from Litware, Inc. configurations' LCS repository. In this procedure we will simulate this by updating BACS (UK fictitious) on behalf of a service provider.

1. Close the page.
2. Select Litware, inc. provider.
3. Click Set active.
4. Click Reporting configurations.
5. In the tree, expand 'Payments (simplified model)'.
6. In the tree, select 'Payments (simplified model)\BACS (UK fictitious)'.

The draft version owned by Litware, Inc. provider BACS (UK fictitious) is selected to bring in changes to

support new country-specific requirements.

Localize the base format of the electronic document

Assume that there are new country-specific requirements to be supported by Litware, Inc.:

- A value for the creditor's bank SWIFT code in each payment transaction.
- A limit of 100 characters for the length of text for the vendor's name in a generating file.
- New country-specific requirements
- Select the draft version of the desired configuration to introduce required changes.

1. Click Designer.
2. Click Expand/collapse.
3. Click Expand/collapse.
4. In the tree, select 'Xml\Message\Payments\Item\Vendor\Bank'.
5. Click Add to open the drop dialog.
6. In the tree, select 'XML\Element'.
7. In the Name field, type 'SWIFT'.
8. Click OK.
9. In the tree, select 'Xml\Message\Payments\Item\Vendor\Bank\SWIFT'.
10. Click Add to open the drop dialog.
11. In the tree, select 'Text\String'.
12. Click OK.
13. In the tree, select 'Xml\Message\Payments\Item\Vendor\Name\String'.
14. In the Maximum length field, enter '100'.
15. Click the Mapping tab.
16. In the tree, expand 'model'.
17. In the tree, expand 'model\Payments'.
18. In the tree, expand 'model\Payments\Creditor'.
19. In the tree, expand 'model\Payments\Creditor\Agent'.
20. In the tree, select 'model\Payments\Creditor\Agent\SWIFT'.
21. In the tree, select 'Xml\Message\Payments\Item = model.Payments\Vendor\Bank\SWIFT\String'.
22. Click Bind.
23. Click Save.

Validate the localized format

1. Click Validate.
2. Close the page.

Change the status of the current version of the base format configuration

Change the status of the updated base format configuration from Draft to Completed to make it available for generation of payment documents and updates of format configurations derived from it.

1. Click Change status.

Note that the current version of the selected configuration is in Draft status.

2. Click Complete.

3. In the Description field, type a value.
4. Click OK.
5. In the list, find and select the desired record.

Change the base version for the custom format configuration

Proseware, Inc. is informed that a new version 1.2 of BACS (UK fictitious) configuration is available to generate electronic payment documents in accordance to recently announced country-specific requirements. Proseware, Inc. wants to start using it as a standard for the country.

To do this, Proseware, Inc. needs to change the base configuration version for the custom configuration BACS (UK fictitious custom). Instead of version 1.1 of BACS (UK fictitious) use new version 1.2.

1. Go to Organization administration > Workspaces > Electronic reporting.
2. Select the Proseware, Inc. provider to mark it as active.
3. Click Set active.
4. Click Reporting configurations.
5. In the tree, expand 'Payments (simplified model)'.
6. In the tree, expand 'Payments (simplified model)\BACS (UK fictitious)'.
7. In the tree, select 'Payments (simplified model)\BACS (UK fictitious)\BACS (UK fictitious custom)'.

Select the BACS (UK fictitious custom) configuration, which is owned by Proseware, Inc.

Use the draft version of the selected configuration to introduce required changes.

8. Click Rebase.

Select the new version 1.2 of the base configuration to be applied as a new base for updating the configuration.

9. Click OK.

Note that some conflicts have been discovered between merging the custom version and a new base version representing some format changes that can't be merged automatically.

Resolve rebase conflicts

1. Click Designer.

Note that changes to the vendor's name text length limit couldn't be resolved automatically. Therefore, this is presented in a conflicts list. For each conflict of type Update, the following options are available: - Apply a prior base value (button on top of the grid) to bring in the previous base version value (0 in our case). - Apply a base value (button on top of the grid) to bring in the new base version value (100 in our case). - Keep your own (custom) value (60 in our case). Click Apply base value to apply a country-specific limit of 100 characters for vendor's name text length.

Note that Proseware, Inc. and Litware, Inc. have custom and local versions of this format using IBAN and SWIFT codes with related components that are automatically merged in the managing format.

2. Click Apply base value.

Click Apply base value to apply the country-specific limit of 100 characters for vendor names.

3. Click Save.

Saving the format will remove resolved conflicts from the conflicts list.

4. Close the page.

Change the status of the new version of the custom format configuration

1. Click Change status.

Change the status of the updated, custom format configuration from Draft to Completed. This will make the format configuration available for generating payment documents. Note that the current version of the selected configuration is in Draft status.

2. Click Complete.

3. In the Description field, type a value.

4. Click OK.

Note that the created configuration is saved as completed version 1.2.2: version 2 of base BACS (UK fictitious custom) format, which is based on version 2 of base BACS (UK fictitious) format, which is based on version 1 of Payments (simplified model) data model.

Test the customized format for payment files generation

Complete the steps in the "Use created format to generate electronic documents for payments" procedure in parallel Finance and Operations session. Select the created 'BACS (UK fictitious custom)' format in electronic payment method parameters. Make sure that the created payment file contains recently introduced by Proseware, Inc. XML node presenting IBAN account code in accordance to regional requirements. The file also should contain the recently introduced by Litware, Inc. XML node presenting SWIFT bank code in accordance to country requirements.

Formula designer in Electronic reporting (ER)

2/18/2021 • 8 minutes to read • [Edit Online](#)

This topic explains how to use the formula designer in Electronic reporting (ER). When you design a format for a specific electronic document in ER, you can use formulas to transform data so that it meets the requirements for the document's fulfillment and formatting. These formulas resemble formulas in Microsoft Excel. Various types of functions are supported in the formulas: text, date and time, mathematical, logical, information, and data type conversion functions, and also other, business domain-specific functions.

Formula designer overview

ER supports the formula designer. Therefore, at design time, you can configure expressions that can be used for the following tasks at runtime:

- Transform data that is received from an application database and that should be entered in an ER data model that is designed to be a data source for ER formats. (For example, these transformations might include filtering, grouping, and data type conversion.)
- Format data that must be sent to a generating electronic document in accordance with the layout and conditions of a specific ER format. (For example, the formatting might be done in accordance with the requested language or culture, or the encoding).
- Control the process of creating electronic documents. (For example, the expressions can enable or disable the output of specific elements of the format, depending on processing data. They can also interrupt the document creation process or throw messages to users.)

You can open the **Formula designer** page when you perform any of the following actions:

- Bind data source items to data model components.
- Bind data source items to format components.
- Complete maintenance of calculated fields that are part of data sources.
- Define the visibility conditions for user input parameters.
- Design a format's transformations.
- Define the enabling conditions for the format's components.
- Define the file names for the format's FILE components.
- Define the conditions for process control validations.
- Define the message text for process control validations.

Data binding

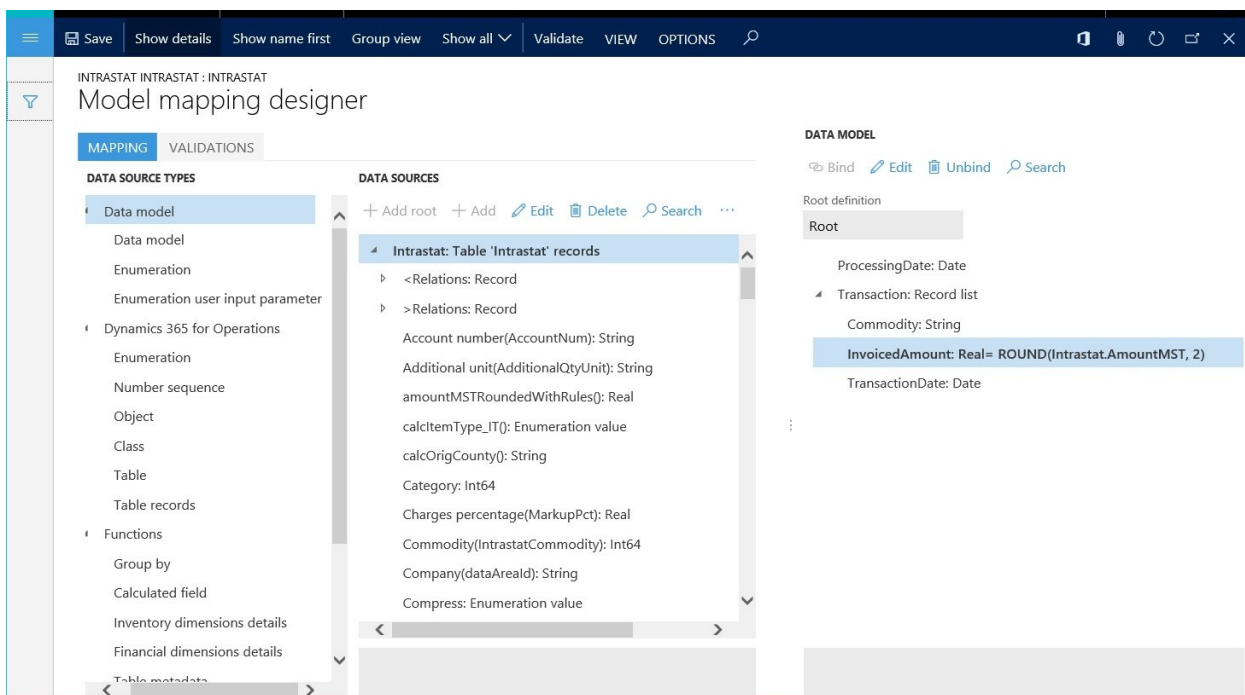

The ER formula designer can be used to define an expression that transforms data that is received from data sources, so that the data can be entered in the data consumer in the following ways at runtime:

- From application data sources and runtime parameters to an ER data model
- From an ER data model to an ER format
- From application data sources and runtime parameters to an ER format

The following illustration shows the design of an expression of this type. In this example, the expression rounds the value of the **Intrastat.AmountMST** field in the Intrastat table to two decimal places and then returns the rounded value.

The following illustration shows how an expression of this type can be used. In this example, the result of the designed expression is entered in the **Transaction.InvoicedAmount** component of the **Tax reporting model** data model.

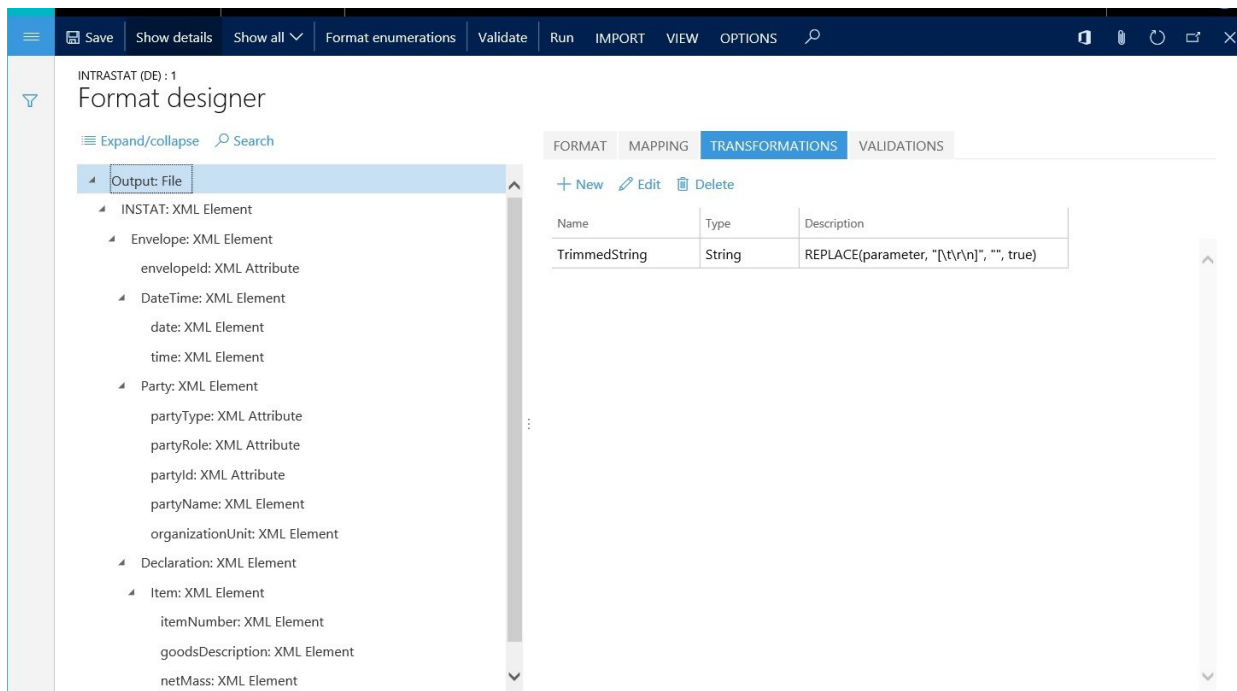

At runtime, the designed formula, `ROUND (Intrastat.AmountMST, 2)`, rounds the value of the **AmountMST** field for each record in the **Intrastat** table to two decimal places. It then enters the rounded value in the **Transaction.InvoicedAmount** component of the **Tax reporting** data model.

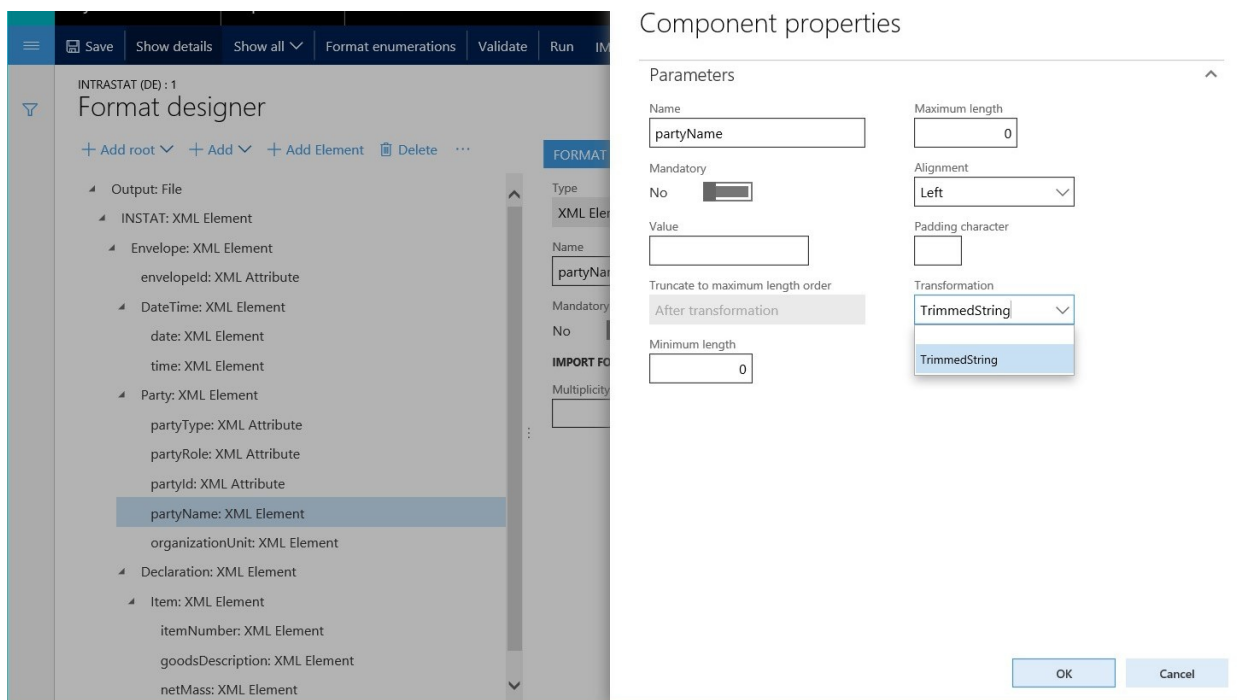

Data formatting

The ER formula designer can be used to define an expression that formats data that is received from data sources, so that the data can be sent as part of the generating electronic document. You might have formatting that must be applied as a typical rule that should be reused for a format. In this case, you can introduce that formatting one time in the format configuration, as a named transformation that has a formatting expression. This named transformation can then be linked to many format components where the output must be formatted according to the formatting expression that you created.

The following illustration shows the design of a transformation of this type. In this example, the `TrimmedString` transformation truncates incoming data of the `String` data type by removing leading and trailing spaces. It then returns the truncated string value.

The following illustration shows how a transformation of this type can be used. In this example, several format components send text as output to the generating electronic document at runtime. All these format components refer to the `TrimmedString` transformation by name.

When format components, such as the `partyName` component in the preceding illustration, refer to the `TrimmedString` transformation, the transformation sends text as output to the generating electronic document. This text doesn't include leading and trailing spaces.

If you have formatting that must be applied individually, you can introduce that formatting as an individual expression of a binding of a specific format component. The following illustration shows an expression of this type. In this example, the `partyType` format component is bound to the data source via an expression that converts incoming data from the `Model.Company.RegistrationType` field in the data source to uppercase text. The expression then sends that text as output to the electronic document.

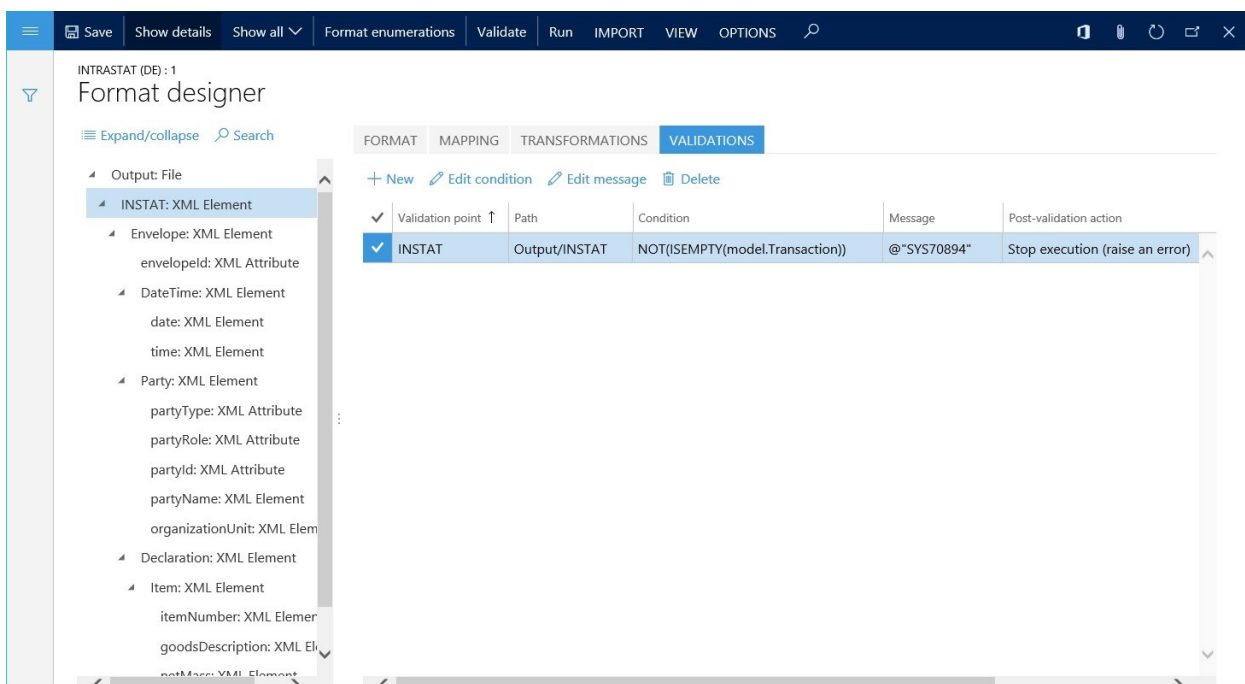

Process flow control

The ER formula designer can be used to define expressions that control the process flow of generating electronic documents. You can perform the following tasks:

- Define conditions that determine when a document creation process must be stopped.
- Specify expressions that either create messages for the user about stopped processes or throw execution log messages about the continuing process of report generation.
- Specify the file names of generating electronic documents, and control the conditions of their creation.

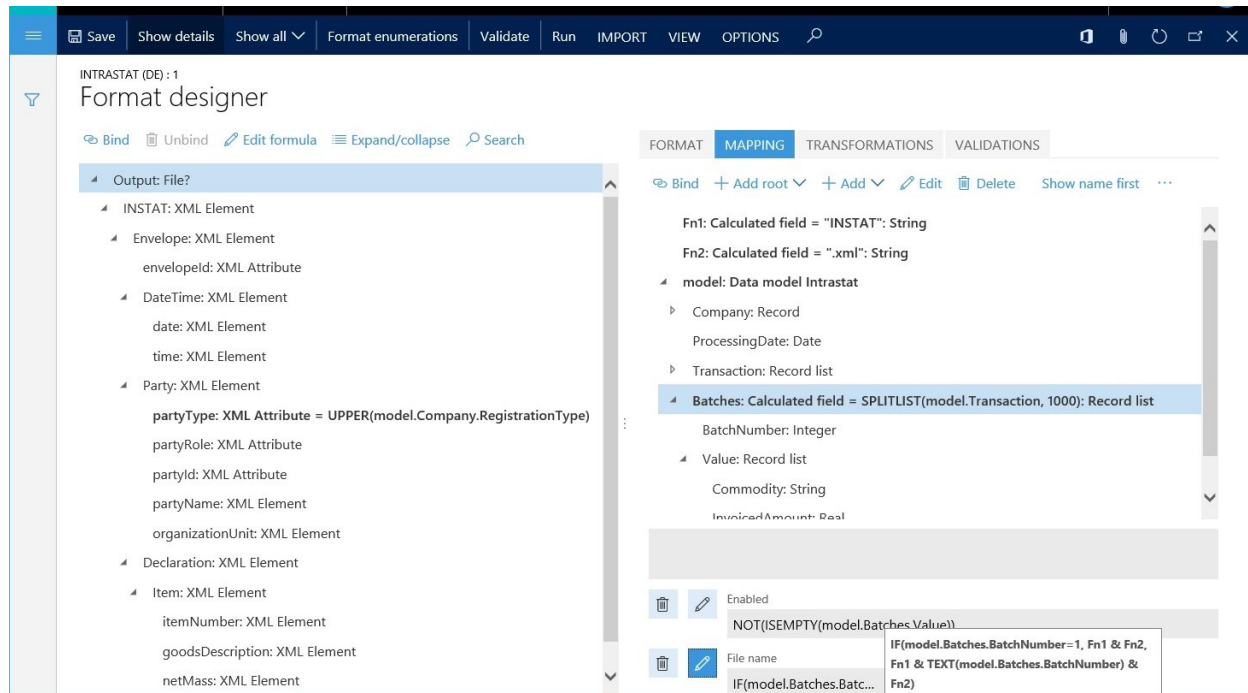

Each rule of the process flow control is designed as an individual validation. The following illustration shows a validation of this type. Here is an explanation of the configuration in this example:

- The validation is evaluated when the **INSTAT** node is created during generation of the XML file.
- If the list of transactions is empty, the validation stops the execution process and returns **FALSE**.
- The validation returns an error message that includes the text of label SYS70894 in the user's preferred language.

The ER formula designer can also be used to generate a file name for a generating electronic document and to control the file creation process. The following illustration shows the design of a process flow control of this type. Here is an explanation of the configuration in this example:

- The list of records from the **model.Intrastat** data source is divided into batches. Each batch contains up to 1,000 records.
- The output creates a zip file that contains one file in XML format for every batch that was created.
- An expression returns a file name for generating electronic documents by concatenating the file name and the file name extension. For the second batch and all subsequent batches, the file name contains the batch ID as a suffix.
- An expression enables (by returning **TRUE**) the file creation process for batches that contain at least one record.

Document content control

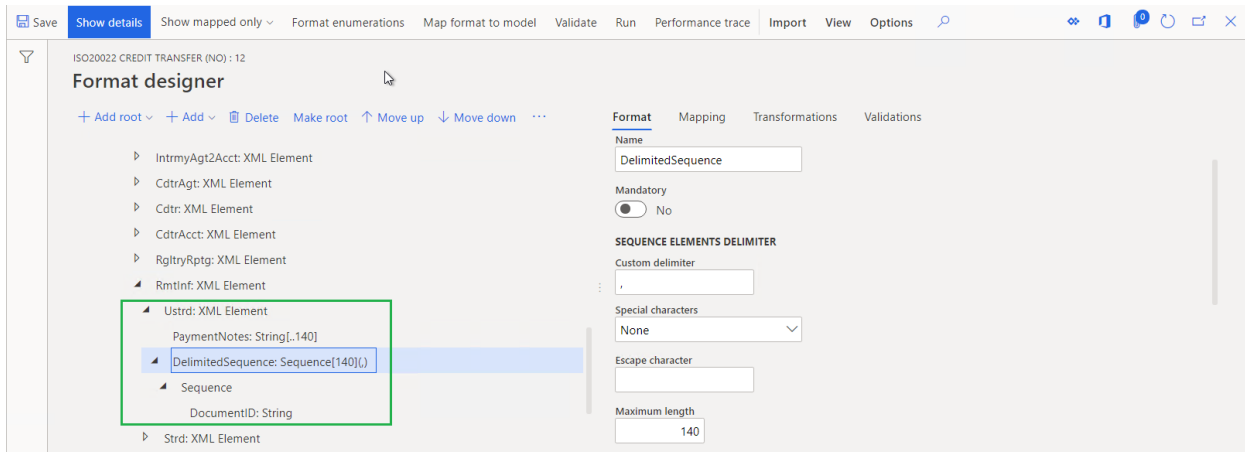

The ER formula designer can be used to configure expressions that control what data will be put into generated electronic documents at runtime. The expressions can enable or disable the output of specific elements of the format, depending on processing data and configured logic. These expressions can be entered for a single format element in the **Enabled** field on the **Mapping** tab of the **Operations designer** page. You can enter the expressions as a logic condition that returns a *Boolean* value:

- If the condition returns **True**, the current format element is run.
- If the condition returns **False**, the current format element is skipped.

The following illustration shows expressions of this type. (Version 11.12.11 of the **ISO20022 Credit transfer (NO)** format configuration that is provided by Microsoft is used as an example.) The **XMLHeader** format component is configured to describe the structure of the credit transfer message according to the ISO 20022 XML message standards. The

XMLHeader/Document/CstmrCdtTrfInitt/PmtInf/CdtTrfTxInf/RmtInf/Ustrd format component is configured to add the **Ustrd** XML element to the generated message and to put the remittance information in an unstructured format as text of the following XML elements:

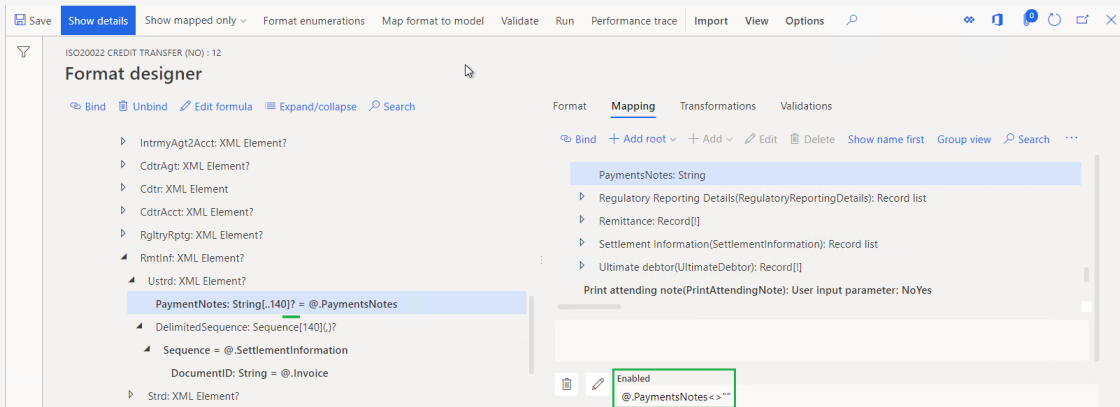

- The **PaymentNotes** component is used to generate the text of payment notes.
- The **DelimitedSequence** component generates comma-separated invoice numbers that are used to settle the current credit transfer.

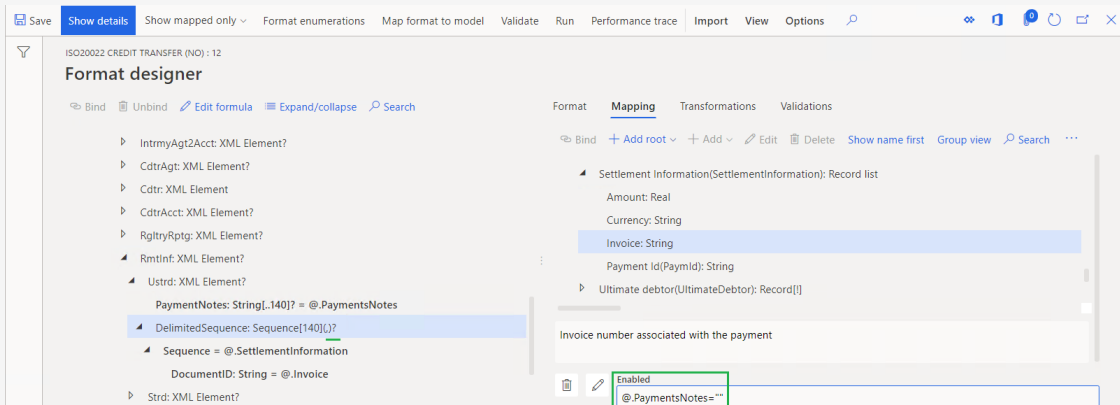

NOTE

The **PaymentNotes** and **DelimitedSequence** components are labeled by using a question mark. A question mark indicates that the use of a component is conditional. In this case, use of the components is based on the following criteria:

- The `@.PaymentsNotes <> ""` expression that is defined for the **PaymentNotes** component enables (by returning **TRUE**) the **Ustrd** XML element to be filled with the text of payment notes, if that text isn't blank for the current credit transfer.

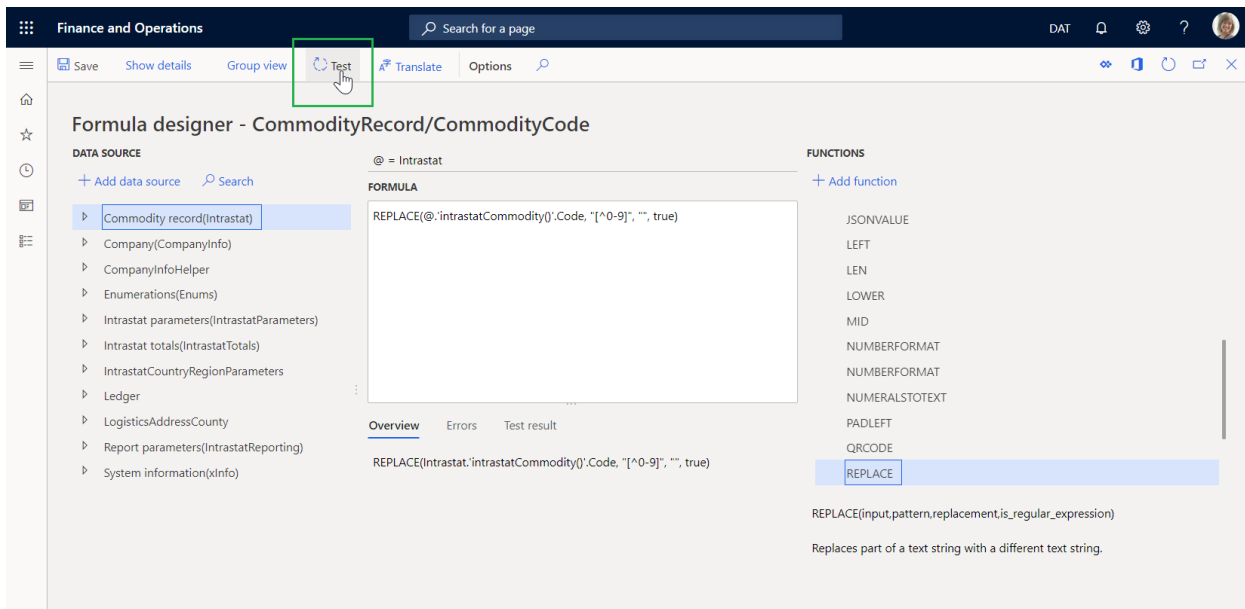

- The `@.PaymentsNotes = ""` expression that is defined for the **DelimitedSequence** component enables (by returning **TRUE**) the **Ustrd** XML element to be filled with a comma-separated list of the invoice numbers that are used to settle the current credit transfer, if the text of payment notes for that credit transfer is blank.

Based on this setup, the message that is generated for each debtor payment, the **Ustrd** XML element, will contain either the text of payment notes or, when that text is blank, a comma-separated list of the invoice numbers that are used to settle the payment.

Validation of configured formulas

On the **Formula designer** page, select **Test** to validate how the configured formula works.

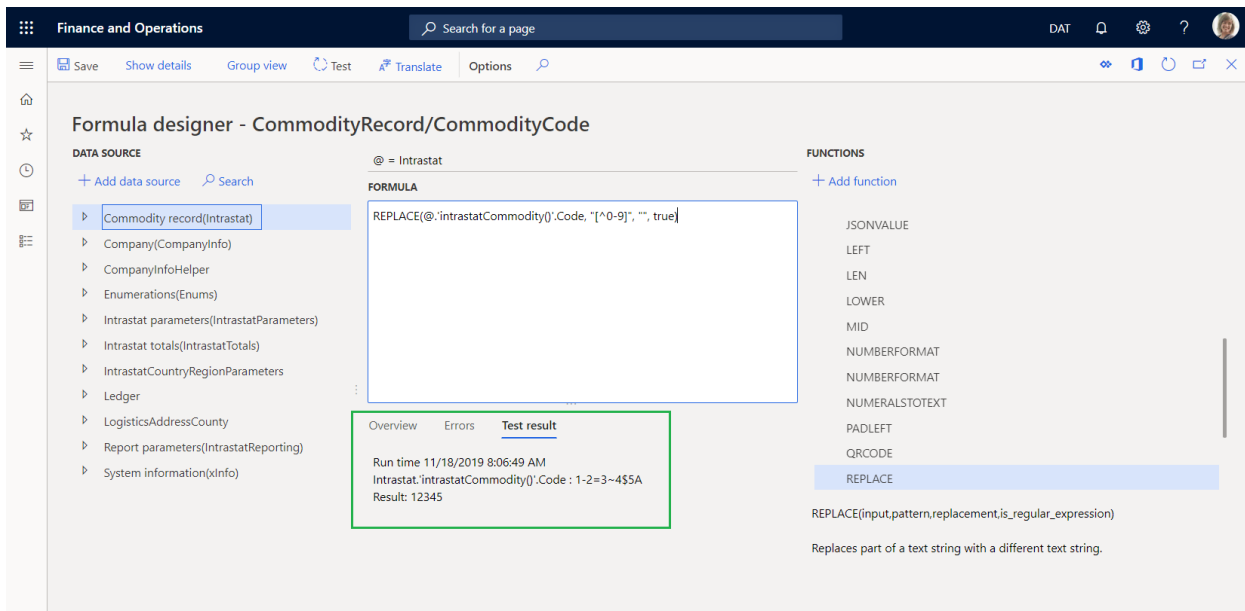

When the values of formula arguments are required, you can open the **Test expression** dialog box from the **Formula designer** page. In most cases, these arguments must be manually defined, because the configured bindings aren't run at design time. The **Test result** tab on the **Formula designer** page shows the result from execution of the configured formula.

The following example shows how you can test the formula that is configured for the foreign trade domain to make sure that the Intrastat commodity code contains only digits.

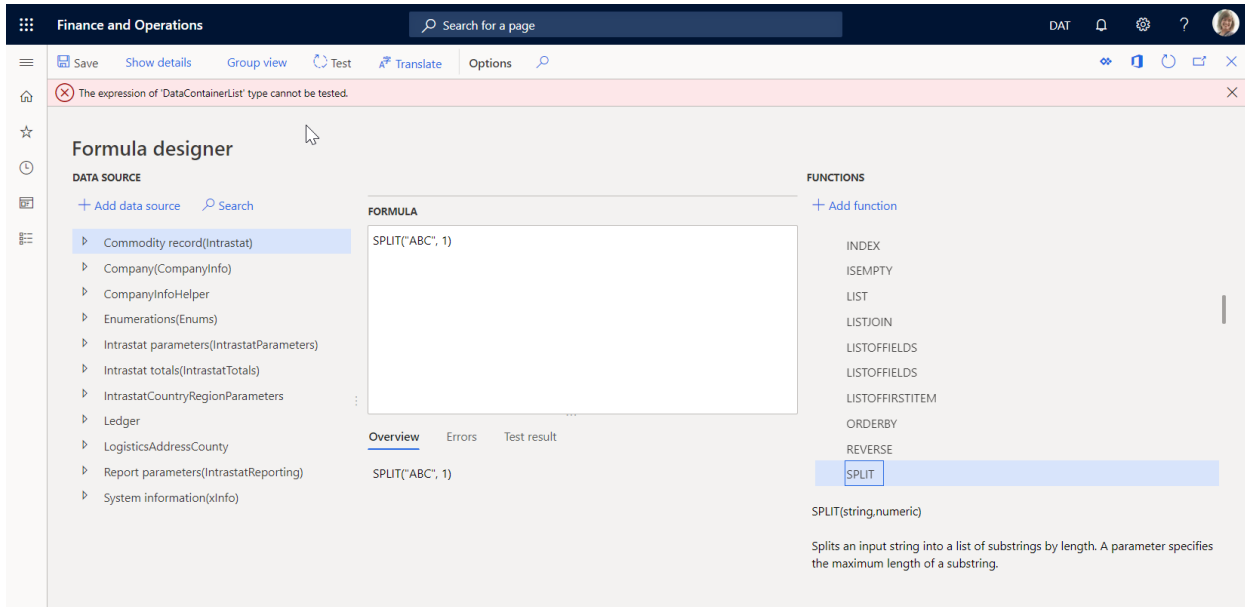

When you test this formula, you can use the **Test expression** dialog box to specify the value of the Intrastat commodity code for testing.

After you specify the Intrastat commodity code and select **OK**, the **Test result** tab on the **Formula designer** page shows the result of execution of the configured formula. You can then evaluate whether the result is acceptable. If the result isn't acceptable, you can update the formula and test it again.

Some formulas can't be tested at design time. For example, a formula might return a result of a data type that can't be shown on the Test result tab. In this case, you receive an error message that states that the formula can't be tested.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Electronic reporting advanced formula editor

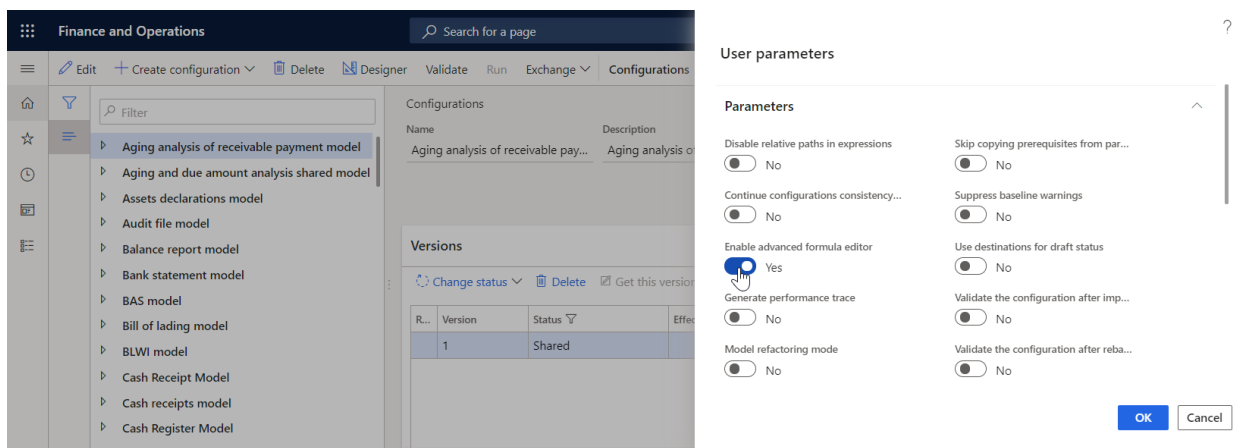

2/18/2021 • 4 minutes to read • [Edit Online](#)

In addition to the [Electronic reporting formula editor](#), you can use the advanced Electronic reporting formula editor to improve the experience of configuring Electronic reporting (ER) expressions. The advanced editor is browser-based and powered by the [Monaco editor](#). The most commonly used advanced editor features are described in this topic:

- [Code autoformatting](#)
- [IntelliSense](#)
- [Code completion](#)
- [Code navigation](#)
- [Code structuring](#)
- [Find and replace](#)
- [Data pasting](#)
- [Syntax colorization](#)

Complete the following steps to start using the advanced formula editor in your instance of Microsoft Dynamics 365 Finance.

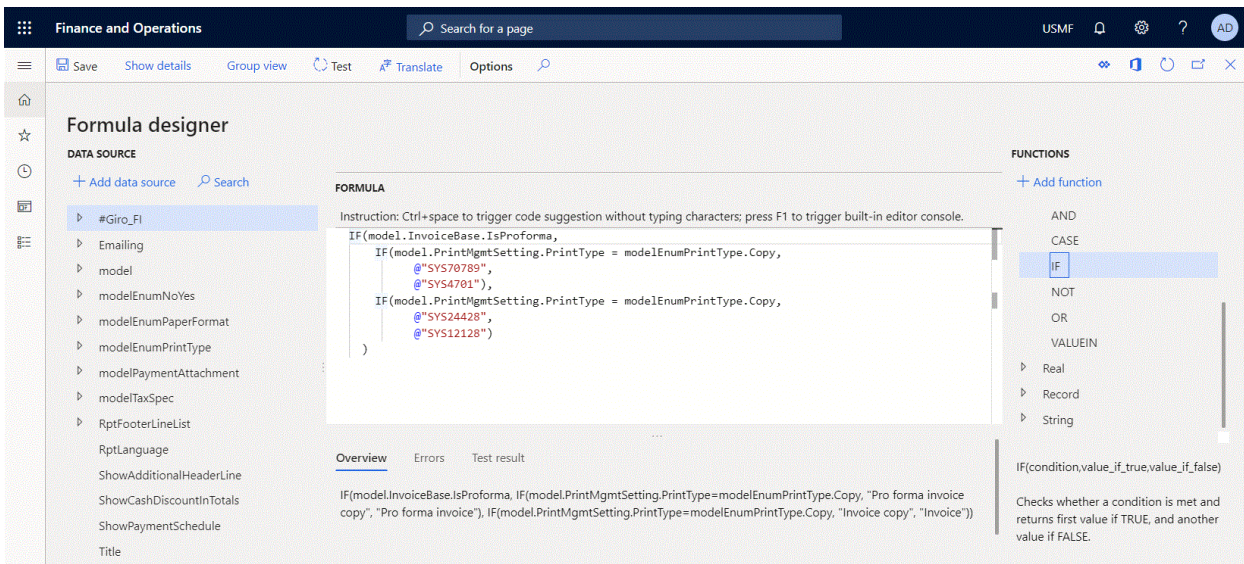

1. Go to **Organization administration > Electronic reporting > Configurations**.
2. On the **Configurations** page, on the Action Pane, on the **Configurations** tab, in the **Advanced settings** group, select **User parameters**.
3. In the **User parameters** dialog box, in the **Execution tracing** section, set the **Enable advanced formula editor** parameter to **Yes**.

NOTE

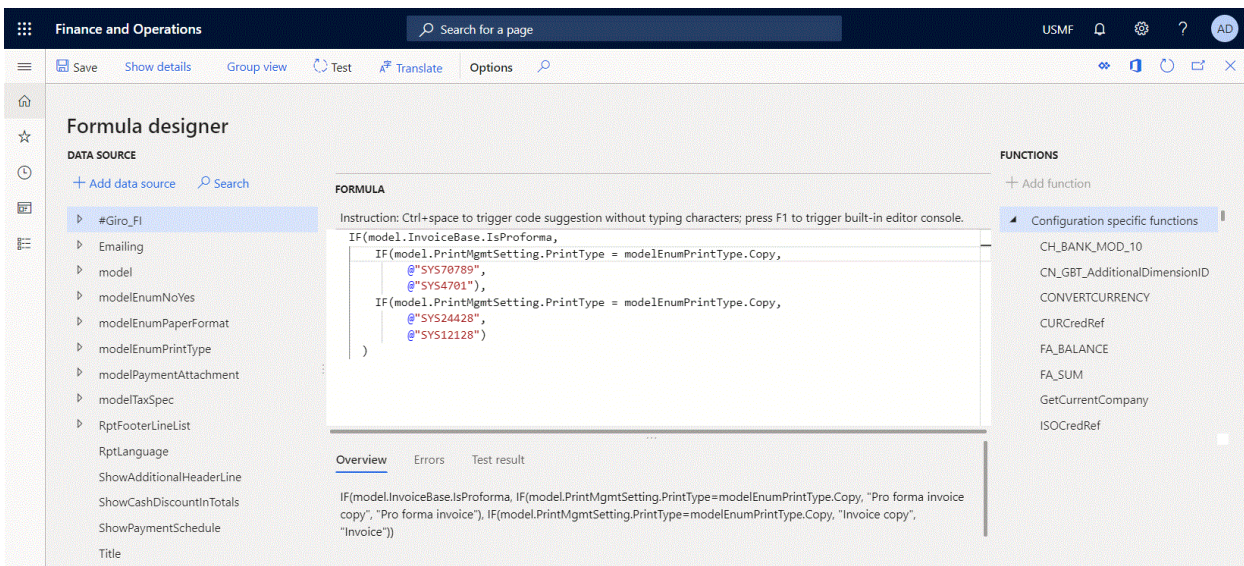

Be aware that this parameter is user specific and company specific.

When you write a complex expression that consists of multiple rows of code, the indentation of a new entered line will be automatic based on the indentation of the previous row. You can select lines and change their indentation by typing **Tab** or **Shift+ Tab**.

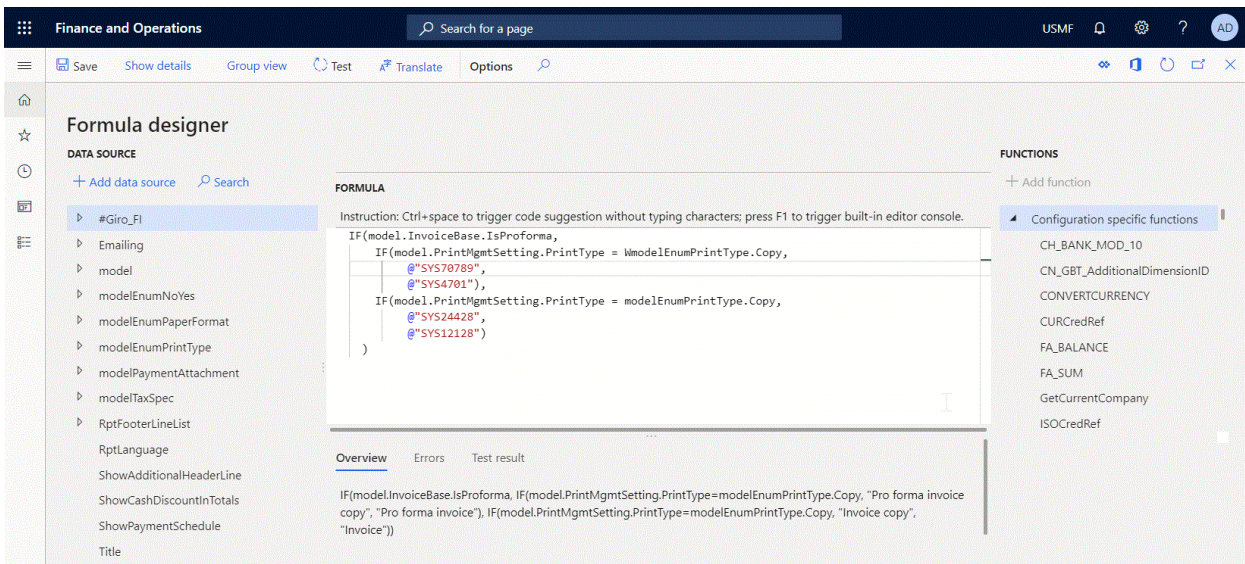

Autoformatting allows you to keep the entire expression well formatted to make further maintenance easier and to simplify understanding of the configured logic.

The editor provides word completion to help you write expression faster and avoid typos. When you start adding new text, the editor automatically offers a list of functions supported in ER functions that contain the characters you have entered. You can also trigger IntelliSense in any place of a configured expression by typing **Ctrl+Space**.

The editor automatically provides code completion by:

- Inserting a closing bracket when an opening bracket is entered, keeping the cursor inside the brackets.
- Inserting the second quotation symbol when the first one is entered, keeping the cursor inside the quotations.
- Inserting the second double quotation symbol when the first one is entered, keeping the cursor inside the quotations.

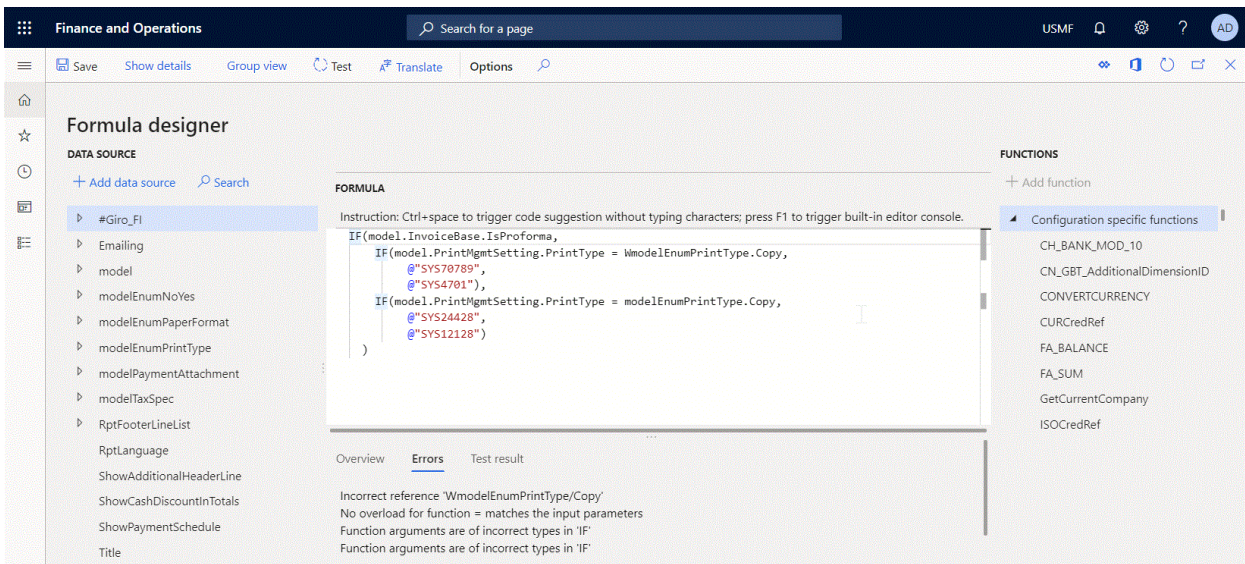

When you point to the typed bracket, the second bracket of this pair is automatically highlighted to show the construct that they support.

You can locate required symbols or lines in your expression by typing the Go to command using the command palette or the context menu.

For example, to jump to line 8, do the following:

- Press **Ctrl+G**, enter the value **8**, and then press **Enter**.
- or-
- Press **F1**, type **G**, select **Go to line**, enter the value **8**, and the press **Enter**.

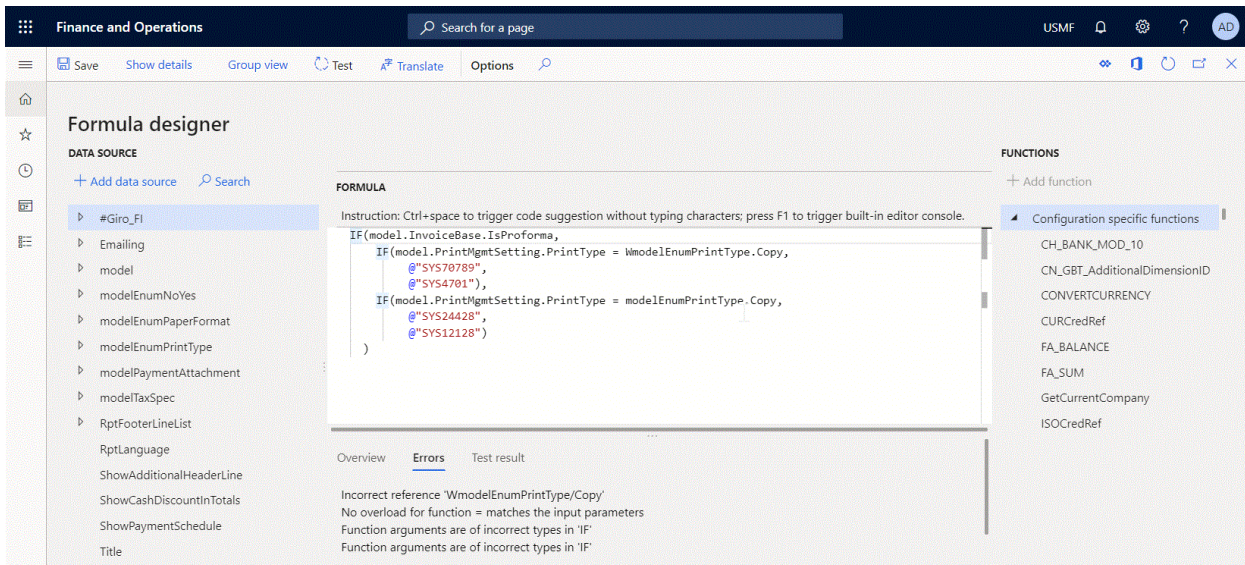

The code for some functions, such as **IF** or **CASE**, is automatically structured. You can expand and collapse any or all of the folding regions of this code to reduce the editable part of an expression in order to focus on only the piece of code that requires your attention. The toggle fold/unfold commands can be used for that.

For example, to fold all regions, do the following:

- Press **Ctrl+K**
- or-
- Press **F1**, press **FO**, select **Fold all**, and then press **Enter**

To unfold all regions, do the following:

- Press **Ctrl+J**
- or-
- Press **F1**, type **UN**, select **Unfold all**, and then press **Enter**

To find occurrences of certain text, select the text in your expression, and do the following:

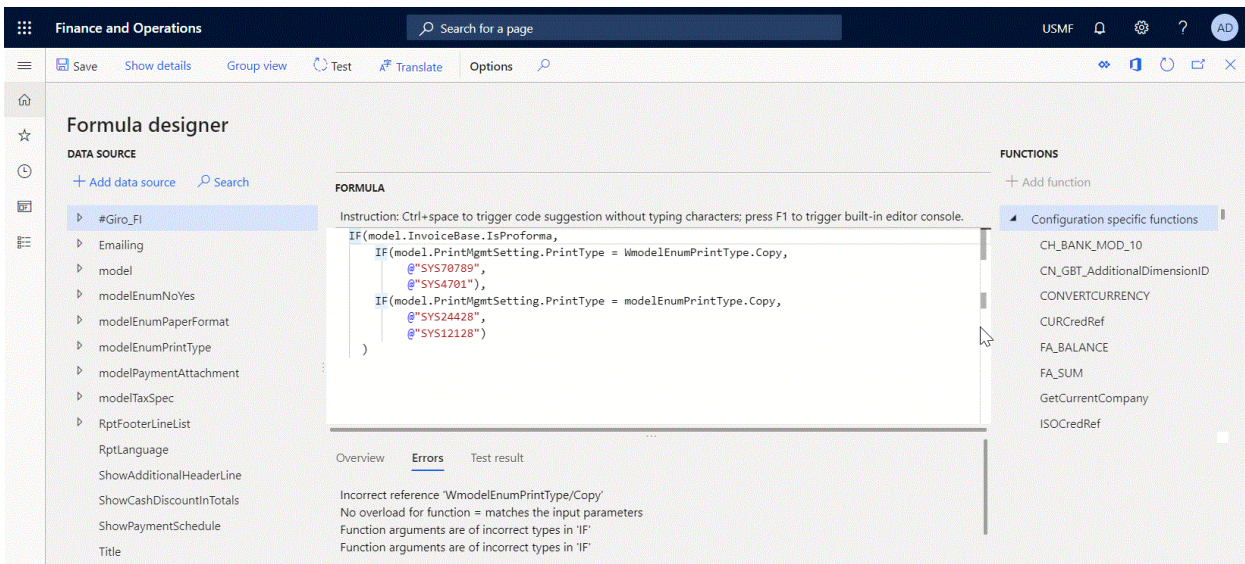

- Press **Ctrl+F** and then press **F3** to find the next occurrence of the selected text, or press **Shift+F3** to find the previous occurrence.
- or-
- Press **F1**, type **F**, and then select the required option to find the selected text.

To replace occurrences of a certain text, select the text in your expression, and do the following:

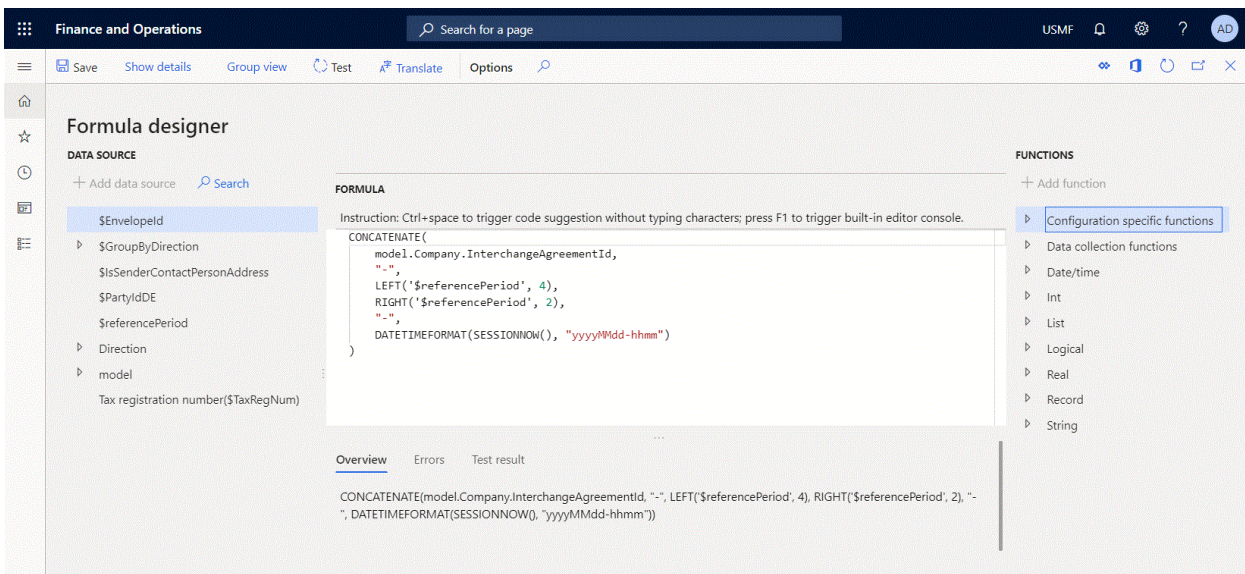

- Press **Ctrl+H**. Enter the alternative text and select the replacement option to replace either the selected text or all occurrences of this text in the current expression.
- or-
- Press **F1**, type **R**, and then select the required option to replace the selected text. Enter the alternative text and select the replacement option to replace either the selected text or all occurrences of this text in the current expression.

To change all occurrences of a certain text, select the text in your expression, and do the following:

- Press **Ctrl+F2** and then enter the alternative text.
- or-
- Press **F1**, type **C**, and then select the required option to change the selected text. Enter the alternative text.

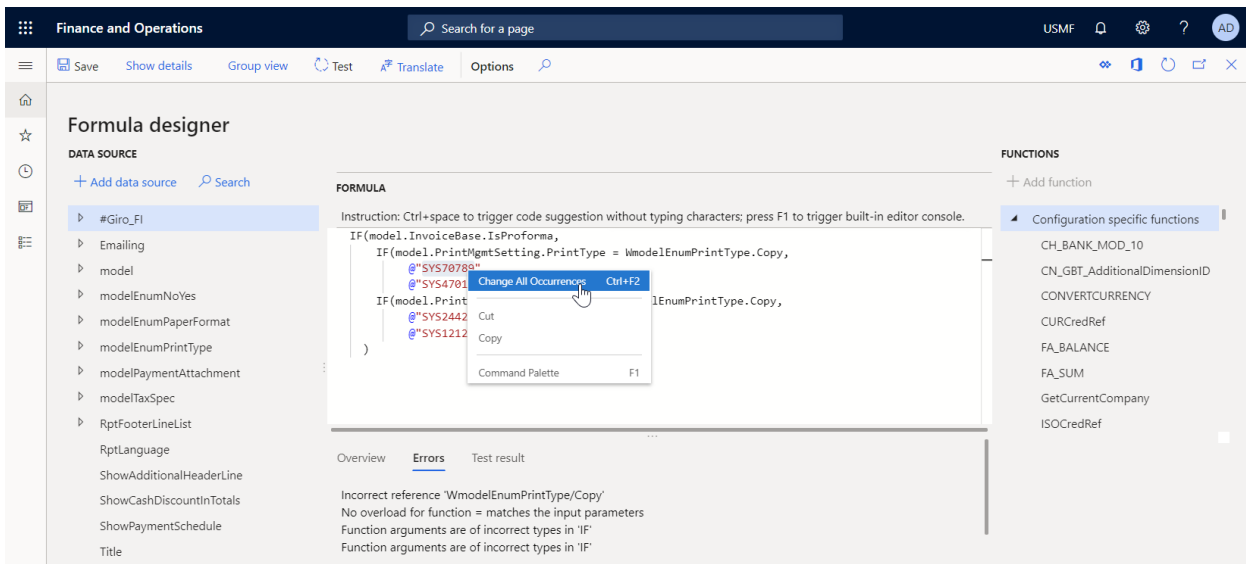

You can select **Add data source**, which pastes to the current expression a data source that is currently selected on the **Data source** left panel. Similarly, you can select **Add function**, which pastes to the current expression a function that is currently selected on the **Functions** right panel. If you use the ER formula editor, a selected function or a selected data source will always be pasted to the end of the configured expression. When you use the advanced ER formula editor, a selected function or a selected data source can be pasted to any part of the configured expression. You will need to use the cursor to specify where you want to paste the data.

Currently, different colors are used to highlight the following parts of expressions:

- The text in double brackets that can represent a label ID of a text constant.

Limitations

The editor is currently supported in the following web browsers:

- Chrome
- Edge
- Firefox
- Opera
- Safari

Electronic reporting formula language

2/18/2021 • 7 minutes to read • [Edit Online](#)

Electronic reporting (ER) provides a powerful data transformation experience. The language that is used to express the required data manipulations in the [ER formula designer](#) resembles the formula language in Microsoft Excel.

Basic syntax

ER expressions can contain any or all of the following elements:

- [Constants](#)
- [Operators](#)
- [References](#)
- [Paths](#)
- [Functions](#)

When you design expressions, you can use text and numeric constants (that is, values that aren't calculated). For example, the expression `VALUE ("100") + 20` uses the numeric constant **20** and the string constant **"100"**, and it returns the numeric value **120**.

The ER formula designer supports escape sequences. Therefore, you can specify an expression string that should be handled differently. For example, the expression `"Leo Tolstoy ""War and Peace"" Volume 1"` returns the text string **Leo Tolstoy "War and Peace" Volume 1**.

The following table shows the arithmetic operators that you can use to do basic mathematical operations, such as addition, subtraction, multiplication, and division.

OPERATOR	MEANING	EXAMPLE
+	Addition	<code>1+2</code>
-	Subtraction, negation	<code>5-2</code> , <code>-1</code>
*	Multiplication	<code>7*8</code>
/	Division	<code>9/3</code>

The following table shows the comparison operators that are supported. You can use these operators to compare two values.

OPERATOR	MEANING	EXAMPLE
=	Equal	<code>X=Y</code>
>	Greater than	<code>X>Y</code>
<	Less than	<code>X<Y</code>

OPERATOR	MEANING	EXAMPLE
>=	Greater than or equal to	<code>X>=Y</code>
<=	Less than or equal to	<code>X<=Y</code>
<>	Not equal to	<code>X<>Y</code>

Additionally, you can use an ampersand (&) as a text concatenation operator. In this way, you can join, or concatenate, one or more text strings into a single piece of text.

OPERATOR	MEANING	EXAMPLE
&	Concatenate	<code>"Nothing to print:" & " " & "no records found"</code>

Operator precedence

The order in which the parts of a compound expression are evaluated is important. For example, the result of the expression `1 + 4 / 2` varies, depending on whether the addition or division operation is done first. You can use parentheses to explicitly define how an expression is evaluated. For example, to indicate that the addition operation should be done first, you can change the preceding expression to `(1 + 4) / 2`. If you don't explicitly indicate the order of operations in an expression, the order is based on the default precedence that is assigned to the supported operators. The following table shows the precedence that is assigned to each operator. Operators that have a higher precedence (for example, 7) are evaluated before operators that have a lower precedence (for example, 1).

PRECEDENCE	OPERATORS	SYNTAX
7	Grouping	<code>(...)</code>
6	Member access	<code>...</code>
5	Function call	<code>... (...)</code>
4	Multiplicative	<code>... * ...</code> <code>... / ...</code>
3	Additive	<code>... + ...</code> <code>... - ...</code>
2	Comparison	<code>... < ...</code> <code>... <= ...</code> <code>... = > ...</code> <code>... > ...</code> <code>... = ...</code> <code>... <> ...</code>
1	Separation	<code>... / ...</code>

If an expression includes multiple consecutive operators that have the same precedence, those operations are evaluated from left to right. For example, the expression `1 + 6 / 2 * 3 > 5` returns **true**. We recommend that you use parentheses to explicitly indicate the desired order of operations in expressions, so that the expressions are easier to read and maintain.

All data sources of the current ER component that are available during the design of an expression can be used as named references. The current ER component can be either a model mapping or a format. For example, the current ER model mapping contains the **ReportingDate** data source, which returns a value of the *DateTime* data type. To correctly format that value in the generating document, you can reference the data source in the expression as `DATETIMEFORMAT (ReportingDate, "dd-MM-yyyy")`.

All characters in the name of a referencing data source that don't represent a letter of the alphabet must be preceded by a single quotation mark ('). If the name of a referencing data source contains at least one symbol that doesn't represent a letter of the alphabet, the name must be enclosed in single quotation marks. For example, these non-alphabetic symbols can be punctuation marks or other written symbols. Here are some examples:

- The **Today's date & time** data source must be referred to in an ER expression as `'Today''s date & time'`.
- The **name()** method of the **Customers** data source must be referred to in an ER expression as `Customers.'name()'`.

If the methods of application data sources have parameters, the following syntax is used to call those methods:

- If the **isLanguageRTL** method of the **System** data source has an **EN-US** parameter of the *String* data type, this method must be referred to in an ER expression as `System.isLanguageRTL("EN-US")`.
- Quotation marks aren't required when a method name contains only alphanumeric symbols. However, they are required for a method of a table if the name includes brackets.

When the **System** data source is added to an ER mapping that refers to the **Global** application class, the expression `System.isLanguageRTL("EN-US ")` returns the *Boolean* value **FALSE**. The modified expression `System.isLanguageRTL("AR")` returns the *Boolean* value **TRUE**.

You can limit the way that values are passed to the parameters of this type of method:

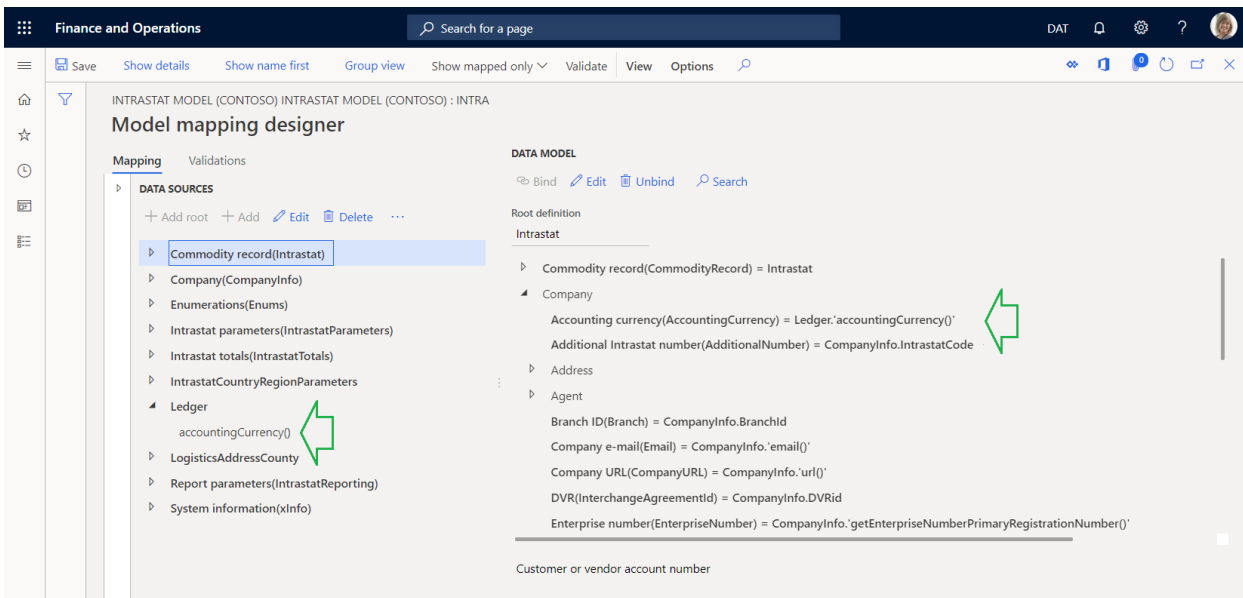

- Only constants can be passed to methods of this type. The values of the constants are defined at design time.
- Only primitive (basic) data types are supported for parameters of this type. The primitive data types include *Integer*, *Real*, *Boolean*, and *String*.

When an expression references a structured data source, you can use the path definition to select a specific primitive element of that data source. A dot character (.) is used to separate individual elements of a structured data source. For example, the current ER model mapping contains the **InvoiceTransactions** data source, and this data source returns a list of records. The **InvoiceTransactions** record structure contains the **AmountDebit** and **AmountCredit** fields, and both these fields return numeric values. Therefore, you can design the following expression to calculate the invoiced amount:

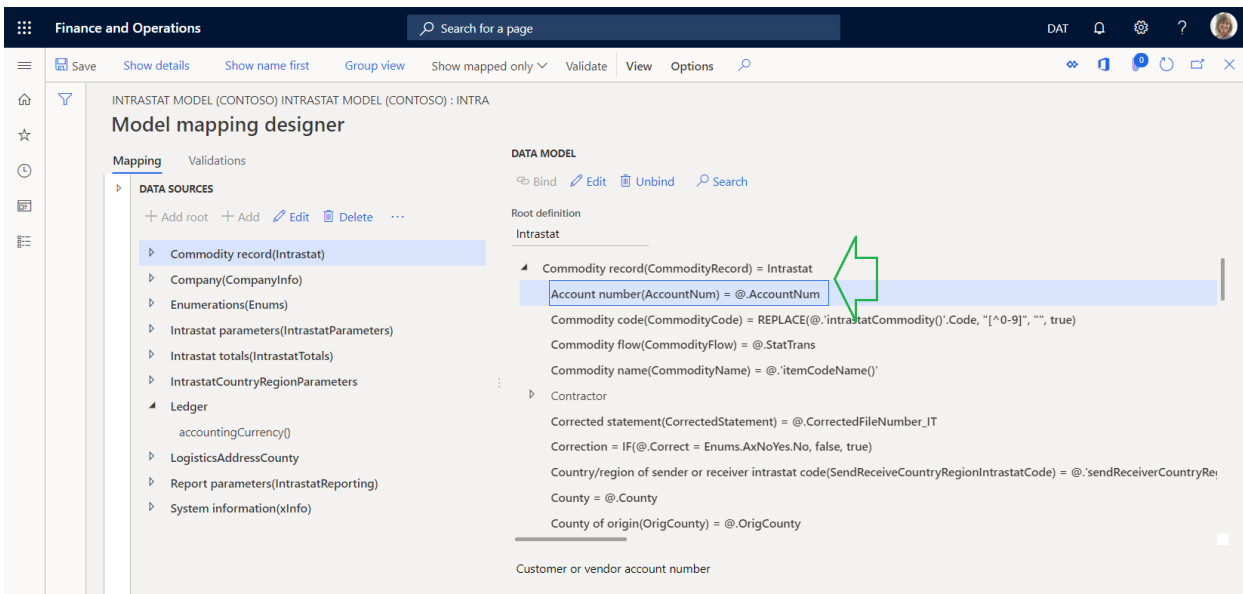

`InvoiceTransactions.AmountDebit - InvoiceTransactions.AmountCredit`. The `InvoiceTransactions.AmountDebit` construction in this expression is the path that is used to access the **AmountDebit** field of the **InvoiceTransactions** data source of the *Record list* type.

Relative path

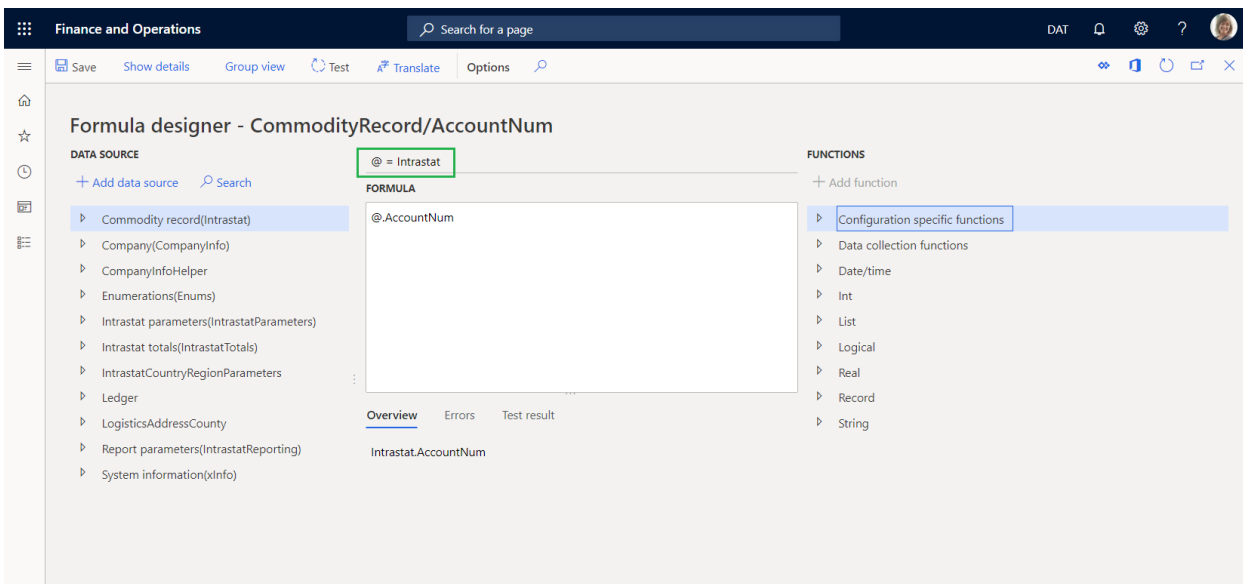

If the path of a structured data source starts with an "at" sign (@), it's a relative path. The "at" sign is shown instead of the remaining part of the absolute path of the hierarchical tree structure that is used. The following illustration shows an example. Here, the absolute path `Ledger.'accountingCurrency()'` indicates that the accounting currency value from the **Ledger** data source is entered in the **AccountingCurrency** field of the data model.

The example in the following illustration shows how a relative path is used. The relative path `@.AccountNum` indicates that the `AccountNum` field of the `Intrastat` data source (which appears one level above the `AccountNum` field in the data model's hierarchical tree) is used to enter the customer or vendor account number in the data model's `AccountNum` field.

The remaining part of the absolute path is also shown in the [ER formula editor](#).

For more information, see [Use a relative path in data bindings of ER models and formats](#).

ER built-in functions can be used in ER expressions. All data sources of the expression context (that is, the current ER model mapping or ER format) can be used as parameters of calling functions, in accordance with the list of arguments for calling functions. Constants can also be used as parameters of calling functions. For example, the current ER model mapping contains the **InvoiceTransactions** data source, and this data source returns a list of records. The **InvoiceTransactions** record structure contains the **AmountDebit** and **AmountCredit** fields, and both these fields return numeric values. Therefore, to calculate the invoiced amount, you can design the following expression that uses the built-in ER rounding function:

```
ROUND (InvoiceTransactions.AmountDebit - InvoiceTransactions.AmountCredit, 2) .
```

When you design ER model mappings and ER reports, you can use ER functions from the following categories:

- [Date and time functions](#)
- [List functions](#)
- [Logical functions](#)
- [Mathematical functions](#)
- [Record functions](#)
- [Text functions](#)
- [Data collection functions](#)
- [Other \(business domain–specific\) functions](#)
- [Type conversion functions](#)

Functions list extension

ER lets you extend the list of functions that are used in ER expressions. Some engineering effort is required. For detailed information, see [Extend the list of Electronic reporting \(ER\) functions](#).

Compound expressions

You can create compound expressions that use functions from different categories, provided that the data types match. When you use functions together, match the data type of the output from one function to the input data type that is required by another function. For example, to avoid a possible "list-is-empty" error in a binding of a field to an ER format element, combine functions from the [List](#) category with a function from the [Logical](#) category, as the following example shows. Here, the formula uses the [IF](#) function to test whether the **IntrastatTotals** list is empty before it returns the value of the required aggregation from that list. If the **IntrastatTotals** list is empty, the formula returns **0** (zero).

```
IF(ISEMPTY(IntrastatTotals), 0.0, IntrastatTotals.aggregated.'$AmountMSTRounded')
```

Multiple solutions

Often, you can get the same data transformation result in multiple ways, by using functions from different categories or different functions from the same category. For example, the previous expression can also be configured by using the [COUNT](#) function from the [List](#) category.

```
IF(COUNT (IntrastatTotals)=0, 0.0, IntrastatTotals.aggregated.'$AmountMSTRounded')
```

List of ER functions in the Date and time category

2/18/2021 • 2 minutes to read • [Edit Online](#)

Electronic reporting (ER) date and time functions can be used to extract information from date and time values, and to perform operations on them. This topic provides a summary of these functions.

List of supported functions

FUNCTION	DESCRIPTION
AddDays	This function returns a <i>DateTime</i> value that is the specified number of days before or after a specified start date.
DateFormat	This function returns a <i>String</i> value that presents a given date value as text in the specified format and in an optionally specified culture.
DateTimeFormat	This function returns a <i>String</i> value that presents a given date/time value as text in the specified format and in an optionally specified culture.
DateTimeValue	This function returns a <i>DateTime</i> value that is converted from a given text value in the specified format and in an optionally specified culture to a date/time value.
DateToDateTime	This function returns a <i>DateTime</i> value that is converted from a given date value to a date/time value in Coordinated Universal Time (Greenwich Mean Time [GMT]).
DateValue	This function returns a <i>Date</i> value that is converted from a given text value in the specified format and in an optionally specified culture to a date value.
DayOfYear	This function returns an <i>Integer</i> value that represents the number of days between January 1 and the specified date.
Days	This function returns an <i>Integer</i> value that represents the number of days between one specified date and a second specified date.
Now	This function returns a <i>DateTime</i> value that represents the current application server date and time.
NullDate	This function returns a <i>Date</i> value that represents the null date (January 1, 1900).
NullDateTime	This function returns a <i>DateTime</i> value that represents the null date/time value (January 1, 1900) in Coordinated Universal Time.
SessionNow	This function returns a <i>DateTime</i> value that represents the current application session date and time.

FUNCTION	DESCRIPTION
SessionToday	This function returns a <i>Date</i> value that represents the current application session date.
Today	This function returns a <i>Date</i> value that represents the current application server date.

ADDDAYS ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `ADDDAYS` function calculates a *DateTime* value that is the specified number of days before or after a specified start date.

Syntax

```
ADDDAYS (datetime, days)
```

Arguments

`datetime` : *DateTime*

A date/time value that represents the start date.

`days` : *Integer*

The number of days before or after `datetime`.

Return values

DateTime

The resulting date/time value.

Usage notes

A positive value for `days` yields a future date. A negative value yields a past date.

Example 1

`ADDDAYS (NOW(), 7)` returns the date and time seven days in the future.

Example 2

`ADDDAYS (NOW(), -3)` returns the date and time three days in the past.

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

DATEFORMAT ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `DATEFORMAT` function returns a *String* value that presents a given date value as text in the specified format and in an optionally specified *culture*. For information about the supported formats, see [standard](#) and [custom](#).

Syntax 1

```
DATEFORMAT (date, format)
```

Syntax 2

```
DATEFORMAT (date, format, culture)
```

Arguments

`date` : *Date*

A date value that represents the date to format.

`format` : *String*

The format of the output string.

NOTE

The format string is case-sensitive when you use either a standard format or a custom format. For example, the [standard](#) "d" format specifier returns the date by using the short date pattern, whereas the standard "D" format specifier returns the date by using the long date pattern. Additionally, the [custom](#) "M" format specifier returns the month from 1 through 12, whereas the custom "m" format specifier returns the minute from 0 through 59.

`culture` : *String*

The culture to use for formatting.

Return values

String

The resulting string value.

Usage notes

If the culture isn't defined as an argument of the called function, the value of `culture` is defined by the calling context. For example, if the `DATEFORMAT` function is called by using syntax 1 in an Electronic reporting (ER) format for a **FILE** element that is configured to use the German culture, the conversion will be done by using the German culture. The default `culture` value is **EN-US**.

Example 1

`DATEFORMAT (TODAY (), "dd-MM-yyyy")` returns the current application server date, December 24, 2015, as the string "24-12-2015", based on the specified custom format.

Example 2

`DATEFORMAT (SESSIONTODAY (), "d", "DE")` returns the current application session date, December 24, 2015, as the string "24-12-2015", based on the selected German culture and the specified format.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

DATETIMEFORMAT ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `DATETIMEFORMAT` function returns a *String* value that presents a given date/time value as text in the specified format and in an optionally specified *culture*. For information about the supported formats, see [standard](#) and [custom](#).

Syntax 1

```
DATETIMEFORMAT (datetime, format)
```

Syntax 2

```
DATETIMEFORMAT (datetime, format, culture)
```

Arguments

`datetime` : *DateTime*

A date/time value that represents the date and time to format.

`format` : *String*

The format of the output string.

NOTE

The format string is case-sensitive when you use either a standard format or a custom format. For example, the [standard](#) "d" format specifier returns the date by using the short date pattern, whereas the standard "D" format specifier returns the date by using the long date pattern. Additionally, the [custom](#) "M" format specifier returns the month from 1 through 12, whereas the custom "m" format specifier returns the minute from 0 through 59.

`culture` : *String*

The culture to use for formatting.

Return values

String

The resulting string value.

Usage notes

If the culture isn't defined as an argument of the called function, the value of `culture` is defined by the calling context. For example, if the `DATETIMEFORMAT` function is called by using syntax 1 in an Electronic reporting (ER) format for a **FILE** element that is configured to use the German culture, the conversion will be done by using the German culture. The default `culture` value is **EN-US**.

When the `DATETIMEFORMAT` function converts a given date/time value, it considers the time zone setting of the application user who is running the ER format that the function is called in the context of.

Example 1

`DATETIMEFORMAT (NOW(), "dd-MM-yyyy")` returns the current application server date/time value, December 24, 2015, as "24-12-2015", based on the specified custom format.

Example 2

`DATETIMEFORMAT (SESSIONNOW(), "d", "DE")` returns the current application session date/time value, December 24, 2015, as "24.12.2015", based on the selected German culture and the specified format.

Example 3

`DATETIMEFORMAT (DATETIMEVALUE("2019-11-12T09:00:00.0000000-07:00", "O"), "O")` returns the string value **2019-11-12T08:00:00.0000000-08:00** when the function is called during a process that was initiated by an application user who has the time zone value **(GMT-08:00) Pacific Time (US & Canada)** in the **Language and country/region preferences** section.

DATETIMEVALUE ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `DATETIMEVALUE` function returns a *DateTime* value that is converted from a given text value in the specified format and in an optionally specified *culture* to a date/time value. For information about the supported formats, see [standard](#) and [custom](#).

Syntax 1

```
DATETIMEVALUE (text, format)
```

Syntax 2

```
DATETIMEVALUE (text, format, culture)
```

Arguments

`text` : *String*

Text that represents the value to format.

`format` : *String*

The format of the given text.

`culture` : *String*

The culture that is used for formatting of the given text.

Return values

DateTime

The resulting date/time value.

Usage notes

When the culture isn't defined as an argument of the called function, the value of `culture` is defined by the calling context. For example, if the `DATETIMEVALUE` function is called by using syntax 1 in an Electronic reporting (ER) format for a FILE element that is configured to use the German culture, the conversion will be done by using the German culture. The default `culture` value is **EN-US**.

Example 1

`DATETIMEVALUE ("21-Dec-2016 02:55:00", "dd-MMM-yyyy hh:mm:ss")` returns **2:55:00 AM on December 21, 2016**, based on the specified custom format and the default application's **EN-US** culture.

Example 2

`DATETIMEVALUE ("21-Jan-2016 02:55:00", "dd-MMM-yyyy hh:mm:ss", "IT")` returns **2:55:00 AM on December 21, 2016**, based on the specified custom format and culture.

However, `DATETIMEVALUE ("21-Jan-2016 02:55:00", "dd-MMM-yyyy hh:mm:ss", "EN-US")` throws an exception to inform the user that the specified string isn't recognized as a valid date/time value for the specified culture.

DATEODATETIME ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `DATEODATETIME` function returns a *DateTime* value that is converted from a given date value to a date/time value in Coordinated Universal Time (Greenwich Mean Time [GMT]).

Syntax

```
DATEODATETIME (date)
```

Arguments

`date` : *Date*

A date value that represents the date to convert.

Return values

DateTime

The resulting date/time value.

Example 1

`DATEODATETIME (CompInfo. 'getCurrentDate()')` returns the date of the current Microsoft Dynamics 365 Finance session, December 24, 2015, as **12/24/2015 12:00:00 AM**. In this example, **CompInfo** is an Electronic reporting (ER) data source of the **Finance and Operations/Table** type, and it refers to the **CompanyInfo** table.

Example 2

`DATEODATETIME (DATEVALUE ("2019-11-12T16:00:00.0000000-07:00", "0"))` returns the date/time value **11/12/2019 12:00:00 AM**.

Additional resources

DATEVALUE ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `DATEVALUE` function returns a *Date* value that is converted from a given text value in the specified format and in an optionally specified *culture* to a date value. For information about the supported formats, see [standard](#) and [custom](#).

Syntax 1

```
DATEVALUE (text, format)
```

Syntax 2

```
DATEVALUE (text, format, culture)
```

Arguments

`text` : *String*

Text that represents the value to format.

`format` : *String*

The format of the given text.

`culture` : *String*

The culture that is used for formatting of the given text.

Return values

Date

The resulting date value.

Usage notes

When the culture isn't defined as an argument of the called function, the value of `culture` is defined by the calling context. For example, if the `DATEVALUE` function is called by using syntax 1 in an Electronic reporting (ER) format for a FILE element that is configured to use the German culture, the conversion will be done by using the German culture. The default `culture` value is **EN-US**.

Example 1

`DATEVALUE ("21-Dec-2016", "dd-MMM-yyyy")` returns the date value **December 21, 2016**, based on the specified custom format and the default application's **EN-US** culture.

Example 2

`DATEVALUE ("21-Jan-2016", "dd-MMM-yyyy", "IT")` returns the date value **January 21, 2016**, based on the specified custom format and culture.

However, `DATEVALUE ("21-Jan-2016", "dd-MMM-yyyy", "EN-US")` throws an exception to inform the user that the specified string isn't recognized as a valid date for the specified culture.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

DAYOFYEAR ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `DAYOFYEAR` function returns an *Integer* value that represents the number of days between January 1 and the specified date.

Syntax

```
DAYOFYEAR (date) as Integer
```

Arguments

`date` : *Date*

A date value that represents the date to use for the calculation of the number of days.

Return values

Integer

The resulting numeric value.

Example 1

```
DAYOFYEAR (DATEVALUE ("01-03-2016", "dd-MM-yyyy")) returns 61.
```

Example 2

```
DAYOFYEAR (DATEVALUE ("01-01-2016", "dd-MM-yyyy")) returns 1.
```

Additional resources

DAYS ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `DAYS` function returns an *Integer* value that represents the number of days between one specified date and a second specified date.

Syntax

```
DAYS (date 1, date 2) as Integer
```

Arguments

`date 1` : *Date*

A date value that represents the start date for the calculation of the number of days.

`date 2` : *Date*

A date value that represents the end date for the calculation of the number of days.

Return values

Integer

The resulting numeric value.

Usage notes

The `DAYS` function returns a positive value when the first date is later than the second date, it returns **0** (zero) when the first date equals the second date, and it returns a negative value when the first date is earlier than the second date.

Example

```
DAYS (TODAY (), DATEVALUE( DATETIMEFORMAT( ADDDAYS ( NOW(), 1), "yyyyMMdd"), "yyyyMMdd")) returns -1.
```

NOW ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `NOW` function returns a *DateTime* value that represents the current application server date and time.

Syntax

```
NOW ( )
```

Return values

DateTime

The resulting date/time value.

Example

`DATETIMEFORMAT (NOW(), "dd-MM-yyyy")` returns the current application server date/time value, December 24, 2015, as "24-12-2015", based on the specified custom format.

Additional resources

NULLDATE ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `NULLDATE` function returns a *Date* value that represents the **null** date (January 1, 1900).

Syntax

```
NULLDATE () as
```

Return values

Date

The resulting date value.

Example 1

`DATEFORMAT (NULLDATE(), "yyyy-MM-dd")` returns the **null** date, January 1, 1900, as "1900-01-01", based on the specified custom format.

Example 2

The expression `IF(Invoice.DocumentDate = NULLDATE(), true, false)` returns **True** when the value of the **DocumentDate** field equals the **null** date. In this example, **Invoice** is an Electronic reporting (ER) data source of the **Finance/Table records** type, and it refers to the **CustInvoiceJour** table.

Additional resources

NULLDATETIME ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `NULLDATETIME` function returns a *DateTime* value that represents the **null** date/time value (January 1, 1900) in Coordinated Universal Time (Greenwich Mean Time [GMT]).

Syntax

```
NULLDATETIME ( )
```

Return values

DateTime

The resulting date/time value.

Example

`DATETIMEFORMAT(NULLDATETIME(), "O")` returns the string value `1900-01-01T00:00:00.0000000+00:00` when it's called during a process that was initiated by an application user who has the time zone value (GMT) Coordinated Universal Time in the **Language and country/region preferences** section.

SESSIONNOW ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `SESSIONNOW` function returns a *DateTime* value that represents the current application session date and time.

Syntax

```
SESSIONNOW ()
```

Return values

DateTime

The resulting date/time value.

Example

`DATETIMEFORMAT (SESSIONNOW(), "d", "DE")` returns the current application session date/time value, December 24, 2015, as "24.12.2015", based on the selected German culture and the specified format.

Additional resources

SESSIONTODAY ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `SESSIONTODAY` function returns a *Date* value that represents the current application session date.

Syntax

```
SESSIONTODAY ()
```

Return values

Date

The resulting date value.

Example

`DATEFORMAT (SESSIONTODAY (), "d", "DE")` returns the current application session date, December 24, 2015, as the string "24-12-2015", based on the selected German culture and the specified format.

List of ER functions in the list category

2/18/2021 • 3 minutes to read • [Edit Online](#)

Electronic reporting (ER) list functions can be used to extract information from, and perform operations on, data sources of the *Record list* and *Container (record)* data types. This topic provides a summary of these functions.

List of supported functions

FUNCTION	DESCRIPTION
AllItems	This function runs as an in-memory selection. It returns a new flattened <i>Record list</i> value that consists of a list of records that represents all items that match the specified path.
AllItemsQuery	This function runs as a joined SQL query. It returns a new flattened <i>Record list</i> value that consists of a list of records that represents all items that match the specified path.
Count	This function returns an <i>Integer</i> value that represents the number of records in the specified list, if the list isn't empty. If the list is empty, this function returns 0 (zero).
EmptyList	This function returns an empty <i>Record list</i> value by using the specified list as a source for the list structure.
Enumerate	This function returns a new <i>Record list</i> value that consists of enumerated records of the specified list.
Filter	This function returns the specified list as a <i>Record list</i> value after the query has been changed so that it filters for the specified condition.
First	This function returns the first record of the specified list as a <i>Container (record)</i> value, if that list isn't empty. If the list is empty, this function throws an exception.
FirstOrDefault	This function returns the first record of the specified list as a <i>Container (record)</i> value, if that record isn't empty. If the record is empty, this function returns a null <i>Container (record)</i> value.
Index	This function returns a <i>Container (record)</i> value that is selected by using the specified numeric index in the specified list. If the index is out of range for the records in the specified list, this function throws an exception.
IsEmpty	This function returns a <i>Boolean</i> value of TRUE if the specified list contains no records. Otherwise, it returns a <i>Boolean</i> value of FALSE .
List	This function returns a <i>Record list</i> value that consists of a new list that is created from the specified arguments.

FUNCTION	DESCRIPTION
ListDistinct	This function calculates the specified expression as a selector for every record of the specified list. It returns a new <i>Record list</i> value that contains a single record for each unique selector value.
ListJoin	This function returns a <i>Record list</i> value that represents a new joined list that is created from the specified arguments.
ListOfFields	This function returns a <i>Record list</i> value that is created based on the structure of the specified argument of the <i>Enumeration</i> or <i>Container (record)</i> type.
ListOfFirstItem	This function returns a <i>Record list</i> value that consists of only the first record of the specified list.
OrderBy	This function returns the specified list as a <i>Record list</i> value after it has been sorted according to the specified arguments. These arguments can be defined as expressions.
Reverse	This function returns the specified list as a <i>Record list</i> value in reversed sort order.
Split	This function splits the specified input string into substrings and returns the result as a new <i>Record list</i> value.
SplitList	This function splits the specified list into sublists (or batches), each of which contains the specified number of records. It then returns the result as a new <i>Record list</i> value that consists of the batches.
SplitListByLimit	This function splits the specified list into a new list of sublists (batches). The number of records in each batch is dynamically calculated. The function then returns the result as a new <i>Record list</i> value that consists of the batches.
StringJoin	This function returns a <i>String</i> value that consists of concatenated values of the specified field from the specified list. The values can be separated by the specified delimiter.
Where	This function returns the specified list as a <i>Record list</i> value after it has been filtered according to the specified condition.

ALLITEMS ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `ALLITEMS` function runs as an in-memory selection and returns a new flattened *Record list* value as a list of records that represents all items that match the specified path.

Syntax

```
ALLITEMS (path)
```

Arguments

`path` : *Record list*

The valid path of a data source of the *Record list* data type.

Return values

Record list

The resulting list of records.

Usage notes

The path must be defined as a valid data source path of a data source element of the *Record list* data type. Data elements such as the path string and date should raise an error in the Electronic reporting (ER) expression builder at design time.

We don't recommend that you use this function for transactional data sources that might contain a large volume of data. Instead, consider using the [ALLITEMSQUERY](#) function.

Example 1

If you enter `SPLIT("abcdef" , 2)` as data source `DS`, the expression `COUNT(ALLITEMS (DS))` returns 3.

Example 2

If you enter `Vend` as the data source of the *Record list* data type that refers to the `VendTable` application table, the expression `ALLITEMS (Vend.'<Relations'.ContactPerson)` returns a flattened list of records that has the `ContactPerson` table structure and contains all contact persons that can be accessed by using the `ContactPerson.ContactForParty == VendTable.Party` relation, and that is available for all vendors from the referenced vendor table.

Additional resources

[List functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

ALLITEMSQUERY ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `ALLITEMSQUERY` function runs as a joined SQL query. It returns a new flattened *Record list* value that consists of a list of records that represent all items that match the specified path.

Syntax

```
ALLITEMSQUERY (path)
```

Arguments

`path` : *Record list*

The valid path of a data source of the *Record list* data type. It must contain at least one relation.

Return values

Record list

The resulting list of records.

Usage notes

The specified path must be defined as a valid data source path of a data source element of the *Record list* data type. It must also contain at least one relation. Data elements such as the path *String* and *Date* should raise an error in the Electronic reporting (ER) expression builder at design time.

When this function is applied to data sources of the *Record list* data type that refer to an application object that can be directly called by using SQL (for example, an table, entity, or query), it runs as a joined SQL query. Otherwise, it runs in memory as the `ALLITEMS` function.

Example

You define the following data sources in your model mapping:

- A `CustInv` data source of the *Table records* type that refers to the `CustInvoiceTable` table
- A `FilteredInv` data source of the *Calculated field* type that contains the expression

```
FILTER (CustInv, CustInv.InvoiceAccount = "US-001")
```

- A `JourLines` of the *Calculated field* type that contains the expression

```
ALLITEMSQUERY ( FilteredInv.'<Relations'.CustInvoiceJour.'<Relations'.CustInvoiceTrans)
```

When you run the model mapping to call the `JourLines` data source, the following SQL statement is run:

```
SELECT ... FROM CUSTINVOICETABLE T1 CROSS JOIN CUSTINVOICEJOUR T2 CROSS JOIN  
CUSTINVOICETRANS T3 WHERE...
```

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

COUNT ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `COUNT` function returns an *Integer* value that represents the number of records in the specified list, if the list isn't empty. If the list is empty, this function returns **0** (zero).

Syntax

```
COUNT (list)
```

Arguments

`list` : *Record list*

The valid path of a data source of the *Record list* data type.

Return values

Integer

The resulting numeric value.

Example

`COUNT (SPLIT("abcd" , 3))` returns 2, because the `SPLIT` function that is used in this example creates a list that consists of two records.

Additional resources

[List functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

EMPTYLIST ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `EMPTYLIST` function returns an empty *Record list* value by using the specified list as a source for the list structure.

Syntax

```
EMPTYLIST (list)
```

Arguments

`list` : *Record list*

The valid path of a data source of the *Record list* data type.

Return values

Record list

The resulting list of records.

Example

`EMPTYLIST (SPLIT ("abc", 1))` returns a new empty list that has the same structure as the list that is returned by the `SPLIT` function that is used.

Additional resources

[List functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

ENUMERATE ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `ENUMERATE` function returns a new *Record list* value that consists of enumerated records of the specified list.

Syntax

```
ENUMERATE (list)
```

Arguments

`list`: *Record list*

The valid path of a data source of the *Record list* data type.

Return values

Record list

The resulting list of records.

Usage notes

The list of enumerated records that is returned exposes the following additional elements:

- The record of fields (**Value** component)
- The current record index (**Number** component)

Example

In the following illustration, an **Enumerated** data source is created as an enumerated list of vendor records from the **Vendors** data source that refers to the `VendTable` table.

```
└─ Enumerated: = ENUMERATE(Vendors):Record list
```

```
  └─ Number: Integer
```

```
    └─ Value: Record
```

```
      └─ Vendors: Table 'VendTable' records
```

The following illustration shows the Electronic reporting (ER) format. In this format, data bindings are created to generate output in XML format. This output presents individual vendors as enumerated nodes.

```
└─ root: XML Element
```

```
  └─ vendor: XML Element= Enumerated
```

```
    └─ name: XML Attribute= Enumerated.Value.'name()'
```

```
      └─ index: XML Attribute= Enumerated.Number
```

The following illustration shows the result when the designed format is run.

```
<?xml version="1.0" encoding="UTF-8"?>
- <root>
  <vendor index="1" name="Contoso Asia"/>
  <vendor index="2" name="Finanzamt Berlin"/>
  <vendor index="3" name="Opal Audio"/>
  <vendor index="4" name="Property Management"/>
  <vendor index="5" name="City-wide Advertising"/>
  <vendor index="6" name="Contoso Entertainment System"/>
</root>
```

Additional resources

List functions

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

FILTER ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `FILTER` function returns the specified list as a *Record list* value after the query has been changed so that it filters for the specified condition.

Syntax

```
FILTER (list, condition)
```

Arguments

`list` : *Record list*

The valid path of a data source of the *Record list* data type.

`condition` : *Boolean*

A valid conditional expression that is used to filter records of the specified list.

Return values

Record list

The resulting list of records.

Usage notes

This function differs from the [WHERE](#) function, because the specified condition is applied to any Electronic reporting (ER) data source of the *Table records* type at the database level. The list and condition can be defined by using tables and relations.

If one or both arguments that are configured for this function (`list` and `condition`) don't allow this request to be translated to the direct SQL call, an exception is thrown at design time. This exception informs the user that either `list` or `condition` can't be used to query the database.

Example 1

If **Vendor** is configured as an ER data source that refers to the VendTable table, the expression

```
FILTER (Vendors, Vendors.VendGroup = "40")
```

 returns a list of only vendors that belong to vendor group 40.

Example 2

If **Vendor** is configured as an ER data source that refers to the VendTable table, and if **parmVendorBankGroup** is configured as an ER data source that returns a value of the *String* data type, the expression

```
FILTER ( Vendor.'<Relations'.VendBankAccount, Vendor.'<Relations'.VendBankAccount.BankGroupID = parmVendorBankGroup)
```

returns a list of only vendor accounts that belong to a specific bank group.

Example 3

You enter data source *DS* of the *Calculated field* type, and it contains the expression `SPLIT ("A,B,C", ",")`. You then enter another expression, `FILTER(DS, DS.Value = "B")`. When you try to save this expression in the ER formula designer, the following exception is thrown: "Validation error: The list expression of FILTER function is not queryable."

Additional resources

List functions

NOTE

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

FIRST ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `FIRST` function returns the first record of the specified list as a *Container (record)* value, if that list isn't empty. If the list is empty, this function throws an exception.

Syntax

```
FIRST (list)
```

Arguments

`list` : *Record list*

The valid path of a data source of the *Record list* data type.

Return values

Container (record)

The resulting record value.

Example 1

The expression `FIRST(SPLIT("ABC",1)).Value` returns the text value "A".

Example 2

The expression `FIRST(SPLIT("",1)).Value` throws an exception at runtime.

Additional resources

[List functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

FIRSTORNULL ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `FIRSTORNULL` function returns the first record of the specified list as a *Container (record)* value, if that record isn't empty. If the record is empty, this function returns a null *Container (record)* value.

Syntax

```
FIRSTORNULL (list)
```

Arguments

`list` : *Record list*

The valid path of a data source of the *Record list* data type.

Return values

Container (record)

The resulting record value.

Example

The expression `FIRSTORNULL(SPLIT("",1)).Value` returns an empty string ("").

Additional resources

[List functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

INDEX ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `INDEX` function returns a *Container (record)* value that is selected by using the specified numeric index in the specified list. If the index is out of range for the records in the specified list, an exception is thrown.

Syntax

```
INDEX (list, index)
```

Arguments

`list` : *Record list*

The valid path of a data source of the *Record list* data type.

`index` : *Integer*

A numeric index that indicates the position of the desired record in the specified list.

Return values

Container (record)

The resulting record value.

Example 1

If you enter data source `DS` of the *Calculated field* type, and it contains the expression `SPLIT ("A|B|C", "|")`, the expression `DS.Value` returns the text value "B" for the second record of this record list. The expression `INDEX (SPLIT ("A|B|C", "|"), 2).Value` also returns the text value "B".

Example 2

If you enter data source `DS` of the *Calculated field* type, and it contains the expression `SPLIT ("A|B|C", "|")`, the expression `INDEX (SPLIT ("A|B|C", "|"), 4).Value` throws an exception at runtime.

Additional resources

[List functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

IEMPTY ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `IEMPTY` function returns a *Boolean* value of **TRUE** if the specified list contains no records. Otherwise, it returns a *Boolean* value of **FALSE**.

Syntax

```
IEMPTY (list)
```

Arguments

`list` : *Record list*

The valid path of a data source of the *Record list* data type.

Return values

Boolean

The resulting *Boolean* value.

Example 1

If you enter data source `DS` of the *Calculated field* type, and it contains the expression `SPLIT ("A|B|C", "|")`, the expression `IEMPTY(DS)` returns **FALSE**.

Example 2

The expression `IEMPTY (SPLIT ("",1))` returns **TRUE**.

Additional resources

[List functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

LIST ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `LIST` function returns a *Record list* value that consists of a new list of records that is created from the specified arguments.

Syntax

```
LIST (record 1 [, record 2, ..., record N])
```

Arguments

`record 1` : *Container (record)*

A reference to a data source of the *Record* data type. This argument is required.

`record N` : *Container (record)*

A reference to a data source of the *Record* data type. These additional arguments are optional.

Return values

Record list

The resulting list of records.

Usage notes

The structure of the list that is created contains only the fields that are presented in the structure of every record that is mentioned in the arguments.

Example

You enter data source **Record 1** of the *Container* type. This data source contains the following nested fields of the *Calculated field* type:

- **Code**: This field contains an expression that returns a value of the *String* type.
- **Amount**: This field contains an expression that returns a value of the *Real* type.

You then enter data source **Record 2** of the *Container* type. This data source contains the following nested fields of the *Calculated field* type:

- **Amount**: This field contains an expression that returns a value of the *Real* type.
- **IsValid**: This field contains an expression that returns a value of the *Boolean* type.

In this case, the expression `LIST('Record 1', 'Record 2')` returns a new list that contains two records. The structure of this list consists of a single **Amount** field of the *Real* type, because this field is the only field that is presented in every argument of the called function.

Additional resources

List functions

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

LISTJOIN ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `LISTJOIN` function returns a *Record list* value that represents a new joined list of records that is created from the specified arguments.

Syntax

```
LIST (list 1 [, list 2, ..., list N])
```

Arguments

`list 1` : *Record list*

A reference to a data source of the *Record list* data type. This argument is mandatory.

`list N` : *Record list*

A reference to a data source of the *Record list* data type. These additional arguments are optional.

Return values

Record list

The resulting list of records.

Usage notes

The structure of the list that is created contains only the fields that are present in the structure of every record list that is referenced in the arguments.

Example

You enter data source **Record 1** of the `Container` type. This data source contains the following nested fields of the `Calculated field` type:

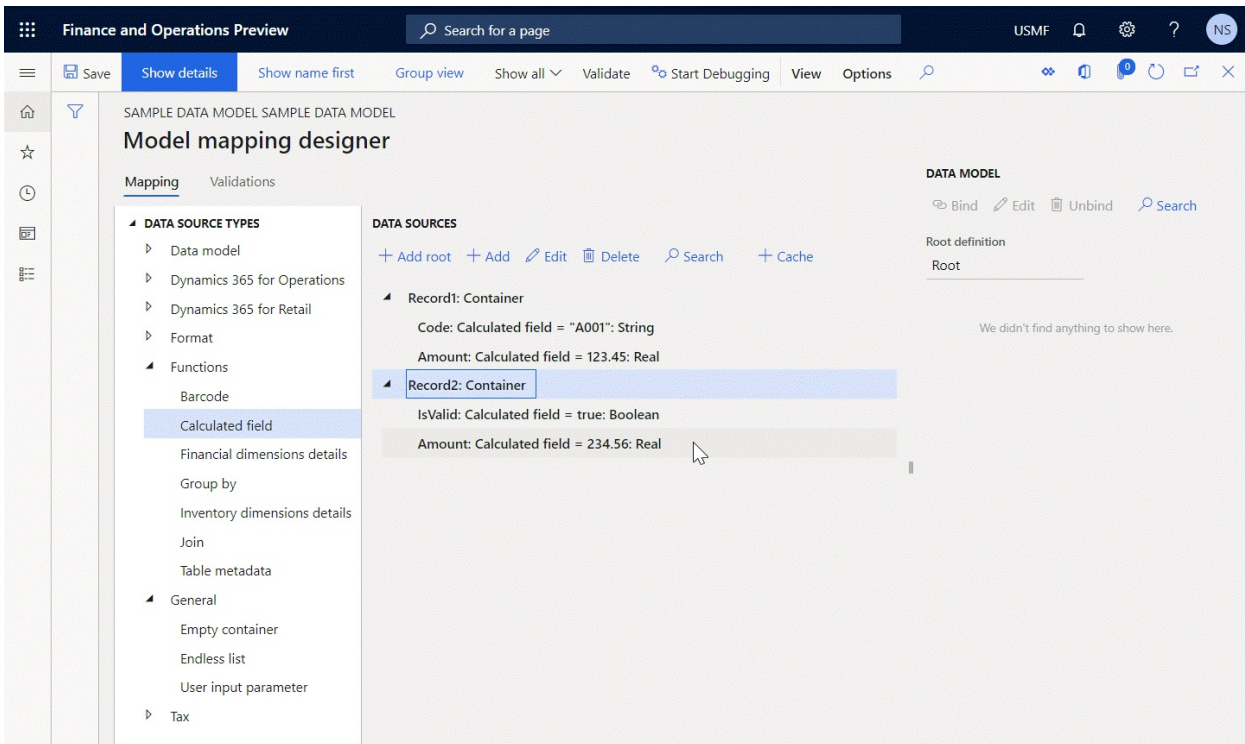

- **Code**: This field contains an expression that returns a value of the `String` type.
- **Amount**: This field contains an expression that returns a value of the `Real` type.

You then enter data source **Record 2** of the `Container` type. This data source contains the following nested fields of the `Calculated field` type:

- **Amount**: This field contains an expression that returns a value of the `Real` type.
- **IsValid**: This field contains an expression that returns a value of the `Boolean` type.

In this case, the expression `LISTJOIN(LIST('Record 1'), LIST('Record 2'))` returns a new list that contains two records.

The structure of this list consists of a single **Amount** field of the `Real` type, because this field is the only field that is presented in every argument of the called function.

Additional resources

[List functions](#)

[Debug data sources of an executed ER format to analyze data flow and transformation](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

LISTOFFIELDS ER function

2/18/2021 • 3 minutes to read • [Edit Online](#)

The `LISTOFFIELDS` function returns a *Record list* value that is created based on the structure of the specified argument of the *Enumeration* or *Container (record)* type.

Syntax 1

```
LISTOFFIELDS (path)
```

Syntax 2

```
LISTOFFIELDS (path, language)
```

Arguments

`path` : Data source reference

The valid reference path of a data source of one of the following data types:

- Model enumeration
- Format enumeration
- Application enumeration
- Container (record)

`language` : *String*

Text that represents a language code.

Return values

Record list

The resulting list of records.

Usage notes

The list that is created consists of records that have the following fields:

- **Name** (*String* data type)
- **Label** (*String* data type)
- **Description** (*String* data type)
- **IsTranslated** (*Boolean* data type)

If the `path` argument refers to a data source of the *Container (Record)* type, for every field of the referenced container record, a new record is added to the list that is created. For every record that is created, the **Name** field returns the name of the field of the referenced container record that the current record was created for.

If the `path` argument refers to a data source of one of the *Enumeration* types, for every enumeration value of

the referenced enumeration, a new record is added to the list that is created. For every record that is created, the **Name** field returns the value of the referenced enumeration that the current record was created for, the **Description** field returns the description of that enumeration, and the **Label** field returns the label of that enumeration.

At runtime, when syntax 1 is used, the **Label** and **Description** fields must return values that are based on the language settings of the Electronic reporting (ER) format that is running:

- If the labels and descriptions for the requested language are available, the **Label** and **Description** fields return values that are based on that language, and the **IsTranslated** field returns **True**.
- If the labels and descriptions for the requested language aren't available, the **Label** and **Description** fields return values that are based on the default EN-US language, and the **IsTranslated** field returns **False**.

At runtime, when syntax 2 is used, the **Label** and **Description** fields must return values that are based on the language that is defined as the second argument of the called function:

- If the labels and descriptions for the requested language are available, the **Label** and **Description** fields return values that are based on that language, and the **IsTranslated** field returns **True**.
- If the labels and descriptions for the requested language aren't available, the **Label** and **Description** fields return values that are based on the **EN-US** language, and the **IsTranslated** field returns **False**.

Example 1

In the following illustration, an enumeration is introduced in an ER data model.

ReportDirection		
Enumeration values		
Name	Label (*Recommended to use labels)	Description
Both	Both	
Export	Dispatches	
Import	Arrivals	

The following illustration shows these details:

- The model enumeration is inserted into a report as a data source.
- An ER expression uses the model enumeration as a parameter of the `LISTOFFIELDS` function.
- A data source of the *Record list* type is inserted into a report by using the ER expression that is created.

FORMAT **MAPPING** TRANSFORMATIONS VALIDATIONS

Bind + Add root + Add Edit Delete Show name first Group view

- enumDirectionInReport: Data model enumeration ReportDirection
 - Arrivals(Import): Enumeration value
 - Both: Enumeration value
 - Dispatches(Export): Enumeration value
 - listDirectionInReport: Calculated field = LISTOFFIELDS(enumDirectionInReport): Record list**
 - Description: String
 - Label: String
 - Name: String
- model: Data model Intrastat

The following example shows the ER format elements that are bound to the data source of the *Record list* type that was created by using the `LISTOFFIELDS` function.

- Root: XML Element
 - Directions: XML Element = listDirectionInReport
 - name: XML Attribute = listDirectionInReport.Name
 - label: XML Attribute = listDirectionInReport.Label
 - desc: XML Attribute = listDirectionInReport.Description

The following illustration shows the result when the designed format is run.

```
<?xml version="1.0" encoding="UTF-8"?>
- <Root>
  <Directions desc="" label="Both" name="Both"/>
  <Directions desc="" label="Dispatches" name="Export"/>
  <Directions desc="" label="Arrivals" name="Import"/>
</Root>
```

NOTE

Based on the language settings of the parent FILE and FOLDER format elements, translated text for labels and descriptions is entered in the output of the ER format.

Example 2

You use the *Calculated field* data source type to configure `enumType_de` and `enumType_deCH` data sources for the `enumType` data model enumeration:

- `enumType_de` = LISTOFFIELDS (enumType, "de")
- `enumType_deCH` = LISTOFFIELDS (enumType, "de-CH")

In this case, you can use the following expression to get the label of the enumeration value in Swiss German, if that translation is available. If the Swiss German translation isn't available, the label is in German.

```
IF (NOT (enumType_deCH.IsTranslated), enumType_de.Label, enumType_deCH.Label)
```

LISTOFFIRSTITEM ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `LISTOFFIRSTITEM` function returns a *Record list* value that consists of only the first record of the specified list.

Syntax

```
LISTOFFIRSTITEM (list)
```

Arguments

`list`: *Record list*

The valid path of a data source of the *Record list* data type.

Return values

Record list

The resulting list of records.

Example

The expression `FIRST(LISTOFFIRSTITEM (SPLIT ("ABC",1))).Value` returns the text value "A".

Additional resources

ORDERBY ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `ORDERBY` function returns the specified list as a *Record list* value after it has been sorted according to the specified arguments. These arguments can be defined as expressions.

Syntax

```
ORDERBY (list , expression 1[, expression 2, ..., expression N])
```

Arguments

`list` : *Record list*

The valid path of a data source of the *Record list* data type.

`expression 1` : *Field*

The valid path of a field of the data source that is referenced by the `list` argument of the called function. The referenced field must be a field of the primitive data type. This argument is required.

`expression N` : *Field*

The valid path of a field of the data source that is referenced by the `list` argument of the called function. The referenced field must be a field of the primitive data type. These additional arguments are optional.

Return values

Record list

The resulting list of records.

Example 1

If you enter data source `DS` of the *Calculated field* type, and it contains the expression `SPLIT ("C|B|A", "|")`, the expression `FIRST(ORDERBY(DS, DS. Value)).Value` returns the text value "A".

Example 2

If `Vendor` is configured as an Electronic reporting (ER) data source that refers to the `VendTable` table, the expression `ORDERBY (Vendors, Vendors.'name()')` returns a list of vendors that is sorted by name in ascending order.

Additional resources

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

REVERSE ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `REVERSE` function returns the specified list as a *Record list* value in reversed sort order.

Syntax

```
REVERSE (list)
```

Arguments

`list`: *Record list*

The valid path of a data source of the *Record list* data type.

Return values

Record list

The resulting list of records.

Example 1

If you enter data source `DS` of the *Calculated field* type, and it contains the expression `SPLIT ("C|B|A", "|")`, the expression `FIRST(REVERSE(ORDERBY(DS, DS. Value)))` returns the text value "C".

Example 2

If `Vendor` is configured as an Electronic reporting (ER) data source that refers to the `VendTable` table, the expression `REVERSE (ORDERBY (Vendors, Vendors.'name()'))` returns a list of vendors that is sorted by name in descending order.

Additional resources

SPLIT ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `SPLIT` function splits the specified input string into substrings and returns the result as a new *Record list* value.

Syntax 1

```
SPLIT (input, length)
```

This syntax is used to split the specified input string into substrings, each of which has the specified length.

Syntax 2

```
SPLIT (input, delimiter)
```

This syntax is used to split the specified input string into substrings, based on the specified delimiter.

Arguments

`input` : *String*

The text to split.

`length` : *Integer*

The maximum length of a single substring.

`delimiter` : *String*

A delimiter that is used to separate substrings.

Return values

Record list

The resulting list of records.

Usage notes

The record structure of the list that is returned consists of the **Value** field of the *String* type. Every record of the list that is returned contains generated substrings in this field.

If the `delimiter` argument is empty, the new list that is returned consists of one record that has the **Value** field of the *String* type. This field contains the input text.

If the `input` argument is empty, a new empty list is returned. If either the `input` or `delimiter` argument is unspecified (null), an application exception is thrown.

Example 1

`SPLIT ("abcd", 3)` returns a new list that consists of two records that have the **Value** field of the *String* type. The **Value** field in the first record contains the text "abc", and the **Value** field in the second record contains the text "d".

Example 2

`SPLIT ("XAb aBy", "aB")` returns a new list that consists of three records that have the **Value** field of the *String* type. The **Value** field in the first record contains the text "X", the **Value** field in the second record contains the text " ", and the **Value** field in the third record contains the text "y".

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

SPLITLIST ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `SPLITLIST` function splits the specified list into sublists (or batches), each of which contains the specified number of records. It then returns the result as a new *Record list* value that consists of the batches.

Syntax

```
SPLITLIST (list, number)
```

Arguments

`list` : *Record list*

The valid path of a data source of the *Record list* data type.

`number` : *Integer*

The maximum number of records per batch.

Return values

Record list

The resulting list of records.

Usage notes

The list of batches that is returned contains the following elements:

- **Value:** *List*

The list of records that belong to the current batch.

- **BatchNumber:** *Integer*

The number of the current batch in the returned list.

Example

In the following illustration, a **Lines** data source is created as a record list that has three records. This list is divided into batches, each of which contains up to two records.

```
← Lines: = SPLITLIST(SPLIT("abcdef", 2), 2):Record list
```

```
    BatchNumber: Integer
```

```
    ← Value: Record list
```

```
        Value: String
```

The following illustration shows the designed format layout. In this format layout, bindings to the **Lines** data source are created to generate output in XML format. This output presents individual nodes for each batch and the records in it.

- └─ root: XML Element
 - └─ batch: XML Element= Lines
 - number: XML Attribute= Lines.BatchNumber
 - └─ record: XML Element= Lines.Value
 - value: XML Attribute= Lines.Value.Value

The following illustration shows the result when the designed format is run.

```
<?xml version="1.0" encoding="UTF-8"?>
- <root>
  - <batch number="1">
    <record value="ab"/>
    <record value="cd"/>
  </batch>
  - <batch number="2">
    <record value="ef"/>
  </batch>
</root>
```

Additional resources

List functions

NOTE

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

SPLITLISTBYLIMIT ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `SPLITLISTBYLIMIT` function splits the specified list into a new list of sublists (batches). The number of records in each batch is dynamically calculated. The function then returns the result as a new *Record list* value that consists of the batches.

Syntax

```
SPLITLISTBYLIMIT (list, limit value, limit source)
```

Arguments

`list` : *Record list*

The valid path of a data source of the *Record list* data type.

`limit value` : *Integer or Real*

The maximum value of the limit that is used to split the original list into batches.

`limit source` : *Field*

The valid path of a field of the *Integer* or *Real* type in the specified list. The value of this field defines the step that the total sum is increased on.

Return values

Record list

The resulting list of records.

Usage notes

The list of batches that is returned contains the following elements:

- **Value:** *List*

The list of records that belong to the current batch.

- **BatchNumber:** *Integer*

The number of the current batch in the returned list.

The limit isn't applied to a single item of the original list if the limit source exceeds the defined limit.

Example

The following illustration shows an Electronic reporting (ER) format.

Bind Unbind Edit formula Expand/collapse

- Root: XML Element
 - ListOfItems: XML Element
 - Item: XML Element = model.Item
 - Name: XML Attribute = model.Item.Name
 - Weight: XML Attribute = model.Item.Weight

The following illustration shows the data sources that are used for the format.

FORMAT **MAPPING** TRANSFORMATIONS

Bind + Add root + Add Edit

- model: Data model Intrastat
 - Item: Record list
 - Name: String
 - Weight: Real

The following illustration shows the result when the format is run. In this case, the output is a flat list of commodity items.

```
<?xml version="1.0" encoding="UTF-8"?>
- <Root>
  - <ListOfItems>
    <Item Weight="1" Name="Speaker"/>
    <Item Weight="2" Name="Projector"/>
    <Item Weight="3" Name="Radio receiver"/>
    <Item Weight="4" Name="Monitor"/>
    <Item Weight="5" Name="Transmitter or receiver"/>
    <Item Weight="6" Name="Parts and components"/>
    <Item Weight="11" Name="Hardware"/>
  </ListOfItems>
</Root>
```

In the following illustrations, the same format has been adjusted so that it presents the list of commodity items in batches if a single batch must include commodities and the total weight should not exceed a limit of 9.

Bind Unbind Edit formula Expand/collapse Search

- Root: XML Element
 - ListOfItems: XML Element
 - Item: XML Element = model.Item
 - Name: XML Attribute = model.Item.Name
 - Weight: XML Attribute = model.Item.Weight
 - ListOfBatches: XML Element
 - Batch: XML Element = batches
 - Id: XML Attribute = batches.BatchNumber
 - TotalWeight: XML Attribute = batches.total.aggregated.total
 - ListOfItems: XML Element
 - Item: XML Element = batches.Value
 - Name: XML Attribute = batches.Value.Name
 - Weight: XML Attribute = batches.Value.Name

4 batches: Calculated field = SPLITLISTBYLIMIT(model.Item, 9, model.Item.Weight): Record list

BatchNumber: Integer

4 total: Record list 'batches/Value' group by

4 aggregated: Record

total: Real

grouped: Record

▸ lines: Record list

4 Value: Record list

Name: String

Weight: Real

4 model: Data model Intrastat

4 Item: Record list

Name: String

Weight: Real

The following illustration shows the result when the adjusted format is run.

```
<?xml version="1.0" encoding="UTF-8"?>
- <Root>
  - <ListOfItems>
    <Item Weight="1" Name="Speaker"/>
    <Item Weight="2" Name="Projector"/>
    <Item Weight="3" Name="Radio receiver"/>
    <Item Weight="4" Name="Monitor"/>
    <Item Weight="5" Name="Transmitter or receiver"/>
    <Item Weight="6" Name="Parts and components"/>
    <Item Weight="11" Name="Hardware"/>
  </ListOfItems>
  - <ListOfBatches>
    - <Batch TotalWeight="6.0" Id="1">
      - <ListOfItems>
        <Item Weight="Speaker" Name="Speaker"/>
        <Item Weight="Projector" Name="Projector"/>
        <Item Weight="Radio receiver" Name="Radio receiver"/>
      </ListOfItems>
    </Batch>
    - <Batch TotalWeight="9.0" Id="2">
      - <ListOfItems>
        <Item Weight="Monitor" Name="Monitor"/>
        <Item Weight="Transmitter or receiver" Name="Transmitter or receiver"/>
      </ListOfItems>
    </Batch>
    - <Batch TotalWeight="6.0" Id="3">
      - <ListOfItems>
        <Item Weight="Parts and components" Name="Parts and components"/>
      </ListOfItems>
    </Batch>
    - <Batch TotalWeight="11.0" Id="4">
      - <ListOfItems>
        <Item Weight="Hardware" Name="Hardware"/>
      </ListOfItems>
    </Batch>
  </ListOfBatches>
</Root>
```

NOTE

The limit isn't applied to the last item of the original list, because the value (11) of the limit source (**weight**) exceeds the defined limit (9). To ignore sublists during report generation, use either the `WHERE` function or the **Enabled** expression of the corresponding format element, as you require.

List functions

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

STRINGJOIN ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `STRINGJOIN` function returns a *String* value that consists of concatenated values of the specified field from the specified list. The values can be separated by the specified delimiter.

Syntax

```
STRINGJOIN (list, field, delimiter)
```

Arguments

`list` : *Record list*

The valid path of a data source of the *Record list* data type.

`field` : *Field*

The valid path of a field of the *String* data type in the specified list.

`delimiter` : *String*

A delimiter that is used to separate substrings.

Return values

String

The resulting text value.

Example

If you enter `SPLIT("abc" , 1)` as data source `DS`, the expression `STRINGJOIN (DS, DS.Value, "-")` returns "a-b-c".

Additional resources

[List functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

WHERE ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `WHERE` function returns the specified list as a *Record list* value after it has been filtered according to the specified condition.

Syntax

```
WHERE (list, condition)
```

Arguments

`list` : *Record list*

The valid path of a data source of the *Record list* data type.

`condition` : *Boolean*

A valid conditional expression that is used to filter records of the specified list.

Return values

Record list

The resulting list of records.

Usage notes

This function differs from the `FILTER` function, because the specified condition is applied to any Electronic reporting (ER) data source of the *Record list* type that is present in memory.

If the arguments that are configured for this function (`list` and `condition`) allow this request to be translated to the direct SQL call, a warning message is thrown at design time. This message informs the user that performance might be improved if the `FILTER` function is used instead of `WHERE`.

Example 1

If `Vendor` is configured as an ER data source that refers to the `VendTable` table, the expression

```
WHERE (Vendors, Vendors.VendGroup = "40")
```

 returns a list of only vendors that belong to vendor group 40.

Example 2

If you enter data source `DS` of the *Calculated field* type, and it contains the expression `SPLIT ("A|B|C", "|")`, the expression `WHERE(DS, DS.Value = "B")` returns a list of only one record that contains the text `"B"` in the `Value` field.

List of ER functions in the logical category

2/18/2021 • 2 minutes to read • [Edit Online](#)

Electronic reporting (ER) logical functions can be used to work with logical values to perform more than one comparison in a single expression or test multiple conditions. This topic provides a summary of these functions.

List of supported functions

FUNCTION	DESCRIPTION
And	This function returns a <i>Boolean</i> value of TRUE if all the specified conditions are true. Otherwise, it returns a <i>Boolean</i> value of FALSE .
Case	This function evaluates the value of the specified expression against the specified alternative options and returns the result of the first option that equals the value of the specified expression. Otherwise, it returns an optional default result, if a default result is specified as the last argument of the called function that isn't preceded by an option. The value that is returned can be a value of any of the supported data types.
If	This function returns the first specified value if the specified condition is met. Otherwise, it returns the second specified value. The value that is returned can be a value of any of the supported data types.
Not	This function returns the reversed logical value of the specified condition as a <i>Boolean</i> value.
Or	This function returns a <i>Boolean</i> value of FALSE if all the specified conditions are false. If any specified condition is true, the function returns a <i>Boolean</i> value of TRUE .
ValueIn	This function determines whether the specified input matches any value of a specified item in the specified list. It returns a <i>Boolean</i> value of TRUE if the specified input matches the result of running the specified expression for at least one record of the specified list. Otherwise, it returns a <i>Boolean</i> value of FALSE .
ValueInLarge	This function determines whether the specified input of the <i>Int64</i> or <i>Integer</i> type matches any value of a specified item in the specified list. It returns a <i>Boolean</i> value of TRUE if the specified input matches the result of running the specified expression for at least one record of the specified list. Otherwise, it returns a <i>Boolean</i> value of FALSE .

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

AND ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `AND` function returns a *Boolean* value of **TRUE** if all the specified conditions are true. Otherwise, it returns a *Boolean* value of **FALSE**.

Syntax

```
AND (condition 1[, condition 2, ..., condition N])
```

Arguments

`condition 1` : *Boolean*

A valid conditional expression that must be tested. This argument is required.

`condition N` : *Boolean*

A valid conditional expression that must be tested. These additional arguments are optional.

Return values

Boolean

The resulting *Boolean* value.

Usage notes

In the arguments of logical functions, you can use data source references, numeric and text values, Boolean values, comparison operators, and other Electronic reporting (ER) functions. However, all the arguments must be evaluated to a *Boolean* value of **TRUE** or **FALSE**.

Example

`AND (1=1, "a"="a")` returns **TRUE**.

`AND (1=2, "a"="a")` returns **FALSE**.

Additional resources

[Logical functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

CASE ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `CASE` function evaluates the value of the specified expression against the specified alternative options and returns the result of the first option that equals the value of the specified expression. Otherwise, it returns the optional default result, if a default result is specified as the last argument of the called function that isn't preceded by an option. The value that is returned can be a value of any of the supported data types.

Syntax

```
CASE (expression, option 1, result 1[, option 2, result 2, ..., option N, result N, default result])
```

Arguments

`expression` : *Primitive data type* (Boolean, numeric, or text)

A valid expression that returns a value of the primitive data type.

`option 1` : *Primitive data type* (Boolean, numeric, or text)

A valid expression that returns a value of the same primitive data type as the `expression` argument of the called function. This argument is required.

`result 1` : *Any of the supported data types*

The returned result that corresponds to the preceding option. This argument is required.

`option N` : *Primitive data type* (Boolean, numeric, or text)

A valid expression that returns a value of the same primitive data type as the `expression` argument of the called function. This argument is optional.

`result N` : *Any of the supported data types*

The returned result that corresponds to the preceding option. This argument is optional.

`default result` : *Any of the supported data types*

The result that should be returned if there is no match. This argument is optional.

Return values

Any of the supported data types

The resulting value of any of the supported data types.

Usage notes

An exception is thrown at runtime if there is no match and an optional default result isn't defined.

All results must be specified by using the same data type. An exception is thrown at design time if the data types of the configured results don't match.

If the first result value and the *N*th result value are values of the *Container (record)* or *Record list* data type, the

result has only the fields that exist in both values.

Example

`CASE(DATETIMEFORMAT(NOW(), "MM"), "10", "WINTER", "11", "WINTER", "12", "WINTER", "")` returns the string "WINTER" if the current application session date is between October and December. Otherwise, it returns a blank string.

Additional resources

[Logical functions](#)

NOTE

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

IF ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `IF` function returns the first specified value if the specified condition is met. Otherwise, it returns the second specified value. The value that is returned can be a value of any of the supported data types.

Syntax

```
IF (condition, first value, second value) as any of the supported data types
```

Arguments

`condition` : *Boolean*

A valid conditional expression that must be tested.

`first value` : *Any of the supported data types*

The result that is returned if the condition is met.

`second value` : *Any of the supported data types*

The result that is returned if the condition isn't met.

Return values

Any of the supported data types

The resulting value of any of the supported data types.

Usage notes

The `first value` and `second value` arguments must be specified by using the same data type. An exception is thrown at design time if the data types of the configured values don't match.

If the first value and the second value are values of the *Container (record)* or *Record list* data type, the result has only the fields that exist in both values.

Example

```
IF (1=2, "condition is met", "condition is not met") returns the string "condition is not met".
```

Additional resources

[Logical functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

NOT ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `NOT` function returns the reversed logical value of the specified condition as a *Boolean* value.

Syntax

```
NOT (condition)
```

Arguments

`condition`: *Boolean*

A valid conditional expression that must be reversed.

Return values

Boolean

The resulting *Boolean* value.

Example

`NOT (TRUE)` returns `FALSE`.

Additional resources

[Logical functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

OR ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `OR` function returns a *Boolean* value of **FALSE** if all the specified conditions are false. If any specified condition is true, the function returns a *Boolean* value of **TRUE**.

Syntax

```
OR (condition 1[, condition 2, ..., condition N])
```

Arguments

`condition 1` : *Boolean*

A valid conditional expression that must be tested. This argument is required.

`condition N` : *Boolean*

A valid conditional expression that must be tested. These additional arguments are optional.

Return values

Boolean

The resulting *Boolean* value.

Example

`OR (1=2, "a"="a")` returns **TRUE**.

Additional resources

[Logical functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

VALUEIN ER function

2/18/2021 • 3 minutes to read • [Edit Online](#)

The `VALUEIN` function determines whether the specified input matches any value of a specified item in the specified list. It returns a *Boolean* value of **TRUE** if the specified input matches the result of running the specified expression for at least one record of the specified list. Otherwise, it returns a *Boolean* value of **FALSE**.

Syntax

```
VALUEIN (input, list, list item expression)
```

Arguments

`input`: *Field*

The valid path of an item of a data source of the *Record list* type. The value of this item will be matched.

`list`: *Record list*

The valid path of a data source of the *Record list* data type.

`list item expression`: *Boolean*

A valid conditional expression that either points to or contains a single field of the specified list that should be used for the matching.

Return values

Boolean

The resulting *Boolean* value.

Usage notes

In general, the `VALUEIN` function is translated to a set of **OR** conditions. If the list of **OR** conditions is large and the maximum total length of an SQL statement might be exceeded, consider using the `VALUEINLARGE` function.

```
(input = list.item1.value) OR (input = list.item2.value) OR ...
```

In some cases, it can be translated to a database SQL statement by using the `EXISTS JOIN` operator.

Example 1

In your model mapping, you define the **List** data source of the *Calculated field* type. This data source contains the expression `SPLIT ("a,b,c", ",")`.

When a data source is called, if it has been configured as the `VALUEIN ("B", List, List.Value)` expression, it returns **TRUE**. In this case, the `VALUEIN` function is translated to the following set of conditions:

```
((("B" = "a") or ("B" = "b") or ("B" = "c")), where ("B" = "b") equals TRUE.
```

When a data source is called, if it has been configured as the `VALUEIN ("B", List, LEFT(List.Value, 0))`

expression, it returns **FALSE**. In this case, the `VALUEIN` function is translated to the following condition: `("B" = "")`, which doesn't equal **TRUE**.

The upper limit for the number of characters in the text of such a condition is 32,768 characters. Therefore, you should not create data sources that might exceed this limit at runtime. If the limit is exceeded, the application stops running, and an exception is thrown. For example, this situation can occur if the data source is configured as `WHERE (List1, VALUEIN (List1.ID, List2, List2.ID))`, and the `List1` and `List2` lists contain a large volume of records.

In some cases, the `VALUEIN` function is translated to a database statement by using the `EXISTS JOIN` operator. This behavior occurs when the `FILTER` function is used and the following conditions are met:

- The **ASK FOR QUERY** option is turned off for the data source of the `VALUEIN` function that refers to the list of records. No additional conditions will be applied to this data source at runtime.
- No nested expressions are configured for the data source of the `VALUEIN` function that refers to the list of records.
- A list item of the `VALUEIN` function refers to a field of the specified data source, not to an expression or method of that data source.

Consider using this option instead of the `WHERE` function that is described earlier in this example.

Example 2

You define the following data sources in your model mapping:

- The `In` data source of the *Table records* type. This data source refers to the `Intrastat` table.
- The `Port` data source of the *Table records* type. This data source refers to the `IntrastatPort` table.

When a data source is called that has been configured as the `FILTER (In, VALUEIN(In.Port, Port, Port.PortId))` expression, the following SQL statement is generated to return filtered records of the `Intrastat` table.

```
select ... from Intrastat
exists join TableId from IntrastatPort
where IntrastatPort.PortId = Intrastat.Port
```

For `dataAreaId` fields, the final SQL statement is generated by the using `IN` operator.

Example 3

You define the following data sources in your model mapping:

- The `Le` data source of the *Calculated field* type. This data source contains the expression `SPLIT ("DEMF,GBSI,USMF", ",")`.
- The `In` data source of the *Table records* type. This data source refers to the `Intrastat` table, and the **Cross-company** option is turned on for it.

When a data source is called that has been configured as the `FILTER (In, VALUEIN (In.dataAreaId, Le, Le.Value))` expression, the final SQL statement contains the following condition.

```
Intrastat.dataAreaId IN ('DEMF', 'GBSI', 'USMF')
```

List of ER functions in the mathematical category

2/18/2021 • 2 minutes to read • [Edit Online](#)

Electronic reporting (ER) mathematical functions can be used to do many common mathematical calculations. This topic provides a summary of these functions.

List of supported functions

FUNCTION	DESCRIPTION
Abs	This function returns the absolute value (modulus) of the specified number as a <i>Real</i> value. In other words, it returns the number without its sign.
Power	This function returns a <i>Real</i> value that represents the result of raising the specified positive number to the specified power.
Round	This function returns the specified number as a <i>Real</i> value after it has been rounded to the specified number of decimal places.
RoundDown	This function returns the specified number as a <i>Real</i> value after it has been rounded down to the specified number of decimal places.
RoundUp	This function returns the specified number as a <i>Real</i> value after it has been rounded up to the specified number of decimal places.

ABS ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `ABS` function returns the absolute value (modulus) of the specified number as a *Real* value. In other words, it returns the number without its sign.

Syntax

```
ABS (number)
```

Arguments

`number` : *Real*

A numeric value that you want the modulus of.

Return values

Real

The resulting numeric value.

Example

`ABS (-1)` returns 1.

Additional resources

[Mathematical functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

POWER ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `POWER` function returns a *Real* value that represents the result of raising the specified positive number to the specified power.

Syntax

```
POWER (number, power)
```

Arguments

`number` : *Real* or *Integer*

A numeric value that must be raised to the specified power.

`power` : *Real* or *Integer*

A numeric value that represents the specific power.

Return values

Real

The resulting numeric value.

Example 1

`POWER (10, 2)` returns 100.

Example 2

`POWER (4, 0.5)` returns 2.

Additional resources

[Mathematical functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

ROUND ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `ROUND` function returns the specified number as a *Real* value after it has been rounded to the specified number of decimal places.

Syntax

```
ROUND (number, decimals)
```

Arguments

`number` : *Real*

A numeric value that must be rounded.

`decimals` : *Integer*

A numeric value that represents the number of decimal places.

Return values

Real

The resulting numeric value.

Usage notes

If the value of the `decimals` argument is more than 0 (zero), the specified number is rounded to that many decimal places.

If the value of the `decimals` argument is 0 (zero), the specified number is rounded to the nearest even integer.

If the value of the `decimals` argument is less than 0 (zero), the specified number is rounded to the left of the decimal point.

Example 1

`ROUND (1200.767, 2)` rounds to two decimal places and returns **1200.77**.

Example 2

`ROUND (1200.767, -3)` rounds to the nearest multiple of 1,000 and returns **1000**.

Example 3

`ROUND (1200.5, 0)` rounds to the nearest even integer and returns **1200**, while `ROUND (1201.5, 0)` does the same and returns **1202**.

Additional resources

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

ROUNDDOWN ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `ROUNDDOWN` function returns the specified number as a *Real* value after it has been rounded down to the specified number of decimal places.

Syntax

```
ROUNDDOWN (number, decimals)
```

Arguments

`number` : *Real*

A numeric value that must be rounded down.

`decimals` : *Integer*

A numeric value that represents the number of decimal places.

Return values

Real

The resulting numeric value.

Usage notes

This function behaves like `ROUND`, but it always rounds the specified number down (toward zero).

Example 1

`ROUNDDOWN (1200.767, 2)` rounds down to two decimal places and returns **1200.76**.

Example 2

`ROUNDDOWN (1700.767, -3)` rounds down to the nearest multiple of 1,000 and returns **1000**.

Additional resources

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

ROUNDUP ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `ROUNDUP` function returns the specified number as a *Real* value after it has been rounded up to the specified number of decimal places.

Syntax

```
ROUNDUP (number, decimals)
```

Arguments

`number` : *Real*

A numeric value that must be rounded up.

`decimals` : *Integer*

A numeric value that represents the number of decimal places.

Return values

Real

The resulting numeric value.

Usage notes

This function behaves like `ROUND`, but it always rounds the specified number up (away from zero).

Example 1

`ROUNDUP (1200.763, 2)` rounds up to two decimal places and returns **1200.77**.

Example 2

`ROUNDUP (1200.767, -3)` rounds up to the nearest multiple of 1,000 and returns **2000**.

List of ER functions in the record category

2/18/2021 • 2 minutes to read • [Edit Online](#)

Electronic reporting (ER) record functions can be used to extract information from, and perform operations on, data sources of the *Container (record)* data type. This topic provides a summary of these functions.

List of supported functions

FUNCTION	DESCRIPTION
NullContainer	This function returns a null <i>Container (record)</i> value that has the same structure as the specified record list or record.
EmptyRecord	This function returns a null <i>Container (record)</i> value that has the same structure as the specified record list or record.

Additional resources

[Electronic Reporting overview](#)

[Formula designer in Electronic reporting](#)

[Electronic reporting formula language](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

EMPTYRECORD ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `EMPTYRECORD` function returns a null *Container (record)* value that has the same structure as the specified record list or record.

Syntax

```
EMPTYRECORD (list)
```

Arguments

`list` : *Record list* or *Container (record)*

The valid path of a data source of either the *Record list* or *Container (record)* type.

Return values

Container (record)

The resulting record value.

Usage notes

NOTE

A null record is a record where all fields have an empty value. An empty value is 0 (zero) for numbers, an empty string for strings, and so on.

Example

`EMPTYRECORD (SPLIT ("abc", 1))` returns a new empty record that has the same structure as the list that is returned by the `SPLIT` function. For more information, see [SPLIT](#).

Additional resources

[Record functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

NULLCONTAINER ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `NULLCONTAINER` function returns a null *Container (record)* value that has the same structure as the specified record list or record.

Syntax

```
NULLCONTAINER (list)
```

Arguments

`list` : *Record list* or *Container (record)*

The valid path of a data source of either the *Record list* or *Container (record)* type.

Return values

Container (record)

The resulting record value.

Usage notes

NOTE

This function is obsolete. Use the `EMPTYRECORD` function instead. For more information, see [EMPTYRECORD](#).

Example

`NULLCONTAINER (SPLIT ("abc", 1))` returns a new empty record that has the same structure as the list that is returned by the `SPLIT` function. For more information, see [SPLIT](#).

Additional resources

[Record functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

List of ER functions of the text category

2/18/2021 • 2 minutes to read • [Edit Online](#)

Electronic reporting (ER) text functions can be used to perform operations on data sources of the *String* data type. This topic provides a summary of these functions.

List of supported functions

FUNCTION	DESCRIPTION
Char	This function returns a <i>String</i> value that presents a single character that is referenced by the specified Unicode number.
Concatenate	This function returns all the specified text strings as a <i>String</i> value after they have been joined into one string.
Format	This function returns the specified string a <i>String</i> value after it has been formatted by substituting any occurrences of %N with the Mth argument.
GetEnumValueByName	This function searches for a specific <i>Enum</i> value in the specified enumeration data source by using the enumeration name that is specified as a <i>String</i> value. If the <i>Enum</i> value is found, the function returns it.
GuidValue	This function converts the specified input of the <i>String</i> type to a data item of the <i>GUID</i> type.
JsonValue	This function parses data in JavaScript Object Notation (JSON) format that is accessed at the specified path, and it extracts a scalar value that is based on the specified ID. It then returns the extracted scalar value as a <i>String</i> value.
Left	This function returns a <i>String</i> value that presents the specified number of characters from the start of the specified string.
Len	This function returns an <i>Integer</i> value that presents the number of characters in the specified string.
Lower	This function returns the specified text string as a <i>String</i> value after it has been converted to lowercase letters.
Mid	This function returns a <i>String</i> value that presents the specified number of characters from the specified string, starting at the specified position.
NumberFormat	This function returns a <i>String</i> value that presents the specified number in the specified format and in an optionally specified culture.

FUNCTION	DESCRIPTION
NumeralsToText	This function returns the specified number as a <i>String</i> value after it has been spelled out (that is, converted to text strings) in the specified language.
PadLeft	This function returns a <i>String</i> value of the specified length, where the start of the specified string is padded with one or more instances of the specified characters.
QrCode	This function returns a <i>Container</i> value that presents the Quick Response code (QR code) image for the specified string in binary format.
Replace	This function returns the specified text string as a <i>String</i> value after all or part of it has been replaced with another string.
Right	This function returns a <i>String</i> value that presents the specified number of characters from the end of the specified string.
Text	This function returns the specified number as a <i>String</i> value after it has been converted to a text string that is formatted according to the server locale settings of the current application instance.
Translate	This function returns a <i>String</i> value that contains the result of the replacement the specified text in characters for another provided set of characters.
Trim	This function returns the specified text string as a <i>String</i> value after leading and trailing spaces have been truncated, and after multiple spaces between words have been removed.
Upper	This function returns the specified text string as a <i>String</i> value after it has been converted to uppercase letters.

Additional resources

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

CHAR ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `CHAR` function returns a *String* value that presents a single character that is referenced by the specified Unicode number.

Syntax

```
CHAR (number)
```

Arguments

`number` : *Integer*

A number that corresponds to an expected single character.

Return values

String

The resulting text value.

Usage notes

The string that this function returns depends on the encoding that is selected in the parent **FILE** format element. For a list of the supported encodings, see [Encoding class](#).

Example

`CHAR (255)` returns "ÿ".

Additional resources

[Text functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

CONCATENATE ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `CONCATENATE` function returns all the specified text strings as a *String* value after they have been joined into one string.

Syntax

```
CONCATENATE (text 1[, text 2, ..., text N])
```

Arguments

`text 1` : *String*

A reference to a data source of the *String* data type. This argument is required.

`text N` : *String*

A reference to a data source of the *String* data type. These additional arguments are optional.

Return values

String

The resulting text value.

Example

```
CONCATENATE ("abc", "def") returns "abcdef".
```

Usage notes

The expression `"abc" & "def"` also returns **"abcdef"**.

Additional resources

[Text functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

FORMAT ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `FORMAT` function returns the specified string as a *String* value after it has been formatted by substituting any occurrences of %N with the *N*th argument.

Syntax

```
FORMAT (string, argument 1[, argument 2, ..., argument N])
```

Arguments

`string` : *String*

A reference to a data source of the *String* type that must be formatted. This argument is required.

`argument 1` : *String*

The first argument, which is used to replace occurrences of %1. This argument is required.

`argument N` : *String*

The *N*th argument, which is used to replace occurrences of %2, %3, and so on. These additional arguments are optional.

Return values

String

The resulting text value.

Usage notes

If an argument isn't provided for a parameter, the parameter is returned as "%N" in the string. For values of the *Real* type, the default string conversion is limited to two decimal places.

Example

In the following illustration, the **PaymentModel** data source returns a list of customer records by using the **Customer** component. It returns the processing date value by using the **ProcessingDate** field.

▲ model: Data model PaymentModel

▲ Customer: Record list

Name: String

ProcessingDate: DateTime

In the Electronic reporting (ER) format that is designed to generate an electronic file for selected customers, **PaymentModel** is selected as a data source, and it controls the process flow. If a selected customer is stopped for the date when the report is processed, an exception is thrown to notify the user. The formula that is designed

for this type of processing control can use the following resources:

- Label SYS70894, which has the following text:
 - For the EN-US language: "Nothing to print"
 - For the DE language: "Nichts zu drucken"
- Label SYS18389, which has the following text:
 - For the EN-US language: "Customer %1 is stopped for %2."
 - For the DE language: "Debitor '%1' wird für %2 gesperrt."

Here is the expression that can be designed.

```
FORMAT (CONCATENATE (@"SYS70894", ". ", @"SYS18389"), model.Customer.Name, DATETIMEFORMAT  
(model.ProcessingDate, "d"))
```

If a report is processed for the **Litware Retail** customer on December 17, 2015, in the **EN-US** culture and the **EN-US** language, this formula returns the following text, which can be presented to the user as an exception message:

Nothing to print. Customer Litware Retail is stopped for 12/17/2015.

If the same report is processed for the **Litware Retail** customer on December 17, 2015, in the **DE** culture and the **DE** language, the formula returns the following text, which uses a different date format:

Nichts zu drucken. Debitor 'Litware Retail' wird für 17.12.2015 gesperrt.

NOTE

The following syntax is applied in ER formulas for labels:

- For labels from resources in the Microsoft Dynamics 365 Finance app: @X, where X is the label ID in the Application Object Tree (AOT)
- For labels that reside in ER configurations: @"GER_LABEL:X", where X is the label ID in the ER configuration

Text functions

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

GETENUMVALUEBYNAME ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `GETENUMVALUEBYNAME` function searches for a specific *Enum* value in the specified enumeration data source by using the enumeration name that is specified as a *String* value. If the *Enum* value is found, the function returns it. Otherwise, the function returns the **null** enumeration value.

Syntax

```
GETENUMVALUEBYNAME (enumeration data source path, enumeration value text)
```

Arguments

enumeration data source path : *Enumeration*

The valid path of a data source of one of the following enumeration types:

- Electronic reporting (ER) model enumeration
- ER format enumeration
- Microsoft Dynamics 365 Finance enumeration

enumeration value text : *String*

A string value that represents the name of a single enumeration value.

Return values

Nullable *Enum*

The resulting enumeration value.

Usage notes

No exception is thrown if an *Enum* value isn't found by using the name of the enumeration value that is specified as a *String* value.

Example 1

In the following illustration, the **ReportDirection** enumeration is introduced in a data model. Notice that labels are defined for the enumeration values.

Report direction(ReportDirection)

Enumeration values

[+ New](#) [Delete](#)

Name	Label (*Recommended to use labels)	Description
Both	Both	
Export	Dispatches	
Import	Arrivals	

The following illustration shows these details:

- The **\$Direction** data source is configured in an ER report. This data source is configured based on the **ReportDirection** model enumeration.
- The `$IsArrivals` expression is designed to use the model enumeration–based **\$Direction** data source as a parameter of this function.
- The value of this comparison expression is **TRUE**.

Bind + Add root + Add Edit Delete Show name first Group view Search ...

\$IsArrivals: Calculated field = GETENUMVALUEBYNAME('\$Direction', "Arrivals")='\$Direction'.Import: Boolean

▾ **\$Direction:** Data model enumeration ReportDirection

- Arrivals(Import): Enumeration value
- Both: Enumeration value
- Dispatches(Export): Enumeration value

▸ model: Data model Intrastat

Example 2

The `GETENUMVALUEBYNAME` and `LISTOFFIELDS` functions let you fetch values and labels of supported enumerations as text values. (The supported enumerations are application enumerations, data model enumerations, and format enumerations.)

In the following illustration, the **TransType** data source is introduced in a model mapping. This data source refers to the **LedgerTransType** application enumeration.

DATA MODEL

Bind Edit Unbind

Root definition

Root

▸ Transaction: Record list

The following illustration shows the **TransTypeList** data source that is configured in a model mapping. This data source is configured based on the **TransType** application enumeration. The `LISTOFFIELDS` function is used to return all enumeration values as a list of records that contain fields. In this way, the details of every enumeration value are exposed.

NOTE

The **EnumValue** field is configured for the **TransTypeList** data source by using the `GETENUMVALUEBYNAME(TransType, TransTypeList.Name)` expression. This field returns an enumeration value for every record in this list.

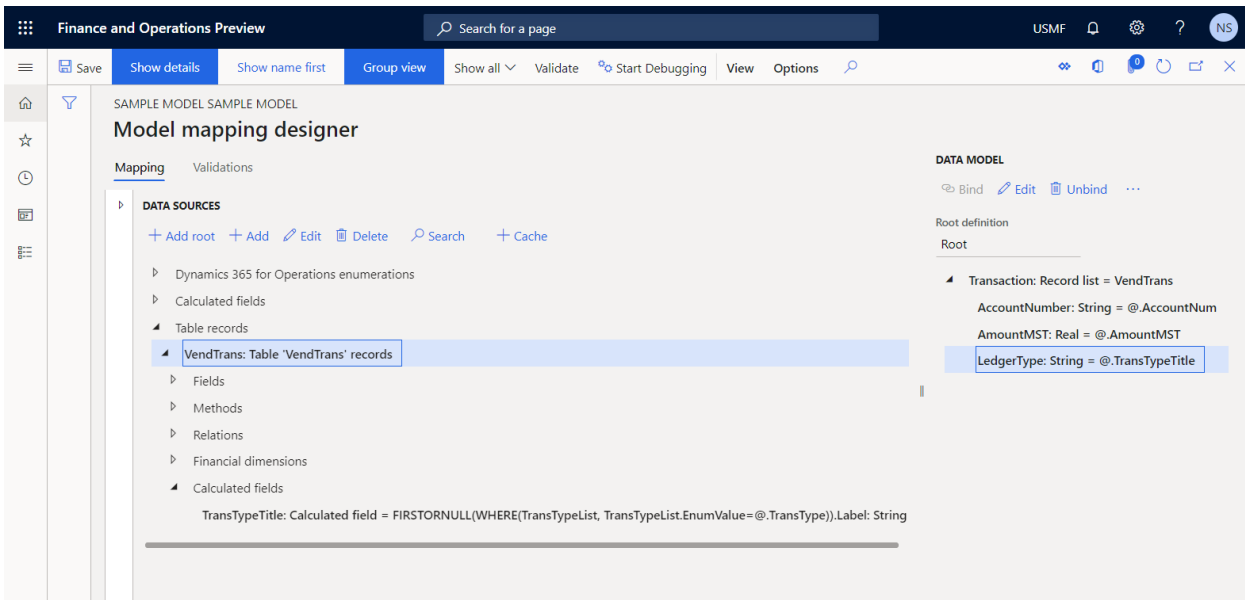

The following illustration shows the **VendTrans** data source that is configured in a model mapping. This data source returns vendor transaction records from the **VendTrans** application table. The ledger type of every transaction is defined by the value of the **TransType** field.

NOTE

The **TransTypeTitle** field is configured for the **VendTrans** data source by using the `FIRSTORNULL(WHERE(TransTypeList, TransTypeList.EnumValue = @.TransType)).Label` expression. This field returns the label of an enumeration value of the current transaction as text, if this enumeration value is available. Otherwise, it returns a blank string value.

The **TransTypeTitle** field is bound to the **LedgerType** field of a data model that enables this information to be used in every ER format that uses the data model as a source of data.

The following illustration shows how you can use the [data source debugger](#) to test the configured model mapping.

The **LedgerType** field of a data model exposes labels of transaction types as expected.

If you plan to use this approach for a large amount of transactional data, you must consider execution performance. For more information, see [Trace the execution of ER formats to troubleshoot performance issues](#).

[FIRSTORNULLE ER function](#)

[WHERE ER function](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

GUIDVALUE ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `GUIDVALUE` function converts the specified input of the *String* type to a data item of the *GUID* type.

Syntax

```
GUIDVALUE (input)
```

Arguments

`input`: *String*

The valid path of a data source of the *String* type.

Return values

GUID

The resulting globally unique identifier (GUID) value.

Usage notes

To do a conversion in the opposite direction (that is, to convert specified input of the *GUID* data type to a data item of the *String* data type), you can use the [TEXT](#) function.

Example

You define the following data sources in your model mapping:

- A `myID` data source of the *Calculated field* type that contains the expression `GUIDVALUE ("AF5CCDAC-F728-4609-8C8B-A4B30B0C0AA0")`
- A `Users` data source of the *Table records* type that refers to the `UserInfo` table

You can then use an expression such as `FILTER (Users, Users.objectId = myID)` to filter the `UserInfo` table by the `objectId` field of the *GUID* data type.

Additional resources

[Text functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

JSONVALUE ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `JSONVALUE` function parses data in JavaScript Object Notation (JSON) format that is accessed at the specified path, and it extracts a scalar value that has the specified ID. It then returns the extracted scalar value as a *String* value.

Syntax

```
JSONVALUE (input, path)
```

Arguments

`input`: *String*

The valid path of a data source of the *String* type that contains JSON data.

`path`: *String*

The identifier of a scalar value of JSON data.

Return values

String

The resulting text value.

Example

The `JsonField` data source contains the following data in JSON format: `{"BuildNumber":"7.3.1234.1", "KeyThumbprint":"7366E"}`. In this case, the expression `JSONVALUE (JsonField, "BuildNumber")` returns the following value of the *String* data type: `"7.3.1234.1"`.

Additional resources

[Text functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

LEFT ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `LEFT` function returns a *String* value that presents the specified number of characters from the start of the specified string.

Syntax

```
LEFT (text, number)
```

Arguments

`text` : *String*

A *String* value that represents the original text.

`number` : *Integer*

The number of characters that must be returned from the start of the original text.

Return values

String

The resulting text value.

Example

`LEFT ("Sample", 3)` returns "Sam".

Additional resources

[Text functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

LEN ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `LEN` function returns the number of characters in the specified string as an *Integer* value.

Syntax

```
LEN (text)
```

Arguments

`text` : *String*

A *String* value that specifies the text.

Return values

Integer

The resulting numeric value.

Example

`LEN ("Sample")` returns 6.

Additional resources

[Text functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

LOWER ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `LOWER` function returns the specified text string as a *String* value after it has been converted to lowercase letters.

Syntax

```
LOWER (text)
```

Arguments

`text` : *String*

A *String* value that specifies the text.

Return values

String

The resulting text value.

Example

```
LOWER ("Sample") returns "sample".
```

Additional resources

[Text functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

MID ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `MID` function returns a *String* value that presents the specified number of characters from the specified string, starting at the specified position.

Syntax

```
MID (text, starting position, number of characters)
```

Arguments

`text` : *String*

A *String* value that specifies the text to return characters from.

`starting position` : *Integer*

An *Integer* value that specifies the position of the first character that must be returned from the specified text.

`number of characters` : *Integer*

An *Integer* value that specifies the number of characters that must be returned, starting at the specified starting position.

Return values

String

The resulting text value.

Usage notes

If the value of the `starting position` argument is less than 0 (zero), the characters that are returned are counted from the first position in the specified string.

If the value of the `starting position` argument exceeds length of the specified string, an empty string is returned.

Example

`MID ("Sample", 2, 3)` returns **"amp"**.

Additional resources

[Text functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

NUMBERFORMAT ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `NUMBERFORMAT` function returns a *String* value that presents the specified number in the specified format and in an optionally specified *culture*. For information about the supported formats, see [standard](#) and [custom](#).

Syntax 1

```
NUMBERFORMAT (number, format)
```

Syntax 2

```
NUMBERFORMAT (number, format, culture)
```

Arguments

`number` : *Integer* or *Real*

A numeric value that specifies the number that must be formatted.

`format` : *String*

A *String* value that represents the format.

`culture` : *String*

A *String* value that represents the culture to use for formatting.

Return values

String

The resulting text value.

Usage notes

If the culture isn't defined as an argument of the called function, the context that this function is run in determines the culture that is used to format numbers.

Example 1

For the **EN-US** culture, `NUMBERFORMAT (0.45, "p")` returns "45.00 %", and `NUMBERFORMAT (10.45, "#")` returns "10".

Example 2

`NUMBERFORMAT (10/3, "F2", "de")` returns 3,33, whereas `NUMBERFORMAT (10/3, "F2", "en-us")` returns 3.33.

Additional resources

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

NUMERALSTOTEXT ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `NUMERALSTOTEXT` function returns the specified number as a *String* value after it has been spelled out (that is, converted to text strings) in the specified language.

Syntax

```
NUMERALSTOTEXT (number, language, currency, print currency name flag, decimal points)
```

Arguments

`number` : *Integer or Real*

A numeric value that specifies the number that must be spelled out.

`language` : *String*

A *String* value that represents the language code.

`currency` : *String*

A *String* value that represents the currency code.

`print currency name flag` : *Boolean*

A *Boolean* value that indicates whether a currency name must be added to the spelled-out text.

`decimal points` : *Integer*

An *Integer* value that indicates the number of decimal places that the spelled-out text should have.

Return values

String

The resulting text value.

Usage notes

The language code is optional. If it's defined as an empty string, the language code for the running context is used. The default language code is **EN-US**. The language code for the running context is defined in a **Folder** or **File** element of the Electronic reporting (ER) format that is running.

The currency code is optional. If it's defined as an empty string, the company currency for the running context is used.

NOTE

The `print currency name flag` and `decimal points` arguments are analyzed only for the following language codes: **CS**, **ET**, **HU**, **LT**, **LV**, **PL**, and **RU**. Additionally, the `print currency name flag` argument is analyzed only for companies where the country's or region's context supports declension of currency names.

Example 1

`NUMERALSTOTEXT (1234.56, "EN-US", "", false, 2)` returns "One Thousand Two Hundred Thirty Four and 56".

Example 2

`NUMERALSTOTEXT (120, "PL", "", false, 0)` returns "Sto dwadzieścia".

Example 3

`NUMERALSTOTEXT (120.21, "RU", "EUR", true, 2)` returns "Сто двадцать евро 21 евроцент".

Additional resources

[Text functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

PADLEFT ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `PADLEFT` function returns a *String* value of the specified length, where the start of the specified string is padded with the specified characters.

Syntax

```
PADLEFT (text, length, padding chars)
```

Arguments

`text` : *String*

A *String* value that represents the original text.

`length` : *Integer*

An *Integer* value that represents the final number of characters in the padded string.

`padding chars` : *String*

The characters to use for padding.

Return values

String

The resulting text value.

Example

`PADLEFT ("1234", 10, " ")` returns the text string " 1234".

Additional resources

[Text functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

QR CODE ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `QR CODE` function returns a *Container* value that presents the Quick Response code (QR code) image for the specified string in binary format.

Syntax

```
QR CODE (text)
```

Arguments

`text` : *String*

A *String* value that represents the original text.

Return values

Container

The resulting binary stream.

Example

You can configure an Electronic reporting (ER) format to generate an outbound document in Microsoft Office format (Excel workbooks or Word documents) by using a predefined template. This template may contain a **Picture** object (Excel workbook) or a **Picture Content Control** (Word document) as a placeholder for a QR code image. You need to add to the configured ER format a **Cell** element that will be used to fill this placeholder in. To specify what information will be stored in a QR code, you need to define a binding for this **Cell** element. For example, you can configure such binding as containing the following expression:

```
QR CODE (model.ListOfShelfLabels.LabelText)`
```

When you run the configured ER format, the text value of the **LabelText** field of the **model.ListOfShelfLabels** data source will be used to generate a QR code image. This image will replace a QR code image placeholder in the document template using to generate an outbound document. When this image of the generated document is scanned, it returns the text that was taken from the **LabelText** field of the **model.ListOfShelfLabels** data source. For more information, see [Embed images and shapes in documents that you generate by using ER](#).

REPLACE ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `REPLACE` function returns the specified text string as a *String* value after all or part of it has been replaced with another string.

Syntax

```
REPLACE (text, pattern, replacement, regular expression flag)
```

Arguments

`text` : *String*

The valid path of a data source of the *String* type.

`pattern` : *String*

If the `regular expression flag` argument is **FALSE**, this argument contains the text that must be replaced.

If the `regular expression flag` argument is **TRUE**, this argument contains a regular expression that defines both a search pattern and the replacement text.

`replacement` : *String*

If the `regular expression flag` argument is **FALSE**, this argument contains the text to use as a replacement.

If the `regular expression flag` argument is **TRUE**, this argument isn't used.

`regular expression flag` : *Boolean*

A *Boolean* value that indicates whether a regular expression is used to do the replacement.

Return values

String

The resulting text value.

Usage notes

If the `regular expression flag` argument is **TRUE**, this function returns the specified string after it has been changed by applying the regular expression that is specified by the `pattern` argument. The regular expression is used to find the characters that must be replaced.

If the `regular expression flag` argument is **FALSE**, this function returns the specified string after the set of characters that are defined in the `pattern` argument have been replaced by characters of the `replacement` argument.

Example 1

```
REPLACE ("+1 923 456 4971", "[^0-9]", "", true)
```

 applies a regular expression that removes all non-numeric

symbols, and it returns "19234564971".

Example 2

`REPLACE ("abcdef", "cd", "GH", false)` replaces the pattern "cd" with the string "GH" and returns "abGHef".

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

RIGHT ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `RIGHT` function returns a *String* value that presents the specified number of characters from the end of the specified string.

Syntax

```
RIGHT (text, number)
```

Arguments

`text` : *String*

A *String* value that represents the original text.

`number` : *Integer*

The number of characters that must be returned from the end of the original text.

Return values

String

The resulting text value.

Example

```
RIGHT ("Sample", 3) returns "ple".
```

Additional resources

[Text functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

TEXT ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `TEXT` function returns the specified number as a *String* value after it has been converted to a text string that is formatted according to the server locale settings of the current application instance.

Syntax

```
TEXT (number)
```

Arguments

`number`: *Integer* or *Real*

A number that must be converted to a text string.

Return values

String

The resulting text value.

Usage notes

For values of the *Real* type, the string conversion is limited to two decimal places.

Example

If the server locale of the Microsoft Dynamics 365 Finance instance is defined as EN-US, `TEXT (NOW ())` returns the current Finance session date, December 17, 2015, as the text string "12/17/2015 07:59:23 AM".

`TEXT (1/3)` returns "0.33".

Additional resources

[Text functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

TRANSLATE ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `TRANSLATE` function returns a *String* value that contains the result of the character replacement of specified text in characters of another provided set.

Syntax

```
TRANSLATE (text , pattern, replacement)
```

Arguments

`text` : *String*

The valid path of a data source of the *String* type.

`pattern` : *String*

The text that must be replaced.

`replacement` : *String*

The text to use as a replacement.

Return values

String

The resulting text value.

Usage notes

The `TRANSLATE` function replaces one character at a time. The function replaces the first character of the `text` argument with the first character of the `pattern` argument and then the second character and follows the same flow until finished. When a character from the `text` and `pattern` arguments match, it is replaced by a character from the `replacement` argument that is located in the same position as the character from the `pattern` argument. If a character appears multiple times in the `pattern` argument, the `replacement` argument mapping that corresponds to the first occurrence of this character is used.

Example 1

`TRANSLATE ("abcdef", "cd", "GH")` replaces the "c" character of the specified "abcdef" text with the "G" character of the `replacement` text due to the following:

- The "c" character is presented in the `pattern` text in the first position.
- The first position of the `replacement` text contains the "G" character.

Example 2

`TRANSLATE ("abcdef", "ccd", "GH")` returns "abGdef".

Example 3

`TRANSLATE ("abccba", "abc", "123")` returns `"123321"`.

TRIM ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `TRIM` function returns the specified text string as a *String* value after leading and trailing spaces have been truncated, and after multiple spaces between words have been removed.

Syntax

```
TRIM (text )
```

Arguments

`text` : *String*

The valid path of a data source of the *String* type.

Return values

String

The resulting text value.

Example

`TRIM (" Sample text ")` returns "Sample text".

Additional resources

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

UPPER ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `UPPER` function returns the specified text string as a *String* value after it has been converted to uppercase letters.

Syntax

```
UPPER (text )
```

Arguments

`text` : *String*

The valid path of a data source of the *String* type.

Return values

String

The resulting text value.

Example

`UPPER ("Sample")` returns "SAMPLE".

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

List of ER functions in the data collection category

2/18/2021 • 2 minutes to read • [Edit Online](#)

Electronic reporting (ER) data collection functions are used to do counting and summing in an ER format that is being run, based on data of the output that has already been generated in **Text** or **Xml** format. This approach is used to help improve performance of an ER format that is run, to enter values of running totals in generated documents, and for other purposes. This topic provides a summary of these functions.

List of supported functions

FUNCTION	DESCRIPTION
CollectedList	This function returns a <i>Record list</i> value that contains the list of values that were returned by the Collected data key value property of format elements and collected when the format elements were used to generate an outbound document during the format run, and that satisfies the specified conditions. Each condition consists of a key range and a key value.
CountIF	This function returns an <i>Integer</i> value that represents the number of format elements that was collected when the format elements were used to generate an outbound document during the format run, and that satisfies the specified condition. The condition consists of a key range and a key value.
CountIFs	This function returns an <i>Integer</i> value that represents the number of format elements that was collected when the format elements were used to generate an outbound document during the format run, and that satisfies the specified conditions. Each condition consists of a key range and a key value.
FormatElementName	This function returns a <i>String</i> value that represents the name of the current ER format's element.
SumIF	This function returns a <i>Real</i> value that represents the sum of values that were returned by bindings of format elements and collected when the format elements were used to generate an outbound document during the format run, and that satisfies the specified condition. The condition consists of a key range and a key value.
SumIFs	This function returns a <i>Real</i> value that represents the sum of values that were returned by bindings of format elements and collected when the format elements were used to generate an outbound document during the format run, and that satisfies the specified conditions. Each condition consists of a key range and a key value.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

COLLECTEDLIST ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `COLLECTEDLIST` function a *Record list* value that contains the list of values that were returned by the **Collected data key value** property of format elements and collected when the format elements were used to generate outbound documents during the format run, and that satisfies the specified conditions. Each condition consists of a key range and a key value.

Syntax

```
COLLECTEDLIST (condition 1 range, condition 1 value[, condition 2 range, condition 2 value, ..., condition N range, condition N value])
```

Arguments

`condition 1 range`: *String*

A value that is returned by the expression that has been configured in the **Collected data key name** property of an Electronic reporting (ER) format component. This argument is mandatory.

`condition 1 value`: *String*

A value that is returned by the expression that has been configured in the **Collected data key value** property of an ER format component. This argument is mandatory.

`condition N range`: *String*

A value that is returned by the expression that has been configured in the **Collected data key name** property of an ER format component. These additional arguments are optional.

`condition N value`: *String*

A value that is returned by the expression that has been configured in the **Collected data key value** property of an ER format component. These additional arguments are optional.

Return values

Record list

The resulting list of records.

Usage notes

The **Collected data key name** and **Collected data key value** properties can be configured for either the **Sequence** component or the **XML Element** component of an ER format that resides under the **Common\File** component where the **Collect output details** option is turned on.

This function returns an empty list when the **Collect output details** option of the current **Common\File** component is turned off.

In `condition range` arguments, the wildcard character "*" can be used to represent any multiple characters.

In `condition value` arguments, the wildcard character "*" can be used to represent any multiple characters.

Example

For more information about how to use this function, see the [ER Use data of format output for counting and summing](#) task guide, which is part of the **Acquire/Develop IT service/solution components** business process.

COUNTIF ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `COUNTIF` function returns an *Integer* value that represents the number of format elements that was collected when the format elements were used to generate an outbound document during the format run, and that satisfies the specified condition. The condition consists of a key range and a key value.

Syntax

```
COUNTIF (condition range, condition value)
```

Arguments

`condition range`: *String*

A value that is returned by the expression that has been configured in the **Collected data key name** property of an Electronic reporting (ER) format component.

`condition value`: *String*

A value that is returned by the expression that has been configured in the **Collected data key value** property of an ER format component.

Return values

Integer

The resulting numeric value.

Usage notes

The **Collected data key name** and **Collected data key value** properties can be configured for either the **Sequence** component or the **XML Element** component of an ER format that resides under the **Common\File** component where the **Collect output details** option is turned on.

This function returns a 0 (zero) value when the **Collect output details** option of the current **Common\File** component is turned off.

In the `condition range` argument, the wildcard character "*" can be used to represent any multiple characters.

In the `condition value` argument, the wildcard character "*" can be used to represent any multiple characters.

Example

For more information about how to use this function, see the [ER Use data of format output for counting and summing](#) task guide, which is part of the **Acquire/Develop IT service/solution components** business process.

Additional resources

COUNTIFS ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `COUNTIFS` function returns an *Integer* value that represents the number of format elements that was collected when the format elements were used to generate an outbound document during the format run, and that satisfies the specified conditions. Each condition consists of a key range and a key value.

Syntax

```
COUNTIFS (condition 1 range, condition 1 value[, condition 2 range, condition 2 value, ..., condition N range, condition N value])
```

Arguments

`condition 1 range`: *String*

A value that is returned by the expression that has been configured in the **Collected data key name** property of an Electronic reporting (ER) format component. This argument is mandatory.

`condition 1 value`: *String*

A value that is returned by the expression that has been configured in the **Collected data key value** property of an ER format component. This argument is mandatory.

`condition N range`: *String*

A value that is returned by the expression that has been configured in the **Collected data key name** property of an ER format component. These additional arguments are optional.

`condition N value`: *String*

A value that is returned by the expression that has been configured in the **Collected data key value** property of an ER format component. These additional arguments are optional.

Return values

Integer

The resulting numeric value.

Usage notes

The **Collected data key name** and **Collected data key value** properties can be configured for either the **Sequence** component or the **XML Element** component of an ER format that resides under the **Common\File** component where the **Collect output details** option is turned on.

This function returns a 0 (zero) value when the **Collect output details** option of the current **Common\File** component is turned off.

In `condition range` arguments, the wildcard character "*" can be used to represent any multiple characters.

In `condition value` arguments, the wildcard character "*" can be used to represent any multiple characters.

Example

For more information about how to use this function, see the [ER Use data of format output for counting and summing](#) task guide, which is part of the **Acquire/Develop IT service/solution components** business process.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

FORMATELEMENTNAME ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `FORMATELEMENTNAME` function returns a *String* value that represents the name of the current Electronic reporting (ER) format's element.

Syntax

```
FORMATELEMENTNAME ()
```

Return values

String

The resulting text value.

Usage notes

This function can be called in ER expressions that were configured for the **Collected data key name** and **Collected data key value** properties of an ER format component from the **Text** group that resides under the **Common\File** component where the **Collect output details** option is turned on.

Example

For more information about how to use this function, see the [ER Use data of format output for counting and summing](#) task guide, which is part of the **Acquire/Develop IT service/solution components** business process.

Additional resources

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

SUMIF ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `SUMIF` function returns a *Real* value that represents the sum of values that were returned by bindings of format elements and collected when the format elements were used to generate an outbound document during the format run, and that satisfies the specified condition. The condition consists of a key range and a key value.

Syntax

```
SUMIF (key name for summing, condition range, condition value)
```

Arguments

`key name for summing`: *String*

A value that is returned by the expression that has been configured in the **Collected data key name** property of the Electronic reporting (ER) format component for which the value of the binding must be used for summing purposes.

The **Collected data key value** property can be configured for either a **Sequence** component or an **XML Element** component of an ER format that resides under the **Common\File** component where the **Collect output details** option is turned on.

Return values

Real

The resulting numeric value.

Usage notes

This function returns a 0 (zero) value when the **Collect output details** option of the current **Common\File** component is turned off.

In the `condition range` argument, the wildcard character "*" can be used to represent any multiple characters.

In the `condition value` argument, the wildcard character "*" can be used to represent any multiple characters.

Example

For more information about how to use this function, see the [ER Use data of format output for counting and summing](#) task guide, which is part of the **Acquire/Develop IT service/solution components** business process.

For more information and examples about using this function, see [Defer the execution of sequence elements in ER formats](#) and [Defer the execution of XML elements in ER formats](#).

Additional resources

[Data collection functions](#)

NOTE

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

SUMIFS ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `SUMIFS` function returns a *Real* value that represents the sum of values that were returned by bindings of format elements and collected when the format elements were used to generate an outbound document during the format run, and that satisfies the specified conditions. Each condition consists of a key range and a key value.

Syntax

```
SUMIFS (key name for summing, condition 1 range, condition 1 value[, condition 2 range, condition 2 value, ..., condition N range, condition N value])
```

Arguments

`key name for summing`: *String*

A value that is returned by the expression that has been configured in the **Collected data key name** property of the Electronic reporting (ER) format component for which the value of the binding must be used for summing purposes.

The **Collected data key name** property can be configured for either a **Numeric** component or a **String** component of an ER format that resides under the **Common\File** component where the **Collect output details** option is turned on.

`condition 1 range`: *String*

A value that is returned by the expression that has been configured in the **Collected data key name** property of an ER format component. This argument is mandatory.

The **Collected data key name** property can be configured for either a **Sequence** component or an **XML Element** component of an ER format that resides under the **Common\File** component where the **Collect output details** option is turned on.

`condition 1 value`: *String*

A value that is returned by the expression that has been configured in the **Collected data key value** property of an ER format component. This argument is mandatory.

The **Collected data key value** property can be configured for either a **Sequence** component or an **XML Element** component of an ER format that resides under the **Common\File** component where the **Collect output details** option is turned on.

`condition N range`: *String*

A value that is returned by the expression that has been configured in the **Collected data key name** property of an ER format component. These additional arguments are optional.

The **Collected data key name** property can be configured for either a **Sequence** component or an **XML Element** component of an ER format that resides under the **Common\File** component where the **Collect output details** option is turned on.

`condition N value`: *String*

A value that is returned by the expression that has been configured in the **Collected data key value** property of an ER format component. These additional arguments are optional.

The **Collected data key value** property can be configured for either a **Sequence** component or an **XML Element** component of an ER format that resides under the **Common\File** component where the **Collect output details** option is turned on.

Return values

Real

The resulting numeric value.

Usage notes

This function returns a 0 (zero) value when the **Collect output details** option of the current **Common\File** component is turned off.

In the `condition range` arguments, the wildcard character "*" can be used to represent any multiple characters.

In the `condition value` arguments, the wildcard character "*" can be used to represent any multiple characters.

Example

For more information about how to use this function, see the [ER Use data of format output for counting and summing](#) task guide, which is part of the **Acquire/Develop IT service/solution components** business process.

List of ER functions in the business domain-specific category

2/18/2021 • 2 minutes to read • [Edit Online](#)

Electronic reporting (ER) domain-specific functions can be used to perform calculations and data access requests that are specific to the implementation of Microsoft Dynamics 365 Finance. This topic provides a summary of these functions.

List of supported functions

FUNCTION	DESCRIPTION
CH_Bank_Mod_10	This function returns a <i>String</i> value that represents a creditor reference as an MOD10 expression, based on the digits of the specified invoice number.
CN_GBT_AdditionalDimensionID	This function returns a <i>String</i> value that represents a single financial dimension ID that is taken from the specified string. The specified string presents all dimensions as a comma-separated list of IDs.
ConvertCurrency	This function returns a <i>Real</i> value that represents the result of converting the specified monetary amount from the specified source currency to the specified target currency by using the settings of the specified company on the specified date.
CurCredRef	This function returns a <i>String</i> value that represents a creditor reference, based on the digits of the specified invoice number.
FA_Balance	This function returns a <i>Container (record)</i> value that consists of data for the fixed asset balance for the specified fixed asset item, value model code, reporting year, and reporting date.
FA_Sum	This function returns a <i>Container (record)</i> value that consists of data for the fixed asset amounts for the specified fixed asset item, value model code, and period of dates.
GetCurrentCompany	This function returns a <i>String</i> value that represents the code for the legal entity (company) that a user is currently signed in to.
ISOCredRef	This function returns a <i>String</i> value that represents an International Organization for Standardization (ISO) creditor reference, based on the digits and alphabetic symbols of the specified invoice number.

FUNCTION	DESCRIPTION
IsValidCharacterISO7064	This function returns a <i>Boolean</i> value of TRUE if the specified string represents a valid international bank account number (IBAN). Otherwise, it returns a <i>Boolean</i> value of FALSE .
Mod_97	This function returns a <i>String</i> value that represents a creditor reference as a MOD97 expression, based on the digits of the specified invoice number.
NumSeqValue	This function returns a <i>String</i> value that represents the new generated value of a number sequence, based on the specified number sequence, scope, and scope ID. The scope ID equals the company code that is supplied by the context that the ER format is run under.
RoundAmount	This function returns a <i>Real</i> value that represents the result of rounding the specified amount to the specified number of decimal places according to the specified rounding rule.
TableName2ID	This function returns a numeric representation of the table ID for the specified table name as an <i>Integer</i> value.

CH_BANK_MOD_10 ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `CH_BANK_MOD_10` function returns a *String* value that represents a creditor reference as an MOD10 expression, based on the digits of the specified invoice number.

Syntax

```
CH_BANK_MOD_10 (invoice number digits)
```

Arguments

`invoice number digits` : *String*

A text value that represents the digits of an invoice number.

Return values

String

The resulting text value.

Example

`CH_BANK_MOD_10 ("VEND-200002")` returns 3.

CN_GBT_ADDITIONALDIMENSIONID ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `CN_GBT_ADDITIONALDIMENSIONID` function returns a *String* value that represents a single financial dimension ID that is taken from the specified string. The specified string presents all dimensions as a comma-separated list of IDs.

Syntax

```
CN_GBT_ADDITIONALDIMENSIONID (text, number)
```

Arguments

`text` : *String*

A *String* value that presents all dimensions as a comma-separated list of IDs.

`number` : *Integer*

An *Integer* value that defines the sequence code of the requested dimension in the specified string.

Return values

String

The resulting text value.

Example

```
CN_GBT_AdditionalDimensionID ("AA,BB,CC,DD,EE,FF,GG,HH", 3) returns "CC".
```

CONVERTCURRENCY ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `CONVERTCURRENCY` function returns a *Real* value that represents the result of converting the specified monetary amount from the specified source currency to the specified target currency by using the settings of the specified company on the specified date.

Syntax

```
CONVERTCURRENCY (amount, source currency, target currency, date, company)
```

Arguments

`amount` : *Integer or Real*

A numeric value that represents the monetary amount that must be converted.

`source currency` : *String*

The code of the source currency.

`target currency` : *String*

The code of the target currency.

`date` : *Date*

A *Date* value that represents the date that is used to determine the exchange rate for the conversion.

`company` : *String*

A *String* value that represents the code of a company that supplies the settings that are used for the conversion.

Return values

Real

The resulting numeric value.

Example

`CONVERTCURRENCY (1, "EUR", "USD", TODAY(), "DEMF")` returns the equivalent of one euro in US dollars on the current session date, based on settings for the **DEMF** company.

Additional resources

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

CURCREDREF ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `CURCREDREF` function returns a *String* value that represents a creditor reference, based on the digits of the specified invoice number.

Syntax

```
CURCREDREF (invoice number digits)
```

Arguments

`invoice number digits` : *String*

A text value that represents the digits of an invoice number.

Return values

String

The resulting text value.

Example

`CURCredRef ("VEND-200002")` returns "2200002".

Additional resources

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

FA_BALANCE ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `FA_BALANCE` function returns a *Container (record)* value that consists of data for the fixed asset balance for the specified fixed asset item, value model code, reporting year, and reporting date.

Syntax

```
FA_BALANCE (fixed asset code, value model code, reporting year, reporting date)
```

Arguments

`fixed asset code` : *String*

A *String* value that represents the code of a fixed asset item that the balance is calculated for.

`value model code` : *String*

A *String* value that represents the code of a value model that the balance is calculated for.

`reporting year` : *Enumeration value*

An enumeration value of the **AssetYear** application enumeration that defines a period for the balance calculation.

`reporting date` : *Date*

A *Date* value that defines a date for the balance calculation.

Return values

Container (record)

The resulting record value.

Example

`FA_BALANCE ("COMP-000001", "Current", AxEnumAssetYear.ThisYear, SESSIONTODAY ())` returns the data container of balances for fixed asset **COMP-000001** that has been prepared for the **Current** value model on the current application session date.

Additional resources

[Other \(business domain-specific\) functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

FA_SUM ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `FA_SUM` function returns a *Container (record)* value that consists of data for the fixed asset amounts for the specified fixed asset item, value model code, and period of dates.

Syntax

```
FA_SUM (fixed asset code, value model code, start date, end date)
```

Arguments

`fixed asset code` : *String*

A *String* value that represents the code of a fixed asset item that the balance is calculated for.

`value model code` : *String*

A *String* value that represents the code of a value model that the balance is calculated for.

`start date` : *Date*

A *Date* value that represents the start date of a period that the fixed asset amounts are calculated for.

`end date` : *Date*

A *Date* value that represents the end date of a period that the fixed asset amounts are calculated for.

Return values

Container (record)

The resulting record value.

Example

`FA_SUM ("COMP-000001", "Current", Date1, Date2)` returns the data container for fixed asset **COMP-000001** that has been prepared for the **Current** value model and for a period from **Date1** to **Date2**.

[Other \(business domain-specific\) functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

GETCURRENTCOMPANY ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `GETCURRENTCOMPANY` function returns a *String* value that represents the code for the legal entity (company) that a user is currently signed in to.

Syntax

```
GETCURRENTCOMPANY ()
```

Return values

String

The resulting text value.

Example

`GETCURRENTCOMPANY ()` returns **USMF** for a user who is signed in to the **Contoso Entertainment System USA** company.

Additional resources

[Other \(business domain–specific\) functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

ISOCREDREF ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `ISOCREDREF` function returns a *String* value that represents an International Organization for Standardization (ISO) creditor reference, based on the digits and alphabetic symbols of the specified invoice number.

Syntax

```
ISOCREDREF (invoice number digits)
```

Arguments

`invoice number digits` : *String*

A text value that represents the digits of an invoice number.

Return values

String

The resulting text value.

Usage notes

NOTE

To eliminate symbols from alphabets that aren't ISO-compliant, the `invoice number digits` argument must be translated before it's passed to this function.

Example

`ISOCredRef ("VEND-200002")` returns "RF23VEND-200002".

ISVALIDCHARACTERISO7064 ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `ISVALIDCHARACTERISO7064` function returns a *Boolean* value of **TRUE** if the specified string represents a valid international bank account number (IBAN). Otherwise, it returns a *Boolean* value of **FALSE**.

Syntax

```
ISVALIDCHARACTERISO7064 (text)
```

Arguments

`text` : *String*

A text value that represents an IBAN.

Return values

String

The resulting text value.

Example

```
ISVALIDCHARACTERISO7064 ("AT61 1904 3002 3457 3201") returns TRUE.
```

```
ISVALIDCHARACTERISO7064 ("AT61") returns FALSE.
```

MOD_97 ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `MOD_97` function returns a *String* value that represents a creditor reference as a MOD97 expression, based on the digits of the specified invoice number.

Syntax

```
MOD_97 (invoice number digits)
```

Arguments

`invoice number digits` : *String*

A text value that represents the digits of an invoice number.

Return values

String

The resulting text value.

Example

`MOD_97 ("VEND-200002")` returns "20000285".

Additional resources

[Other \(business domain-specific\) functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

NUMSEQVALUE ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `NUMSEQVALUE` function returns a *String* value that represents the new generated value of a number sequence, based on the specified number sequence, scope, and scope ID. The scope ID equals the company code that is supplied by the context that the Electronic reporting (ER) format is run under.

Syntax 1

```
NUMSEQVALUE (number sequence code)
```

Syntax 2

```
NUMSEQVALUE (number sequence record ID)
```

Syntax 3

```
NUMSEQVALUE (number sequence code, scope type, scope ID)
```

Arguments

`number sequence code` : *String*

A text value that represents the code of the number sequence that a new value is required in.

`number sequence record ID` : *Int64*

An *Int64* value that represents the record ID of a record in the `NumberSequenceTable` table that contains the definition of the number sequence that a new value is required in.

`scope type` : *Enum value*

An enumeration value of the `ERExpressionNumberSequenceScopeType` enumeration that defines the scope of the number sequence that a new value is required in. The available scope types are **Shared**, **Legal entity**, and **Company**.

`scope ID` : *String*

A *String* value that identifies the scope, based on the specified scope type.

Return values

String

The resulting text value.

Usage notes

For the **Shared** scope type, specify an empty string as the scope ID.

For the **Company** and **Legal entity** scope types, specify the company code as the scope ID. If you specify an empty string as the scope ID for these scope types, the current company code is used.

When syntax 1 is used, the number sequence is requested for the **Company** scope type, and the company code is supplied by the context that the ER format is run under.

Example 1

In your ER format, you define the **AskNumSeq** data source of the *User input parameter* type. This data source refers to the **Description** extended data type (EDT). Next, you define the **NumSeq** data source of the *Calculated field* type. This data source contains the expression `NUMSEQVALUE (AskNumSeq)`. When the **NumSeq** data source is called, it returns the new generated value of the number sequence that was specified at runtime by entering its code in the dialog box. The number sequence is requested for the **Company** scope type. The company code is supplied by the context that the ER format is run under.

Example 2

The following data sources are defined in your model mapping:

- The **LedgerParms** data source of the *Table* type. This data source refers to the LedgerParameters table.
- The **NumSeq** data source of the *Calculated field* type. This data source contains the expression

```
NUMSEQVALUE ( LedgerParameters.'numRefJournalNum()'.NumberSequenceId )
```

When the **NumSeq** data source is called, it returns the new generated value of the number sequence that has been configured in the General ledger parameters for the company that supplies the context that the ER format is run under. This number sequence uniquely identifies journals and acts as a batch number that links the transactions together.

Example 3

The following data sources are defined in your model mapping:

- The **enumScope** data source of the Microsoft Dynamics 365 Finance *enumeration* type. This data source refers to the **ERExpressionNumberSequenceScopeType** enumeration.
- The **NumSeq** data source of the *Calculated field* type. This data source contains the expression

```
NUMSEQVALUE ("Gene_1", enumScope.Company, "")
```

When the **NumSeq** data source is called, it returns the new generated value of the **Gene_1** number sequence that has been configured for the company that supplies the context that the ER format is run under.

Additional resources

[Other \(business domain-specific\) functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

ROUNDAMOUNT ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `ROUNDAMOUNT` function returns a *Real* value as the result of the rounding of the specified number to the nearest multiple of another number according to the specified rounding rule.

Syntax

```
ROUNDAMOUNT (number, decimals, round rule)
```

Arguments

`number` : *Int* or *Real*

A numeric value that must be rounded.

`decimals` : *Int* or *Real*

The number that the value of the `number` parameter must be rounded to a multiple of.

`round rule` : *Enum value*

An enumeration value of the `RoundOffType` enumeration that defines the rounding rule. This enumeration offers the following values:

- Normal (Ordinary)
- Downward (RoundDown)
- Rounding-up (RoundUp)

Return values

Real

The resulting numeric value is a multiple of the value specified by the `decimals` parameter and is closest to the value specified by the `number` parameter.

Usage notes

When the `number` parameter is zero, this function always returns zero.

When the `decimals` parameter is zero, this function rounds to the default round-off value. When the `round rule` parameter is set to `RoundOffType.Ordinary`, the default round-off value is `0.01`. Otherwise, the default round-off value is `1.0`.

When the `round rule` parameter is set to `RoundOffType.Ordinary`, this function rounds to the nearest round-off amount.

When the `round rule` parameter is set to `RoundOffType.RoundDown`, this function rounds towards zero to the nearest round-off amount.

When the `round rule` parameter is set to `RoundOffType.RoundUp`, this function rounds away from zero to the nearest round-off amount.

When the `round rule` parameter is set to **RoundOffType.Ordinary**, this function behaves like the [MROUND](#) Excel function and the [ROUND](#) X++ function.

Remarks

To round a numeric value to a specified number of decimal places, use the [ROUND](#) function.

Example

If the `model.RoundOff` parameter is set to **RoundOffType.Ordinary**,

```
ROUNDAMOUNT (7.45, 1.05, model.RoundOff) returns 7.35.
```

If the `model.RoundOff` parameter is set to **RoundOffType.RoundDown**,

```
ROUNDAMOUNT (7.45, 1.05, model.RoundOff) returns 7.35.
```

If the `model.RoundOff` parameter is set to **RoundOffType.RoundUp**,

```
ROUNDAMOUNT (7.45, 1.05, model.RoundOff) returns 8.4.
```

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

TABLENAME2ID ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `TABLENAME2ID` function returns a numeric representation of the table ID for the specified table name as an *Integer* value.

Syntax

```
TABLENAME2ID (text)
```

Arguments

`text` : *String*

A text value that represents a valid table name.

Return values

Integer

The resulting numeric value.

Usage notes

Execution of this function can have different results in different instances of Microsoft Dynamics 365 Finance, even if the same company name is used.

Example

`TABLENAME2ID ("Intrastat")` returns 1510.

List of ER functions in the type conversion category

2/18/2021 • 2 minutes to read • [Edit Online](#)

Electronic reporting (ER) type conversion functions can be used to convert values between types. This topic provides a summary of these functions.

Type conversion functions

FUNCTION	DESCRIPTION
Int64Value	This function returns an <i>Int64</i> value that represents the specified string.
IntValue	This function returns an <i>Int</i> value that represents the specified string.
NumberValue	This function returns a <i>Real</i> value that is converted from the specified <i>String</i> value. During the conversion, the specified decimal and digit grouping separators are considered.
Value	This function returns a <i>Real</i> value that is converted from the specified <i>String</i> value.

Type conversion functions in the container category

The following table describes the type conversion functions in the [container](#) category.

FUNCTION	DESCRIPTION
Base64StringToContainer	This function converts the specified input of the <i>String</i> type to a data item of the <i>Container</i> type.

Type conversion functions in the date and time category

The following table describes the type conversion functions in the [date and time](#) category.

FUNCTION	DESCRIPTION
DateTimeValue	This function returns a <i>DateTime</i> value that is converted from a given <i>String</i> value in the specified format and in an optionally specified culture to a date/time value.
DateToDateTime	This function returns a <i>DateTime</i> value that is converted from a given <i>Date</i> value to a date/time value in Coordinated Universal Time (Greenwich Mean Time [GMT]).
DateValue	This function returns a <i>Date</i> value that is converted from a given <i>String</i> value in the specified format and in an optionally specified culture to a date value.

Type conversion functions in the list category

The following table describes the type conversion functions in the [list category](#).

FUNCTION	DESCRIPTION
List	This function returns a <i>Record list</i> value as a new list that is created from specified arguments of the <i>Container (record)</i> type.
ListOfFields	This function returns a <i>Record list</i> value that is created based on the structure of a given argument of the <i>Enumeration</i> or <i>Container (record)</i> type.
Split	This function splits the specified <i>String</i> value into substrings and returns the result as a new <i>Record list</i> value.
StringJoin	This function returns a <i>String</i> value that consists of concatenated values of the specified field from the specified <i>Record list</i> value. The values can be separated by the specified delimiter.

Type conversion functions in the text category

The following table describes the type conversion functions in the [text category](#).

FUNCTION	DESCRIPTION
Char	This function returns a <i>String</i> value that represents a single character that is referenced by the specified Unicode number.
GuidValue	This function converts the specified input of the <i>String</i> type to a data item of the <i>GUID</i> type.
NumberFormat	This function returns a <i>String</i> value that represents the specified number in the specified format and in an optionally specified culture.
QrCode	This function returns a <i>Container</i> value that presents the Quick Response code (QR code) image for the specified string in binary format.
Text	This function returns a <i>String</i> value that represents the specified number after it has been converted to a text string that is formatted according to the server locale settings of the current application instance.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

INT64VALUE ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `INT64VALUE` function returns an *Int64* value that represents the specified string.

Syntax 1

```
INT64VALUE (text)
```

Syntax 2

```
INT64VALUE (number)
```

Arguments

`text` : *String*

A text value that must be converted to an *Int64* number.

`number` : *Real or Integer*

A numeric *Real* or *Integer* value that must be converted to an *Int64* number.

Return values

Int64

The resulting numeric value.

Usage notes

Any decimal places are truncated.

Example 1

```
INT64VALUE ("22565422744") returns the Int64 value 22565422744.
```

Example 2

```
INT64VALUE ( VALUE("22565422744.77")) returns the Int64 value 22565422744.
```

Additional resources

[Type conversion functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

INTVALUE ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `INTVALUE` function returns an *Int* value that represents the specified string.

Syntax 1

```
INTVALUE (text)
```

Syntax 2

```
INTVALUE (number)
```

Arguments

`text` : *String*

A text value that must be converted to an *Int* number.

`number` : *Real or Integer*

A numeric *Real* or *Integer* value that must be converted to an *Int* number.

Return values

Int

The resulting numeric value.

Usage notes

Any decimal places are truncated.

Example 1

```
INTVALUE ("100.77")
```

 returns the *Int* value 100.

Example 2

```
INTVALUE (-100.77)
```

 returns the *Int* value -100.

Additional resources

[Type conversion functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

NUMBERVALUE ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `NUMBERVALUE` function returns a *Real* value that is converted from the specified *String* value. During the conversion, the specified decimal and digit grouping separators are considered.

Syntax

```
NUMBERVALUE (text, decimal separator, digit grouping separator)
```

Arguments

`text` : *String*

A text value that must be converted to a *Real* number.

`decimal separator` : *String*

A decimal separator. It's used to separate the integer and fractional parts of a decimal number.

`digit grouping separator` : *String*

A digit grouping separator. It's used as the thousands separator.

Return values

Real

The resulting numeric value.

Example

`NUMBERVALUE("1 234,56", ",", " ")` returns 1234.56.

Additional resources

[Type conversion functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

VALUE ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `VALUE` function returns a *Real* value that is converted from the specified string.

Syntax

```
VALUE (text)
```

Arguments

`text` : *String*

A string value that must be converted to a numeric value.

Return values

Real

The resulting numeric value.

Usage notes

Commas and dot characters (.) are considered decimal separators, and a leading hyphen (-) is used as a negative sign. An exception is thrown at runtime if the specified string contains other non-numeric characters.

Example 1

`VALUE ("1 234,56")` throws an exception.

Example 2

`VALUE ("1234,56")` returns **1234.56**.

Additional resources

[Type conversion functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

DATETIMEVALUE ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `DATETIMEVALUE` function returns a *DateTime* value that is converted from a given text value in the specified format and in an optionally specified `culture` to a date/time value. For information about the supported formats, see [standard](#) and [custom](#).

Syntax 1

```
DATETIMEVALUE (text, format)
```

Syntax 2

```
DATETIMEVALUE (text, format, culture)
```

Arguments

`text` : *String*

Text that represents the value to format.

`format` : *String*

The format of the given text.

`culture` : *String*

The culture that is used for formatting of the given text.

Return values

DateTime

The resulting date/time value.

Usage notes

When the culture isn't defined as an argument of the called function, the value of `culture` is defined by the calling context. For example, if the `DATETIMEVALUE` function is called by using syntax 1 in an Electronic reporting (ER) format for a FILE element that is configured to use the German culture, the conversion will be done by using the German culture. The default `culture` value is **EN-US**.

Example 1

`DATETIMEVALUE ("21-Dec-2016 02:55:00", "dd-MMM-yyyy hh:mm:ss")` returns 2:55:00 AM on December 21, 2016, based on the specified custom format and the default application's **EN-US** culture.

Example 2

`DATETIMEVALUE ("21-Jan-2016 02:55:00", "dd-MMM-yyyy hh:mm:ss", "IT")` returns **2:55:00 AM on December 21, 2016**, based on the specified custom format and culture.

However, `DATETIMEVALUE ("21-Jan-2016 02:55:00", "dd-MMM-yyyy hh:mm:ss", "EN-US")` throws an exception to inform the user that the specified string isn't recognized as a valid date/time value for the specified culture.

Additional resources

[Date and time functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

DATE TODATETIME ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `DATE TODATETIME` function returns a *DateTime* value that is converted from a given date value to a date/time value in Coordinated Universal Time (Greenwich Mean Time [GMT]).

Syntax

```
DATE TODATETIME (date)
```

Arguments

`date` : *Date*

A date value that represents the date to convert.

Return values

DateTime

The resulting date/time value.

Example 1

`DATE TODATETIME (CompInfo. 'getCurrentDate()')` returns the date of the current Microsoft Dynamics 365 Finance session, December 24, 2015, as **12/24/2015 12:00:00 AM**. In this example, **CompInfo** is an Electronic reporting (ER) data source of the **Finance and Operations/Table** type, and it refers to the CompanyInfo table.

Example 2

`DATE TODATETIME (DATEVALUE ("2019-11-12T16:00:00.0000000-07:00", "O"))` returns the date/time value **11/12/2019 12:00:00 AM**.

Additional resources

[Date and time functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

DATEVALUE ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `DATEVALUE` function returns a *Date* value that is converted from a given text value in the specified format and in an optionally specified *culture* to a date value. For information about the supported formats, see [standard](#) and [custom](#).

Syntax 1

```
DATEVALUE (text, format)
```

Syntax 2

```
DATEVALUE (text, format, culture)
```

Arguments

`text` : *String*

Text that represents the value to format.

`format` : *String*

The format of the given text.

`culture` : *String*

The culture that is used for formatting of the given text.

Return values

Date

The resulting date value.

Usage notes

When the culture isn't defined as an argument of the called function, the value of `culture` is defined by the calling context. For example, if the `DATEVALUE` function is called by using syntax 1 in an Electronic reporting (ER) format for a FILE element that is configured to use the German culture, the conversion will be done by using the German culture. The default `culture` value is EN-US.

Example 1

`DATEVALUE ("21-Dec-2016", "dd-MMM-yyyy")` returns the date value **December 21, 2016**, based on the specified custom format and the default application's EN-US culture.

Example 2

`DATEVALUE ("21-Jan-2016", "dd-MMM-yyyy", "IT")` returns the date value **January 21, 2016**, based on the specified custom format and culture.

However, `DATEVALUE ("21-Jan-2016", "dd-MMM-yyyy", "EN-US")` throws an exception to inform the user that the specified string isn't recognized as a valid date for the specified culture.

Additional resources

[Date and time functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

LIST ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `LIST` function returns a *Record list* value that consists of a new list of records that is created from the specified arguments.

Syntax

```
LIST (record 1 [, record 2, ..., record N])
```

Arguments

`record 1` : *Container (record)*

A reference to a data source of the *Record* data type. This argument is required.

`record N` : *Container (record)*

A reference to a data source of the *Record* data type. These additional arguments are optional.

Return values

Record list

The resulting list of records.

Usage notes

The structure of the list that is created contains only the fields that are presented in the structure of every record that is mentioned in the arguments.

Example

You enter data source **Record 1** of the *Container* type. This data source contains the following nested fields of the *Calculated field* type:

- **Code**: This field contains an expression that returns a value of the *String* type.
- **Amount**: This field contains an expression that returns a value of the *Real* type.

You then enter data source **Record 2** of the *Container* type. This data source contains the following nested fields of the *Calculated field* type:

- **Amount**: This field contains an expression that returns a value of the *Real* type.
- **IsValid**: This field contains an expression that returns a value of the *Boolean* type.

In this case, the expression `LIST('Record 1', 'Record 2')` returns a new list that contains two records. The structure of this list consists of a single **Amount** field of the *Real* type, because this field is the only field that is presented in every argument of the called function.

Additional resources

List functions

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

LISTOFFIELDS ER function

2/18/2021 • 3 minutes to read • [Edit Online](#)

The `LISTOFFIELDS` function returns a *Record list* value that is created based on the structure of the specified argument of the *Enumeration* or *Container (record)* type.

Syntax 1

```
LISTOFFIELDS (path)
```

Syntax 2

```
LISTOFFIELDS (path, language)
```

Arguments

`path`: Data source reference

The valid reference path of a data source of one of the following data types:

- Model enumeration
- Format enumeration
- Application enumeration
- Container (record)

`language`: *String*

Text that represents a language code.

Return values

Record list

The resulting list of records.

Usage notes

The list that is created consists of records that have the following fields:

- **Name** (*String* data type)
- **Label** (*String* data type)
- **Description** (*String* data type)
- **IsTranslated** (*Boolean* data type)

If the `path` argument refers to a data source of the *Container (Record)* type, for every field of the referenced container record, a new record is added to the list that is created. For every record that is created, the **Name** field returns the name of the field of the referenced container record that the current record was created for.

If the `path` argument refers to a data source of one of the *Enumeration* types, for every enumeration value of

the referenced enumeration, a new record is added to the list that is created. For every record that is created, the **Name** field returns the value of the referenced enumeration that the current record was created for, the **Description** field returns the description of that enumeration, and the **Label** field returns the label of that enumeration.

At runtime, when syntax 1 is used, the **Label** and **Description** fields must return values that are based on the language settings of the Electronic reporting (ER) format that is running:

- If the labels and descriptions for the requested language are available, the **Label** and **Description** fields return values that are based on that language, and the **IsTranslated** field returns **True**.
- If the labels and descriptions for the requested language aren't available, the **Label** and **Description** fields return values that are based on the default **EN-US** language, and the **IsTranslated** field returns **False**.

At runtime, when syntax 2 is used, the **Label** and **Description** fields must return values that are based on the language that is defined as the second argument of the called function:

- If the labels and descriptions for the requested language are available, the **Label** and **Description** fields return values that are based on that language, and the **IsTranslated** field returns **True**.
- If the labels and descriptions for the requested language aren't available, the **Label** and **Description** fields return values that are based on the **EN-US** language, and the **IsTranslated** field returns **False**.

Example 1

In the following illustration, an enumeration is introduced in an ER data model.

ReportDirection		
Enumeration values		
+ New Delete		
Name	Label (*Recommended to use labels)	Description
Both	Both	
Export	Dispatches	
Import	Arrivals	

The following illustration shows these details:

- The model enumeration is inserted into a report as a data source.
- An ER expression uses the model enumeration as a parameter of the `LISTOFFIELDS` function.
- A data source of the *Record list* type is inserted into a report by using the ER expression that is created.

FORMAT **MAPPING** TRANSFORMATIONS VALIDATIONS

Bind + Add root + Add Edit Delete Show name first Group view

- enumDirectionInReport: Data model enumeration ReportDirection
 - Arrivals(Import): Enumeration value
 - Both: Enumeration value
 - Dispatches(Export): Enumeration value
 - listDirectionInReport: Calculated field = LISTOFFIELDS(enumDirectionInReport): Record list**
 - Description: String
 - Label: String
 - Name: String
- model: Data model Intrastat

The following example shows the ER format elements that are bound to the data source of the *Record list* type that was created by using the `LISTOFFIELDS` function.

```

Root: XML Element
├── Directions: XML Element = listDirectionInReport
    ├── name: XML Attribute = listDirectionInReport.Name
    ├── label: XML Attribute = listDirectionInReport.Label
    └── desc: XML Attribute = listDirectionInReport.Description
  
```

The following illustration shows the result when the designed format is run.

```

<?xml version="1.0" encoding="UTF-8"?>
- <Root>
  <Directions desc="" label="Both" name="Both"/>
  <Directions desc="" label="Dispatches" name="Export"/>
  <Directions desc="" label="Arrivals" name="Import"/>
</Root>
  
```

NOTE

Based on the language settings of the parent FILE and FOLDER format elements, translated text for labels and descriptions is entered in the output of the ER format.

Example 2

You use the *Calculated field* data source type to configure `enumType_de` and `enumType_deCH` data sources for the `enumType` data model enumeration:

- `enumType_de` = `LISTOFFIELDS (enumType, "de")`
- `enumType_deCH` = `LISTOFFIELDS (enumType, "de-CH")`

In this case, you can use the following expression to get the label of the enumeration value in Swiss German, if that translation is available. If the Swiss German translation isn't available, the label is in German.

```
IF (NOT (enumType_deCH.IsTranslated), enumType_de.Label, enumType_deCH.Label)
```

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

SPLIT ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `SPLIT` function splits the specified input string into substrings and returns the result as a new *Record list* value.

Syntax 1

```
SPLIT (input, length)
```

This syntax is used to split the specified input string into substrings, each of which has the specified length.

Syntax 2

```
SPLIT (input, delimiter)
```

This syntax is used to split the specified input string into substrings, based on the specified delimiter.

Arguments

`input` : *String*

The text to split.

`length` : *Integer*

The maximum length of a single substring.

`delimiter` : *String*

A delimiter that is used to separate substrings.

Return values

Record list

The resulting list of records.

Usage notes

The record structure of the list that is returned consists of the **Value** field of the *String* type. Every record of the list that is returned contains generated substrings in this field.

If the `delimiter` argument is empty, the new list that is returned consists of one record that has the **Value** field of the *String* type. This field contains the input text.

If the `input` argument is empty, a new empty list is returned. If either the `input` or `delimiter` argument is unspecified (null), an application exception is thrown.

Example 1

`SPLIT ("abcd", 3)` returns a new list that consists of two records that have the **Value** field of the *String* type. The **Value** field in the first record contains the text "abc", and the **Value** field in the second record contains the text "d".

Example 2

`SPLIT ("XAb aBy", "aB")` returns a new list that consists of three records that have the **Value** field of the *String* type. The **Value** field in the first record contains the text "X", the **Value** field in the second record contains the text " ", and the **Value** field in the third record contains the text "y".

[List functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

STRINGJOIN ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `STRINGJOIN` function returns a *String* value that consists of concatenated values of the specified field from the specified list. The values can be separated by the specified delimiter.

Syntax

```
STRINGJOIN (list, field, delimiter)
```

Arguments

`list` : *Record list*

The valid path of a data source of the *Record list* data type.

`field` : *Field*

The valid path of a field of the *String* data type in the specified list.

`delimiter` : *String*

A delimiter that is used to separate substrings.

Return values

String

The resulting text value.

Example

If you enter `SPLIT("abc" , 1)` as data source `DS`, the expression `STRINGJOIN (DS, DS.Value, "-")` returns "a-b-c".

Additional resources

[List functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

CHAR ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `CHAR` function returns a *String* value that presents a single character that is referenced by the specified Unicode number.

Syntax

```
CHAR (number)
```

Arguments

`number` : *Integer*

A number that corresponds to an expected single character.

Return values

String

The resulting text value.

Usage notes

The string that this function returns depends on the encoding that is selected in the parent **FILE** format element. For a list of the supported encodings, see [Encoding class](#).

Example

`CHAR (255)` returns "ÿ".

Additional resources

[Text functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

GUIDVALUE ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `GUIDVALUE` function converts the specified input of the *String* type to a data item of the *GUID* type.

Syntax

```
GUIDVALUE (input)
```

Arguments

`input` : *String*

The valid path of a data source of the *String* type.

Return values

GUID

The resulting globally unique identifier (GUID) value.

Usage notes

To do a conversion in the opposite direction (that is, to convert specified input of the *GUID* data type to a data item of the *String* data type), you can use the [TEXT](#) function.

Example

You define the following data sources in your model mapping:

- A `myID` data source of the *Calculated field* type that contains the expression `GUIDVALUE ("AF5CCDAC-F728-4609-8C8B- A4B30B0C0AA0")`
- A `Users` data source of the *Table records* type that refers to the `UserInfo` table

You can then use an expression such as `FILTER (Users, Users.objectId = myID)` to filter the `UserInfo` table by the `objectId` field of the *GUID* data type.

Additional resources

[Text functions](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

NUMBERFORMAT ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `NUMBERFORMAT` function returns a *String* value that presents the specified number in the specified format and in an optionally specified *culture*. For information about the supported formats, see [standard](#) and [custom](#).

Syntax 1

```
NUMBERFORMAT (number, format)
```

Syntax 2

```
NUMBERFORMAT (number, format, culture)
```

Arguments

`number` : *Integer or Real*

A numeric value that specifies the number that must be formatted.

`format` : *String*

A *String* value that represents the format.

`culture` : *String*

A *String* value that represents the culture to use for formatting.

Return values

String

The resulting text value.

Usage notes

If the culture isn't defined as an argument of the called function, the context that this function is run in determines the culture that is used to format numbers.

Example 1

For the EN-US culture, `NUMBERFORMAT (0.45, "p")` returns "45.00 %", and `NUMBERFORMAT (10.45, "#")` returns "10".

Example 2

`NUMBERFORMAT (10/3, "F2", "de")` returns 3,33, whereas `NUMBERFORMAT (10/3, "F2", "en-us")` returns 3.33.

Additional resources

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

QRCODE ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `QRCODE` function returns a *Container* value that presents the Quick Response code (QR code) image for the specified string in binary format.

Syntax

```
QRCODE (text)
```

Arguments

`text` : *String*

A *String* value that represents the original text.

Return values

Container

The resulting binary stream.

Example

You can configure an Electronic reporting (ER) format to generate an outbound document in Microsoft Office format (Excel workbooks or Word documents) by using a predefined template. This template may contain a **Picture** object (Excel workbook) or a **Picture Content Control** (Word document) as a placeholder for a QR code image. You need to add to the configured ER format a **Cell** element that will be used to fill this placeholder in. To specify what information will be stored in a QR code, you need to define a binding for this **Cell** element. For example, you can configure such binding as containing the following expression:

```
QRCODE (model.ListOfShelfLabels.LabelText)`
```

When you run the configured ER format, the text value of the **LabelText** field of the **model.ListOfShelfLabels** data source will be used to generate a QR code image. This image will replace a QR code image placeholder in the document template using to generate an outbound document. When this image of the generated document is scanned, it returns the text that was taken from the **LabelText** field of the **model.ListOfShelfLabels** data source. For more information, see [Embed images and shapes in documents that you generate by using ER](#).

TEXT ER function

2/18/2021 • 2 minutes to read • [Edit Online](#)

The `TEXT` function returns the specified number as a *String* value after it has been converted to a text string that is formatted according to the server locale settings of the current application instance.

Syntax

```
TEXT (number)
```

Arguments

`number` : *Integer* or *Real*

A number that must be converted to a text string.

Return values

String

The resulting text value.

Usage notes

For values of the *Real* type, the string conversion is limited to two decimal places.

Example

If the server locale of the Microsoft Dynamics 365 Finance instance is defined as **EN-US**, `TEXT (NOW ())` returns the current Finance session date, December 17, 2015, as the text string "12/17/2015 07:59:23 AM".

`TEXT (1/3)` returns "0.33".

Manage ER model mapping in separate ER configurations

2/18/2021 • 5 minutes to read • [Edit Online](#)

The following steps explain how a user assigned to the System administrator or Electronic reporting developer role can manage Electronic reporting (ER) model mappings in separate ER configurations. In this task guide, you will create required ER configurations for the sample company, Litware, Inc. To complete this task guide, you must first complete the steps in the task guide, "ER Create a configuration provider" and mark it as active.

Because ER configurations are shared among companies, you can complete this task guide using the company data set of your choice. The functionality for this task guide is available if you have installed one of the following hotfixes: <https://fix.lcs.dynamics.com/Issue/Resolved?kb=4012872> for the Dynamics AX 7.0 version or <https://fix.lcs.dynamics.com/Issue/Resolved?kb=4012871> for the Dynamics 365 for Operations version.

1. Go to Organization administration > Workspaces > Electronic reporting.
 - Verify that the configuration provider for the sample company Litware, Inc. is available and marked as active. If you don't see this configuration provider, you must first complete the steps in the task guide, Create a configuration provider, and mark it as active.

Add a new ER model configuration

1. Click Reporting configurations.
 - Add a new model configuration. The name must be unique in the configurations tree.
2. Click Create configuration to open the drop dialog.
3. In the Name field, type 'Sample data model'.
 - Sample data model
4. Click Create configuration.
5. Click Designer.
6. Click New to open the drop dialog.
7. In the Name field, type 'Root'.
 - Root
8. Click Add.
9. Click New to open the drop dialog.
10. In the Name field, type 'Company'.
 - Company
11. Click Add.
12. In the Description field, enter the text, Description of the legal entity or company in which a user logged at run-time.
 - Description of the legal entity or company in which a user logged at run-time.
13. Click Root reference.
14. Click OK.
15. Click Save.
16. Close the page.
17. Click Change status.
18. Click Complete.
19. Click OK.

Add a new ER model-mapping configuration

1. Click Create configuration to open the drop dialog.
2. In the New field, enter 'Model Mapping based on data model Sample data model'.
3. In the Name field, type 'Sample mapping'.
 - Sample mapping
4. Click Create configuration.
5. Expand the Prerequisites section.
 - The Implementations prerequisites group has been added automatically. The group contains the prerequisite component that refers to the parent data model configuration and is marked as Implementation. This means that this Sample-mapping model-mapping configuration is considered the implementation of the data model, Sample data model. Therefore, this component will force ER to download the model-mapping configuration, Sample mapping from an ER repository when the model configuration, Sample data model, is downloaded.
6. Click Designer.
 - The created model-mapping configuration contains a new blank mapping with the same name as the created configuration. When a selected parent model configuration contains model mappings, they will be copied to a new model-mapping configuration.
7. Click Designer.
8. In the tree, select 'Dynamics 365 for Operations\Table'.
9. Click Add root.
10. In the Name field, type 'Company'.
 - Company
11. In the Table field, type 'CompanyInfo'.
 - CompanyInfo
12. Click OK.
13. In the tree, expand 'Company'.
14. In the tree, expand 'Company\find()'.
15. In the tree, select 'Company\find()\Name'.
16. Click Bind.
17. Click Save.
18. Close the page.
19. Close the page.
20. On the Action Pane, click Configurations.
21. Click User parameters.
22. Select Yes in the Run settings field.
23. Click OK.
24. Click Edit.
25. Select Yes in the Run Draft field.

Add a new ER format configuration

1. In the tree, select 'Sample data model'.
2. Click Create configuration to open the drop dialog.
3. In the New field, enter 'Format based on data model Sample data model'.
4. In the Name field, type 'Sample format'.
 - Sample format
5. Click Create configuration.

6. Click Designer.
7. Click Add root to open the drop dialog.
8. In the tree, select 'Text\String'.
9. Click OK.
10. Click the Mapping tab.
11. In the tree, expand 'model'.
12. In the tree, select 'model\Company'.
13. Click Bind.
14. Click Save.
15. Close the page.
 - Run the draft version of the created format for testing purposes.
16. Click Run.
 - On the Versions FastTab, click Run.
17. Click OK.
 - Review the output that contains the name of the company in which the user who is running this format configuration is logged into. The created model-mapping configuration is used by this format configuration because there is only one configuration available that contains required model mappings.

Add alternative ER model-mapping configuration

1. In the tree, select 'Sample data model'.
2. Click Create configuration to open the drop dialog.
3. In the New field, enter 'Model Mapping based on data model Sample data model'.
4. In the Name field, type 'Sample mapping (alternative)'.
 - Sample mapping (alternative)
5. Click Create configuration.
6. Click Designer.
7. Click Designer.
8. In the tree, select 'Dynamics 365 for Operations\Table'.
9. Click Add root.
10. In the Name field, type 'Company'.
 - Company
11. In the Table field, type 'CompanyInfo'.
 - CompanyInfo
12. Click OK.
13. Click Edit.
14. In the tree, select 'String\CONCATENATE'.
15. Click Add function.
16. In the tree, expand 'Company'.
17. In the tree, expand 'Company\find()'.
18. In the tree, select 'Company\find()\Name'.
19. Click Add data source.
20. In the Formula field, type a value.
 - CONCATENATE(Company.'find()'.Name, ";",
21. In the tree, select 'Company\find()\Company(DataArea)'.
22. Click Add data source.

23. In the Formula field, type a value.
 - `CONCATENATE(Company.find().Name, ";", Company.find().DataArea)`
24. Click Save.
25. Close the page.
26. Click Save.
27. Close the page.
28. Close the page.
29. Select Yes in the Run Draft field.

Use an existing ER model-mapping configuration

1. In the tree, select 'Sample data model\Sample format'.
2. Click Run.
 - The selected draft version of the ER format configuration can't be executed because there is more than one model-mapping configuration available for the undefined data model that has been selected as the data source of the running ER format.
 - Next, you will define the alternative model-mapping configuration as the one from which model mappings will be used as data sources for running ER format.
3. In the tree, select 'Sample data model\Sample mapping (alternative)'.
4. Select Yes in the Default for model-mapping field.
5. In the tree, select 'Sample data model\Sample format'.
6. Click Run.
7. Click OK.
 - The default model-mapping configuration is used by this format configuration for generating the electronic document (the created output contains the company code).

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Select data model definitions when you create formats

2/18/2021 • 3 minutes to read • [Edit Online](#)

To complete the steps in this procedure, you must first complete the procedure, ER Create a configuration provider and mark it as active.

This procedure shows how a model's root item can be selected as a data model definition for inserting an Electronic reporting (ER) format configuration that is designed to generate electronic documents. In this procedure, you will add a new ER format configuration for the sample company Litware, Inc.

This procedure is intended for users who have the System administrator or Electronic reporting developer role assigned to them. The steps can be completed by using any dataset.

1. Go to Organization administration > Workspaces > Electronic reporting.
 - Make sure that the configuration provider for the sample company, Litware, Inc., is available and marked as Active. If you don't see this configuration provider, complete the steps in the procedure, Create a configuration provider and mark it as active.
2. Click Reporting configurations.

Add a new ER data model configuration

1. Click Create configuration to open the drop dialog.
 - We add a new ER model configuration containing a data model that is designed to be used as data source for generation ER reports.
2. In the Name field, type 'Payment model (fictitious)'.
 - Payment model (fictitious)
3. Click Create configuration.
4. Click Designer.
 - Open the ER designer to specify the structure of data model of this configuration.
 - Assume that we design the data model for payments business domain to support 2 payment methods – credit transfer and direct debit ones.
5. Click New to open the drop dialog.
6. In the Name field, type 'Payments – credit transfer'.
 - Payments – credit transfer
7. Click Add.
8. Click New to open the drop dialog.
9. In the New node as a field, enter 'Model root'.
10. In the Name field, type 'Payments – direct debit'.
 - Payments – direct debit
11. Click Add.
12. Click Save.
13. Close the page.
14. Click Change status.
 - Complete the draft version of the model to make it available in new model mappings and formats.
15. Click Complete.

16. Click OK.

Start to enter a new ER format configuration

1. Click Create configuration to open the drop dialog.
2. In the New field, enter 'Format based on data model Payment model (fictitious)'.
3. In the Data model definition field, enter or select a value.
 - Note that all root items of the selected data model are currently available for selection as a data model definition. You can continue to design your format by using any of the required root items of the data model. A missing model mapping for the selected root item doesn't prevent you from continuing.
4. Close the page.

Add a new ER model mapping configuration

1. Click Create configuration to open the drop dialog.
2. In the New field, enter 'Model Mapping based on data model Payment model (fictitious)'.
3. In the Name field, type 'Payment model mappings (fictitious)'.
 - Payment model mappings (fictitious)
4. In the Data model definition field, enter or select a value.
5. Click Create configuration.

Design ER model mappings

1. Click Designer.
 - Use the ER designer to specify the model mappings for the required root items.
2. Click Designer.
 - Simulate setting of selected model mapping for the selected model's root item.
3. In the tree, select 'Dynamics 365 for Operations\Table records'.
4. Click Add root.
5. In the Name field, type 'Ledger'.
6. In the Table field, type 'LedgerJournalTrans'.
 - LedgerJournalTrans
7. Click OK.
8. Click Save.
9. Close the page.
10. Close the page.

Start to enter another new ER format configuration

1. In the tree, select 'Payment model (fictitious)'.
2. Click Create configuration to open the drop dialog.
3. In the New field, enter 'Format based on data model Payment model (fictitious)'.
4. In the Data model definition field, enter or select a value.
 - Note that now only one root item is available to map to the application data sources. When at least one model mapping is introduced, only the model's root items that are mapped to application data sources can be selected as a model definition while the ER format is added.
5. Close the page.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

RCS enhanced filtering options for finding configurations in the RCS/Global repository

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic describes enhanced filtering capabilities for Regulatory Configuration Services (RCS) Global repository, which have been improved to include the ability to filter with the following criteria:

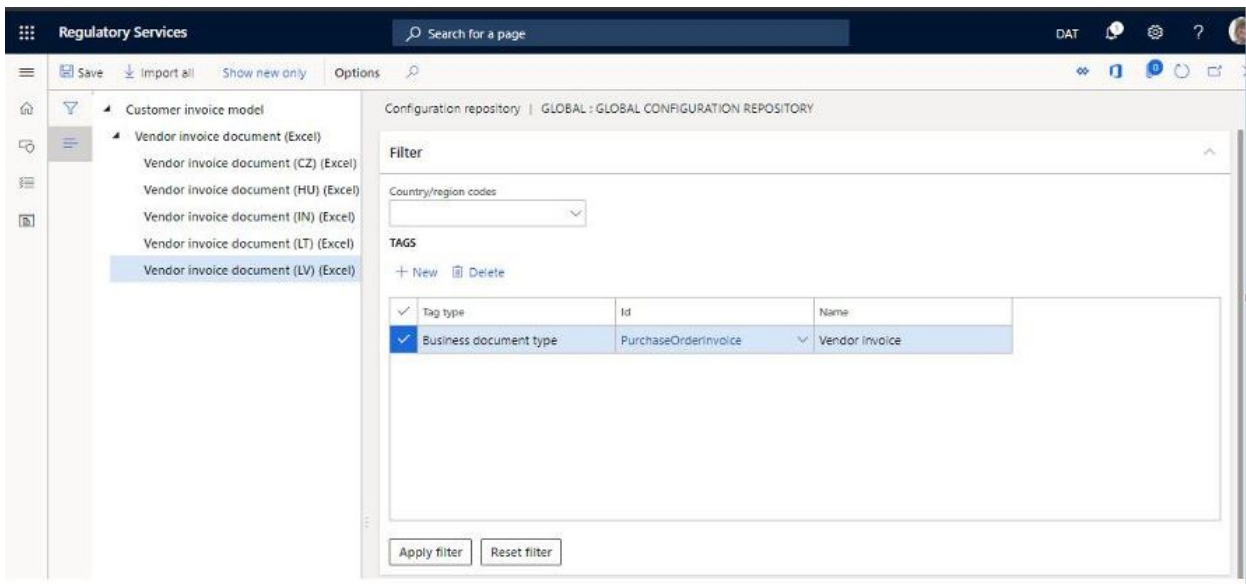

- **Country/region** - Based on ISO country codes
- **Tags** types for:
 - Functional area
 - Feature area
 - Industry
 - Business document

To make it easier to discover specific or related configurations you can apply filters, either individually or as a group. For example, to find a single type of 'configurable business documents that are related to vendor invoices, you could apply a **Business document type** filter to search for that type of document.

The screenshot shows the 'Filter' section of the 'GLOBAL : GLOBAL CONFIGURATION REPOSITORY'. It includes a 'Country/region codes' dropdown, a 'TAGS' section with '+ New' and 'Delete' buttons, and a table with columns 'Tag type', 'Id', and 'Name'. The 'Tag type' column has a dropdown menu open showing options: 'Functional area', 'Feature area', 'Industry', and 'Business document type'. The 'Functional area' option is selected. Below the table are 'Apply filter' and 'Reset filter' buttons.

Tag type	Id	Name
Functional area		

You can further refine the search by selecting document type, for example 'vendor invoice' and clicking **Apply filter**. The following example shows the results when filtering on **Business document type** with the document type added.

Filtered results can be imported into a users RCS repository or a Dynamics 365 Finance environment, either individually or as a set. To do this, select the group of configurations, and click **Import**.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Generate reports by adding content as raw XML

2/18/2021 • 2 minutes to read • [Edit Online](#)

You can use the new **RAW XML** format element to design Electronic reporting (ER) formats that generate outgoing documents in XML format. In some cases, you might prefer to add raw XML data to these reports for one or more of the following reasons:

- It's more convenient to use raw XML for the original design and ongoing maintenance of a report, because the XML structure can be automatically generated by executing a runtime expression. Therefore, multiple bindings don't have to be determined for multiple format elements at design time. It is possible when the data sources that you're using contain information that can be used to make XML elements while the report is generated.
- No other method can be used to fill the report with XML content that was previously received and stored in the system. For example, the XML response that is generated might have to contain the content of an XML request that was sent earlier.
- No other method can be used to insert characters into the generated document based on their numeric codes. For some languages and characters, codes of this type don't exist. Examples include the Greek letter rho (ρ) and HTML entity codes such as é for an *e* that has an acute accent (é).

NOTE

Be aware that the framework doesn't control whether the XML content that is placed to the generated document by using the **RAW XML** format element is correct.

To learn more about this feature, play the **ER Use raw XML data to generate XML reports (Part 1: Design data model)** and **ER Use raw XML data to generate XML reports (Part 2: Design and run report)** task guides, which are part of the **7.5.4.3 Acquire/Develop IT service/solution components (10677)** business process, and can be downloaded from the [Microsoft Download Center](#). These task guides walk you through the process of configuring an ER format to insert raw XML data into generated files.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Cross-company data sources in Electronic reporting (ER)

2/18/2021 • 4 minutes to read • [Edit Online](#)

You can design Electronic reporting (ER) formats to generate outgoing documents in various formats. When a document is generated, an ER format calls data sources that were configured in a corresponding ER model mapping. To configure access to application tables for record retrieval, you can use ER data sources of the **Table records** type. When the accessing table is a shared table (that is, a table where data is saved without a company identifier), this data source returns all records. When the accessing table is a company-dependent table (that is, a table where data is saved per company), this data source returns only the records that have been saved for the current company (that is, the company context that the ER format is running under).

Every data source of the **Table records** type in a model mapping can be now marked as a cross-company data source. Therefore, you can use data sources of the **Table records** type to access cross-company data in application tables.

If you mark a data source as cross-company, the following behavior occurs:

- For a data source that refers to any shared table except CompanyInfo, the data source returns all records that exist in the referenced table.
- For a data source that refers to the CompanyInfo table, even though CompanyInfo is a shared table, the data source returns the records that contain the identifier of a company from the defined scope.
- For any company-dependent table, the data source returns the records of the referenced table that contain the identifier of a company from the defined scope.

In the system query dialog box, when the **Ask for query** option is turned on for any data source that is marked as cross-company, you can manually select one or more companies to include on the **Company range** tab.

IMPORTANT

Like other filters, the company filter is persisted as a last-used value for queries when you run an ER format. The filter isn't automatically changed if you change the cross-company value for a data source. To use a different cross-company value for another data source, delete the corresponding user-specific selection.

For every data source that is marked as cross-company, you can select the records that you want by using the **FILTER** and **WHERE** functions in ER expressions. The **dataAreaID** field can also be used as a company identifier. Currently, the **dataAreaID** field is limited to the following types of conditions when the **FILTER** function is used:

- Only conditions that have a single **dataAreaID** field comparison are supported.
- Only comparisons that have expressions that don't depend on records list items are allowed.

Therefore, the following expression is valid.

```
FILTER (MyTable, MyTable.dataAreaID = $StringUserInputParameter)
While shown below expressions will not pass the validation:
FILTER (MyTable, MyTable.dataAreaID = MyTable2RecordsList.MyField)
FILTER (MyTable,
    OR(
        MyTable.dataAreaID = $StringUserInputParameter1,
        MyTable.dataAreaID = $StringUserInputParameter2
    )
)
```

By default, the scope includes all companies of the current application. However, it can be restricted. To restrict the scope of cross-company data access for a single ER format, assign a specific organization hierarchy to the format. When a hierarchy is defined for an ER format, only records for legal entities that are presented in the assigned hierarchy are returned, even though the format calls cross-company data sources. When a reference to a hierarchy that no longer exists is defined for an ER format, the default scope is applied, and the format calls cross-company data sources. In this situation, records for all application companies are returned.

Note that when the **Use draft** option is turned on for the assigned to a single ER format organization hierarchy, the legal entities from the draft version of this hierarchy will be used to identify the scope for cross-company data sources. If the draft version does not exist, the legal entities from the last published version of this organization hierarchy will be used for this.

Note that when the **Use draft** option is turned off for the assigned to a single ER format organization hierarchy, the legal entities from the last published version of this organization hierarchy will be used to identify the scope for cross-company data sources. Date effectiveness of organization hierarchies is not supported yet in the ER framework.

The hierarchy can be assigned to a format in a specific page that can be accessed from the ER workspace or by using the **Organization administration > Electronic reporting > Legal entity filter for formats** menu item. To access the page, the **Maintain legal entity filters for format** privilege (ERMaintainFormatMappingLegalEntityFilters) must be granted to a user. The scope restriction of hierarchy-based legal entities for the format is applied in addition to the restriction that the user can manually specify in the system query dialog box. The intersection of these restrictions is used when the format is run.

To learn more about this feature, play the task guide, **ER Access records of company dependent tables in cross-company mode**, which is part of the 7.5.4.3 Acquire/Develop IT service/solution components (10677) business process, and can be downloaded from the [Microsoft Download Center](#). This task guide walks you through the process of configuring an ER model mapping and ER format to access application tables in cross-company mode.

Download the following files to complete the task guide:

- [ER model configuration - CrossCompanyDataAccessModel.xml](#)
- [ER format configuration - CrossCompanyDataAccessFormat.xml](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

ER Design a configuration for generating reports in OPENXML format (November 2016)

2/18/2021 • 4 minutes to read • [Edit Online](#)

This topic explains how a user in the System Administrator or Electronic Reporting Developer role can create a new Electronic reporting (ER) configuration that contains a template for generating electronic documents in OPENXML format. This configuration will be used for processing vendor payments.

In this example, you will create a configuration for sample company, Litware, Inc. These steps can be performed in GBSI company.

To complete these steps, you must first complete the steps in the "Create a configuration provider and mark it as active" procedure. You must also have an Excel file which will be imported when creating the template. This file can be accessed from the [Template of Payment Report](#).

Upload the Payments data model configuration

1. In the navigation pane, go to **Modules > Organization administration > Workspaces > Electronic reporting**.
2. In the list, mark the configuration provider for sample company, Litware, Inc. If you don't see this configuration provider, you must first complete the steps in [Create configuration providers and mark them as active](#).
3. Select **Set active**.
4. Select **Repositories**. Select a repository for the Operations Resources type, if available. If its available, skip the following steps about creating a new repository.
5. Select **Add** to open the drop dialog.
6. In the **Configuration repository type** field, enter `Operations resourcesdd`.
7. Select **Create repository**.
8. Select **OK**.
9. Select **Open**.
10. In the tree, select **Payment model**.
11. Select **Import**. Import this data model. It will be used as a data source in a new format configuration. Skip this step if this configuration has been already imported.
12. Select **Yes**.
13. Close the pages until you return to the Electronic reporting page.

Create a new format configuration

1. Select **Reporting configurations**.
2. In the tree, select **Payment model**.
3. Select **Create configuration** to open the drop dialog.
4. In the **New** field, enter `Format based on data model PaymentModel`. Create a format that is based on the PaymentModel data model.
5. In the **Name** field, type `Sample worksheet report`. Sample worksheet report
6. In the **Description** field, type `Sample worksheet report for vendors' payments`. Sample worksheet report for vendors' payments.
7. In the **Data model definition** field, enter or select a value. Select the **CustomerCreditTransferInitiation**

definition.

8. Select **Create configuration**.

Design a new document in OPENXML worksheet format

1. In the tree, select **Payment model\Sample worksheet report**.
2. Select **Designer**.
3. On the Action Pane, select **Import**.
4. Select **Import from Excel**.
5. Select **Attachments**. Attach the existing Excel document as a template.
6. Select **New**.
7. Select **File**. Point to the existing Excel file.
8. Close the page.
9. In the **Template** field, enter or select a value. Select the attached Excel file to be used as a template.
10. Select **OK**. Note that ER format components have been created in the designing format based on the structure of the referring MS Excel document (named ranges).

Create a new data source to calculate totals by currency codes

1. Select the **Mapping** tab.
2. Select **Add root** to open the drop dialog.
3. In the tree, select **Functions\Group by**.
4. In the **Name** field, type `PaymentByCurrency`.
5. Select **Edit group by**.
6. In the tree, expand **model**, then select **model\Payments**.
7. Select **Add field to**.
8. Select **What to group**.
9. In the tree, expand **model\Payments**, then select **model\Payments\Currency**.
10. Select **Add field to**.
11. Select **Grouped fields**.
12. In the tree, select **model\Payments\Instructed Amount(InstructedAmount)**.
13. Select **Add field to**, then select **Aggregation fields**.
14. In the **Method** field, select an option. Select the **SUM aggregation** function.
15. In the **Name** field, type `TotalInstructedAmount`.
16. Select **Save**.
17. Close the page.
18. Select **OK**.

Map format components to data sources

1. In the tree, select **model\Payments\Initiating Party(InitiatingParty)\Name** and **Excel\ReportHeader\CompanyName**.
2. Select **Bind**.
3. In the tree, select **model\Payments\Creditor\Identification\Source ID(SourceID)** and **Excel\PaymLines\VendAccountName**.
4. Select **Bind**.
5. In the tree, select **model\Payments\Creditor\Name** and **Excel\PaymLines\VendName**.
6. Select **Bind**.

7. In the tree, select `model\Payments\Creditor Agent(CreditorAgent)\Name` and `Excel\PaymLines\Bank`.
8. Select **Bind**.
9. In the tree, select `model\Payments\Creditor Agent(CreditorAgent)\Routing Number(RoutingNumber)` and `Excel\PaymLines\RoutingNumber`.
10. Select **Bind**.
11. In the tree, select `model\Payments\Creditor Account(CreditorAccount)\Identification\Number` and `Excel\PaymLines\AccountNumber`.
12. Select **Bind**.
13. In the tree, select `model\Payments\Instructed Amount(InstructedAmount)` and `Excel\PaymLines\Debit`.
14. Select **Bind**.
15. In the tree, select `model\Payments\Currency` and `Excel\PaymLines\Currency`.
16. Select **Bind**.
17. In the tree, select `PaymentByCurrency\grouped\Currency` and `Excel\SummaryLines\SummaryCurrency`.
18. Select **Bind**.
19. In the tree, select `PaymentByCurrency\aggregated\TotalInstructedAmount` and `Excel\SummaryLines\SummaryAmount`.
20. Select **Bind**.
21. In the tree, select `PaymentByCurrency` and `Excel\SummaryLines`.
22. Select **Bind**.
23. In the tree, select `model\Payments` and `Excel\PaymLines`.
24. Select **Bind**.
25. Select **Save**, then close the page.

Use the created configuration for payments processing

1. Select **Change status**.
2. Select **Complete**.
3. Select **OK**.
4. In the navigation pane, go to **Modules > Accounts payable > Payment setup > Methods of payment**.
5. Use the Quick Filter to filter on the **Method of payment** field with a value of **Electronic**.
6. Select **Edit**.
7. Expand the **File formats** section.
8. Select **Yes** in the **Generic electronic reporting** field.
9. In the **Export format configuration** field, enter or select a value. Select the **Sample worksheet report** configuration.
10. Select **Save**.
11. Close the page.

Use the created configuration for testing of payment journals processing

1. In the navigation pane, go to **Modules > Accounts payable > Payments > Payment journal**.
2. Select **New** to create a new payment journal.
3. In the **Name** field, type **VendPay**.
4. Select **Lines**.

5. In the **Account** field, specify the values `GB_SI_000001`.
6. Set **Debit** to `1000`.
7. Select **New**.
8. In the **Account** field, specify the values `GB_SI_000005`.
9. Set **Debit** to `2000`.
10. In the **Currency** field, type `EUR`.
11. In the **Offset account** field, specify the values `GBSI OPER`.
12. In the **Method of payment** field, type `Electronic`.
13. Select **Save**.
14. Select **Generate payments**.
15. In the **Method of payment** field, type `Electronic`.
16. In the **File name** field, type `Payments`.
17. In the **Bank account** field, type `GBSI OPER`.
18. Select **OK**, then select **OK** again. Review the created worksheet, including details of payment lines as well as totals for each currency code used in this payment message.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Reuse ER configurations with Excel templates to generate reports in Word format

2/18/2021 • 6 minutes to read • [Edit Online](#)

To generate reports as Microsoft Word documents, you can [configure](#) a new [Electronic reporting \(ER\) format](#). Alternatively, you can reuse an ER format that was originally designed to generate reports as Excel workbooks. In this case, you must replace the Excel template with a Word template.

The following procedures show how a user in either the System administrator role or the Electronic reporting developer role can configure an ER format to generate reports as Word files by reusing an ER format that was designed to generate reports as Excel files.

These procedures can be completed in the GBSI company.

Prerequisites

To complete these procedures, you must first follow the steps in the [Design a configuration for generating reports in OPENXML format](#) task guide.

You must also download and locally save the following templates for the sample report:

- [Template of Payment Report \(SampleVendPaymDocReport.docx\)](#)
- [Bounded Template of Payment Report \(SampleVendPaymDocReportBounded.docx\)](#)

These procedures are for a feature that was added in Dynamics 365 for Operations version 1611 (November 2016).

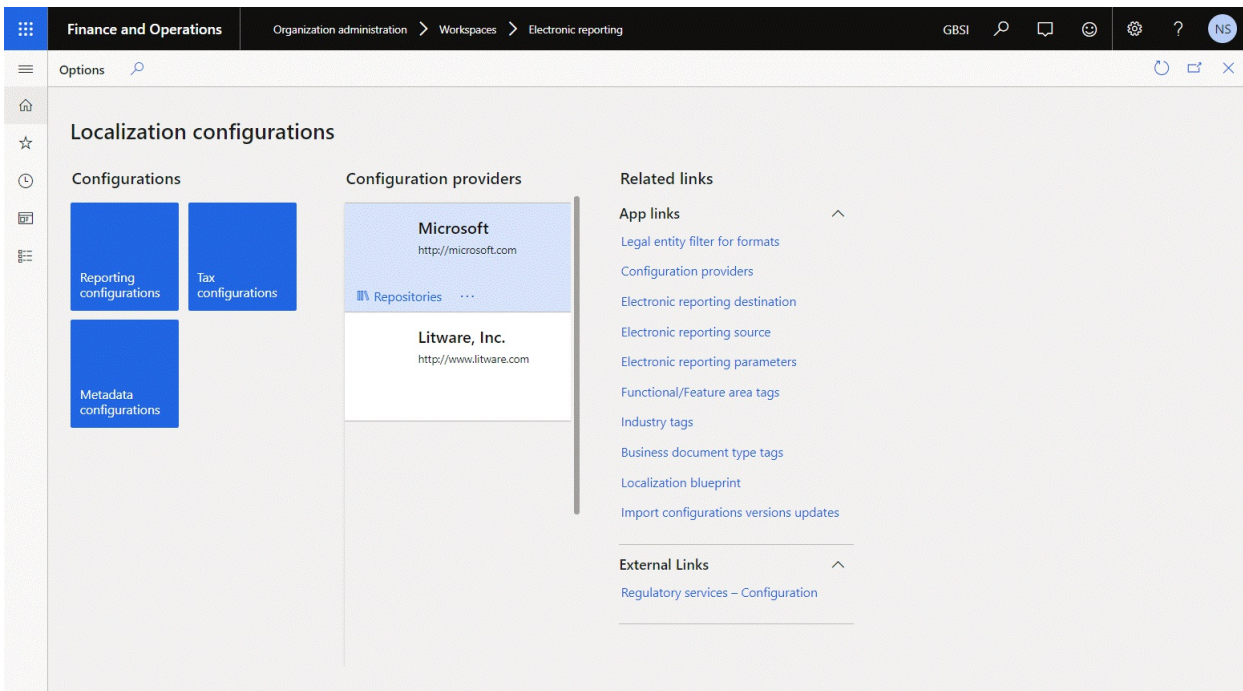

Select the existing ER report configuration

1. In Dynamics 365 Finance, go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. Make sure that the **Litware, Inc.** configuration provider is selected as **Active**. If it isn't, follow the steps in the [Create configuration providers and mark them as active](#) task guide.
3. Select **Reporting configurations**. You will reuse the existing ER configuration that was designed to generate the report output in OPENXML format.
4. On the **Configurations** page, in the configuration tree in the left pane, expand **Payment model**, and select **Sample worksheet report**.

NOTE

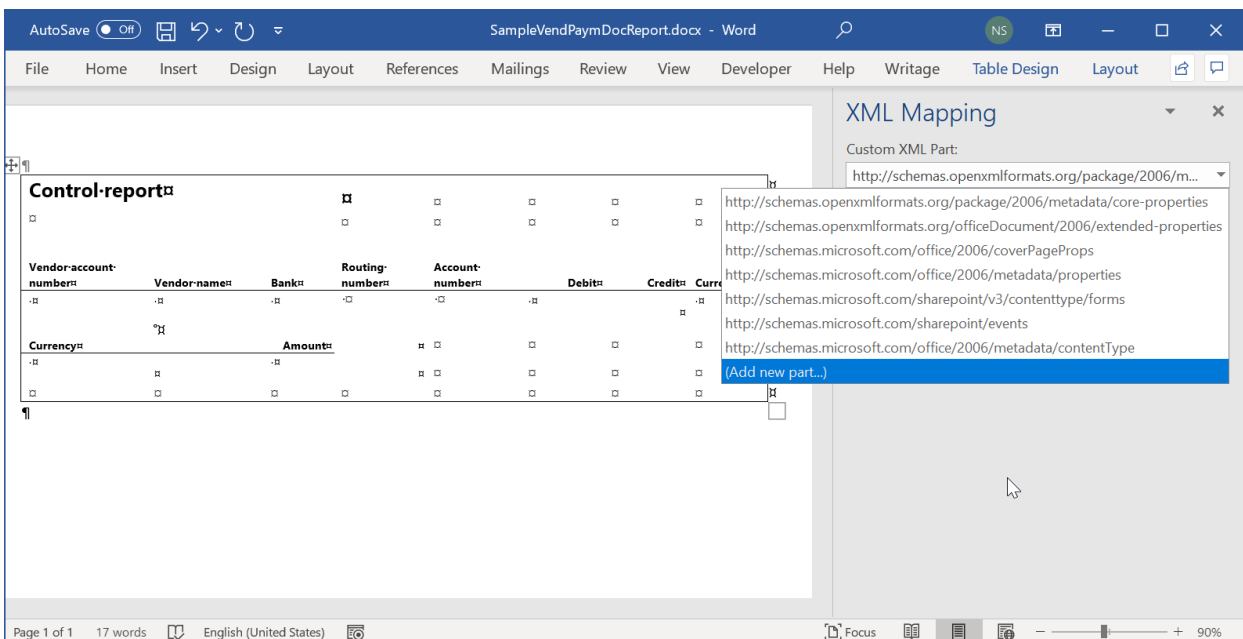

The draft version of the selected ER format can be edited on the **Versions** FastTab.

5. Select **Designer**.
6. On the **Format designer** page, notice that the title of the root format element indicates that an Excel template is currently used.

Review the downloaded Word template

1. In the Word desktop application, open the **SampleVendPaymDocReport.docx** template file that you downloaded earlier.
2. Verify that the template contains only the layout of the document that you want to generate as ER output.

Replace the Excel template with the Word template and add a custom XML part

Currently, the Excel document is used as a template to generate the output in OPENXML format. You will replace this template with the **SampleVendPaymDocReport.docx** Word template file that you downloaded earlier. You will also extend the Word template by adding a custom XML part.

1. In Finance, on the **Format designer** page, on the **Format** tab, select **Attachments**.
2. On the **Attachments** page, select **Delete** to remove the existing Excel template. Select **Yes** to confirm the change.

3. Select **New > File**.

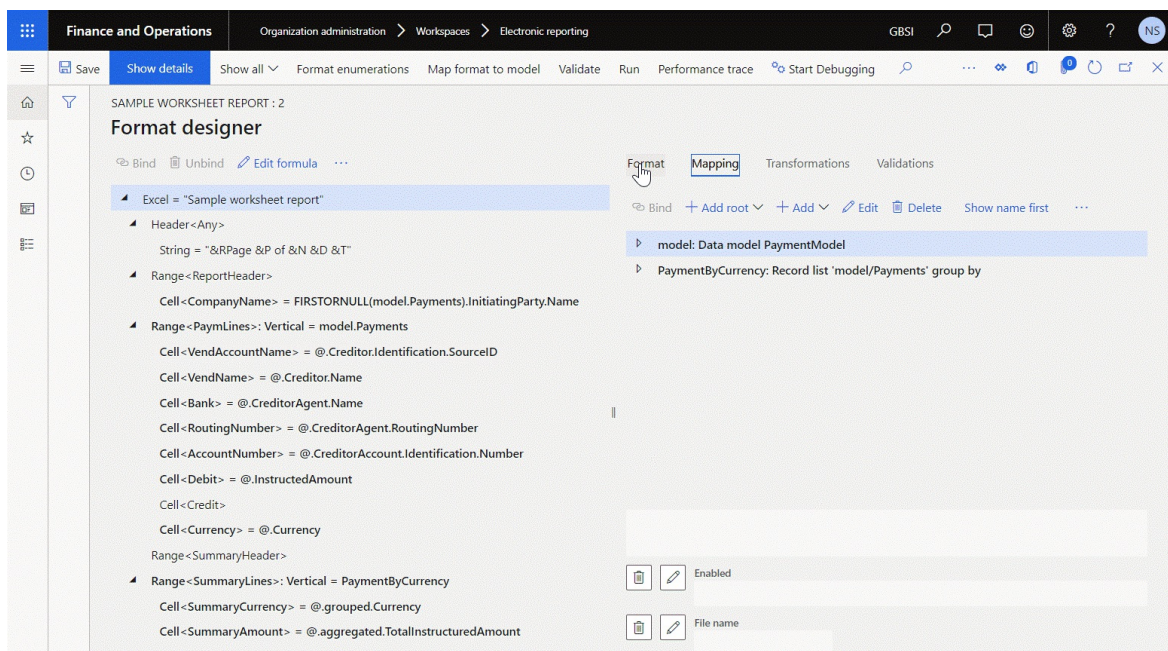

NOTE

You must select a document type that has been [configured](#) in the ER parameters to store templates of ER formats.

4. Select **Browse**, and then browse to and select the **SampleVendPaymDocReport.docx** file that you downloaded earlier.
5. Select **OK**.
6. Close the **Attachments** page.
7. On the **Format designer** page, in the **Template** field, enter or select the **SampleVendPaymDocReport.docx** file to use that Word template instead of the Excel template that was previously used.
8. Select **Save**.

In addition to storing configuration changes, the **Save** action updates the attached Word template. The hierarchical structure of the designed format is added to the attached Word document as a new custom XML part that is named **Report**. The attached Word template contains the layout of the document that will be generated as ER output and the structure of data that ER will enter in that template at runtime.

9. Notice that the title of the root format element indicates that a Word template is currently used.

10. On the **Format** tab, select **Attachments**.

You can now map the elements of the **Report** custom XML part to the content controls of the Word document.

If you're familiar with the process of designing Word documents as forms that contain [content controls](#) that are mapped to elements of [custom XML parts](#), complete all steps in the next procedure to create the document. For more information, see [Create forms that users complete or print in Words](#). Otherwise, skip the next procedure.

Get a Word document that has a custom XML part and do data mapping

1. In Finance, on the **Attachments** page, select **Open** to download the selected template from Finance and store it locally as a Word document.

2. In the Word desktop application, open the document that you just downloaded.
3. On the **Developer** tab, select **XML Mapping Pane**.

NOTE

If the **Developer** tab doesn't appear on the ribbon, customize the ribbon to add it.

4. In the **XML Mapping** pane, in the **Custom XML Part** field, select the **Report** custom XML part.
5. Map the elements of the selected **Report** custom XML part and the content controls of the Word document.
6. Save the updated Word document locally as **SampleVendPaymDocReportBounded.docx**.

Review the Word template where the custom XML part is mapped to content controls

1. In the Word desktop application, open the **SampleVendPaymDocReportBounded.docx** template file.
2. Verify that the template contains the layout of the document that you want to generate as ER output. The content controls that are used as placeholders for data that ER will enter in this template at runtime are based on the mappings that are configured between elements of the **Report** custom XML part and the content controls of the Word document.

Upload the Word template where the custom XML part is mapped to content controls

1. In Finance, on the **Attachments** page, select **Delete** to remove the Word template that has no mappings between elements of the **Report** custom XML part and content controls. Select **Yes** to confirm the change.
2. Select **New > File** to add a new template file that contains mappings between elements of the **Report** custom XML part and content controls.

NOTE

You must select a document type that has been [configured](#) in the ER parameters to store templates of ER formats.

3. Select **Browse**, and then browse to and select the **SampleVendPaymDocReportBounded.docx** file that you downloaded or prepared by completing the procedure in the [Get a Word that has a custom XML part to do data mapping](#) section.
4. Select **OK**.
5. Close the **Attachments** page.
6. On the **Format designer** page, in the **Template** field, select the document that you just downloaded.
7. Select **Save**.
8. Close the **Format designer** page.

Mark the configured format as runnable

To run the draft version of the editable format, you must make it [runnable](#).

1. In Finance, on the **Configurations** page, on the Action Pane, on the **Configurations** tab, in the **Advanced settings** group, select **User parameters**.
2. In the **User parameters** dialog box, set the **Run settings** option to **Yes**, and then select **OK**.
3. Select **Edit** to make the current page editable, as required.
4. For the currently selected **Sample worksheet report** configuration, set the **Run Draft** option to **Yes**.
5. Select **Save**.

Run the format to create output in Word format

1. In Finance, go to **Accounts payable > Payments > Payment journal**.
2. In a payment journal that you entered earlier, select **Lines**.
3. On the **Vendor payments** page, select all rows in the grid.
4. Select **Payment status > None**.

	DEBIT	CREDIT	BALANCE	DEBIT	CREDIT	BALANCE
VOUCHER	2,000.00	2,000.00	0.00	3,151.10	3,151.10	0.00
JOURNAL	3,000.00	3,000.00	0.00	4,726.60	4,726.60	0.00

5. On the Action Pane, select **Generate payments**.
6. In the dialog box that appears, follow these steps:
 - a. In the **Method of payment** field, select **Electronic**.

- b. In the **Bank account** field, select **GBSI OPER**.
 - c. Select **OK**.
7. In the **Electronic report parameters** dialog box, select **OK**.
 8. The generated output is presented in Word format and contains the details of the processed payments. Analyze the generated output.

Control report
Contoso Consulting GB

Vendor account number	Vendor name	Bank	Routing number	Account number	Debit	Credit	Currency
GB_SI_000005	West Side Mart				2000		GBP
GB_SI_000001	Consumer Equipment				1000		GBP

Currency	Amount
GBP	3000.0

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Design ER configurations to fill in PDF templates

2/18/2021 • 14 minutes to read • [Edit Online](#)

The procedures in this topic are examples that show how a user in either the **System administrator** role or the **Electronic reporting developer** role can configure an Electronic reporting (ER) format that generates reports as PDF files by using fillable PDF documents as report templates. These steps can be performed in any company of Dynamics 365 Finance or Regulatory Configuration Services (RCS).

Prerequisites

Before you begin, you must have one of the following types of access, depending on the service that you use to complete the procedures in this topic:

- Access to Finance for one of the following roles:
 - Electronic reporting developer
 - Electronic reporting functional consultant
 - System administrator
- Access to RCS for one of the following roles:
 - Electronic reporting developer
 - Electronic reporting functional consultant
 - System administrator

You must also complete the [Create configuration providers and mark them as active](#) procedure.

Finally, you must download the following files from [CustomerSource](#).

CONTENT DESCRIPTION	FILE NAME
Template for the first page of the report	IntrastatReportTemplate1.pdf
Template for other pages of the report	IntrastatReportTemplate2.pdf
Sample ER format - PDF	Intrastat report (PDF).version.1.1.xml
Sample ER format - Excel	Intrastat (import from Excel).version.1.1.xml
Sample dataset	Intrastat sample data.xlsx

Design the format configuration

Get access to the list of configurations provided by Microsoft

1. Go to **Organization administration > Workspaces > Electronic reporting**.
2. Make sure that the **Litware, Inc.** provider is available and marked as active.
3. On the tile for the **Microsoft** provider, select **Repositories**.

NOTE

If a repository of the LCS type already exists, skip the remaining steps of this procedure.

4. Select **Add**.
5. In the drop-down dialog box, in the **Configuration repository type** field group, select the **LCS** option.
6. Select **Create repository**.
7. Select **OK**.

Get the model configurations provided by Microsoft

1. On the left side of the **Configuration repositories** page, select the **Show filters** button (the funnel symbol).
2. Add a filter for a value of **LCS** in the **Type** field, and use the **begins with** operator.
3. Select **Apply**.
4. Select **Open**.
5. In the tree, select **Intrastat model**.
6. On the **Versions** FastTab, select version **1**.

NOTE

If the **Import** button on the **Versions** FastTab is unavailable, skip the remaining steps of this procedure.

7. Select **Import**.
8. Select **Yes** to confirm the import of the selected version of the **Intrastat model** model configuration.

Create a new format configuration

1. In the **Electronic reporting** workspace, select the **Reporting configurations** tile.
2. In the tree, select **Intrastat model**.
3. Select **Create configuration**.

NOTE

If the **Create configuration** button isn't available, you must turn on design mode on the **Electronic reporting parameters** page that can be opened from the **Electronic reporting** workspace.

4. In the drop-down dialog box, in the **New** field group, select the **Format based on data model Intrastat** option.
5. In the **Name** field, enter **Intrastat report (PDF)**.
6. In the **Description** field, enter **Intrastat report in PDF format**.

NOTE

The active configuration provider is automatically entered. This provider will be able to maintain this configuration. Although other providers can use this configuration, they won't be able to maintain it.

7. Optional: In the **Format type** field, you can select a specific format of electronic document. If you select **PDF**, at design time, the ER Operations designer will offer just the format elements that are applicable only to documents that are generated in PDF format (**PDF\File**, **PDF\PDF Merger**, etc.). If you leave this field blank, a format of electronic document will be specified at design time in the ER Operations designer when a first format element will be added. For example, if you add the **Excel\File** as the first format element, the ER Operations designer will offer you just the format elements that are applicable only to documents that are generated in Excel format (**Excel\Cell**, **Excel\Range**, etc.). format.

8. Select **Create configuration**.

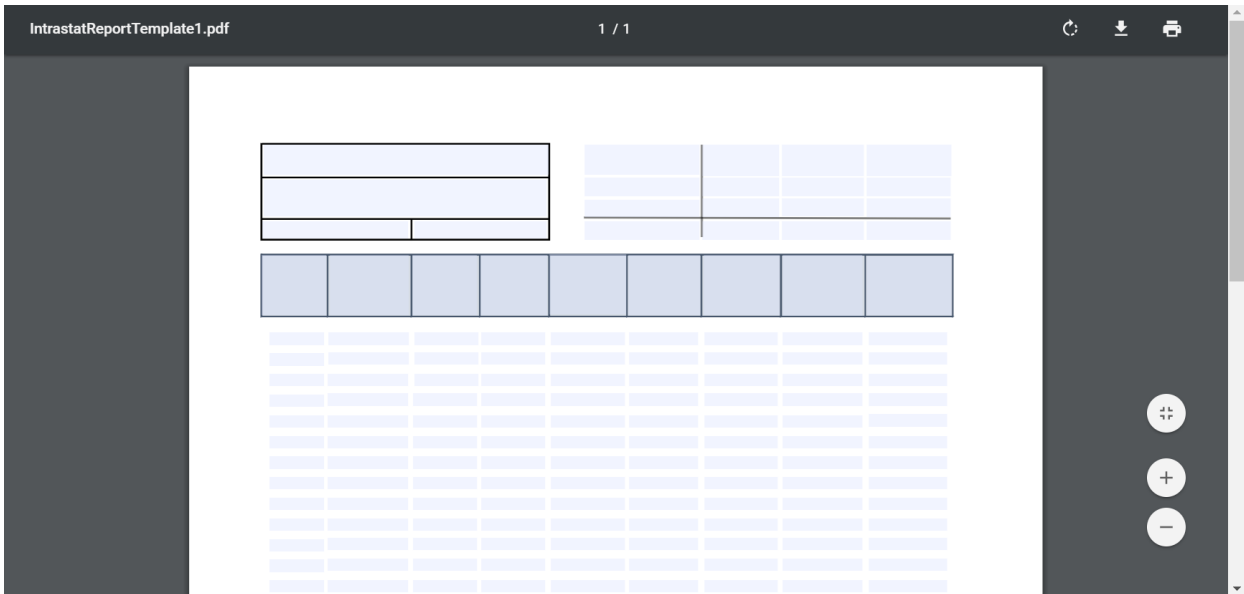

A new ER format configuration is created. You can use the draft version of this configuration to store the ER format component that is designed to generate electronic documents in PDF format.

Design the format of an electronic document

Next, in the ER format configuration that you created, you will design the ER format that generates the **Intrastat control** report in PDF format. The first page of this report must show a summary of the report and details of the foreign trade transactions that are reported on. The other pages must show only details of the foreign trade transactions that are reported on. Because the report pages that are generated must have different layouts, two different templates in PDF format will be used in the ER format.

In any PDF viewer, open the PDF templates that you downloaded. Notice that each template contains multiple fields that must be filled in. In each template, details of foreign trade transactions are presented as 42 rows, each of which has nine fields. The row number appears at the end of each field's name (for example, **Date 1...Date 42** and **Commodity 1...Commodity 42**).

The following illustration shows the PDF template for the first page of the report.

The following illustration shows the PDF template for other pages of the report.

1. On the **Configurations** page, select **Designer**.
2. Select **Add root**.
3. In the drop-down dialog box, in the tree, select **PDF > PDF Merger**.

When you select the **PDF Merger** element as the root element of the format, all PDF documents that are generated at run time will be merged into a single final PDF document. If you need only one PDF template to generate all the required documents by using the ER format that you design, you can select **PDF file** as the root element.

4. In the **Name** field, enter **Output**.
5. In the **Language preferences** field, select **User preference**. The report will be generated in the preferred language of the user who runs it.
6. In the **Culture preferences** field, select **User preference**. Values and dates that are presented on the pages of the report will be formatted based on the preferred locale of the user who runs the report.
7. Select **OK**.
8. On the Action Pane, on the **Import** tab, select **Import from PDF**.

When a fillable PDF document is imported as a template for this ER format, all the required ER format elements (**PDF file**, **Field group**, and **Field** elements) are automatically created in the format that is designed, based on the structure of the PDF document that is imported.

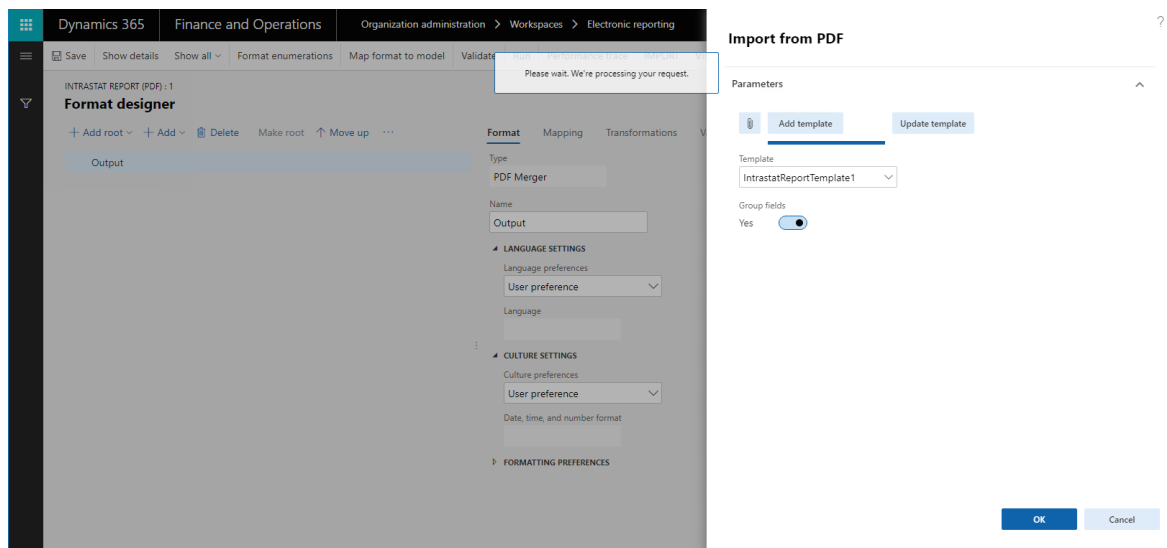

9. Select **Browse**. Navigate to and select the **IntrastatReportTemplate1.pdf** file that you downloaded earlier as a prerequisite.
10. Select **OK**.

The selected file is loaded, and the **Template** field in the **Import from PDF** dialog box is filled in.

11. Set the **Group fields** option to **Yes**. If the selected PDF document contains any field groups, they will be used to group the ER format elements that are created. A **Field group** format element will be created for this purpose.

If this option is set to **No**, the required ER format elements will be created as a flat list of elements that are nested under the **PDF File** format element that is created.

12. Select **OK**.

- In the tree, expand **Output**.

Notice that the **PDF File** component has been automatically created to manage the creation of the first page of the report that is generated at run time.

- In the tree, expand **Output > PDF File**.

Notice that the structured list of format elements has been automatically created in this ER format, based on the structure of the fillable PDF document that you imported earlier.

- In the tree, select **Output > PDF File**.

- In the **Name** field, enter **Page 1**.

This format element will be used to generate the first page of the **Intrastat control** report. That page will show a summary of the report and details of foreign trade transactions.

If you leave the **Language preferences** field blank, the **Language preferences** setting of the parent **PDF Merger** element will determine the language of the report that is generated by using this format element. You can select another value to override the setting of the parent element.

If you leave the **Culture preferences** field blank, the **Culture preferences** setting of the parent **PDF Merger** element will determine the locale of the report that is generated by using this format element. The locale determines the format of values and dates on the pages of the report. You can select another value to override the setting of the parent element.

- On the Action Pane, select the **Import** tab. Notice that the **Update from PDF** button has become available for selected format element, **PDF File**.

You can use this button to import the updated PDF template to the edited format. When the updated PDF template is imported, the list of format elements will be changed accordingly:

- For any new fields in the updated PDF template, new format elements are created in the edited ER format.
- If the updated PDF template no longer includes fields that correspond to any existing format elements in the edited ER format, those format elements are deleted from the ER format.

- On the **Format** tab, select **Attachments**.

Notice that the imported PDF document is attached to the edited ER format.

19. Continue to design this format by importing the second PDF template, adding necessary bindings to data sources, and so on.
20. Select **Save**.
21. Close the page.
22. Select **Delete**.
23. Select **Yes**.

To learn how new **PDF Merger**, **PDF File**, **Field group** and **Field** format elements can be used to generate documents in PDF format, you can import and analyze the sample ER format.

Import the format configuration

Next, you will import the sample ER format that you previously downloaded to generate the **Intradat control** report in PDF format. The first page of the report must show a summary of the report and details of the foreign trade transactions that are reported on. The other pages must show only details of the foreign trade transactions that are reported on.

1. On the **Configurations** page, select **Exchange > Load from XML file**.
2. Select **Browse**. Navigate to and select the **Intradat report (PDF).version.1.1.xml** file that you downloaded earlier as a prerequisite.
3. Select **OK**.

Analyze the format configuration

Format layout

1. On the **Configurations** page, in the tree, select **Intradat model > Intradat report (PDF)**.
2. Select **Designer**.
3. Select **Show details**.
4. In the tree, expand **Output: PDF Merger**.

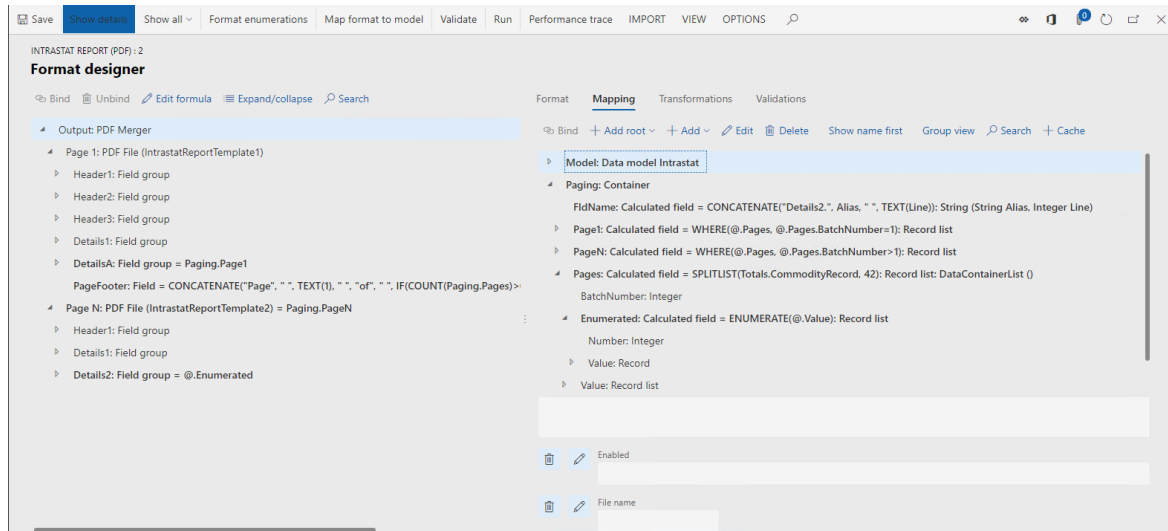

Notice that this ER format contains two **PDF File** elements, each of which uses a different PDF template. One template is used to generate the first page of the report in PDF format, and the other template is used to generate the other pages.

- In the tree, expand **Output: PDF Merger > Page 1: PDF File (IntrastatReportTemplate1)**.
- In the tree, expand **Output: PDF Merger > Page N: PDF File (IntrastatReportTemplate2)**.

Notice that, because the content of the two PDF templates differs, the structure of the nested format elements for the two **PDF File** elements also differs.

Format mapping

- On the **Format designer** page, select the **Mapping** tab.
- In the tree, expand **Paging > Pages**.

Note the following details:

- The **Output > Page 1** format element of the **PDF File** type isn't bound to any data source, and the **Enabled** expression of this format element is empty. Therefore, at run time, the **IntrastatReportTemplate1** PDF template will be filled in only one time when an individual PDF document is generated.
- The **Output > Page N** format element of the **PDF File** type is bound to the **Paging.PageN** data source of the **Record list** type, and the **Enabled** expression of this format element is empty. Therefore, at run time, the **IntrastatReportTemplate2** PDF template will be filled in for each record from the bound record list when an individual PDF document is generated.
- Because the **Page 1: PDF File** and **Page N: PDF File** format elements are children of the **Output: PDF Merger** format element, all PDF documents that are filled in will be merged into a single final PDF document.
- The **Paging.Page1** and **Paging.PageN** data sources are configured as filters of records from the **Paging.Pages** data source. This data source is configured to split the whole set of foreign trade transactions into batches. Each batch contains up to 42 records. The following ER expression is used to split the transactions into batches:

`SPLITLIST(Totals.CommodityRecord,42)`
- The **Paging.Pages** data source contains the **Paging.Pages.Enumerated** element that returns the details of each record that is included in a batch. These details include the record's sequence in the current batch (the **Paging.Pages.Enumerated.Number** field). The **Paging.Pages.Enumerated.Number** field is used in the **Name** expression of **PDF Field** format elements to dynamically generate a field name that is based on the transaction number in a batch. The field name that is generated is then used to fill in the correct PDF field in the PDF template that is used.

- The **Output > Page N > Details 2** format element of the **PDF Group** type is bound to the **Paging.PageN.Enumerated** data source (or **@.Enumerated** if the **Relative path** view mode is used) of the **Record list** type. Therefore, at run time, the nested elements of this PDF group will be filled in for each record from the bound record list. In this way, individual PDF lines are virtually generated when for each Nth of 42 records of the **Paging.PageN.Enumerated** list the following PDF fields are filled in: **Date N**, **Direction N**, **Commodity N**, etc. Therefore, in this respect, the behavior of this **Field group** format element resembles the behavior of the **XML > Sequence** and **Text > Sequence** format elements.

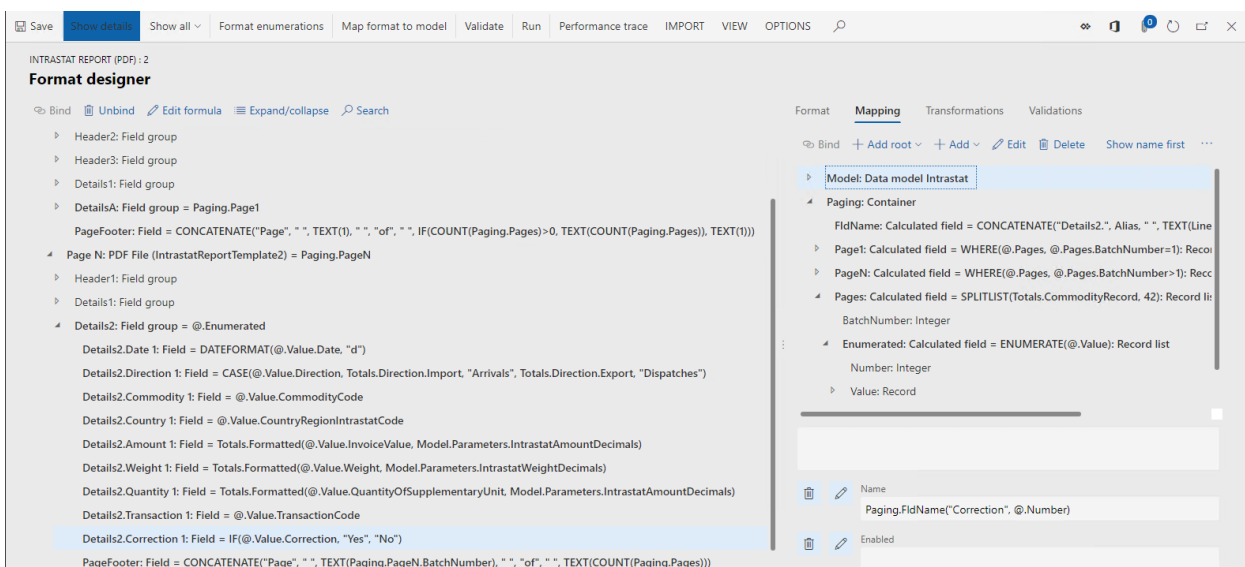

3. In the tree, expand **Output > Page N > Details2**.

4. In the tree, select **Output > Page N > Details2 > PageFooter**.

Notice that the **Name** attribute of this format element is defined as **PageFooter**. Also notice that the **Name** expression of the format element is empty.

5. In the tree, select **Output > Page N > Details2 > Correction 1**.

Notice that the **Name** attribute of this format element is defined as **Correction 1**. Also notice that the **Name** expression of the format element is defined as **Paging.FldName("Correction",@.Number)**.

Note that the **Field** format element is used to fill in an individual field of a fillable PDF document that is defined as a template of the parent **PDF File** format element. The binding of the **PDF File** format element or its nested elements, if it has any nested elements, specifies the value that is entered in corresponding PDF fields. Different properties of the **Field** format element can be used to specify which PDF field is filled in by an individual format element:

- On the **Format** tab, the **Name** attribute of the format element
- On the **Mapping** tab, the **Name** expression of the format element

Because both properties are optional for a **Field** format element, the following rules are applied to specify the target PDF field:

- If the **Name** attribute is blank, and the **Name** expression returns an empty string at run time, an exception is thrown at run time to notify the user that a PDF field can't be found in the PDF template that is being used to fill in the PDF document.
- If the **Name** attribute is defined, and the **Name** expression is blank, the PDF field that has the same name as the **Name** attribute of the format element is filled in.
- If the **Name** attribute is defined, and the **Name** expression is configured, the PDF field that has the same name as the value that is returned by the **Name** expression of the format element is filled in.

NOTE

A PDF check box can be filled in as selected in the following ways:

- When the corresponding **Field** format element is bound to a data source field of the **Boolean** data type that has the **True** value
- When the corresponding **Field** format element contains a nested **String** format element that is bound to a data source field that has a text value of **1**, **True**, or **Yes**

Run the format configuration

Import the format configuration

Next, you will load the **Intrastat (import from Excel)** sample ER format. This format is designed to parse a user-selected Microsoft Excel workbook that simulates foreign trade transactions.

1. On the **Configurations** page, select **Exchange > Load from XML file**.
2. Select **Browse**. Navigate to and select the **Intrastat (import from Excel).version.1.1.xml** file that you downloaded earlier as a prerequisite.
3. Select **OK**.
4. In the tree, select **Intrastat model > Intrastat (import from Excel)**.
5. Select **Edit**.
6. Set the **Default for model mapping** option to **Yes**.

NOTE

If you previously set the **Default for model mapping** option to **Yes** for the **Intrastat model** configuration or another configuration that is nested under the **Intrastat model** configuration, set this option to **No**.

When the **Default for model mapping** option is set to **Yes**, the imported **Intrastat (import from Excel)** ER format is assigned as the default data source for the **Intrastat report (PDF)** format configuration. Then, when the **Intrastat report (PDF)** format configuration is run, the content of the Excel workbook that is parsed by the **Intrastat (import from Excel)** ER format will simulate foreign trade transactions that must be reported. The following illustration shows an example of an Excel workbook.

	A	B	C	D	E	F	G	H	I	J	K	L	M	N	O	P

Run the format configuration

1. On the Configurations page, in the tree, select **Intrastat model > Intrastat report (PDF)**.
2. Select **Run**.
3. Select **Browse**. Navigate to and select the **Intrastat sample data.xlsx** file that you downloaded earlier as a prerequisite.
4. Select **OK**.
5. In the **Report direction** field, select **Both** to fill in all transactions from the imported Excel workbook in the PDF report that is generated.
6. Select **OK**.
7. Review the PDF document that is generated.

The follow illustration shows an example of the first page of the report that is generated.

out.Admin.pdf 1 / 3

Intrastat report				Number of lines	Amount	Weight	
Contoso Entertainment System Germany				Subtotal for arrivals	76	15946.33	19061.00
Reporting date				Subtotal for dispatches	24	5103.17	5989.00
2/4/2019				Total for report	100	21049.50	25050.00

Embed images and shapes in documents that you generate by using ER

2/18/2021 • 6 minutes to read • [Edit Online](#)

You can use the Electronic reporting (ER) tool to design reports that you can run to generate required electronic documents. You can use Microsoft Excel or Microsoft Word documents to specify the layout of a report. The ER Operations designer lets you attach the Excel or Word document as a template for the report. The named elements in the attached template are associated with the format elements of the ER report. Format elements of the report are bound to data sources. These elements specify the data that will be entered, at run time, in the documents that are generated.

This new functionality goes beyond existing ER capabilities for creating documents in Microsoft Office formats. For more information, play the following task guides. You can find these task guides under the 7.5.4.3 Acquire/Develop IT service/solution components (10677) business process.

- ER Design a configuration for generating reports in OPENXML format
- ER Design a configuration for generating reports in Microsoft WORD format

Embed an image in an Excel document

First, you must add a placeholder for the image in an Excel document. Open an Excel workbook, and add a picture as a placeholder for the image that you will add later. Then use the ER tool to add a new ER format configuration to include the report that you're designing. Attach the Excel workbook as a template for the format of the report, and then import the content of the workbook into the ER format. The format definition will be created automatically. The image placeholder that you added will be included in the ER format definition as a **CELL** element.

NOTE

You can manually specify the format definition instead of importing it. When you save your changes, the format will be validated.

Next, bind the **CELL** element of the ER format to the field from the format's data source that provides the picture's data in binary format at run time. When an ER data model is used as a format's data source, the data type of the field must be **CONTAINER**. Currently, an ER data model field that has the **CONTAINER** data type can be bound to several types of data sources that return images in binary format. You can access a field in a data table and a file that is attached to the data table's record by using the Document management framework.

IMPORTANT

- If you want to fill the image placeholder in the document that you're creating by using the Excel template, the ER format must contain the **CELL** element that refers to the named picture element in the Excel template. Otherwise, no image placeholder will appear in the report's output. If the binding of a **CELL** element returns no data at run time, the document that is generated will show the image placeholder from the template. To hide an image in the document that you're generating, define a **CELL** element, and specify that the **Enabling** expression should return a value of **FALSE**.
- In the Excel template, use a unique name for every element. These elements include pictures and cells. If you duplicate an element name, the content of the report that is generated will be ambiguous and confusing.

Embed a shape in an Excel document

First, you must add a placeholder for the shape in an Excel document. Open an Excel workbook, and select **Shape**, **Text box**, or **WordArt** as a placeholder for the shape. Then use the ER tool to add a new ER format configuration to include the report that you're designing. Attach the Excel workbook as a template for the format of the report, and then import the content of the workbook into the ER format. The format definition will be created automatically. The shape placeholder that you added will be included in the ER format definition as a **CELL** element that refers to the named Excel shape element.

NOTE

You can manually specify the format definition instead of importing it. When you save your changes, the format will be validated.

Next, bind the **CELL** element in the ER format to the field from the format's data source that provides the data at run time. This data can be converted to a text string. When the **CELL** element in the ER format refers to a shape element in the Excel template that supports text, the text that is provided through this binding at run time will be shown in a shape in the document that is generated.

IMPORTANT

- If you want to use the Excel template that includes the shape placeholder to generate a new document, the ER format must contain a **CELL** element that refers to the Excel shape element. Otherwise, no shape placeholder will appear in the report's output. If the binding of a **CELL** element that refers to the named Excel shape element returns no data at run time, the document that is generated will show the text of the shape placeholder from the Excel template. To hide a shape in the document that you're generating, define a **CELL** element that refers to the named Excel shape element, and specify that the **Enabling** expression should return a value of **FALSE**.
- In the Excel template, use a unique name for every element. These elements include shapes and cells. If you duplicate an element name, the content of the report that is generated will be ambiguous and confusing.

Embed an image in a Word document

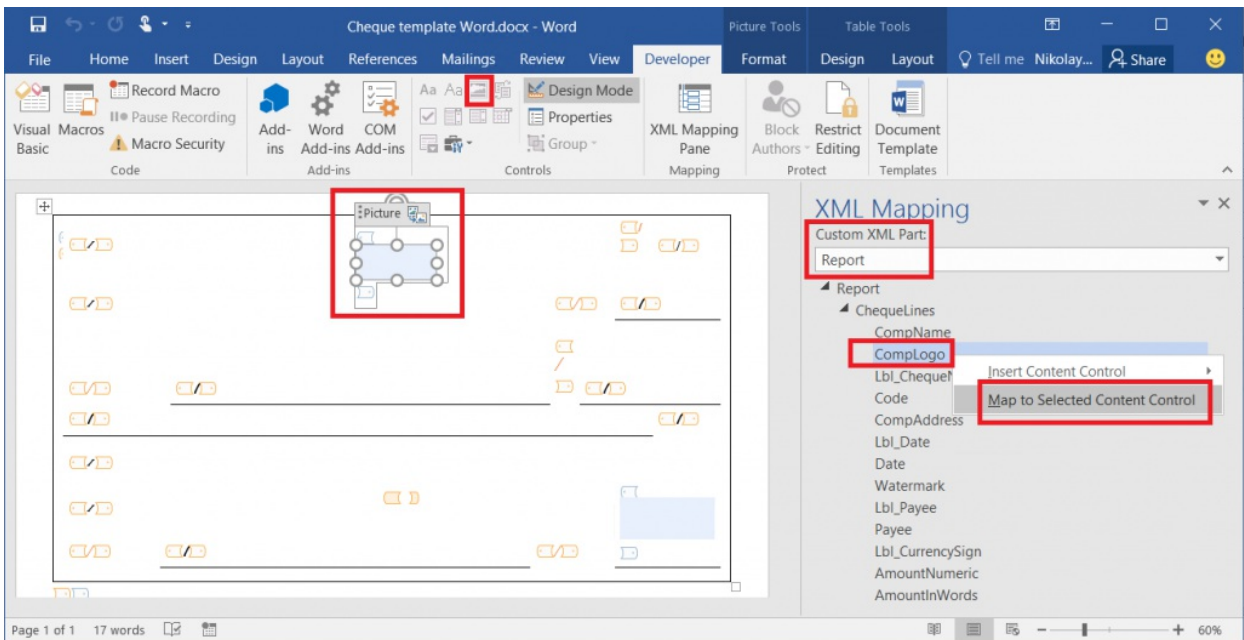

IMPORTANT

You can reuse the ER format that uses an Excel template to create documents that include embedded images. In the ER format, make sure that a name is specified for the **CELL** element that refers to a named picture element in Excel, and that is bound to a data source that returns a picture at run time.

First, you must configure the Word document's layout. Use the **Picture Content** control to create a placeholder for the embedded image. To access this control, you must first make the **Developer** tab visible on the Word Ribbon.

Next, delete the Excel template from the ER format, and attach the Word template document. Update the reference to the template, and save your changes. The structure of the current ER format is saved to the Word template as a new custom XML part that is named **Report**.

Next, save the Word template for the current ER format to your local computer. Open the template, and open the **XML Mapping** pane. Find the custom XML part that is named **Report**, and then point to the **CELL** element in the ER report that is bound to a data source that returns an image in binary format. Map this XML part's item to the selected **Picture Content** control, and save your changes.

Finally, delete the Word template from the ER format, and attach the Word document that includes the mapped custom XML parts. Update the format reference to the template, and save the changes that you made to this ER format.

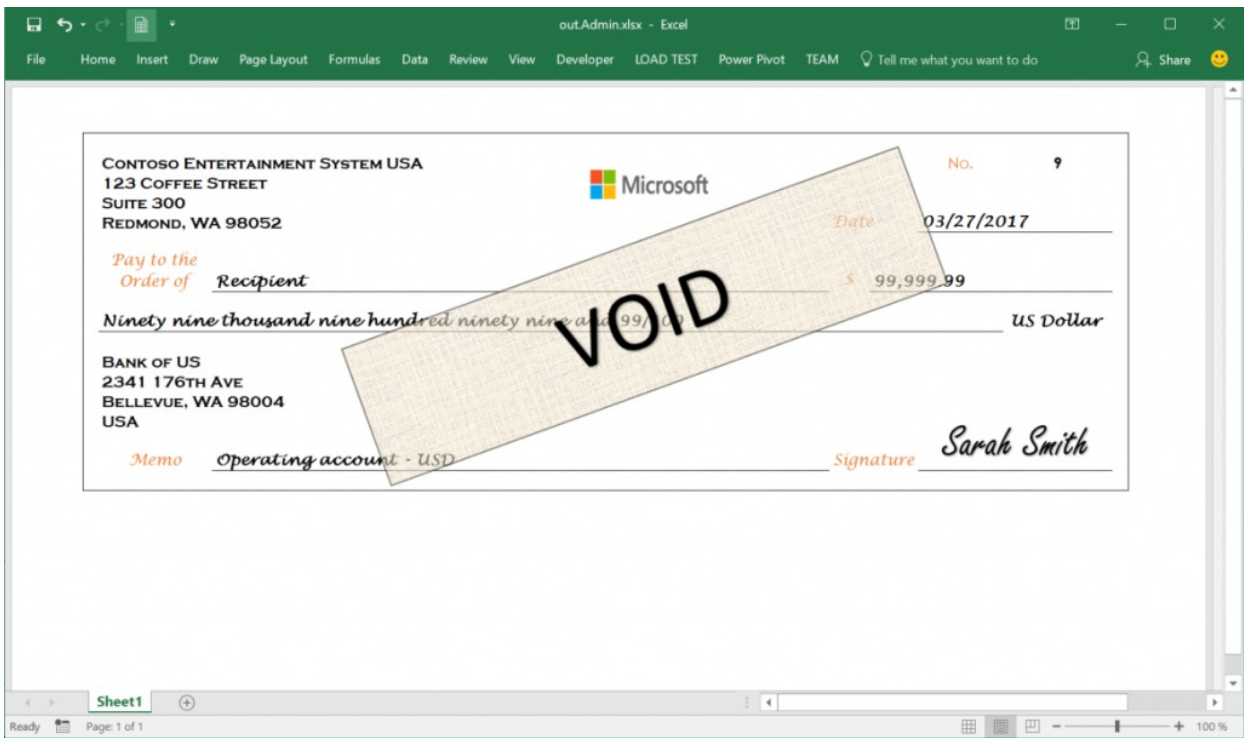

More information

To become familiar with the details of this feature, play the set of task guides, **ER Make reports in MS Office formats with embedded images**. These task guides show how you can embed the images of a company logo and an authorized person's signature in the payment checks that are generated by using the ER tool in Excel and Word documents.

The following table lists the files that are required in order to complete the **ER Make reports in MS Office formats with embedded images** task guides. [Download](#) and save the files to your local computer.

DESCRIPTION	FILE NAME
ER data model configuration	Model for cheques.xml
ER format configuration	Cheques printing format.xml
Company logo image	Company logo.png
Signature image	Signature image.png
Alternative signature image	Signature image 2.png
Microsoft Word template for printing payment checks	Cheque template Word.docx
Microsoft Excel template for printing payment checks	Cheque template.xlsx

The following graphic provides an example of the test printout for a payment check that is generated from the Excel template.

Design configurations to generate reports in Office format that have embedded images

2/18/2021 • 3 minutes to read • [Edit Online](#)

To complete the steps in this procedure, first complete the procedure, "ER Create a configuration provider and mark it as active." This procedure explains how to design Electronic reporting (ER) configurations to generate a Microsoft Excel or Word document that contains embedded images. In this procedure, you will create the required ER configurations for the sample company, Litware, Inc. These steps can be completed using the USMF dataset. This procedure is created for users with the assigned role of system administrator or electronic reporting developer. Before you begin, download and save the files listed in the Help topic, [Embed images and shapes in documents that you generate by using ER](#). The files are: Model for cheques.xml, Cheques printing format.xml, Company logo.png, Signature image.png, Signature image 2.png, and Cheque template Word.docx.

Verify prerequisites

1. Go to Organization administration > Workspaces > Electronic reporting.
2. Make sure that the configuration provider for the sample company, Litware, Inc., is available and marked as Active. If you don't see this configuration provider, complete the steps in the procedure, "Create a configuration provider and mark it as active."
3. Click Reporting configurations.

Add a new ER model configuration

1. Instead of creating a new model, you can load the ER model configuration file (Model for cheques.xml) that you saved earlier. This file contains the sample data model for payment cheques and the mapping of the data model to the data components of the Dynamics 365 for Operations application.
2. On the Versions FastTab, click Exchange.
3. Click Load from XML file.
4. Click Browse, and then select Model for cheques.xml.
5. Click OK.
6. The loaded model will be used as a data source of information to generate documents that contain images in Excel and Word.

Add a new ER format configuration

1. Instead of creating a new format, you can load the ER format configuration file (Cheques printing format.xml) that you saved earlier. This file contains the sample layout of the format to print cheques using the pre-printed form and the mapping of this format to the 'Model for cheques' data model.
2. Click Exchange.
3. Click Load from XML file.
4. Click Browse and select the Cheques printing format.xml file.
5. Click OK.
6. In the tree, expand 'Model for cheques'.
7. In the tree, select 'Model for cheques\Cheques printing format'.
8. The loaded format will be used to generate documents that contain images in Excel and Word.

Configure ER user parameters

1. On the Action Pane, click Configurations.
2. Click User parameters.
3. Select Yes in the Run settings field.
Turn on the 'Run draft' flag to start the draft version of the selected format instead of the completed one.
4. Click OK.

Configure Cash & bank management parameters

1. Go to Cash and bank management > Bank accounts > Bank accounts.
2. Use the Quick Filter to filter on the Bank account field with a value of 'USMF OPER'.
3. On the Action Pane, click Set up.
4. Click Check.
5. Expand the Setup section.
6. Click Edit.
7. Select Yes in the Company logo field.
8. Click Company logo.
9. Click Change.
10. Click Browse and select the file that you downloaded earlier, Company logo.png.
11. Click Save.
12. Close the page.
13. Expand the Signature section.
14. Select Yes in the Print first signature field.
15. Click Change.
16. Click Browse and select the file that you downloaded earlier, Signature image.png.
17. Expand the Copies section.
18. In the Watermark field, select an option.
19. Select Yes in the Generic electronic Export format field.
20. Select 'Cheques printing form' configuration.
21. Now the selected ER format will be used for printing cheques.
22. Click Attach.
23. Click New.
24. Click File.
25. Click Browse and select the file that you downloaded earlier, Signature image 2.png.
26. Close the page.
27. Close the page.
28. Close the page.
29. Go to Cash and bank management > Setup > Cash and bank management parameters.
30. Select Yes in the Allow prenote creation on inactive bank accounts: field.
31. Click Save.
32. Close the page.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Review configurations to generate reports in Office format that have embedded images

2/18/2021 • 3 minutes to read • [Edit Online](#)

To complete these steps, you must first complete the steps in the "ER Make reports in MS Office formats with embedded images (Part 1: Set up parameters)" task guide.

This procedure shows how to design Electronic reporting (ER) configurations to generate electronic documents that contain embedded images in Microsoft Excel and Microsoft Word. In this example, you will review ER configurations for the sample company Litware, Inc.

This procedure is intended for users who have the System administrator or Electronic reporting developer role assigned to them. The steps can be completed by using the USMF data set.

Review the imported data model

1. Go to Organization administration > Electronic reporting > Configurations.
2. In the tree, select 'Model for cheques'.
3. Click Designer.
 - This model is designed to represent payment cheques from the business standpoint and the mapping of this model to the application's data sources. Review this model by the ER Operations designer. Note the attributes of the model elements that are presented: structure, name, description, data type, and so on.
4. In the tree, expand 'root'.
5. In the tree, select 'root\cheques'.
6. In the tree, expand 'root\cheques'.
7. In the tree, expand 'root\cheques\attributes'.
8. In the tree, expand 'root\payer'.
9. In the tree, select 'root\istestrun'.
10. In the tree, select 'root\layout'.
 - The layout element of this model represents the details of the printing cheque form layout for the selected bank account. It also includes two nodes of the Container data type to store images.
11. In the tree, expand 'root\layout'.
12. In the tree, select 'root\layout\company logo'.
13. In the tree, expand 'root\layout\company logo'.
14. In the tree, select 'root\layout\company logo\image'.
15. In the tree, select 'root\layout\company logo\isprinted'.
16. In the tree, select 'root\layout\signature'.
17. In the tree, expand 'root\layout\signature'.
18. In the tree, select 'root\layout\signature\image'.
19. In the tree, select 'root\layout\signature\isprinted'.
 - Note that two image data model elements are bound to the fields of the tables that contain images of the company logo and the authorized person's signature in binary format.
20. In the tree, expand 'root\layout\watermark'.
21. Click Map model to datasource.
22. Click Designer.

23. In the tree, expand 'chequeselected'.
24. In the tree, expand 'layout'.
25. In the tree, expand 'layout\company logo'.
26. In the tree, expand 'layout\signature'.
27. In the tree, expand 'layout\watermark'.
28. Toggle 'Show details' on.
 - Note that the cheques data model element is bound to the TmpChequePrintout table that, at runtime, will contain records for cheques that the user has selected for printing.
29. Close the page.
30. Close the page.
31. Close the page.

Review the imported format

1. In the tree, expand 'Model for cheques'.
2. In the tree, select 'Model for cheques\Cheques printing format'.
3. Click Designer.
4. Click Attachments.
5. Click Open.
 - Open the attached report's template in Excel.
 - Review the attached report's Excel template that will be used to print cheques. The template contains two cheques per page and is designed to print cheques to the preprinted form. Note that two blank images are embedded. These blank images are for the company logo and the signature of the person who is authorizing a payment. Verify that the images are named CompLogo and SignatureImage, respectively, in Excel.
6. Close the page.
7. In the tree, expand 'Report'.
8. In the tree, expand 'Report\ChequeLines'.
9. In the tree, select 'Report\ChequeLines\CompLogo'.
10. Toggle 'Show details' on.
 - Note that the 'CompLogo' format's cell element represents the Excel item that is used to populate the company logo image in the report. This format element is bound to the image data model element that, at runtime, contains a company logo image in binary format.
11. Click the Mapping tab.
12. Click Edit enabled.
 - Note that you can make the 'CompLogo' format's cell element so that it's no longer enabled. In this case, the associated Excel image element will hide a company logo in the generated report. If the enabled expression returns TRUE and the defined binding brings no image, the associated Excel image element will show an image that has been saved in the Excel template.
13. Close the page.
14. In the tree, expand 'labels: Container'.
 - Some labels that are presented in the preprinted cheque form will be included in the report when it's created for testing purposes. However, those labels won't be printed during real printing, because the preprinted form already includes them.
15. Close the page.

NOTE

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Generate reports in Office format that have embedded images

2/18/2021 • 3 minutes to read • [Edit Online](#)

The following steps explain how a user playing either 'System administrator' or 'Electronic reporting developer' role can design Electronic reporting (ER) configurations to generate electronic documents in MS office formats (Excel and Word) containing embedded images.

In this example, you will use created ER configurations for sample company, 'Litware, Inc.'. To complete these steps, you must first complete the steps in the "ER Make reports in MS Office formats with embedded images (Part 2: Review configurations)" task guide. These steps can be performed in 'USMF' company.

Run format with initial model mapping

1. Go to Cash and bank management > Bank accounts > Bank accounts.
2. Use the Quick Filter to filter on the Bank account field with a value of 'USMF OPER'.
3. On the Action Pane, click Set up.
4. Click Check.
5. Click Print test.
 - Run the format for testing purposes.
6. Select Yes in the Negotiable check format field.
7. Click OK.
 - Review the created output. The company logo is presented in the report as well as the authorized person's signature. The signature image is taken from the field of the 'Container' data type of the cheque layout record that is associated with the selected bank account.
8. Expand the Copies section.
9. Click Edit.
10. In the Watermark field, enter 'Print watermark as Void'.
 - Change the watermark layout setting to show the watermark text in generating document in an Excel shape element.
11. Click Print test.
12. Click OK.
 - Review the created output. The watermark is shown in the created report in accordance to the selection option.
13. Close the page.
14. On the Action Pane, click Manage payments.
15. Click Checks.
16. Click Show filters.
17. Apply the following filters: Enter a filter value of "381","385","389" on the "Check number" field using the "is one of" filter operator.
18. In the list, mark all rows.
19. Click Print check copy.
 - Run the format to reprint the selected cheques.
 - Review the created output. The selected cheques have been reprinted. The company logo and labels are not printed out since they are presented on the pre-printed form.

Modify the mapping of the imported data model

1. Close the page.
2. Close the page.
3. Go to Organization administration > Electronic reporting > Configurations.
4. In the tree, select 'Model for cheques'.
5. Click Designer.
6. Click Map model to datasource.
7. Click Designer.
 - We will change the binding of the data model's signature item to get the signature image from the file that has been attached to the cheque layout record that is associated with the selected bank account.
8. Turn off Show details.
9. In the tree, expand 'layout'.
10. In the tree, expand 'layout\signature'.
11. In the tree, select 'layout\signature\image = chequesaccount.<Relations'.BankChequeLayout.Signature1Bmp'.
12. In the tree, expand 'chequesaccount'.
13. In the tree, expand 'chequesaccount<Relations'.
14. In the tree, expand 'chequesaccount<Relations\BankChequeLayout'.
15. In the tree, expand 'chequesaccount<Relations\BankChequeLayout<Relations'.
16. In the tree, expand 'chequesaccount<Relations\BankChequeLayout<Relations<Documents'.
17. In the tree, select 'chequesaccount<Relations\BankChequeLayout<Relations<Documents\getFileContentAsContainer()'.
18. Click Bind.
19. Click Save.
20. Close the page.
21. Close the page.
22. Close the page.
23. Close the page.

Run format using the adjusted model mapping

1. Go to Cash and bank management > Bank accounts > Bank accounts.
2. Use the Quick Filter to find records. For example, filter on the Bank account field with a value of 'USMF OPER'.
3. On the Action Pane, click Set up.
4. Click Check.
5. Click Print test.
6. Click OK.
 - Review the created output. The image from the Document Management attachment is presented as the signature of an authorized person.

Use MS Word document as a template in the imported format

1. Close the page.
2. Close the page.
3. Go to Organization administration > Electronic reporting > Configurations.
4. In the tree, expand 'Model for cheques'.
5. In the tree, select 'Model for cheques\Cheques printing format'.

6. Click Designer.
7. Click Attachments.
8. Click Delete.
9. Click Yes.
10. Click New.
11. Click File.
 - Click Browse and select the downloaded in advance 'Cheque template Word.docx' file.
12. Close the page.
13. In the Template field, enter or select a value.
14. Click Save.
15. Close the page.
16. Click Edit.
17. Select Yes in the Run Draft field.
18. Close the page.
19. Go to Cash and bank management > Bank accounts > Bank accounts.
20. Use the Quick Filter to filter on the Bank account field with a value of 'USMF OPER'.
21. Click Check.
22. Click Print test.
23. Click OK.
 - Review the created output. The output has been generated as a Word document with embedded images presenting the company logo, the signature of an authorized person and the selected text of the watermark.

Modify Electronic reporting formats by reapplying Excel templates

2/18/2021 • 2 minutes to read • [Edit Online](#)

The Electronic reporting (ER) tool is used to generate business documents in an electronic format. To generate a business document, you must create an ER format, and then use the ER designer to define the layout of the business document and specify the data that should be included in it. You can then run the ER format to generate the business document.

The ER tool can be used to generate business documents as Microsoft Excel files. You can use an Excel document as a template for these documents. To define the document layout in the ER designer, you can import the contents of the Excel document that you want to use as a template into the defined ER format. For more details, and to practice this scenario, play the task guide **ER Design a configuration for generating reports in OPENXML format** (part of the 7.5.4.3 Acquire/Develop IT service/solution components (10677) business process).

If you edit the Excel document that is used as a template for a business document, new ER functionality lets you reapply the updated template to the ER format. The ER format is then updated so that it adheres to the updated template. For more details about this functionality, play the task guide **ER Modify a format by reapplying an Excel template** (part of the 7.5.5.3 Acquire/Develop IT service/solution components (10683) business process). In the task guide step where you import an updated template, use the modified template of the Payment Report Excel file, SampleVendPaymWsReport2, as a template.

NOTE

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Define the dependency of ER configurations on other components

2/18/2021 • 6 minutes to read • [Edit Online](#)

To complete these steps, you must first complete the steps in the task guide, ER Manage model mapping configurations, and you must have access to Microsoft Dynamics Lifecycle Services (LCS).

This procedure shows how to design an Electronic reporting (ER) configuration and specify its dependency from other software components, so that you can help guarantee that the configuration is correctly downloaded to a specific version of Finance and Operations. In this example, you will create required ER configurations for the sample company Litware, Inc.

This procedure is intended for users who have the System administrator or Electronic reporting developer role assigned to them. The steps can be performed in any company, because ER configurations are shared among companies.

1. Go to Organization administration > Electronic reporting > Configurations.
 - Make sure that the configurations tree contains the 'Sample data model' configuration and subordinate items. Otherwise, complete the steps in the task guide, ER Manage model mapping configurations, and then start this guide again.

Define the dependency of ER configurations from other components

1. In the tree, expand 'Sample data model'.
2. In the tree, select 'Sample data model\Sample mapping'.
 - We selected the draft version of the 'Sample mapping' model mapping configuration. We will now define its dependency from other software components. This step is considered a prerequisite for controlling the download of this configuration's version from an ER repository and any further use of this version.
3. Expand the Prerequisites section.
 - Note that the 'Implementations' prerequisites group has been added automatically at this stage. This group contains the prerequisite component that refers to the data model configuration and has the Implementation flag turned on. This flag indicates that the 'Sample mapping' mapping configuration is considered the implementation of the 'Sample data model' data model. This component will force ER to download the 'Sample mapping' mapping configuration from an ER repository whenever the 'Sample data model' model configuration is downloaded.
4. Click Edit.
 - A single dependency of the current version of a configuration from a software component can be specified by using the definition of the component's type, and either the component version or a range of component versions.
 - Desired dependencies can be grouped together. When the 'All of' grouping type is selected, the dependency condition of this group is considered satisfied when each dependency condition from this group and subordinate group is satisfied. When the 'One of' grouping type is selected, the dependency condition of this group is considered satisfied when at least one dependency condition from this group is satisfied.
5. Click New.
6. Select Product prerequisite component.
7. Select Microsoft Dynamics 365 for Operations (1611).

8. In the Version field, type '[7.1.1541.3036,8)'.
 - [7.1.1541.3036,8)
 - Dependencies that you enter will be evaluated when this configuration is downloaded from any ER repository. This configuration version will be downloaded from the ER repository when version 1 of the 'Sample data model' configuration is either already in place or downloaded in advance. If it's downloaded in advance, it must be completed in Finance and Operations version 7.1.1541.3036 or later, but must not exceed major version 8.
9. Click Save.
10. Close the page.
11. Click Change status.
12. Click Complete.
13. Click OK.
14. In the tree, select 'Sample data model\Sample mapping (alternative)'.- 15. Click Edit.
- 16. Click New.
- 17. Select Product prerequisite component.
- 18. Select Microsoft Dynamics AX 7.0 RTW.
- 19. In the Version field, type '[7.0.1265.3015,7.1)'.
 - [7.0.1265.3015,7.1)
 - Dependencies will be evaluated when the configuration is downloaded from any ER repository. This configuration version will be downloaded from the ER repository when version 1 of the 'Sample data model' configuration is either already in place or downloaded in advance. If it's downloaded in advance, it must be completed in Microsoft Dynamics 365 for Finance and Operations, Enterprise edition, the version of which must be 7.0.1265.3015 or later, but must not exceed minor version 1.
- 20. Click Save.
- 21. Close the page.
- 22. Click Change status.
- 23. Click Complete.
- 24. Click OK.

Configure the ER repository

1. Close the page.
2. Go to Organization administration > Workspaces > Electronic reporting.
 - Open the list of ER repositories for the current ER provider, Litware, Inc.
3. In the list, mark the selected row.
4. Click Repositories.
5. Click Show filters.
6. Enter a filter value of "LCS" on the "Type name" field using the "contains" filter operator.
 - If the LCS repository is already registered for the current ER provider, you can skip the remaining steps in this sub-task. If the LCS repository isn't already registered, complete the remaining steps.
7. Click Add to open the drop dialog.
8. In the Configuration repository type field, enter 'LCS'.
9. Click Create repository.
10. In the Project field, enter or select a value.
 - Select the desired LCS project from the lookup of the 'Project' field.
11. Click OK.
12. Close the page.

Upload configurations to LCS

1. Click Reporting configurations.
2. In the tree, select 'Sample data model'.
3. Select the completed version of this configuration.
4. Click Change status.
5. Click Share.
6. Click OK.
 - Version 1 of this model configuration has been uploaded to LCS by using the LCS project for the ER repository that was previously configured.
7. In the tree, expand 'Sample data model'.
8. In the tree, select 'Sample data model\Sample mapping'.
9. Select the completed version of this configuration.
10. Click Change status.
11. Click Share.
12. Click OK.
 - Version 1.1 of this model mapping configuration has been uploaded to LCS by using the LCS project for the ER repository that was previously configured.
13. In the tree, select 'Sample data model\Sample mapping (alternative)'.
14. Select the completed version of this configuration.
15. Click Change status.
16. Click Share.
17. Click OK.
 - Version 1.1 of this model mapping configuration has been uploaded to LCS by using the LCS project for the ER repository that was previously configured.

Evaluate ER configuration dependencies

We will delete created configurations from the system and download them back from the LCS repository.

1. In the tree, select 'Sample data model\Sample mapping'.
2. Click Delete.
3. Click Yes.
4. In the tree, select 'Sample data model\Sample mapping (alternative)'.
5. Click Delete.
6. Click Yes.
7. In the tree, select 'Sample data model\Sample format'.
8. Click Delete.
9. Click Yes.
10. In the tree, select 'Sample data model'.
11. Click Delete.
12. Click Yes.
13. Close the page.
 - Open the list of ER repositories for the current ER provider, Litware, Inc.
14. Click Repositories.
15. Click Show filters.
16. Enter a filter value of "LCS" on the "Type name" field using the "contains" filter operator.
17. Click Open.

18. In the tree, select 'Sample data model'.
 - Note that you can view an evaluation of whether prerequisite conditions have been satisfied for each version of the ER configurations for the current repository. To view this evaluation, click Check prerequisites.
19. Click Check prerequisites.
20. Click Import.
21. Click Yes.
22. Close the page.
23. Close the page.
24. Close the page.
25. Go to Organization administration > Electronic reporting > Configurations.
26. In the tree, expand 'Sample data model'.
 - Note that the model 'Sample mapping' mapping configuration has been downloaded together with the selected data model configuration. The two files are downloaded together because 'Sample mapping' has been defined as implementing the selected data model, and because it's applicable for the application. The 'Sample mapping (alternative)' configuration hasn't been downloaded because the condition for the required application version isn't satisfied.
 - If you sign in to Finance and Operations, register the same provider, access the same LCS project, and download the same data model configuration, the 'Sample mapping (alternative)' configuration will download, whereas the 'Sample mapping' configuration will be skipped.

NOTE

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

ER Use financial dimensions as a data source (Part 1 - Design data model)

2/18/2021 • 2 minutes to read • [Edit Online](#)

The following steps explain how either a system administrator or electronic reporting developer can configure an Electronic reporting (ER) model to use financial dimensions as a data source for ER reports. These steps can be performed in any company.

To complete these steps, you must first complete the steps in the procedure, "Create a configuration provider and mark it as active".

Create a new data model

1. Go to Organization administration > Workspaces > Electronic reporting.
 - Make sure that the "Litware, Inc." provider is available and marked as active.
2. Click Reporting configurations.
3. Click Create configuration to open the drop dialog.
4. In the Name field, type 'Financial dimensions sample model'.
5. Click Create configuration.
6. Click Designer.
7. Click New to open the drop dialog.
8. In the Name field, type 'Entry'.
9. Click Add.
10. Click New to open the drop dialog.
11. In the Name field, type 'Company'.
12. Click Add.
 - We will add to our model a new record list. This list will expose (for any ER reports using this model as data source) the settings of selected financial dimensions. Each financial dimension will be presented in this list as a record with appropriate fields representing dimension's setting.
13. Click New to open the drop dialog.
14. In the Name field, type 'Dimensions setting'.
15. In the Item type field, select 'Record list'.
16. Click Add.
17. Click New to open the drop dialog.
18. In the Name field, type 'Code'.
19. In the Item type field, select 'String'.
20. Click Add.
21. Click New to open the drop dialog.
22. In the Name field, type 'Name'.
23. Click Add.
24. In the tree, select 'Entry'.
25. Click New to open the drop dialog.
26. In the Name field, type 'Journal'.
27. In the Item type field, select 'Record list'.
28. Click Add.

29. Click New to open the drop dialog.
30. In the Name field, type 'Batch'.
31. In the Item type field, select 'String'.
32. Click Add.
33. Click New to open the drop dialog.
34. In the Name field, type 'Transaction'.
35. In the Item type field, select 'Record list'.
36. Click Add.
37. Click New to open the drop dialog.
38. In the Name field, type 'Date'.
39. In the Item type field, select 'Date'.
40. Click Add.
41. Click New to open the drop dialog.
42. In the Name field, type 'Debit'.
43. In the Item type field, select 'Real'.
44. Click Add.
45. Click New to open the drop dialog.
46. In the Name field, type 'Credit'.
47. Click Add.
48. Click New to open the drop dialog.
49. In the Name field, type 'Currency'.
50. In the Item type field, select 'String'.
51. Click Add.
52. Click New to open the drop dialog.
53. In the Name field, type 'Voucher'.
54. Click Add.
55. Click New to open the drop dialog.
56. In the Name field, type 'Dimensions data'.
57. In the Item type field, select 'Record list'.
58. Click Add.
 - We added to our model a new record list. This list will expose (for any ER reports using this model as data source) the values of selected financial dimensions. Each financial dimension will be presented in this list as a record with appropriate fields representing dimension's values. Dimension name will be also presented in this record as a field to be used, if needed, for selection purposes.
59. Click New to open the drop dialog.
60. In the Name field, type 'Code'.
61. In the Item type field, select 'String'.
62. Click Add.
63. Click New to open the drop dialog.
64. In the Name field, type 'Description'.
65. Click Add.
66. Click New to open the drop dialog.
67. In the Name field, type 'Name'.
68. Click Add.
69. Click Save.
70. Close the page.

ER Use financial dimensions as a data source (Part 2 - Model mapping)

2/18/2021 • 4 minutes to read • [Edit Online](#)

The following steps explain how a user assigned to the system administrator or electronic reporting developer role can configure an Electronic reporting (ER) model to use financial dimensions as a data source for ER reports. These steps can be performed in any company.

To complete these steps, you must first complete the steps in the "ER Use financial dimensions as a data source (Part 1: Design data model)" procedure.

Add required data sources to model mapping

1. Go to Organization administration > Electronic reporting > Configurations.
2. In the tree, select 'Financial dimensions sample model'.
3. Click Designer.
4. Click Map model to datasource.
5. Click New.
6. In the Definition field, select Entry.
7. In the Name field, type 'Dimensions data mapping'.
8. In the Description field, type 'Dimensions data mapping'.
9. Click Save.
10. Click Designer.
11. In the tree, select 'Dynamics 365 for Operations\Table'.
12. Click Add root.
13. In the Name field, type 'Company'.
14. In the Table field, type 'CompanyInfo'.
15. Click OK.
16. In the tree, select 'Functions\Financial dimensions details'.
17. Click Add root.
 - This data source specifies how the scope of financial dimensions will be defined for any report that will use this model as a data source.
18. In the Name field, type a value.
19. Select Yes in the Ask for dimensions field.
 - Select Yes to allow the user to select dimensions at run-time on the User dialog form. If set to No, all financial dimensions of the current instance will be used by default.
20. In the Financial dimensions selection field, select 'Legal entity'.
 - Select All to allow the user to select desired dimensions for the current instance in the Lookup field. Select Legal entity to allow the user to select dimensions for the company in the Lookup field. Select Dimension to allow the user to select dimensions using a single dimension set.
21. Select Yes in the Ask for main account field.
 - Set 'Ask for main account' to Yes to allow users to select the main account as part of the list of dimensions. If set to No, the main account will not be included to the list of dimensions and the 'Is main account mandatory' option is enabled. If 'Is main account mandatory' is set to Yes, include the main account in the list of dimensions regardless of the user's selection.

22. Click OK.

23. In the tree, select 'Dynamics 365 for Operations\Table records'.

24. Click Add root.

25. In the Name field, type 'LedgerJournal'.

26. Select Yes in the Ask for query field.

27. In the Table field, type 'LedgerJournalTable'.

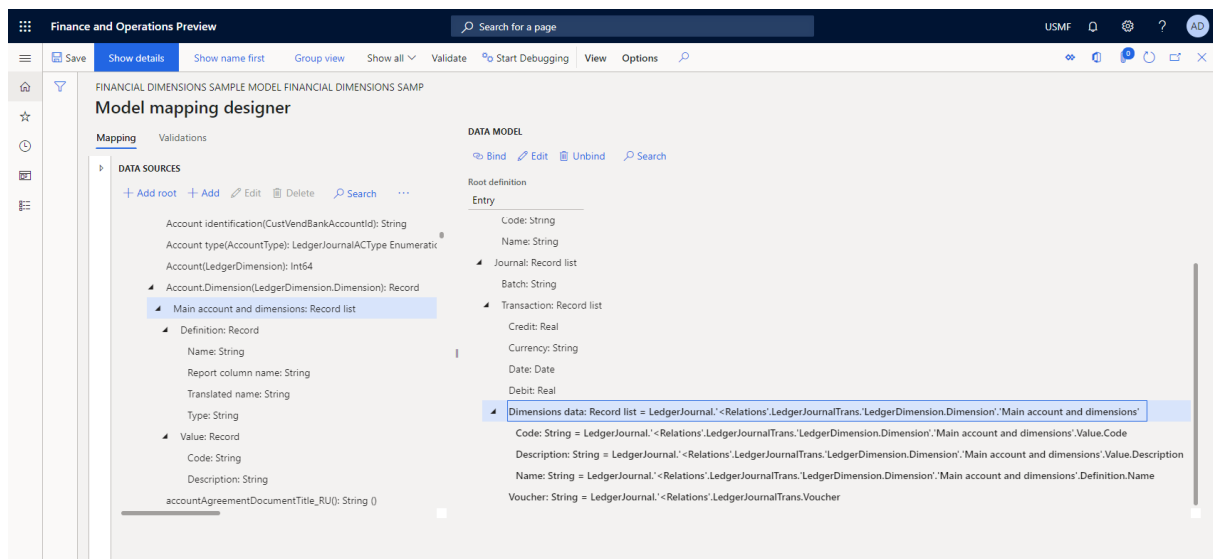

28. Click OK.

Map data model elements to added data sources

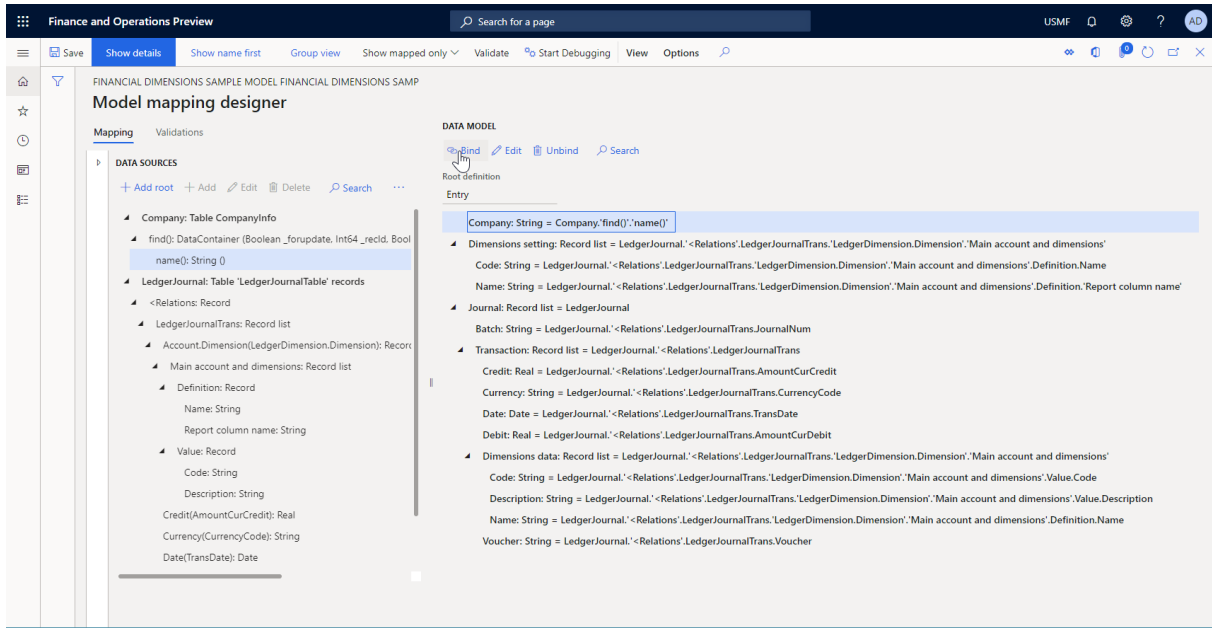

1. In the tree, expand 'Journal'.
2. In the tree, expand 'Journal\Transaction'.
3. In the tree, expand 'Journal\Transaction\Dimensions data'.
4. In the tree, expand 'Dimensions setting'.
5. In the tree, expand 'LedgerJournal'.
6. In the tree, expand 'LedgerJournal<Relations'.

7. In the tree, expand 'LedgerJournal<Relations\LedgerJournalTrans'.
8. In the tree, select 'LedgerJournal<Relations\LedgerJournalTrans\Voucher'.
9. In the tree, select 'Journal\Transaction\Voucher'.
10. Click Bind.
11. In the tree, select
'LedgerJournal<Relations\LedgerJournalTrans\Account.Dimension(LedgerDimension.Dimension)'.
 - Note that for any reference to financial dimensions that is set to, for instance, LedgerDimension, a corresponding data source item is available (LedgerDimension.Dimension). This data source item offers the financial dimensions of that dimensions set as the record's list.
12. In the tree, expand
'LedgerJournal<Relations\LedgerJournalTrans\Account.Dimension(LedgerDimension.Dimension)'.
13. In the tree, expand
'LedgerJournal<Relations\LedgerJournalTrans\Account.Dimension(LedgerDimension.Dimension)\Main account and dimensions'.
14. In the tree, expand
'LedgerJournal<Relations\LedgerJournalTrans\Account.Dimension(LedgerDimension.Dimension)\Main account and dimensions\Value'.
15. In the tree, expand
'LedgerJournal<Relations\LedgerJournalTrans\Account.Dimension(LedgerDimension.Dimension)\Main account and dimensions\Definition'.
16. In the tree, select
'LedgerJournal<Relations\LedgerJournalTrans\Account.Dimension(LedgerDimension.Dimension)\Main account and dimensions\Definition\Name'.
17. In the tree, select 'Journal\Transaction\Dimensions data\Name'.
18. Click Bind.
19. In the tree, select
'LedgerJournal<Relations\LedgerJournalTrans\Account.Dimension(LedgerDimension.Dimension)\Main account and dimensions\Value\Description'.
20. In the tree, select 'Journal\Transaction\Dimensions data\Description'.
21. Click Bind.
22. In the tree, select
'LedgerJournal<Relations\LedgerJournalTrans\Account.Dimension(LedgerDimension.Dimension)\Main account and dimensions\Value\Code'.
23. In the tree, select 'Journal\Transaction\Dimensions data\Code'.
24. Click Bind.
25. In the tree, select
'LedgerJournal<Relations\LedgerJournalTrans\Account.Dimension(LedgerDimension.Dimension)\Main account and dimensions'.
26. In the tree, select 'Journal\Transaction\Dimensions data'.
27. Click Bind.

28. In the tree, select 'LedgerJournal<Relations>LedgerJournalTrans\Debit(AmountCurDebit)'.
29. In the tree, select 'Journal\Transaction\Debit'.
30. Click Bind.
31. In the tree, select 'LedgerJournal<Relations>LedgerJournalTrans\Date(TransDate)'.
32. In the tree, select 'Journal\Transaction\Date'.
33. Click Bind.
34. In the tree, select 'LedgerJournal<Relations>LedgerJournalTrans\Currency(CurrencyCode)'.
35. In the tree, select 'Journal\Transaction\Currency'.
36. Click Bind.
37. In the tree, select 'LedgerJournal<Relations>LedgerJournalTrans\Credit(AmountCurCredit)'.
38. In the tree, select 'Journal\Transaction\Credit'.
39. Click Bind.
40. In the tree, select 'LedgerJournal<Relations>LedgerJournalTrans'.
41. In the tree, select 'Journal\Transaction'.
42. Click Bind.
43. In the tree, select 'LedgerJournal\Journal batch number(JournalNum)'.
44. In the tree, select 'Journal\Batch'.
45. Click Bind.
46. In the tree, select 'LedgerJournal'.
47. In the tree, select 'Journal'.
48. Click Bind.
49. In the tree, expand 'Dimensions'.
50. In the tree, expand 'Dimensions\Main account and dimensions'.
51. In the tree, expand 'Dimensions\Main account and dimensions\Definition'.
52. In the tree, select 'Dimensions\Main account and dimensions\Definition\Name'.
53. In the tree, select 'Dimensions setting\Code'.
54. Click Bind.
55. In the tree, select 'Dimensions\Main account and dimensions\Definition\Report column name'.
56. In the tree, select 'Dimensions setting\Name'.
57. Click Bind.
58. In the tree, select 'Dimensions\Main account and dimensions'.
59. In the tree, select 'Dimensions setting'.
60. Click Bind.
61. In the tree, select 'Company'.

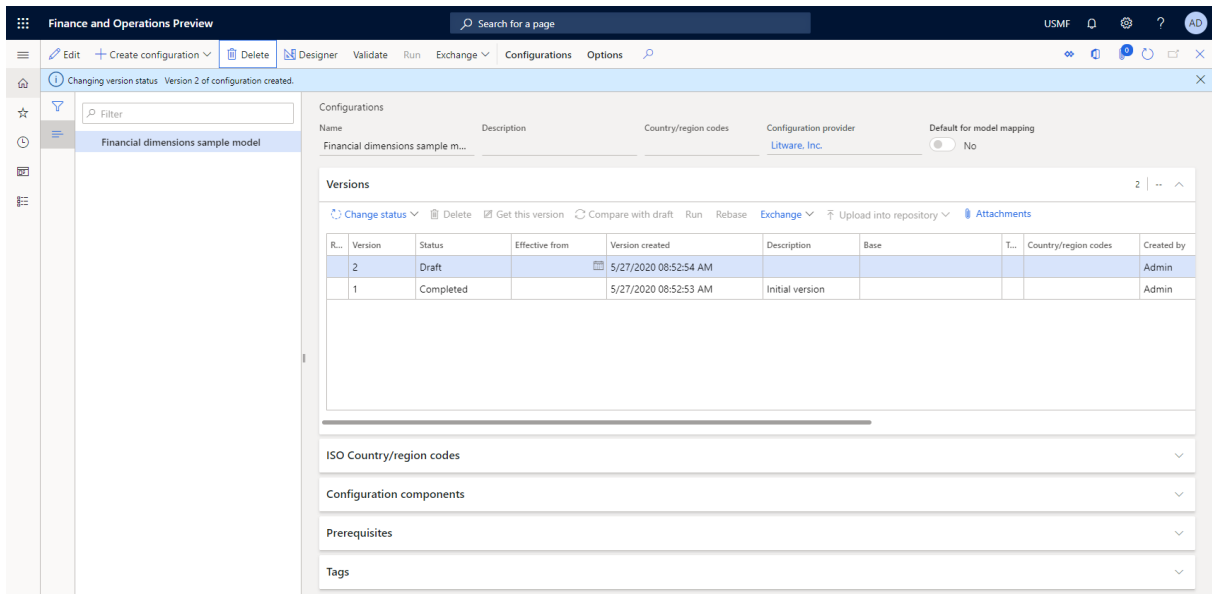

62. Click Edit.
63. In the expressionAsStringText field, enter 'Company.find().name()'.
 - Company.find().name()
64. Click Save.

65. Close the page.
66. Click Save.
67. Close the page.

Complete this draft model's version

1. Close the page.
2. Close the page.
3. Click Change status.
4. Click Complete.
5. Click OK.

ER Use financial dimensions as a data source (Part 3 - Design the report)

2/18/2021 • 4 minutes to read • [Edit Online](#)

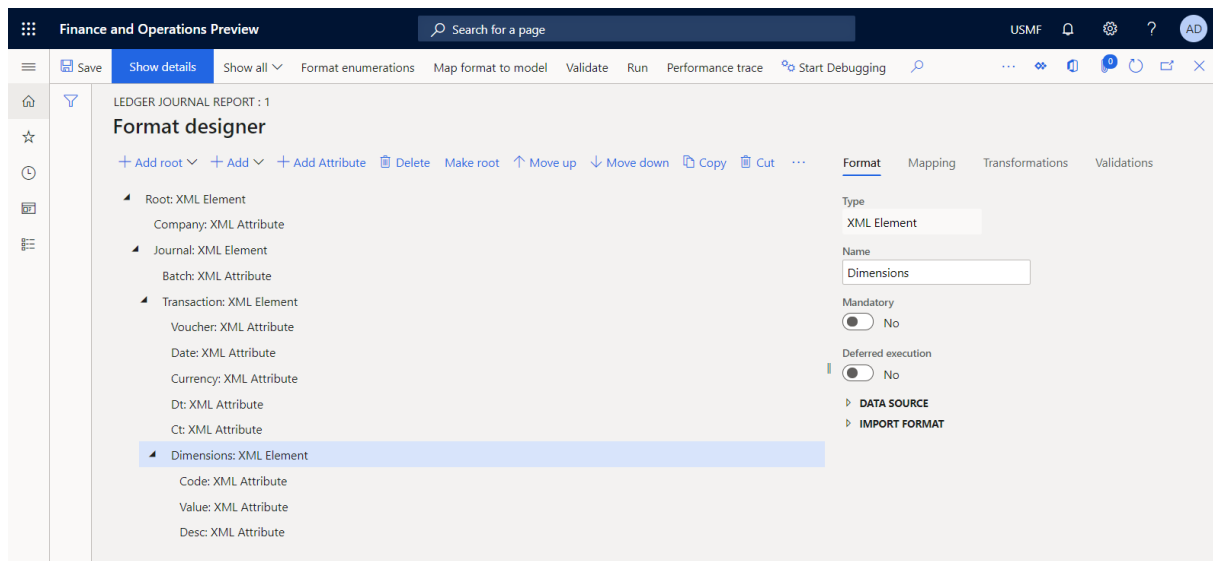

The following steps explain how a user assigned to the system administrator or electronic reporting developer role can configure an Electronic reporting (ER) model to use financial dimensions as a data source for ER reports. These steps can be performed in any company.

To complete these steps, you must first complete the steps in the "ER Use financial dimensions as a data source (Part 2: Model mapping)" procedure.

Design a report to present financial dimensions

1. Go to Organization administration > Electronic reporting > Configurations.
2. In the tree, select 'Financial dimensions sample model'.
3. Click Create configuration to open the drop dialog.
4. In the New field, enter 'Format based on data model Financial dimensions sample model'.
 - Use the model that was created in advance as the data source for your new report.
5. In the Name field, type 'Ledger journal report'.
6. In the Data model definition field, select Entry.
7. Click Create configuration.
8. Click Designer.
9. Click Add root to open the drop dialog.
10. In the tree, select 'XML\Element'.
11. In the Name field, type 'Root'.
12. Click OK.
13. Click Add to open the drop dialog.
14. In the tree, select 'XML\Attribute'.
15. In the Name field, type 'Company'.
16. Click OK.
17. Click Add to open the drop dialog.
18. In the tree, select 'XML\Element'.
19. In the Name field, type 'Journal'.
20. Click OK.
21. In the tree, select 'Root: XML Element\Journal: XML Element'.
22. Click Add to open the drop dialog.
23. In the tree, select 'XML\Attribute'.
24. In the Name field, type 'Batch'.
25. Click OK.
26. Click Add to open the drop dialog.
27. In the tree, select 'XML\Element'.
28. In the Name field, type 'Transaction'.
29. Click OK.
30. In the tree, select 'Root: XML Element\Journal: XML Element\Transaction: XML Element'.
31. Click Add to open the drop dialog.

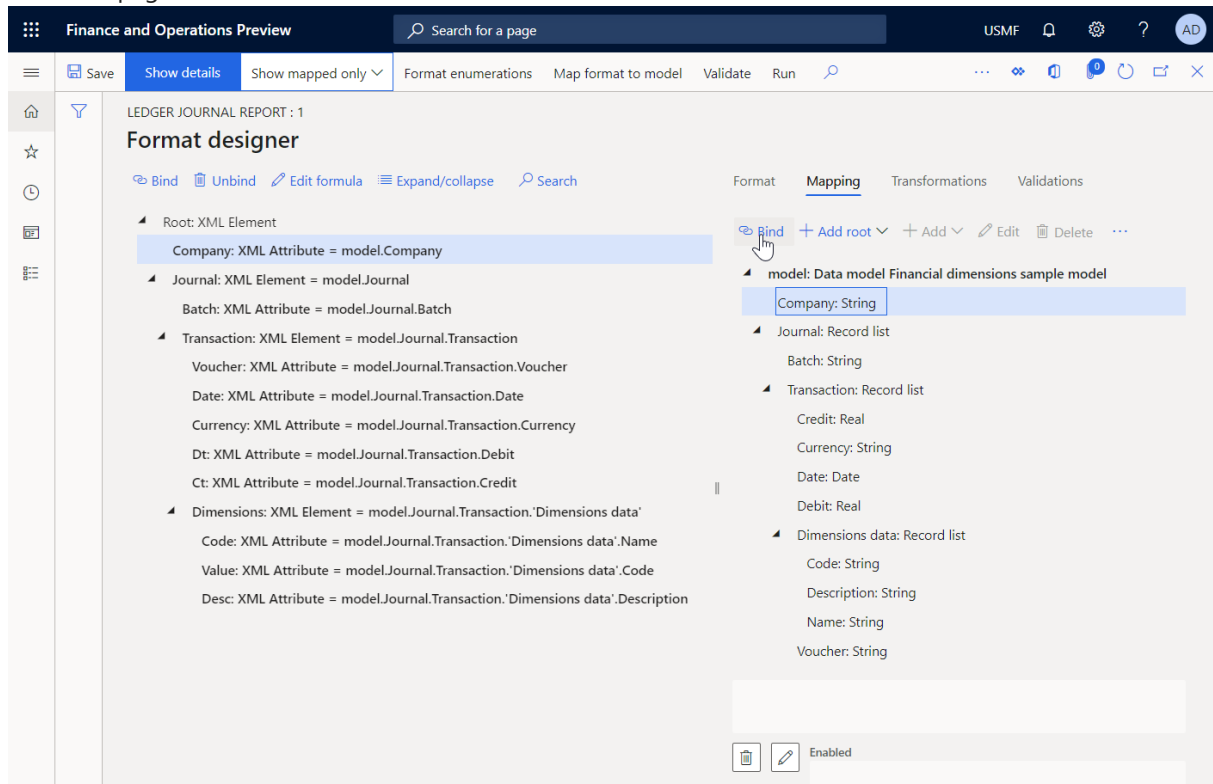

32. In the tree, select 'XML\Attribute'.
33. In the Name field, type 'Voucher'.
34. Click OK.
35. Click Add Attribute.
36. In the Name field, type 'Date'.
37. Click OK.
38. Click Add Attribute.
39. In the Name field, type 'Currency'.
40. Click OK.
41. Click Add Attribute.
42. In the Name field, type 'Dt'.
43. Click OK.
44. Click Add Attribute.
45. In the Name field, type 'Ct'.
46. Click OK.
47. Click Add to open the drop dialog.
48. In the tree, select 'XML\Element'.
49. In the Name field, type 'Dimensions'.
50. Click OK.
51. In the tree, select 'Root: XML Element\Journal: XML Element\Transaction: XML Element\Dimensions: XML Element'.
52. Click Add to open the drop dialog.
53. In the tree, select 'XML\Attribute'.
54. In the Name field, type 'Code'.
55. Click OK.
56. Click Add Attribute.
57. In the Name field, type 'Value'.
58. Click OK.
59. Click Add Attribute.
60. In the Name field, type 'Desc'.
61. Click OK.

Map report elements to data sources

1. Click the Mapping tab.
2. In the tree, expand 'model: Data model Financial dimensions sample model'.
3. In the tree, expand 'model: Data model Financial dimensions sample model\Journal: Record list'.
4. In the tree, expand 'model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list'.
5. In the tree, expand 'model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Dimensions data: Record list'.
6. In the tree, select 'Root: XML Element\Journal: XML Element\Transaction: XML Element\Dimensions: XML Element\Desc: XML Attribute'.
7. In the tree, select 'model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Dimensions data: Record list\Description: String'.
8. Click Bind.
9. In the tree, select 'Root: XML Element\Journal: XML Element\Transaction: XML Element\Dimensions: XML Element\Value: XML Attribute'.
10. In the tree, select 'model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Dimensions data: Record list\Code: String'.
11. Click Bind.
12. In the tree, select 'Root: XML Element\Journal: XML Element\Transaction: XML Element\Dimensions: XML Element\Code: XML Attribute'.
13. In the tree, select 'model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Dimensions data: Record list\Name: String'.
14. Click Bind.
15. In the tree, select 'model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Dimensions data: Record list'.
16. In the tree, select 'Root: XML Element\Journal: XML Element\Transaction: XML Element\Dimensions: XML Element'.
17. Click Bind.
18. In the tree, select 'Root: XML Element\Journal: XML Element\Transaction: XML Element\Ct: XML Attribute'.
19. In the tree, select 'model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Credit: Real'.
20. Click Bind.
21. In the tree, select 'Root: XML Element\Journal: XML Element\Transaction: XML Element\Dt: XML Attribute'.
22. In the tree, select 'model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Debit: Real'.
23. Click Bind.
24. In the tree, select 'Root: XML Element\Journal: XML Element\Transaction: XML Element\Currency: XML Attribute'.
25. In the tree, select 'model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Currency: String'.
26. Click Bind.
27. In the tree, select 'Root: XML Element\Journal: XML Element\Transaction: XML Element\Date: XML Attribute'.
28. In the tree, select 'model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Date: Date'.
29. Click Bind.
30. In the tree, select 'Root: XML Element\Journal: XML Element\Transaction: XML Element\Voucher: XML Attribute'.
31. In the tree, select 'model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Voucher: String'.

32. Click Bind.
33. In the tree, select 'Root: XML Element\Journal: XML Element\Transaction: XML Element'.
34. In the tree, select 'model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list'.
35. Click Bind.
36. In the tree, select 'Root: XML Element\Journal: XML Element\Batch: XML Attribute'.
37. In the tree, select 'model: Data model Financial dimensions sample model\Journal: Record list\Batch: String'.
38. Click Bind.
39. In the tree, select 'Root: XML Element\Journal: XML Element'.
40. In the tree, select 'model: Data model Financial dimensions sample model\Journal: Record list'.
41. Click Bind.
42. In the tree, select 'Root: XML Element\Company: XML Attribute'.
43. In the tree, select 'model: Data model Financial dimensions sample model\Company: String'.
44. Click Bind.
45. Click Save.
46. Close the page.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

ER Use financial dimensions as a data source (Part 4 - Run the report)

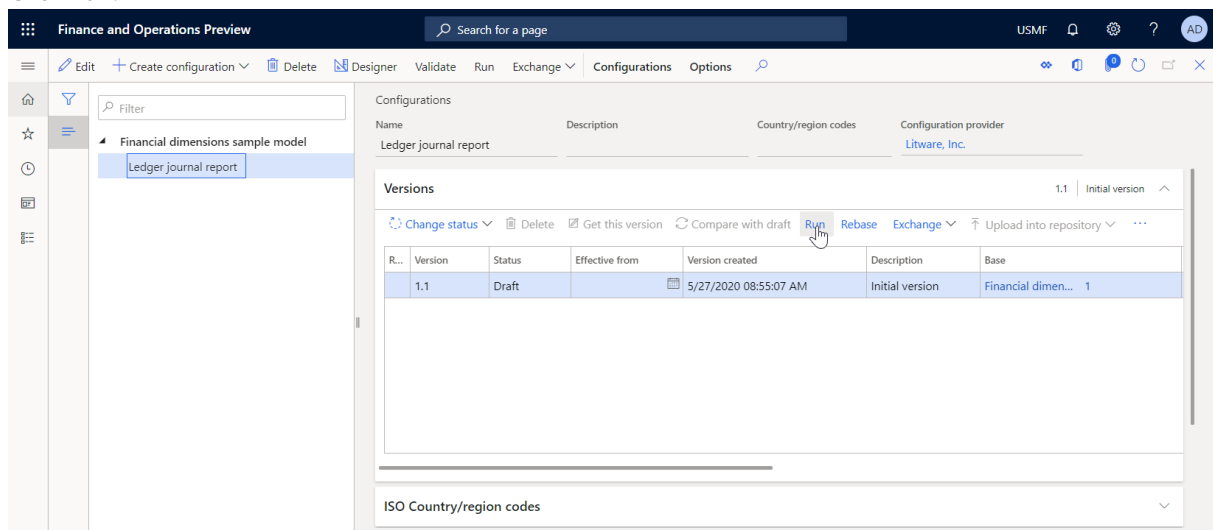

2/18/2021 • 2 minutes to read • [Edit Online](#)

The following steps explain how a user assigned to the system administrator or electronic reporting developer role can configure an Electronic reporting (ER) model to use financial dimensions as a data source for ER reports. These steps can be performed in the DEMF company.

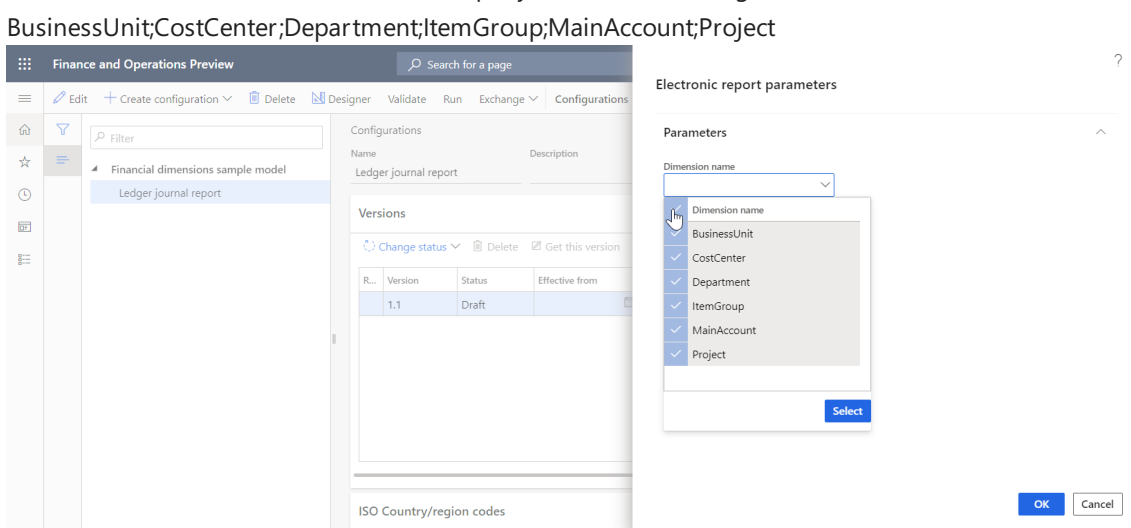

To complete these steps, you must first complete the steps in the "ER Use financial dimensions as a data source (Part 3: Design the report)" procedure. You must also configure default document types on the Electronic reporting parameters page. Default document types are also set when you download and import any ER configuration.

Run report

1. Go to Organization administration > Electronic reporting > Configurations.
2. In the tree, expand 'Financial dimensions sample model'.
3. In the tree, select 'Financial dimensions sample model\Ledger journal report'.
4. Click Run.

5. In the Dimension name field, enter or select a value.
- To select all dimensions in the current company, enter the following information:
BusinessUnit;CostCenter;Department;ItemGroup;MainAccount;Project

6. Expand the Records to include section.
7. Click Filter.
8. Select the row for the Ledger journal table and the Journal batch number field.
9. In the Criteria field, type '00057'.
10. Click OK.
11. Click OK.

- Review the generated output. For each transaction of the selected batch, the financial dimensions from the corresponding dimensions set are presented. Run this report and select different dimensions to see that the report is not dependent on the number of selected dimensions or the number of dimensions configured for this instance.

ER Configure format to do counting and summing (Part 1 - Create format)

2/18/2021 • 2 minutes to read • [Edit Online](#)

The following steps explain how a user assigned to the system administrator or electronic reporting developer role can configure an Electronic reporting (ER) format to do counting and summing based on data of the already generated text output. These steps can be performed in any company.

To complete these steps, you must first complete the steps in the "Create a configuration provider and mark it as active" procedure.

This procedure is for a feature that was added in Dynamics 365 for Operations version 1611.

Get access to the list of configurations provided by Microsoft

1. Go to Organization administration > Workspaces > Electronic reporting.
 - Make sure that the "Litware, Inc." provider is available and marked as active.
2. Select the "Litware, Inc." provider.
3. Click Repositories.
 - If a repository of the "Operations resources" type already exists, skip the remaining steps of the current sub-task.
4. Click Add to open the drop dialog.
5. In the Configuration repository type field, enter 'Operations resources'.
6. Click Create repository.
7. Click OK.

Get the Intrastat configurations provided by Microsoft

1. Click Open.
2. In the tree, select 'Intrastat model\Intrastat (DE)'.
3. Click Import.
 - Click Import for version 1.1 of the selected configuration.
4. Click Yes.
5. Close the page.
6. Close the page.
7. Click Reporting configurations.
8. In the tree, expand 'Intrastat model'.
9. In the tree, select 'Intrastat model\Intrastat (DE)'.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

ER Configure format to do counting and summing (Part 2 - Configure computations)

2/18/2021 • 4 minutes to read • [Edit Online](#)

The following steps explain how a user assigned to the system administrator or electronic reporting developer role can configure an Electronic reporting (ER) format to do counting and summing based on data of the already generated text output. These steps can be performed in any company.

To complete these steps, you must first complete the steps in the "ER Configure format to do counting and summing (Part 1: Create format)" procedure.

This procedure is for a feature that was added in Dynamics 365 for Operations version 1611.

Create a format configuration to add counting and summing details

1. Go to Organization administration > Workspaces > Electronic reporting.
2. Click Reporting configurations.
3. In the tree, expand 'Intrastat model'.
4. In the tree, select 'Intrastat model\Intrastat (DE)'.
 - Assume that you need to customize the format provided by Microsoft by adding lines with summary details at the end of the Intrastat report. You need to do that by deriving our own instance of the Intrastat configuration from the Microsoft instance to make modifications.
5. Click Create configuration to open the drop dialog.
6. In the New field, enter 'Derive from Name: Intrastat (DE), Microsoft'.
7. In the Name field, type 'Intrastat (DE) with counting & summing'.
8. Click Create configuration.

Configure this report to do counting and summation based on output details

1. Click Designer.
2. Select Yes in the Collect output details field.
 - This flag will activate at run-time the process of collecting output details for generating the Intrastat file.
 - You need to do counting for different Intrastat directions, so add a dedicated model enumeration to the data sources' list of this format configuration.
3. Click the Mapping tab.
4. Click Add root to open the drop dialog.
5. In the tree, select 'Data model\Enumeration '.
6. In the Name field, type 'Direction'.
7. In the Model enumeration field, enter or select a value.
 - Select the value Direction.
8. Click OK.
9. Click Add root to open the drop dialog.
10. In the tree, select 'Functions\Calculated field'.
11. In the Name field, type '\$BlockName'.

12. Click Edit formula.
13. In the Formula field, enter ""block"".
14. Click Save.
15. Close the page.
16. Click OK.
17. Click Add root to open the drop dialog.
18. In the tree, select 'Functions\Calculated field'.
19. In the Name field, type '\$RecName'.
20. Click Edit formula.
21. In the Formula field, enter ""record"".
22. Click Save.
23. Close the page.
24. Click OK.
25. Click Add root to open the drop dialog.
26. In the tree, select 'Functions\Calculated field'.
27. In the Name field, type '\$InvName'.
28. Click Edit formula.
29. In the Formula field, enter ""InvoicedAmountEUR"".
30. Click Save.
31. Close the page.
32. Click OK.
33. In the tree, select 'Intrastat\Data'.
34. Click Edit button for the 'Collected data key name' field
35. Click Add data source.
 - \$BlockName
36. Click Save.
37. Close the page.
38. Click the Edit button for the Collected data key value field.
39. In the Formula field, enter 'IF(Intrastat.CommodityRecord.Direction=Direction.Import, "Import", "Export")'.
 - IF(Intrastat.CommodityRecord.Direction=Direction.Import, "Import", "Export")
40. Click Save.
41. Close the page.
 - Count the lines of this sequence. The results will be used with the name "block" separately for different directions. Value "Import" will be used for any arrivals Intrastat transactions. The value "Export" will be used for any Intrastat dispatches transactions. Consider this to be a virtual Excel spreadsheet. For each transaction a row where the first column "block" is filled with the values "Import" and "Export" accordingly.
42. In the tree, expand 'Intrastat\Data: Sequence'.
43. In the tree, select 'Intrastat\Data: Sequence\Arrivals?'.
44. Click Edit button for the 'Collected data key name' field.
 - Count the lines of this sequence. The results will be memorized using the name "record".
45. In the tree, select '\$RecName'.
46. Click Add data source.
47. Click Save.
48. Close the page.
49. Click Edit button for the 'Collected data key value' field
50. In the Formula field, enter 'Intrastat.CommodityRecord.CommodityCode'.

51. Click Save.
52. Close the page.
 - Count the lines of this sequence. The results will be used with the name "record" separately for different commodity codes. Consider this to be a virtual Excel spreadsheet. For each transaction a row where the first column "block" is filled with the values "Import" and "Export" accordingly and the second block "record" is filled with the commodity code value.
53. In the tree, select 'Intrastat\Data: Sequence\Dispatches?'
54. Click Edit button for the 'Collected data key name' field
55. In the tree, select '\$RecName'.
56. Click Add data source.
57. Click Save.
58. Close the page.
59. Click the Edit button for the 'Collected data key value' field.
60. In the Formula field, enter 'Intrastat.CommodityRecord.CommodityCode'.
61. Click Save.
62. Close the page.
63. In the tree, expand 'Intrastat\Data: Sequence\Dispatches: Sequence?'
64. In the tree, expand 'Intrastat\Data: Sequence\Dispatches: Sequence?\Record = Intrastat.CommodityRecord'
65. Click the Format tab.
66. In the tree, select 'Intrastat\Data\Dispatches\Record\Invoice amount EUR'
67. Click the Mapping tab.
68. Click the Edit button for the 'Collected data key name' field.
69. In the tree, select '\$InvName'.
70. Click Add data source.
71. Click Save.
72. Close the page.
 - Summarize the invoiced amount values for lines of this sequence. The results will be used with the name "InvoicedAmountEUR" separately for different Intrastat directions and commodity codes. Consider this to be a virtual creation in Excel spreadsheet. For each transaction a row where the first column "block" is filled with the values "Import" and "Export" accordingly. The second block "record" is filled with the commodity code value, and the third column "InvoicedAmountEUR" is filled with the invoice amount value.
73. In the tree, expand 'Intrastat\Data\Arrivals?'
74. In the tree, expand 'Intrastat\Data\Arrivals?\Record = Intrastat.CommodityRecord'
75. Click the Format tab.
76. In the tree, select 'Intrastat\Data\Arrivals\Record\Invoice amount EUR'
77. Click the Mapping tab.
78. Click the Edit button for the 'Collected data key name' field.
79. In the tree, select '\$InvName'.
80. Click Add data source.
81. Click Save.
82. Close the page.
83. Click Save.
84. Close the page.

NOTE

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

ER Configure format to do counting and summing (Part 3 - Use computations to make the output)

2/18/2021 • 3 minutes to read • [Edit Online](#)

The following steps explain how a user assigned to the system administrator or electronic reporting developer role can configure an Electronic reporting (ER) format to do counting and summing based on data of the already generated text output. These steps can be performed in any company.

To complete these steps, you must first complete the steps in the "ER Configure format to do counting and summing (Part 2: Configure computations)" procedure.

This procedure is for a feature that was added in Dynamics 365 for Operations version 1611.

Configure this report to use counting and summing info

1. Go to Organization administration > Workspaces > Electronic reporting.
2. Click Reporting configurations.
3. In the tree, expand 'Intrastat model'.
4. In the tree, expand 'Intrastat model\Intrastat (DE)'.
5. In the tree, select 'Intrastat model\Intrastat (DE)\Intrastat (DE) with counting & summing'.
6. Click Designer.
7. Click the Mapping tab.
8. Click Add root to open the drop dialog.
 - Add a new data source to get the list of memorized blocks.
9. In the tree, select 'Functions\Calculated field'.
10. In the Name field, type '\$BlocksList'.
 - \$BlocksList
11. Click Edit formula.
12. In the tree, select 'Data collection functions\COLLECTEDLIST'.
13. Click Add function.
14. Click Add data source.
15. In the Formula field, enter 'COLLECTEDLIST('\$BlockName', '
 - COLLECTEDLIST('\$BlockName',
16. In the Formula field, enter 'COLLECTEDLIST('\$BlockName', "*"')'.
 - COLLECTEDLIST('\$BlockName', "*"')
17. Click Save.
 - The pattern "*" means that all blocks will be included to the list for this record.
18. Close the page.
19. Click OK.
20. Click the Format tab.
21. In the tree, select 'Intrastat\Data'.
22. Click Add to open the drop dialog.
23. In the tree, select 'Text\Sequence'.
24. In the Name field, type 'Totals by blocks'.
 - Totals by blocks

25. In the Special characters field, select 'New line - Windows (CR LF)'.
26. Click OK.
27. In the tree, select 'Intrastat\Data\Totals by blocks'.
28. Click Add to open the drop dialog.
29. In the tree, select 'Text\String'.
30. In the Name field, type 'Block code'.
 - Block code
31. Click OK.
32. Click Add String.
33. In the Name field, type 'Lines counting'.
 - Lines counting
34. Click OK.
35. Click Add String.
36. In the Name field, type 'Total amount'.
 - Total amount
37. Click OK.
38. Click the Mapping tab.
39. In the tree, select '\$BlocksList'.
40. Click Bind.
 - Create a summary line for each memorized block.
41. Click the Format tab.
42. In the tree, select 'Intrastat\Data\Totals by blocks\Block code'.
43. Click the Mapping tab.
44. Click Edit formula.
45. In the Formula field, enter '"Block id: " & '.
 - "Block id: " &
46. In the tree, expand '\$BlocksList'.
47. In the tree, select '\$BlocksList\Value'.
48. Click Add data source.
49. Click Save.
50. Close the page.
51. Click the Format tab.
52. In the tree, select 'Intrastat\Data\Totals by blocks\Lines counting'.
53. Click the Mapping tab.
54. Click Edit formula.
 - Create output for the number of lines for each block presented in this report.
55. In the Formula field, enter '"Number of lines in this block: " & '.
 - "Number of lines in this block: " &
56. In the Formula field, enter '"Number of lines in this block: " & TEXT('.
 - "Number of lines in this block: " & TEXT(
57. In the tree, select 'Data collection functions\COUNTIFS'.
58. Click Add function.
59. Click Add data source.
60. In the Formula field, enter '"Number of lines in this block: " & TEXT(COUNTIFS('\$BlockName', '.
 - "Number of lines in this block: " & TEXT(COUNTIFS('\$BlockName',
61. In the tree, expand '\$BlocksList'.

62. In the tree, select '\$BlocksList\Value'.
63. Click Add data source.
64. In the Formula field, enter "'Number of lines in this block: " & TEXT(COUNTIFS('\$BlockName', '\$BlocksList'.Value, '
• "Number of lines in this block: " & TEXT(COUNTIFS('\$BlockName', '\$BlocksList'.Value,
65. In the tree, select '\$RecName'.
66. Click Add data source.
67. In the Formula field, enter "'Number of lines in this block: " & TEXT(COUNTIFS('\$BlockName', '\$BlocksList'.Value, '\$RecName', "*"'))'.
• "Number of lines in this block: " & TEXT(COUNTIFS('\$BlockName', '\$BlocksList'.Value, '\$RecName', "*"'))
68. Click Save.
69. Close the page.
70. Click the Format tab.
71. In the tree, select 'Intrastat\Data\Totals by blocks\Total amount'.
72. Click the Mapping tab.
73. Click Edit formula.
• Create output that will be the total of the invoiced amount for each block presented in this report.
74. In the Formula field, enter "'Sum of invoiced amount: " & TEXT(SUMIFS('\$InvName', '\$BlockName', '\$BlocksList'.Value, '\$RecName', "*"'))'.
• "Sum of invoiced amount: " & TEXT(SUMIFS('\$InvName', '\$BlockName', '\$BlocksList'.Value, '\$RecName', "*"'))
75. Click Save.
76. Close the page.
77. Click Save.
78. Close the page.

ER Configure format to do counting and summing (Part 4 - Run format)

2/18/2021 • 2 minutes to read • [Edit Online](#)

The following steps explain how a user assigned to the system administrator or electronic reporting developer role can configure an Electronic reporting (ER) format to do counting and summing based on data of the already generated text output. These steps can be performed in the DEMF company.

To complete these steps, you must first complete the steps in the "ER Configure format to do counting and summing (Part 3: Use computations to make the output)" procedure.

This procedure is for a feature that was added in Dynamics 365 for Operations version 1611.

Test this configuration for generation of the Intrastat reports

1. Go to Organization administration > Workspaces > Electronic reporting.
2. Click Reporting configurations.
3. In the tree, expand 'Intrastat model'.
4. In the tree, expand 'Intrastat model\Intrastat (DE)'.
5. In the tree, select 'Intrastat model\Intrastat (DE)\Intrastat (DE) with counting & summing'.
6. On the Action Pane, click Configurations.
7. Click User parameters.
8. Select Yes in the Run settings field.
9. Click OK.
10. Click Edit.
11. Select Yes in the Run Draft field.
12. Click Save.
13. Go to Tax > Setup > Foreign trade > Foreign trade parameters.
14. Expand the Electronic reporting section.
15. Select the "Intrastat (DE) with counting & summing" configuration.
16. Select the "Intrastat (DE) with counting & summing" configuration.
17. Click Save.
18. Close the page.
19. Go to Tax > Declarations > Foreign trade > Intrastat.
20. Click Output.
21. Click Report.
 - Run the Intrastat report generation process.
22. In the From date field, set the date to '2000-01-01'.
 - Define start and end dates for the reporting period that include the existing on the form transactions.
23. In the To date field, set the date to '2022-12-31'.
 - Define start and end dates for the reporting period that include the existing on the form transactions.
24. In the Direction field, select 'Arrivals'.
25. Select Yes in the Generate file field.
26. Click OK.
 - Review the created output with the summary lines in the end.

27. Click New.
28. In the list, mark the selected row.
29. In the Direction field, select 'Dispatches'.
30. In the Item number field, enter or select a value.
31. In the Commodity field, enter or select a value.
32. Set Weight to '10'.
33. Set Invoice amount to '10000'.
34. Set Statistical amount to '10000'.
35. Click Output.
36. Click Report.
37. In the Direction field, select 'Dispatches'.
38. Click OK.
 - Review the created output with the summary lines in the end. Note that it has been changed in comparison to the first run.

Run this configuration in debug mode to review the collected counting & summing data

1. Go to Organization administration > Electronic reporting > Configurations.
2. In the tree, expand 'Intrastat model'.
3. In the tree, expand 'Intrastat model\Intrastat (DE)'.
4. In the tree, select 'Intrastat model\Intrastat (DE)\Intrastat (DE) with counting & summing'.
5. On the Action Pane, click Configurations.
6. Click User parameters.
7. Select Yes in the Run in debug mode field.
8. Click OK.
9. Close the page.
10. Go to Tax > Declarations > Foreign trade > Intrastat.
11. Click Output.
12. Click Report.
13. Click OK.
14. Close the page.
15. Go to Organization administration > Electronic reporting > Configurations.
16. In the tree, expand 'Intrastat model'.
17. In the tree, expand 'Intrastat model\Intrastat (DE)'.
18. In the tree, select 'Intrastat model\Intrastat (DE)\Intrastat (DE) with counting & summing'.
19. Click Debug logs.
 - Note that a debug log record has been created for the execution process of the selected configuration.
20. Click Attach.
21. Click Open.
 - Review the created XML file that contains counting and summing details that were collected during the execution of the selected configuration.

NOTE

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

ER Use horizontally expandable ranges to dynamically add columns in Excel reports (Part 1 - Design format)

2/18/2021 • 5 minutes to read • [Edit Online](#)

The following steps explain how a user assigned to the system administrator or electronic reporting developer role can configure an Electronic reporting (ER) format to generate reports as OPENXML worksheets (Excel) files in which the required columns can be created dynamically as horizontally expandable ranges. These steps can be performed in any company.

To complete these steps, you must first complete these three task guides:

"ER Create a configuration provider and mark it as active"

"ER Use financial dimensions as a data source (Part 1: Design data model)"

"ER Use financial dimensions as a data source (Part 2: Model mapping)"

You must also download and save a local copy of the template with a sample report found here, [Sample Financial Dimensions Web Service Report](#).

This procedure is for a feature that was added in Dynamics 365 for Operations version 1611.

Create a new report configuration

1. Go to Organization administration > Electronic reporting > Configurations.
2. In the tree, select 'Financial dimensions sample model'.
3. Click Create configuration to open the drop dialog.
4. In the New field, enter 'Format based on data model Financial dimensions sample model'.
 - Use the model created in advance as the data source for your new report.
5. In the Name field, type 'Sample report with horizontally expandable ranges'.
 - Sample report with horizontally expandable ranges
6. In the Description field, type 'To make Excel output with dynamically adding columns'.
 - To make Excel output with dynamically adding columns
7. In the Data model definition field, select Entry.
8. Click Create configuration.

Design the report format

1. Click Designer.
2. Turn on the 'Show details' toggle button.
3. On the Action Pane, click Import.
4. Click Import from Excel.
5. Click Attachments.
 - Import the report's template. Use Excel file that you downloaded for that.
6. Click New.
7. Click File.
8. Close the page.

9. In the Template field, enter or select a value.
 - Select the downloaded template.
10. Click OK.
 - Add a new range to dynamically create Excel output with as many columns as you selected (in the user dialog form) for financial dimensions. Each cell for every column will represent a single financial dimension's name.
11. Click Add to open the drop dialog.
12. In the tree, select 'Excel\Range'.
13. In the Excel range field, type 'DimNames'.
 - DimNames
14. In the Replication direction field, select 'Horizontal'.
15. Click OK.
16. In the tree, select 'Excel = "SampleFinDimWsReport"\Range: Horizontal'.
17. Click Move up.
18. In the tree, select 'Excel = "SampleFinDimWsReport"\Cell'.
19. Click Cut.
20. In the tree, select 'Excel = "SampleFinDimWsReport"\Range: Horizontal'.
21. Click Paste.
22. In the tree, expand 'Excel = "SampleFinDimWsReport"\Range: Horizontal'.
23. In the tree, expand 'Excel = "SampleFinDimWsReport"\Range: Vertical'.
24. In the tree, expand 'Excel = "SampleFinDimWsReport"\Range: Vertical\Range: Vertical'.
25. In the tree, select 'Excel = "SampleFinDimWsReport"\Range: Vertical\Range: Vertical'.
 - Add a new range to dynamically create Excel output with as many columns as you selected (in the user dialog form) for financial dimensions. Each cell for every column will represent a single financial dimension's value for each reporting transaction.
26. Click Add Range.
27. In the Excel range field, type 'DimValues'.
 - DimValues
28. In the Replication direction field, select 'Horizontal'.
29. Click OK.
30. In the tree, select 'Excel = "SampleFinDimWsReport"\Range: Vertical\Range: Vertical\Cell'.
31. Click Cut.
32. In the tree, select 'Excel = "SampleFinDimWsReport"\Range: Vertical\Range: Vertical\Range: Horizontal'.
33. Click Paste.
34. In the tree, expand 'Excel = "SampleFinDimWsReport"\Range: Vertical\Range: Vertical\Range: Horizontal'.

Map format elements to data sources

1. Click the Mapping tab.
2. In the tree, expand 'model: Data model Financial dimensions sample model'.
3. In the tree, expand 'model: Data model Financial dimensions sample model\Journal: Record list'.
4. In the tree, expand 'model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list'.
5. In the tree, expand 'model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Dimensions data: Record list'.
6. In the tree, select 'Excel = "SampleFinDimWsReport"\Range: Vertical\Range: Vertical\Range: Horizontal\Cell'.
7. In the tree, select 'model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Dimensions data: Record list'.

Record list\Dimensions data: Record list\Code: String'.

8. Click Bind.
9. In the tree, select 'Excel = "SampleFinDimWsReport"\Range: Vertical\Range: Vertical\Range: Horizontal'.
10. In the tree, select 'model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Dimensions data: Record list'.
11. Click Bind.
12. In the tree, select 'Excel = "SampleFinDimWsReport"\Range: Vertical\Range: Vertical\Cell'.
13. In the tree, select 'model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Credit: Real'.
14. Click Bind.
15. In the tree, select 'Excel = "SampleFinDimWsReport"\Range: Vertical\Range: Vertical\Cell'.
16. In the tree, select 'model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Debit: Real'.
17. Click Bind.
18. In the tree, select 'Excel = "SampleFinDimWsReport"\Range: Vertical\Range: Vertical\Cell'.
19. In the tree, select 'model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Currency: String'.
20. Click Bind.
21. In the tree, select 'Excel = "SampleFinDimWsReport"\Range: Vertical\Range: Vertical\Cell'.
22. In the tree, select 'model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Date: Date'.
23. Click Bind.
24. In the tree, select 'Excel = "SampleFinDimWsReport"\Range: Vertical\Range: Vertical\Cell'.
25. In the tree, select 'model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Voucher: String'.
26. Click Bind.
27. In the tree, select 'Excel = "SampleFinDimWsReport"\Range: Vertical\Range: Vertical\Cell'.
28. In the tree, select 'model: Data model Financial dimensions sample model\Journal: Record list\Batch: String'.
29. Click Bind.
30. In the tree, select 'Excel = "SampleFinDimWsReport"\Range: Vertical\Range: Vertical'.
31. In the tree, select 'model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list'.
32. Click Bind.
33. In the tree, select 'Excel = "SampleFinDimWsReport"\Range: Vertical\Cell'.
34. In the tree, select 'model: Data model Financial dimensions sample model\Journal: Record list\Batch: String'.
35. Click Bind.
36. In the tree, select 'Excel = "SampleFinDimWsReport"\Range: Vertical'.
37. In the tree, select 'model: Data model Financial dimensions sample model\Journal: Record list'.
38. Click Bind.
39. In the tree, expand 'model: Data model Financial dimensions sample model\Dimensions setting: Record list'.
40. In the tree, select 'model: Data model Financial dimensions sample model\Dimensions setting: Record list\Code: String'.
41. In the tree, select 'Excel = "SampleFinDimWsReport"\Range: Horizontal\Cell'.
42. Click Bind.
43. In the tree, select 'model: Data model Financial dimensions sample model\Dimensions setting: Record list'.
44. In the tree, select 'Excel = "SampleFinDimWsReport"\Range: Horizontal'.
45. Click Bind.

46. In the tree, select 'Excel = "SampleFinDimWsReport"\Cell'.
47. In the tree, select 'model: Data model Financial dimensions sample model\Company: String'.
48. Click Bind.
49. Click Save.
50. Close the page.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

ER Use horizontally expandable ranges to dynamically add columns in Excel reports (Part 2 - Run format)

2/18/2021 • 2 minutes to read • [Edit Online](#)

The following steps explain how a user assigned to the system administrator or electronic reporting developer role can configure an Electronic reporting (ER) format to generate reports as OPENXML worksheets (Excel) files in which the required columns can be created dynamically as horizontally expandable ranges. These steps can be performed in the DEMF company.

To complete these steps, you must first complete the steps in the "ER Use horizontally expandable ranges to dynamically add columns in Excel reports (Part 1: Design format)" procedure.

This procedure is for a feature that was added in Dynamics 365 for Operations version 1611.

Find created format

1. Go to Organization administration > Electronic reporting > Configurations.
2. In the tree, expand 'Financial dimensions sample model'.
3. In the tree, select 'Financial dimensions sample model\Sample report with horizontally expandable ranges'.

Execute format to create Excel output

1. Click Run.
2. In the Dimension name field, type 'BusinessUnit;CostCenter;Department'.
 - In the Dimension name field, enter or select a value. To select all dimensions for the current company, enter the following: BusinessUnit;CostCenter;Department;ItemGroup;MainAccount;Project
3. Expand the Records to include section.
4. Click Filter.
5. Select the row for the Ledger journal table and the Journal batch number field.
6. In the Criteria field, type '00057..00058'.
 - 00057..00058
7. Click OK.
8. Click OK.
 - Review the generated output. Note that the newly created Excel file contains the same number of columns that were selected for financial dimensions. The report header in those columns represents financial dimensions' names. The transactions' lines in those columns represent financial dimensions. Run this report and select different dimensions to see that the report is not dependent on the number of selected dimensions or the number of dimensions configured for this instance.

NOTE

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

ER Use Document Management files in format outputs (Part 1 - Prepare data model)

2/18/2021 • 2 minutes to read • [Edit Online](#)

The following steps explain how a user assigned to the system administrator or electronic reporting developer role can configure an Electronic reporting (ER) format to use Document Management files (attachments) in ER output. These steps can be performed in any company.

To complete these steps, you must first complete the steps in the "Create a configuration provider and mark it as active" procedure.

This procedure is for a feature that was added in Dynamics 365 for Operations version 1611.

Get access to the list of configurations provided by Microsoft

1. Go to Organization administration > Workspaces > Electronic reporting.

Make sure that the 'Litware, Inc.' provider is available and marked as active.

2. Select the 'Litware, Inc.' provider.
3. Click Repositories.

If a repository of the 'Operations resources' type already exists, skip the remaining steps of the current sub-task.

4. Click Add to open the drop dialog.
5. In the Configuration repository type field, enter 'Operations resources'.
6. Click Create repository.
7. Click OK.

Get the Customer invoice model configurations provided by Microsoft

1. Click Show filters.
2. Apply the following filters: Enter a filter value of "Operations resources" on the "Name" field using the "begins with" filter operator; Enter a filter value of "" on the "Description" field using the "begins with" filter operator

3. Click Show filters.
4. Click Open.
5. In the tree, select 'Customer invoice model'.

Select the model configuration 'Customer invoice model' to import it.

6. Click Import.
Click Import for version 1 of the selected configuration.
7. Click Yes.

8. Close the page.
9. Close the page.
10. Click Reporting configurations.
11. In the tree, select 'Customer invoice model'.

Create the derived model to support access to the Document Management files.

You will create our own configuration of the Customer invoice model deriving it from the configuration provided by Microsoft. You will use this configuration to implement access to the Document Management files and make them available for electronic documents that you will create based on this model.

1. Click Create configuration to open the drop dialog.
2. In the New field, enter 'Derive from Name: Customer invoice model, Microsoft'.
3. In the Name field, type 'Customer invoice model (custom)'.
4. Click Create configuration.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

ER Use Document Management files in format outputs (Part 2 - Extend data model)

2/18/2021 • 2 minutes to read • [Edit Online](#)

The following steps explain how a user assigned to the System Administrator or Electronic Reporting Developer role can configure an Electronic reporting (ER) format to use Document Management files (attachments) in ER output. These steps can be performed in any company.

To complete these steps, you must first complete the steps in the "ER Use Document Management files in format outputs (Part 1: Prepare data model)" task guide.

This procedure is for a feature that was added in Dynamics 365 for Operations version 1611.

Extend data model to present the Document Management files in it

1. Go to Organization administration > Workspaces > Electronic reporting.
2. Click Reporting configurations.
3. In the tree, expand 'Customer invoice model'.
4. In the tree, select 'Customer invoice model\Customer invoice model (custom)'.
5. Click Designer.
6. In the tree, select 'Customer invoice(InvoiceCustomer)'.
 - We will extend this data model to expose in it any files that have been attached to a sales order that is related to an electronically processing invoice.
7. Click New to open the drop dialog.
8. In the Name field, type 'Invoice attachments'.
 - Invoice attachments
9. In the Item type field, select 'Record list'.
10. Click Add.
11. Click New to open the drop dialog.
12. In the Name field, type 'File content'.
 - File content
13. In the Item type field, select 'Container'.
14. Click Add.
15. Click New to open the drop dialog.
16. In the Name field, type 'File name'.
 - File name
17. In the Item type field, select 'String'.
18. Click Add.

Map new data model elements to data sources

1. Click Map model to datasource.
2. Use the Quick Filter to filter on the Definition field with a value of 'InvoiceCustomer'.
 - InvoiceCustomer
 - We will map new model elements to appropriate data sources.
3. Click Designer.

4. In the tree, select 'Invoice attachments'.
5. In the tree, expand 'Invoice attachments'.
6. In the tree, select 'Invoice attachments\File name'.
7. Click Edit.
8. In the Formula field, enter
'CustInvoiceJour.'>Relations'.SalesTable.'<Relations'.'<Documents'.'originalFileName()'.
 - CustInvoiceJour.'>Relations'.SalesTable.'<Relations'.'<Documents'.'originalFileName()'
9. Click Save.
10. Close the page.
11. In the tree, select 'Invoice attachments\File content'.
12. Click Edit.
13. In the Formula field, enter
'CustInvoiceJour.'>Relations'.SalesTable.'<Relations'.'<Documents'.'getFileContentAsContainer()'.
 - CustInvoiceJour.'>Relations'.SalesTable.'<Relations'.'<Documents'.'getFileContentAsContainer()'
14. Click Save.
15. Close the page.
16. In the tree, select 'Invoice attachments'.
17. Click Edit.
18. In the Formula field, enter 'CustInvoiceJour.'>Relations'.SalesTable.'<Relations'.'<Documents''.
 - CustInvoiceJour.'>Relations'.SalesTable.'<Relations'.'<Documents'
19. Click Save.
20. Close the page.
21. Click Save.
22. Close the page.
23. Close the page.
24. Close the page.
25. Click Change status.
26. Click Complete.
27. Click OK.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

ER Use Document Management files in format outputs (Part 3 - Create format)

2/18/2021 • 2 minutes to read • [Edit Online](#)

The following steps explain how a user assigned to the system administrator or electronic reporting developer role can configure an Electronic reporting (ER) format to use Document Management files (attachments) in ER output. These steps can be performed in any company.

To complete these steps, you must first complete the steps in the "ER Use Document Management files in format outputs (Part 2: Extend data model)" procedure.

This procedure is for a feature that was added in Dynamics 365 for Operations version 1611.

Create a format to process invoices

1. Go to Organization administration > Workspaces > Electronic reporting.
2. Click Reporting configurations.
3. In the tree, expand 'Customer invoice model'.
4. In the tree, select 'Customer invoice model\Customer invoice model (custom)'.
 - You will create a format to generate electronic messages with information about any files that have been attached to a sales order that is related to an electronically processing invoice.
5. Click Create configuration to open the drop dialog.
6. In the New field, enter 'Format based on data model Customer invoice model (custom)'.
7. In the Name field, type 'Electronic invoice sample message'.
 - Electronic invoice sample message
8. In the Data model definition field, enter or select a value.
 - InvoiceCustomer
9. Click Create configuration.

Design a format to populate attachments into generating a message in MIME format

1. Click Designer.
2. Click Add root to open the drop dialog.
3. In the tree, select 'XML\Element'.
4. In the Name field, type 'Invoice'.
 - Invoice
5. Click OK.
6. Click Add to open the drop dialog.
7. In the tree, select 'XML\Attribute'.
8. In the Name field, type 'SalesOrder'.
 - SalesOrder
9. Click OK.
10. Click Add Attribute.
11. In the Name field, type 'InvoiceNumber'.
 - InvoiceNumber

12. Click OK.
13. Click Add Attribute.
14. In the Name field, type 'InvoiceAmount'.
 - InvoiceAmount
15. Click OK.
16. Click Add to open the drop dialog.
17. In the tree, select 'XML\Element'.
18. In the Name field, type 'EnclosedDocs'.
 - EnclosedDocs
19. Click OK.
20. In the tree, select 'Invoice\EnclosedDocs'.
21. Click Add Element.
22. In the Name field, type 'Document'.
 - Document
23. Click OK.
24. In the tree, select 'Invoice\EnclosedDocs\Document'.
25. Click Add to open the drop dialog.
26. In the tree, select 'XML\Attribute'.
27. In the Name field, type 'FileName'.
 - FileName
28. Click OK.
29. Click Add to open the drop dialog.
30. In the tree, select 'XML\Element'.
31. In the Name field, type 'FileContent'.
 - FileContent
32. Click OK.
33. In the tree, select 'Invoice\EnclosedDocs\Document\FileContent'.
34. Click Add to open the drop dialog.
35. In the tree, select 'Text\Base64'.
36. Click OK.

Map format elements to data model as data source

1. In the tree, select 'Invoice\SalesOrder'.
2. Click the Mapping tab.
3. In the tree, expand 'model'.
4. In the tree, select 'model\Sales order number(SalesId)'.
5. Click Bind.
6. In the tree, select 'Invoice\InvoiceNumber'.
7. In the tree, expand 'model\Base invoice(InvoiceBase)'.
8. In the tree, select 'model\Base invoice(InvoiceBase)\Invoice number(Id)'.
9. Click Bind.
10. In the tree, select 'Invoice\InvoiceAmount'.
11. In the tree, select 'model\Base invoice(InvoiceBase)\Invoice amount(Amount)'.
12. Click Bind.
13. In the tree, expand 'model\Invoice attachments'.
14. In the tree, select 'model\Invoice attachments\File content'.

15. In the tree, select 'Invoice\EnclosedDocs\Document\FileContent\Base64'.
16. Click Bind.
17. In the tree, select 'model\Invoice attachments\File name'.
18. In the tree, select 'Invoice\EnclosedDocs\Document\FileName'.
19. Click Bind.
20. In the tree, select 'model\Invoice attachments'.
21. In the tree, select 'Invoice\EnclosedDocs\Document'.
22. Click Bind.
23. Click Save.
24. Close the page.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

ER Use Document Management files in format outputs (Part 4 - Run format)

2/18/2021 • 2 minutes to read • [Edit Online](#)

The following steps explain how a user assigned to the system administrator or electronic reporting developer role can configure an Electronic reporting (ER) format to use Document Management files (attachments) in ER output. These steps can be performed in the DEMF company.

To complete these steps, you must first complete the steps in the "ER Use Document Management files in format outputs (Part 3: Create format)" procedure.

This procedure is for a feature that was added in Dynamics 365 for Operations version 1611.

Add necessary attachments for sales order of a single invoice

1. Go to Accounts receivable > Invoices > Open customer invoices.
2. Use the Quick Filter to find records. For example, filter on the Invoice field with a value of 'CIV-000148'.
 - CIV-000148
3. Click to follow the selected invoice's link.
 - CIV-000148
4. Click to follow the link in the Sales order field.
 - 000148
5. In the Lines or header field, select the option of Header.
 - Select Header to indicate that this will be the target for adding attachments.
6. Click Attach.
 - Add a few files as attachments for this sales order. Use the files of the document types that are supported by the Document Management (with file extensions DOCX, DPF, XML, JPG, etc.). Browse and select files to be attached and further processed with the related invoice in the ER electronic message.
7. Click New.
8. Click File.
9. Click New.
10. Click File.
11. Close the page.
12. Close the page.
13. Close the page.
14. Close the page.

Run the designed report for the selected invoice

1. Go to Organization administration > Electronic reporting > Configurations.
2. In the tree, expand 'Customer invoice model'.
3. In the tree, expand 'Customer invoice model\Customer invoice model (custom)'.
4. In the tree, select 'Customer invoice model\Customer invoice model (custom)\Electronic invoice sample message'.
5. Click Run.
6. Expand the Records to include () section.

7. Click Filter.
8. Select the row of the Customer invoice journal and the Sales order field.
9. In the Criteria field, type '000148'.
 - In the criteria "Sales order" field, type the order number 000148.
10. Click OK.
11. Click OK.
 - Review the generated output. Note that for each attachment a single XML node has been created. The attachment's content is populated to the XML output in MIME (base64) text format.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

ER Use Document Management files in format outputs (Part 5 - Modify and run format)

2/18/2021 • 2 minutes to read • [Edit Online](#)

The following steps explain how a user assigned to the system administrator or electronic reporting developer role can configure an Electronic reporting (ER) format to use Document Management files (attachments) in ER output. These steps can be performed in the DEMF company.

To complete these steps, you must first complete the steps in the "ER Use Document Management files in format outputs (Part 4: Run format)" procedure.

This procedure is for a feature that was added in Dynamics 365 for Operations version 1611.

Modify the format to populate attachments into generating messages in binary format

1. Go to Organization administration > Electronic reporting > Configurations.
2. In the tree, expand 'Customer invoice model'.
3. In the tree, expand 'Customer invoice model\Customer invoice model (custom)'.
4. In the tree, select 'Customer invoice model\Customer invoice model (custom)\Electronic invoice sample message'.
5. Click Designer.
 - You will populate the invoice message in the generating output as an XML file using UNICODE encoding.
6. Click Add root to open the drop dialog.
7. In the tree, select 'Common\File'.
8. In the Name field, type 'Xml message'.
 - Xml message
9. In the Encoding field, type 'UTF-8'.
 - UTF-8
10. Click OK.
 - Configure the generating output as a zipped file.
11. Click Add root to open the drop dialog.
12. In the tree, select 'Common\Folder'.
13. In the Name field, type 'Zip output'.
 - Zip output
14. Click OK.
15. In the tree, select 'Zip output'.
 - Add attachments to the generating zipped file as files with original names and extensions.
16. Click Add to open the drop dialog.
17. In the tree, select 'Common\File'.
18. In the Name field, type 'Attached file'.
 - Attached file
19. Click OK.
20. In the tree, select 'Zip output\Attached file'.

21. Click Add to open the drop dialog.
22. In the tree, select 'Text\Base64'.
23. Click OK.

Map new format elements to data model

1. Click the Mapping tab.
2. In the tree, expand 'model'.
3. In the tree, expand 'model\Invoice attachments'.
4. In the tree, select 'Zip output\Attached file\Base64'.
5. In the tree, select 'model\Invoice attachments\File content'.
6. Click Bind.
7. In the tree, select 'Zip output\Attached file'.
8. Click Edit filename.
9. In the tree, expand 'model'.
10. In the tree, expand 'model\Invoice attachments'.
11. In the tree, select 'model\Invoice attachments\File name'.
12. Click Add data source.
13. Click Save.
14. Close the page.
15. In the tree, select 'model\Invoice attachments'.
16. Click Bind.
17. Click Save.
18. Close the page.

Run the designed report for the selected invoice

1. Click Run.
2. Expand the Records to include () section.
3. Click Filter.
4. Select the row of the Customer invoice journal and the Sales order field.
5. In the Criteria field, In the criteria "Sales order" field, type the order number 000148.
 - 000148
6. Click OK.
7. Click OK.
 - Review the generated output. Note,that in addition to the invoice message in XML format, a single file has been created for each attachment. The attachment files are populated with the zipped output in binary format.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Generate electronic documents and update application data by using ER

2/18/2021 • 2 minutes to read • [Edit Online](#)

You can design Electronic reporting (ER) formats that can be used in the application to generate outgoing electronic documents. You can also design ER formats that parse incoming electronic documents and use the content in those documents to update application data.

With this functionality, a single ER format can be used to generate outgoing electronic documents and then update the application data. This feature can be used in the following scenarios:

- To prevent repeated usage of application data in subsequent processes you can mark an application's data immediately after it is used to generate electronic documents. For example, you can mark payment transactions as already processed immediately after they have been included in a generated payment message.
- To store the processing details of electronic documents that have been generated using ER logic. For example, a unique payment message identification that is generated using the ER expression. The expression is based on information entered in the ER dialog box when the ER format is run to generate documents.

To learn more about this feature, play the set of ER Generate documents with application data update Task guides (part of the 7.5.4.3 Acquire/Develop IT service/solution components (10677) business process), which walk you through the details of Intrastat reporting and archiving. The following files are required to complete certain steps in these Task guides. Download and save these files to your local machine.

- [ER data model configuration: Intrastat \(model\)](#)
- [ER model mapping configuration: Intrastat \(mapping\)](#)
- [ER format configuration: Intrastat \(format\)](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Import configurations to generate documents that have application data

2/18/2021 • 4 minutes to read • [Edit Online](#)

To complete the steps in this procedure, you must first complete the procedure, "ER Create a configuration provider and mark it as active".

The steps in this procedure explain how to design Electronic reporting (ER) configurations to generate an electronic document. In this procedure, you will import the required ER configurations that have been created for the sample company, Litware, Inc. and use them to generate electronic documents. This procedure is created for users with the assigned role of system administrator or electronic reporting developer. These steps can be completed using the DEMF dataset. Before you begin, download and save the files listed in the Help topic, "Generate electronic documents and update application data with ER tool" (generate-electronic-documents-update-application-data/). The files are Intrastat (model).xml, Intrastat (mapping).xml, and Intrastat (format).xml.

1. Go to Organization administration > Workspaces > Electronic reporting.
 - Make sure that the configuration provider for the sample company, Litware, Inc., is available and marked as Active. If you don't see this configuration provider, complete the steps in the procedure, Create a configuration provider and mark it as active.
 - The steps in this procedure show how to use ER capabilities to complete an application data update and how to generate an Intrastat report. The details of the reporting process are archived in the application tables. Currently, when the Intrastat reporting process is activated from the Intrastat form, archiving is done based on the logic programmed in the existing source code. In this procedure, you will configure a similar yet simplified logic of application data using only the ER framework. No changes will be made to the source code.

Import ER configurations

1. Click Reporting configurations.
2. Click Exchange.
3. Click Load from XML file.
 - Import the ER model configuration that contains the data model that is designed to be used as the data source for generating the Intrastat report. Later, you will extend this data model definition to use it for an application data update to archive details of the Intrastat reporting process.
 - Click Browse and select the Intrastat (model).xml file.
4. Click OK.
5. In the tree, select 'Intrastat (model)'.
6. Click Designer.
7. In the tree, expand 'For outgoing document'.
8. In the tree, expand 'For outgoing document\Transactions'.
 - Review the structure of the imported data model. Note that the root item 'For outgoing document' is defined to specify the data flow for getting data from the application and using it as data source to generate the Intrastat report. The 'Transactions (Record list)' is used to represent the list of Intrastat transactions that must be reported. Because you will archive reported commodity codes, the unique identifier of a single commodity code 'Commodity rec id (Int64)' is needed in this data flow.
9. Close the page.
10. Click Exchange.

11. Click Load from XML file.
 - Import the ER mapping configuration that specifies the data flow for getting data from the application and then using it to generate the Intrastat report. Later, you will extend this model mapping definition to get data from the Intrastat report and use it for the application data update to archive details of Intrastat reporting process.
 - Click Browse and select the Intrastat (mapping).xml file.
12. Click OK.
13. In the tree, expand 'Intrastat (model)'.
14. In the tree, select 'Intrastat (model)\Intrastat (mapping)'.
15. Click Designer.
 - Note that the current model mapping contains the value 'To model' in the Direction field. This means that this model mapping has been designed for getting data from the application and storing it in the data model.
16. Click Designer.
17. In the tree, expand 'List'.
18. In the tree, expand 'Transactions= List'.
 - Review the structure of the model mapping that uses the data model that is filtered based on the root item, 'For outgoing document.' Note that the added data source, 'List' provides access to the required application data, which is the list of records from the Intrastat table.
19. Close the page.
20. Close the page.
21. Click Exchange.
22. Click Load from XML file.
 - Import the ER format configuration that specifies the layout of the Intrastat report and the process of populating data to the report. Later, you will extend this format definition to put data from the Intrastat report in to the data model and then use it to update application data to archive the details of Intrastat reporting process.
 - Click Browse and select the Intrastat (format).xml file.
23. Click OK.
24. In the tree, select 'Intrastat (model)\Intrastat (format)'.
25. Click Designer.
26. Click Expand/collapse.
27. In the tree, select 'File\Declaration'.
28. Click the Mapping tab.
29. In the tree, select 'File'.
 - Review the structure of the format used to generate the Intrastat report. Note that it is designed to generate an XML file by populating data from the data model, which is based on the root item 'For outgoing document'. Verify that the name for generated file is defined on the user dialog form ('fn' data source is used for that).
30. Close the page.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Design configurations to generate documents that have application data

2/18/2021 • 2 minutes to read • [Edit Online](#)

To complete the steps in this procedure, you must first complete the procedure, ER Generate documents with application data update (Part 1: Import configurations).

The steps in this procedure explain how to design Electronic reporting (ER) configurations to generate an electronic document. In this procedure, you run the ER imported format configuration that has been created for the sample company, Litware, Inc. to generate electronic documents.

This procedure is created for users with the assigned role of system administrator or electronic reporting developer. These steps can be completed using the DEMF dataset.

Before you begin, change the country context for the DEMF company from DEU (Germany) to BEL (Belgium). Click Organization administration > Organizations > Legal entities to update the country code in the primary address of the legal entity DEMF. Restart your application.

Run imported ER format

1. Go to Organization administration > Electronic reporting > Configurations.
2. In the tree, expand 'Intrastat (model)'.
3. In the tree, select 'Intrastat (model)\Intrastat (format)'.
4. Click Run.
 - Run the draft version of the ER format configuration to generate the Intrastat report.
5. In the Enter file name field, type 'intrastat.xml'.
 - Specify the name of the file.
6. Click OK.
 - Review the generated XML file.
7. Close the page.
8. Go to Tax > Declarations > Foreign trade > Intrastat.
 - Open this form to view the Intrastat transactions that are included in the generated electronic document.
9. Click Intrastat archive.
 - Because the executed ER format does not contain any settings for application data update, the details of the completed Intrastat report have not been archived.
10. Close the page.
11. Close the page.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Modify models and mappings to generate documents that have application data

2/18/2021 • 5 minutes to read • [Edit Online](#)

To complete the steps in this procedure, you must first complete the procedure, "ER Generate documents with application data update (Part 2: Generate documents)".

The steps in this procedure explain how to design Electronic reporting (ER) configurations to generate an electronic document and update application data. In this procedure, you will modify the ER configurations to start using them to generate electronic documents and update application data. This procedure is created for users with the assigned role of system administrator or electronic reporting developer. These steps can be completed using the DEMF dataset.

Modify data model

1. Go to Organization administration > Electronic reporting > Configurations.
2. In the tree, select 'Intrastat (model)'.
 - You will extend how you use the data model. Besides using it as data source to generate the Intrastat report, the data model will be used to collect details about the Intrastat reporting process. The details will then be used to update application data.
3. Click Designer.
4. Click New to open the drop dialog.
5. In the New node as a field, enter 'Model root'.
6. In the Name field, type 'For application data update'.
 - For application data update
7. Click Add.
8. In the tree, select 'For application data update'.
 - This new root item is added to specify the data flow for moving data from the Intrastat report (used as a data source) to the application tables (the update destination). Note that different root items must be used for getting data that is posted to the outgoing document and for getting data from the document that is used to update application data.
9. Click New to open the drop dialog.
10. In the Name field, type 'Archive header'.
 - Archive header
11. In the Item type field, select 'Record list'.
12. Click Add.
 - Because you will create a record for each Intrastat report that is generated, you must create a new item for that.
13. Click New to open the drop dialog.
14. In the Name field, type 'File name'.
 - File name
15. In the Item type field, select 'String'.
16. Click Add.
17. Click New to open the drop dialog.
18. In the Name field, type 'Number of lines'.

- Number of lines
19. In the Item type field, select 'Integer'.
 20. Click Add.
 - Add this item to represent the number of Intrastat transactions that are reported during the current reporting process.
 21. Click New to open the drop dialog.
 22. In the Name field, type 'Archive lines'.
 - Archive lines
 23. In the Item type field, select 'Record list'.
 24. Click Add.
 - Add this item to represent the list of Intrastat transactions that are reported during the current reporting process.
 25. Click New to open the drop dialog.
 26. In the Name field, type 'Amount'.
 - Amount
 27. In the Item type field, select 'Real'.
 28. Click Add.
 29. Click New to open the drop dialog.
 30. In the Name field, type 'Commodity rec id'.
 - Commodity rec id
 31. In the Item type field, select 'Int64'.
 32. Click Add.
 33. Click New to open the drop dialog.
 34. In the Name field, type 'Item number'.
 - Item number
 35. In the Item type field, select 'String'.
 36. Click Add.
 37. Click Save.
 38. Close the page.

Modify model mapping

1. In the tree, expand 'Intrastat (model)'.
2. In the tree, select 'Intrastat (model)\Intrastat (mapping)'.
 - Modify the existing model mapping to start using it for the application data update and to archive Intrastat reporting details.
3. Click Designer.
4. Click New.
5. In the Name field, type 'Update archive'.
 - Update archive
6. In the Direction field, select 'To destination'.
7. Click Save.
 - This new mapping specifies the data flow for moving data (Intrastat reporting details) from the data model to the application tables (the update destination). Note that different model's root items must be used to get data from the application for the reporting process and then use the data from data model for the application data update.
8. Click Designer.
9. In the tree, select 'Data model\Data model'.

- Add the required data source. This is the data model that contains details of the reported Intrastat transactions that must be archived.
10. Click Add root.
 11. In the Name field, type 'model'.
 - model
 12. In the Definition field, enter or select the value 'For application data update'.
 - For application data update
 13. Click OK.
 14. In the tree, expand 'model'.
 15. In the tree, select 'Functions\Calculated field'.
 16. In the tree, select 'model\Archive header'.
 17. Click Add.
 - Because you want to enumerate reported Intrastat transactions for archiving, the appropriate data source must be added.
 18. In the Name field, type 'Enumerated lines'.
 - Enumerated lines
 19. Click Edit formula.
 20. In the tree, select 'List\ENUMERATE'.
 21. Click Add function.
 22. In the tree, expand 'model'.
 23. In the tree, expand 'model\Archive header'.
 24. In the tree, select 'model\Archive header\Archive lines'.
 25. Click Add data source.
 26. In the Formula field, enter 'ENUMERATE(model.'Archive header'.'Archive lines')'.
 - ENUMERATE(model.'Archive header'.'Archive lines')
 27. Click Save.
 28. Close the page.
 29. Click OK.
 30. Click Add destination.
 - Add application tables as required destinations that require updates to archive details of reported Intrastat transactions.
 31. In the Name field, type 'Archive'.
 - Archive
 32. In the Table name field, type 'IntrastatArchiveGeneral'.
 - IntrastatArchiveGeneral
 - Keep the record action 'Insert' so you can add records during the detail archiving of each Intrastat reporting process.
 33. Select Yes in the Record infolog field.
 - Select Yes to get information about issues with the application data update.
 34. Select Yes in the Skip record action validation field.
 - Select Yes to suppress validation errors about the empty 'Intrastat archive ID' field. This will be done after records are added, based on the sequence number settings that are configured for this table in the Foreign trade parameters form.
 35. Click OK.
 - Bind elements of the added data source (the filtered model based on the selected root item) with elements from the added destination.
 36. In the tree, expand 'Archive'.

37. In the tree, expand 'Archive<Relations'.
38. In the tree, expand 'Archive<Relations\IntrastatArchiveDetail'.
39. In the tree, select 'Archive<Relations\IntrastatArchiveDetail\Amount(AmountMST)'.
40. In the tree, expand 'model\Archive header\Enumerated lines'.
41. In the tree, expand 'model\Archive header\Enumerated lines\Value'.
42. In the tree, select 'model\Archive header\Enumerated lines\Value\Amount'.
43. Click Bind.
44. In the tree, select 'Archive<Relations\IntrastatArchiveDetail\Commodity(IntrastatCommodity)'.
45. In the tree, select 'model\Archive header\Enumerated lines\Value\Commodity rec id'.
46. Click Bind.
47. In the tree, select 'Archive<Relations\IntrastatArchiveDetail\Item number(ItemId)'.
48. In the tree, select 'model\Archive header\Enumerated lines\Value\Item number'.
49. Click Bind.
50. In the tree, select 'Archive<Relations\IntrastatArchiveDetail\Line number(LineNumber)'.
51. In the tree, select 'model\Archive header\Enumerated lines\Number'.
52. Click Bind.
53. In the tree, select 'Archive<Relations\IntrastatArchiveDetail'.
54. In the tree, select 'model\Archive header\Enumerated lines'.
55. Click Bind.
56. In the tree, select 'Archive\File name(FileName)'.
57. In the tree, select 'model\Archive header\File name'.
58. Click Bind.
59. In the tree, select 'Archive\Number of lines(NumberOfLines)'.
60. In the tree, select 'model\Archive header\Number of lines'.
61. Click Bind.
62. In the tree, select 'Archive'.
63. In the tree, select 'model\Archive header'.
64. Click Bind.
65. Click Save.
66. Close the page.
67. Close the page.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Modify formats to generate documents that have application data

2/18/2021 • 5 minutes to read • [Edit Online](#)

To complete the steps in this procedure, you must first complete the procedure, "ER Generate documents with application data update (Part 3: Modify model and mapping)".

The steps in this procedure explain how to design Electronic reporting (ER) configurations to generate an electronic document and update application data. In this procedure, you will modify the ER configurations to not just use them to generate electronic documents, but also to update application data. This procedure is created for users with the assigned role of system administrator or electronic reporting developer. These steps can be completed using the DEMF dataset.

Modify format to collect details of reporting

1. Go to Organization administration > Electronic reporting > Configurations.
2. In the tree, expand 'Intrastat (model)'.
3. In the tree, select 'Intrastat (model)\Intrastat (format)'.
4. Click Designer.
5. In the tree, expand 'File'.
6. In the tree, expand 'File\Declaration'.
7. In the tree, select 'File\Declaration\Data'.
8. In the Multiplicity field, select 'One many'.
 - Configure this format element to archive details of the Intrastat reporting process. This item represents the archive's header record.
9. In the tree, expand 'File\Declaration\Data'.
10. In the tree, select 'File\Declaration\Data\Item'.
11. In the Multiplicity field, select 'Zero many'.
 - Configure this format element to archive details of the Intrastat reporting process. This item will represent the list of archived lines.
12. In the tree, expand 'File\Declaration\Data\Item'.
13. In the tree, select 'File\Declaration\Data\Item\Dim1'.
14. Select Yes in the Excluded field.
 - You will not archive this data, so you can exclude this format element from the data source of Intrastat reporting details.
15. In the tree, expand 'File\Declaration\Data\Item\Dim1'.
16. In the tree, select 'File\Declaration\Data\Item\Dim1\property'.
17. Select Yes in the Excluded field.
18. In the tree, select 'File\Declaration\Data\Item\Dim1\date'.
19. Select Yes in the Excluded field.
20. In the tree, select 'File\Declaration\Data\Item\Dim2'.
21. Select Yes in the Excluded field.
22. In the tree, expand 'File\Declaration\Data\Item\Dim2'.
23. In the tree, select 'File\Declaration\Data\Item\Dim2\property'.
24. Select Yes in the Excluded field.

25. In the tree, select 'File\Declaration\Data\Item\Dim2\code'.
26. Select Yes in the Excluded field.
27. In the tree, select 'File\Declaration\Data\Item\Dim3'.
 - Several format elements can have the same name. For example, Dim. You cannot explicitly recognize them when you use this format as a data source for archiving Intrastat reporting details, so you need to define the alternative names for these format elements.
28. In the Name field, type 'Amount'.
 - Amount
29. In the Multiplicity field, select 'Exactly one'.
30. In the tree, select 'File\Declaration\Data\Item\Dim4'.
31. In the Name field, type 'Item'.
 - Item
32. In the Multiplicity field, select 'Exactly one'.
 - In addition to the design format elements, the following Intrastat reporting details must be archived: unique record identification of each reported commodity item and name of the generated file. Because this data will not be populated in the Intrastat report, you need to add the format that is related to these detail elements as data source items.
33. In the tree, select 'File\Declaration\Data'.
34. Click Add to open the drop dialog.
35. In the tree, select 'Data source\Item'.
36. In the Name field, type 'File name'.
 - File name
37. In the Data type field, select 'String'.
38. Click OK.
39. In the tree, select 'File\Declaration\Data\Item'.
40. Click Add Item.
41. In the Name field, type 'Commodity rec ID'.
 - Commodity rec ID
42. In the Data type field, select 'Int64'.
43. Click OK.
44. Click the Mapping tab.
45. In the tree, select 'File\Declaration\Data\File name'.
46. Click Bind.
47. In the tree, expand 'model'.
48. In the tree, expand 'model\Transactions'.
49. In the tree, select 'File\Declaration\Data\Item = model.Transactions\Commodity rec ID'.
50. In the tree, select 'model\Transactions\Commodity rec ID'.
51. Click Bind.
52. Click Save.

Modify format to memorize details of reporting

1. Click Map format to model.
2. Click New.
3. In the Definition field, enter or select the 'For application data update' root item.
 - For application data update.
4. In the Name field, type 'Mapping to update data'.
 - Mapping to update data

5. Click Save.

- This mapping defines how the details of the Intrastat report are collected in the data model, the structure of which is specified by the selected root item 'For application data update'. These details, the model mapping with same root item 'For application data update', and the direction 'To destination' will be used for the application data update. The application data update starts immediately after the outgoing Intrastat report is generated. The application data update can be skipped at run-time, but the data model must be empty (containing empty record list).

6. Click Designer.

- The outgoing Intrastat report format is added by default as a data source for this model mapping.
- Bind elements of the designed report (presented as data source) to elements of the data model, which is filtered based on the selected model's root item.

7. In the tree, expand 'Archive header'.

8. In the tree, expand 'Archive header\Archive lines'.

9. In the tree, expand 'format'.

10. In the tree, expand 'format\Declaration: XML Element(Declaration)'.

11. In the tree, expand 'format\Declaration: XML Element(Declaration)\Data: XML Element 1..* (Data)'.

12. In the tree, expand 'format\Declaration: XML Element(Declaration)\Data: XML Element 1..* (Data)\Item: XML Element 0..* (Item)'.

13. In the tree, expand 'format\Declaration: XML Element(Declaration)\Data: XML Element 1..* (Data)\Item: XML Element 0..* (Item)\Dim3: XML Element 1..1 (Amount)'.

14. In the tree, expand 'format\Declaration: XML Element(Declaration)\Data: XML Element 1..* (Data)\Item: XML Element 0..* (Item)\Dim4: XML Element 1..1 (Item)'.

15. In the tree, select 'Archive header\Number of lines'.

16. Click Edit.

17. In the tree, select 'List\COUNT'.

18. Click Add function.

19. In the tree, expand 'format'.

20. In the tree, expand 'format\Declaration: XML Element(Declaration)'.

21. In the tree, expand `format\Declaration: XML Element(Declaration)\Data: XML Element 1..* (Data)`.

22. In the tree, select

`format\Declaration: XML Element(Declaration)\Data: XML Element 1..* (Data)\Item: XML Element 0..* (Item)`.

23. Click Add data source.

24. In the Formula field, enter 'COUNT(format.Declaration.Data.Item)'.

- COUNT(format.Declaration.Data.Item)

25. Click Save.

26. Close the page.

27. In the tree, select 'Archive header\File name'.

28. In the tree, select 'format\Declaration: XML Element(Declaration)\Data: XML Element 1..* (Data)\File name: Item String(File name)'.

29. Click Bind.

30. In the tree, select

`format\Declaration: XML Element(Declaration)\Data: XML Element 1..* (Data)\Item: XML Element 0..* (Item)\Dim4: XML Element 1..1 (Item)\number: String(number)`

31. In the tree, select 'Archive header\Archive lines\Item number'.

32. Click Bind.

33. In the tree, select

`format\Declaration: XML Element(Declaration)\Data: XML Element 1..* (Data)\Item: XML Element 0..* (Item)\Dim3: XML Element 1..1 (Amount)\value: Numeric Real(value)`

34. In the tree, select 'Archive header\Archive lines\Amount'.

35. Click Bind.

36. In the tree, select

```
format\Declaration: XML Element(Declaration)\Data: XML Element 1..* (Data)\Item: XML Element 0..* (Item)\Commodity rec ID: Item Int64(Commodity rec ID)
```

37. In the tree, select 'Archive header\Archive lines\Commodity rec ID'.

38. Click Bind.

39. In the tree, select 'Archive header\Archive lines'.

40. In the tree, select

```
format\Declaration: XML Element(Declaration)\Data: XML Element 1..* (Data)\Item: XML Element 0..* (Item)
```

41. Click Bind.

42. In the tree, select 'Archive header'.

43. In the tree, select `format\Declaration: XML Element(Declaration)\Data: XML Element 1..* (Data)`.

44. Click Bind.

45. Click Save.

46. Close the page.

47. Close the page.

48. Close the page.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Generate documents that have application data

2/18/2021 • 2 minutes to read • [Edit Online](#)

To complete the steps in this procedure, you must first complete the procedure, "ER Generate documents with application data update (Part 4: Modify format)".

The steps in this procedure explain how to design Electronic reporting (ER) configurations to generate an electronic document and update application data. In this procedure, you execute the ER format configuration to generate the Intrastat report and update application data for archiving details of the reporting process.

This procedure is created for users with the assigned role of system administrator or electronic reporting developer. These steps can be completed using the DEMF dataset. Before you begin, make sure that the country context for the DEMF company is BEL (Belgium).

Set up foreign trade parameters

1. Go to Tax > Setup > Foreign trade > Foreign trade parameters.
2. Click the Number sequences tab.

Archiving details of Intrastat reporting process, we need to identify records of each archive we created. A special number sequence must be configured for that.

3. Select the 'Intrastat archive ID' reference.
4. In the Number sequence code field, type a value.

In the 'Number sequence code' field, enter or select the value 'Fore_2'.

5. ResolveChanges the Number sequence code.
6. Click Save.
7. Close the page.

Run modified ER format

1. Go to Organization administration > Electronic reporting > Configurations.
2. In the tree, expand 'Intrastat (model)'.
3. In the tree, select 'Intrastat (model)\Intrastat (format)'.
4. Click Run.
5. In the Enter file name field, type 'intrastat2.xml'.
6. Click OK.

Review ER format execution's results

Review the generated XML file.

1. Close the page.
2. Go to Tax > Declarations > Foreign trade > Intrastat.

Open this form containing Intrastat transactions that have been included to the generated electronic document.

3. Click Intrastat archive.

Since the executed ER format contains now settings for application data update, the details of the completed Intrastat reporting have been archived. In this form, you can see the header record of the created archive.

4. Click Details.

In this form, you can see the details for the created archive.

5. Close the page.

6. Close the page.

7. Close the page.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Parse incoming documents

2/18/2021 • 6 minutes to read • [Edit Online](#)

This topic covers the following three tasks:

- [Parse incoming documents to update application data](#)
- [Parse incoming documents in Excel format](#)
- [Parse incoming documents in CSV format](#)

Parse incoming documents to update application data

You can design Electronic reporting (ER) formats and run them in the application to parse incoming electronic documents and then use their content to update application data.

The following new ER functionality that has been introduced improves the parsing of incoming electronic documents in XML format:

- The **CASE** format element can be used as a root element of the ER format that is configured to parse incoming electronic documents in XML format. The **FILE** format element is supported as a nested element of the **CASE** element. Therefore, you can configure a single ER format to parse incoming electronic documents that might contain different root XML elements.
- A **Parsing order of nested elements** attribute has been introduced for XML format elements in ER formats. You can use this attribute to define a single XML element that is expected in the incoming file. There are two valid sequences of the nested elements:
 - **As in format** – The incoming file is valid when the sequence of nested elements in the file is the same as the order that is described in the ER format.
 - **Any** – The incoming file is valid when all nested elements in the ER format are present in the parsing file, regardless of their sequence in that file.

To become more familiar with the details of this feature, play the task guide, ER - Parse incoming documents to update application data (part of the 7.5.4.3 Acquire/Develop IT service/solution components (10677) business process). This task guide shows how the responses from a web service can be parsed by using an ER format.

To complete some steps of the task guide, you must download the following files:

CONTENT DESCRIPTION	FILE
ER data model configuration	EFSTAmodel.xml
ER format configuration	EFSTAformat.xml
Web service response sample 1	Response1.xml
Web service response sample 2	Response2.xml
Web service response sample 3	Response3.xml
Web service response sample 4	Response4.xml

Parse incoming documents in Excel format

You can design Electronic reporting (ER) formats to parse incoming Microsoft Excel files that represent data in Microsoft Excel workbooks (files in XLSX format). You can then use the content from these files to update application data. This is useful if you:

- Design a new model and format and want to test them at run-time. In this case, Excel will simulate the actual application data.
- Manage data beyond your application in Excel and want to import this data to submit a specific report.

To learn more about this feature, play the task guides **ER Import data from a Microsoft Excel file (Part 1: Design format)** and **ER Import data from a Microsoft Excel file (Part 2: Import data)** (parts of the 7.5.4.3 Acquire/Develop IT service/solution components (10677) business process). These task guides walk through how the incoming Excel file can be parsed by using the ER format to import information from incoming documents and update application data. You can download the task guide files from the [Microsoft Download Center](#).

Download the following files to complete the task guides mentioned above.

CONTENT DESCRIPTION	FILE
Incoming file in .XLSX format - template	1099import-template.xlsx
Incoming file in .XLSX format - sample data	1099import-data.xlsx

If you have not yet played the following task guide, [ER Create required configurations to import data from an external file](#) in the current Finance and Operations application, download the following file.

CONTENT DESCRIPTION	FILE
ER model configuration	1099model.xml

Parse incoming documents in CSV format

You can design Electronic reporting (ER) formats to parse incoming electronic documents that represent tabular data in plain text (files in CSV format) and then use the content from these documents to update application data. The following approach can be used:

- Begin your format's design by adding a new root sequence element to specify that each line in the parsing file is considered a separate record.
 - In the added sequence element, select the appropriate value, for example **New line - Windows (CR LF)**, in the **Special characters** field in the **Sequence element delimiter** field group.
- Continue your format's design by adding a nested sequence element of the added root sequence element to specify that each line in the parsing file is considered as a set of fields.
 - You can specify the character in the **Custom delimiter** field that will be recognized in the parsing line as a fields separator.

NOTE

- You can define different field separators for different sequence elements to parse specific file lines in which fields are separated by different characters.
- The **Custom delimiter** field can be left blank for certain sequence elements. An empty field means that any file line that is parsed by using this sequence will be parsed like a .txt (fixed length text) file line.

- In the **Quotation application** field, select the value when you expect that some fields of any line that is parsed by this sequence element will be enclosed by certain characters. The following options are available:
 - **All** – Include quotation characters in the parsing line for any field of any data type. If you select this, define the desired characters in the **Quotation mark** field that will be used for fields quotation. For example, the double quotes character.
 - **Text only** – Include quotation characters in the parsing line for any field of the **String** data type. If you select this, define the desired characters in the **Quotation mark** field that will be used for fields quotation.
 - **Derive from parent only** – Use the same **Quotation application** field settings that are defined for the parent sequence element. Note that the **Quotation mark** field setting will be taken from the settings of the parent sequence element as well.
 - **None** – Exclude quotation characters in the parsing line for any field of any data type.
- Complete your format's design by adding nested elements for the added sequence element that represents the set of fields of the parsing line. Add the required elements of the **Text** group, such as **String**, **DateTime**, and **Numeric**, to describe the structure of the parsing line as a set of individual fields of different data types.
 - For each format element that represents an individual field of the parsing line, by default, nothing is selected in the **Multiplicity** field. This means that the value of the field in the parsing line is considered required. In the **Multiplicity** field, select **Zero one** to consider the value of this field in the parsing line as optional.

NOTE

The data source item **isMatch** is available when you map this format to ER data model for each **String**, **DateTime**, or **Numeric** format element with the option **Zero one** selected in the **Multiplicity** field. When this field contains a value, **isMatch** will return **True**. If there is no value in the field, it will return **False**.

To learn more about this feature, play the task guide, **ER Create a format configuration to import data from an external CSV file** (part of the 7.5.4.3 Acquire/Develop IT service/solution components (10677) business process), which walks through how the incoming CSV file can be parsed by using the ER format to update application data.

Download the following files to complete the task guide mentioned above.

TITLE	FILE NAME
ER format configuration	1099formatcsv.xml
Sample of incoming file in .csv format	1099entriescsv.csv

Download the following file that is required to complete the task guide mentioned above if you have not played the task guide, **ER Create required configurations to import data from an external file for electronic**

reporting in the current Finance and Operations application.

TITLE	FILE NAME
ER model configuration	1099model.xml

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

ER Create required configurations to import data from an external file

2/18/2021 • 12 minutes to read • [Edit Online](#)

The following steps explain how a user in the System administrator or Electronic reporting developer role can design Electronic reporting (ER) configurations to import data in to the application from an external file. In this example, you will create the required ER configurations for the sample company, Litware, Inc. To complete these steps, you must first complete the steps in the Task guide, "ER Create a configuration provider and mark it as active." These steps can be completed using the USMF data set. You must also download and save the following files locally using links from the Electronic reporting overview topic (<https://go.microsoft.com/fwlink/?linkid=852550>): 1099model.xml, 1099format.xml, 1099entries.xml, 1099entries.xlsx.

ER offers business users the ability to configure the process of importing external data files to tables in either .XML or .TXT format. First, an abstract data model and an ER data model configuration must be designed to represent the data that you are importing. Next, you need to define the structure of the file that you are importing and the method that you will use to port the data from the file to the abstract data model. The ER format configuration that maps to the designed data model must be created for that abstract data model. Then, the data model configuration must be extended with a mapping that describes how the imported data is persisted as abstract data model data and how it is used to update tables. The ER data model configuration must be appended with a new model mapping that describes the binding of the data model to the application's destinations.

The following scenario shows the ER data import capabilities. This includes vendor transactions that are tracked externally and then imported to be reported later in Vendor's settlement for 1099's.

Add a new ER model configuration

1. Go to Organization administration > Workspaces > Electronic reporting.

Verify that the configuration provider for sample company 'Litware, Inc.' is available and marked as active. If you don't see this configuration provider, you must first complete the steps in the procedure, "Create a configuration provider and mark it as active."

2. Click Reporting configurations.

Instead of creating of a new model to support data import, load the file, 1099model.xml, that you previously downloaded. This file contains the custom data model of vendors' transactions. This data model is mapped to the data components that are in the AOT data entity.

3. Click Exchange.

4. Click Load from XML file.

Click Browse and navigate to the 1099model.xml file that you previously downloaded.

5. Click OK.

6. In the tree, select '1099 Payments model'.

Review data model settings

1. Click Designer.

This model is designed to represent vendors' transactions from the business standpoint and are separate from the implementation.

2. In the tree, expand '1099-MISC'.
3. In the tree, select '1099-MISC\Transactions'.
4. In the tree, expand '1099-MISC\Transactions'.

The Transactions element of this model represents individual transactions. The child elements are used to specify required details, such as vendor account and transaction date, for each transaction.

5. Close the page.

Add a new ER format configuration that supports data import

The steps in this subtask show you how a new format configuration can be created to manage data import from external files.

1. Click Create configuration to open the drop dialog.
2. In the New field, enter 'Format based on data model 1099 Payments model'.
3. Select Yes in the Supports data import field.
4. Press ESC key to close this page.

Instead of creating a new format to support data import, load the 1099format.xml file that you previously downloaded. This file contains the defined structure of the file you are importing and the mapping of the structure to the custom data model of vendors' transactions.

5. Click Exchange.
6. Click Load from XML file. Click Browse and navigate to the 1099format.xml file that you previously downloaded.
7. Click OK.
8. In the tree, expand '1099 Payments model'.
9. In the tree, select '1099 Payments model\Format for importing vendors' transactions'.

Review format settings

1. Click Designer.
2. Toggle 'Show details' on.
3. Click Expand/collapse.
4. Click Expand/collapse.

The designed format represents the expected structure of the external file. This file must be in XML format and have the settlement root element. Each vendor's transaction is represented by the transaction element that is defined as having zero-to-many multiplicity. This means that the incoming file may contain anywhere from zero to multiple transactions. Nested elements of the 'transaction' element represent a single transaction's attributes. Note that all attributes, except country, are marked as mandatory, meaning that it is required to have them in the importing file.

Review the settings of the format mapping to the data model

1. Click Map format to model.

The mapping 'For importing vendors' transactions' contains the data transfer rules from the incoming XML file to the selected part of the custom data model, which is defined by selecting the1099-MISC definition.

2. Click Designer.
3. Toggle 'Show details' on.
4. In the tree, expand 'format: Record'.
5. In the tree, select 'format: Record'.

Note that the designed format is presented here as a data source component.

6. In the tree, expand `format: Record*settlement: XML Element 1..1 (settlement): Record`.

7. In the tree, expand

```
format: Record\*settlement: XML Element 1..1 (settlement): Record\transaction: XML Element 0..*
(transaction): Record list
```

8. In the tree, expand

```
format: Record\*settlement: XML Element 1..1 (settlement): Record\transaction: XML Element 0..*
(transaction): Record list\*vendor: XML Element 1..1 (vendor): Record
```

9. In the tree, expand

```
format: Record\*settlement: XML Element 1..1 (settlement): Record\transaction: XML Element 0..*
(transaction): Record list\country: XML Element 0..1 (country): Record
```

10. In the tree, select

```
format: Record\*settlement: XML Element 1..1 (settlement): Record\transaction: XML Element 0..*
(transaction): Record list\*vendor: XML Element 1..1 (vendor): Record
```

Note that the presentation of mandatory and optional format elements is different in the predefined 'format' data source component.

11. In the tree, expand 'Transactions: Record list= format.settlement.'\$enumerated''.

Note that the elements of the format that defines the structure of the imported file are bound to the elements of the custom data model. Based on these bindings, the content of the imported XML file will be stored at run-time in the existing data model. Pay attention to the binding of the country element. For any transaction element in the incoming file that has no such element, the default country code 'USA' will be populated in the data model.

12. Click the Validations tab.

This format mapping may contain user-defined logic to validate the accuracy of the imported data from a business standpoint. For example, based on the setting, for any transaction in the importing file without a defined country code, a warning message will be generated in the Infolog informing the user about the case and indicating the transaction's sequence number.

13. Close the page.

Run the format mapping to the data model

Execute this format mapping for testing purposes. Use the file 1099entries.xml that you previously downloaded.

You can export this file from the 1099entries.xlsx workbook that is used to manage vendor transactions. The generated output will be imported from the selected XML file and populate the custom data model at real import.

1. Click Run.

Click Browse and navigate to the 1099entries.xml file that you previously downloaded.

2. Click OK.

Note the warning message about a missing country code for a transaction in the imported file.

Review the output in XML format, which represents the data that has been imported from the selected file and ported to the data model.

3. Close the page.
4. Close the page.

Review the settings for the model mapping to the destinations

1. In the tree, select '1099 Payments model'.
2. Click Designer.
3. Click Map model to datasource.

The mapping For 1099 manual transactions import has been defined with the To destination direction type. This means that it has been entered to support data import and contains the setting of rules defining how the imported external file and persisted as abstract data model data is used to update tables in the application.

4. Click Designer.
5. In the tree, expand 'model: Data model 1099 Payments model'.
6. In the tree, expand 'model: Data model 1099 Payments model\Transactions: Record list'.

Note that the designed model is presented here as a data source element. At runtime, it will contain the data that is imported from the external file. Several tables were added as data source elements to ensure that the imported data is compliant with the data of the current application, including whether the importing transaction vendor account is available in the system, whether the combination of the importing country and state codes exists, etc.

7. In the tree, select 'model: Data model 1099 Payments model\Transactions: Record list\$failed: Calculated field = IF(OR(ISEMPTY(model.Transactions.'\$refs'.vendor), ISEMPTY(model.Transactions.'\$refs'.vendor1099), ISEMPTY(model.Transactions.'\$refs'.box1099), ISEMPTY(model.Transactions.'\$refs'.country), ISEMPTY(model.Transactions.'\$refs'.state), ISEMPTY(model.Transactions.'\$refs'.location)), true, false): Boolean'.
8. Click Edit.
9. Click Edit formula.

When at least one validation fails for a single imported transaction, this transaction will be marked as failed by the data source attribute '\$failed'.

10. Close the page.
11. Click Cancel.

12. In the tree, select 'tax1099trans: Table 'VendSettlementTax1099' records= model.Validated'.

13. Click Edit destination.

This ER destination was added to specify how the imported data will update the application tables. In this case, the data table VendSettlementTax1099 has been selected. Because the record action Insert has been selected, the imported transactions will be inserted in the table VendSettlementTax1099. Note that a single model mapping may contain several destinations. This means that the imported data can be used to update multiple application's tables at once. Tables, views, and data entities can be used as ER destinations.

If the mapping will be called from a point in the application (such as button or menu item) that was specifically designed for this action, the ER destination should be marked as the integration point. In this example this is the ERTableDestination#VendSettlementTax1099 point.

14. Click Cancel.

15. Click Show all.

16. Click Show mapped only.

17. In the tree, expand 'tax1099trans: Table 'VendSettlementTax1099' records= model.Validated'.

Note that the data source element that contains the only validated transactions is bound to the created destination. You can filter the imported transactions to skip the ones that are incompatible with the applications' data.

18. In the tree, select 'failed: Table 'VendSettlementTax1099Entity' records= model.Failed'.

19. Click the Validations tab.

This model mapping may contain user-defined logic to validate the correctness of the imported data from the existing application data. For example, based on the present setting, for any transaction in the imported file with a vendor account that is not in the system, a warning message will be generated informing the user and indicating the incorrect vendor account code.

Note that the Post validation action option can be used for each validation, to specify whether the import process must be continued or stopped, as well as if the already performed inserts/updates can be kept or rolled back.

20. Click Show mapped only.

21. Click Show all.

22. Close the page.

Execute this model mapping to test the designed format and model mappings. Use the file 1099entries.xml. The data from the selected file will be imported in to the system.

23. Click Run.

Note that the dialog box contains no additional questions about the format mapping that must be used to parse the imported file and then port the data to the data model. This is because there is currently only one format that uses this model, which is marked as designed to support data import.

Define the voucher ID to differentiate the imported transactions from other transactions that may already have been entered manually or imported.

24. In the Enter voucher id field, type 'IMPORT-001'.

Browse to get the '1099entries.xml' file.

25. Click OK.

The list of generated warnings provides information about incorrect vendor accounts, an incorrect tax 1099 box code, missing country codes, etc. Compare this list of warnings to the content that is included in the execution XML file.

26. Close the page.

27. Close the page.

28. Close the page.

29. Close the page.

30. Go to Accounts payable > Periodic tasks > Tax 1099 > Vendor settlement for 1099s.

This form shows the cumulative transactions in the Tax1099Summary table that have been created based on imported transactions.

31. In the From date field, set the date to '2000-01-01'.

32. Click Manual 1099 transactions.

This form contains the list of transactions that were added manually and those that we just imported.

33. Open Voucher column filter.

34. Enter a filter value of "IMPORT-001" on the "Voucher" field using the "begins with" filter operator.

Review the relationship between model and format mappings

1. Close the page.

2. Close the page.

3. Go to Organization administration > Workspaces > Electronic reporting.

4. Click Reporting configurations.

5. In the tree, select '1099 Payments model'.

Assume that you want to support importing the same data but from a .TXT file format.

6. Click Create configuration to open the dialog box.

7. In the New field, enter 'Format based on data model 1099 Payments model'.

8. In the Name field, type 'Import data from TXT file'.

9. Select Yes in the Supports data import field.

10. Click Create configuration.

11. Click Designer.

12. Click Map format to model.

13. Click New.

14. In the Definition field, enter or select a value.

Select '1099-MISC' option.

15. In the Name field, type 'Import data from TXT file'.

16. In the Description field, type 'Import data from TXT file'.

17. Click Save.

18. Close the page.

19. Close the page.

20. Click Edit.

If you installed the hotfix "KB 4012871 Support of GER model mappings in separated configurations with an ability to specify different kinds of prerequisites for deploying them on different versions of Dynamics 365 Finance" ([KB 4012871](#)), execute the next step "Turn the flag 'Default for model mapping' on" for the entered format configuration. Skip the next step otherwise.

21. Select Yes in the Default for model-mapping field.

22. In the tree, select '1099 Payments model'.

23. Click Designer.

24. Click Map model to datasource.

25. Click Run.

If you installed the hotfix, KB 4012871 Support of GER model mappings in separated configurations with an ability to specify different kinds of prerequisites for deploying them on different versions ([KB 4012871](#)), select the preferred model mapping in the lookup field. If you haven't installed the hotfix yet, skip to the next step as the mapping has already been selected by the definition of the default format configuration.

If you have not installed the hotfix, KB 4012871, notice that the dialog box contains an additional model-mapping question that is used to parse the file that you are importing. The data is then ported from the dialog box to the data model. Currently, you can choose which format mapping must be used depending on the type of file that you plan to import.

If you plan to call this model mapping from a point in the application that is specifically designed for the action, the ER destination and the format mapping must be marked as part of the integration.

26. Click Cancel.

27. Close the page.

28. Close the page.

NOTE

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Configure data import from SharePoint

2/18/2021 • 9 minutes to read • [Edit Online](#)

To import data from an incoming file by using the Electronic reporting (ER) framework, you must configure an ER format that supports the import and then run a model mapping of the **To destination** type that uses that format as a data source. To import data, you must navigate to the file that you want to import. The incoming file can be manually selected by user. With the new ER capability to support importing data from Microsoft SharePoint, this process can be configured as unattended. You can use ER configurations to perform data import from files that are stored in Microsoft SharePoint folders. This topic explains how to complete the import from SharePoint. The examples use vendor transactions as business data.

Prerequisites

To complete the examples in this topic, you must have the following access:

- Access one of the following roles:
 - Electronic reporting developer
 - Electronic reporting functional consultant
 - System administrator
- Access to the instance of Microsoft SharePoint Server that is configured for use with the application.
- ER format and model configurations for 1099 payments.

Create required ER configurations

Play the **ER Import data from a Microsoft Excel file** task guides, which are part of the **7.5.4.3 Acquire/Develop IT service/solution components (10677)** business process. These task guides walk you through the process of designing and using ER configurations to interactively import vendor transactions from Microsoft Excel files. For more information, see [Parse incoming documents in Excel format](#). After you have completed the task guides, you will have the following setup.

ER configurations

- ER model configuration, **1099 Payments model**
- ER format configuration, **Format for importing vendors' transactions from Excel**

The screenshot displays the Dynamics 365 Finance and Operations interface. The main window shows the configuration details for an ER format configuration named "Format for importing vendors' t...". The configuration is set to "Country/region codes" and "Run Draft" is enabled. The configuration provider is "Litware, Inc." and "Default for model mapping" is also enabled. Below the configuration details, a table shows the versions of the configuration:

R...	Version	Status	Effective from	Version created	Description	Base
	6.2	Draft		4/2/2018 08:25:58 AM		1099 Payment... 6
	6.1	Completed		4/2/2018 08:21:29 AM	Initial version	1099 Payment... 6

Sample of the incoming file for data import

- Excel file **1099import-data.xlsx**, with vendor transactions that should be imported.

	A	B	C	D	E	F	G	H	I	J	K	L	M	N
1	US-101	3/25/2018	MISC-01	3,000.00	USA	WA								
2	US-103	4/12/2018	MISC-02	4,000.00	USA	IL								
3	US-105	5/1/2018	MISC-03	450.00	USA	CO								
4														
5														
6														
7														

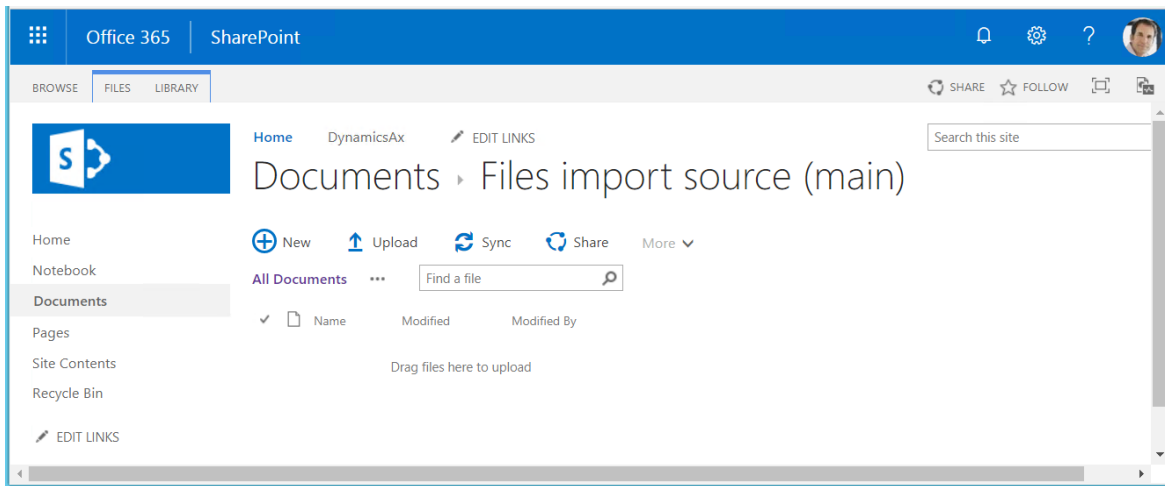

NOTE

The format for importing vendor transactions is selected as the default model mapping. Therefore, if you run a model mapping of the **1099 Payments model**, and that model mapping is of the **To destination** type, the model mapping runs this format to import data from external files. It then uses that data to update application tables.

Configure access to SharePoint for file storage

To store electronic report files in a SharePoint location, you must configure access to the SharePoint Server instance that will be used by the current company. In this example, the company is USMF. For instructions, see [Configure SharePoint storage](#).

1. Complete the steps in [Configure SharePoint storage](#).
2. Open the configured SharePoint site.
3. Create the following folders where incoming electronic reporting files can be stored:
 - Files import source (main) (Example shown in screenshot below)
 - Files import source (alternative)

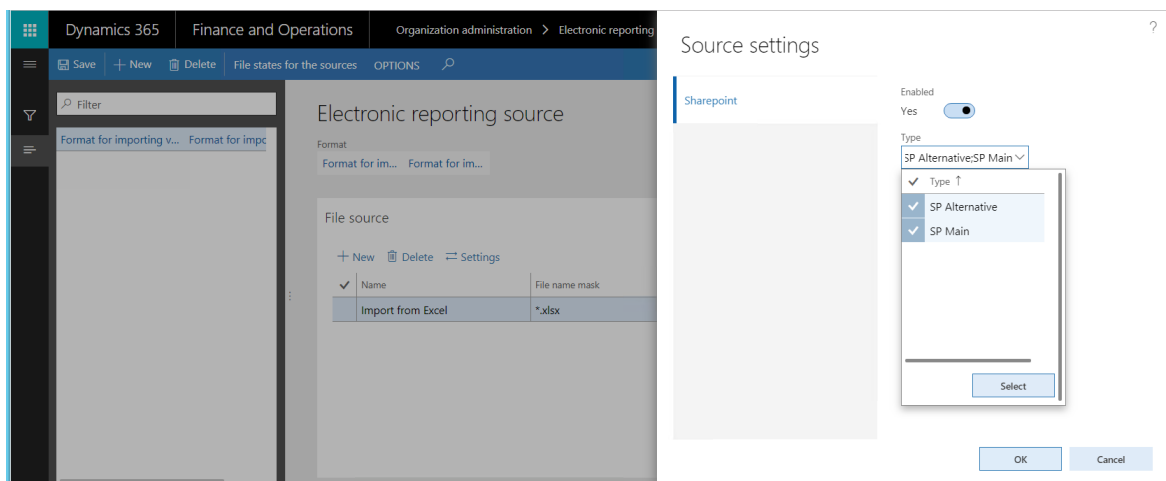

4. (Optional) Create the following folders where the files can be stored after import.
 - Files archive folder - This folder would be for successfully imported files.
 - Files warning folder - This folder would be for files that were imported with a warning.
 - Files error folder - This folder would be for files that failed to import.
5. Go to **Organization administration > Document management > Document types**.
6. Create the following document types that will be used to access the SharePoint folders that you created. For instructions, see [Configure document types](#).

DOCUMENT TYPE	GROUP	LOCATION	SHAREPOINT FOLDER
SP Main	File	SharePoint	Files import source (main)
SP Alternative	File	SharePoint	Files import source (alternative)
SP Archive	File	SharePoint	Files archive folder
SP Warning	File	SharePoint	Files warning folder
SP Error	File	SharePoint	Files error folder

Configure ER sources for the ER format

1. Click **Organization administration > Electronic reporting > Electronic reporting source**.
2. On the **Electronic reporting source** page, configure the source files for data import by using the configured ER format.
3. Define a file name mask, so that only files with the .xlsx extension are imported. The file name mask is optional and is used only when it has been defined. You can define only one mask for each ER format.
4. Change **Sort files before import** to **Do not sort**, if there are several files for import and the import order is not important
5. Select all SharePoint folders that you created earlier.

NOTE

- The ER *source* is defined for each application company individually. By contrast, ER *configurations* are shared across companies.
- When you delete an ER source setting for an ER format, all connected file states (see below) are also deleted by confirmation.

Review the files states for the ER format

1. On the **Electronic reporting source** page, select **File states for the sources** to review the content of the configured file sources for the current ER format.
2. In the **Files** section, review the list of files. This list presents the following:
 - Source files that are applicable, based on the file name mask (if a file name mask is defined), and that are ready for data import. For these files, the **Sources log for the import format** section is blank.
 - Previously imported files. For each of these files, in the **Sources log for the import format** section, you can review the history of import of this file.

You can also open the **File states for the sources** page by selecting **Organization administration** > **Electronic reporting** > **File states for the sources**. In this case, the page provides information about file sources for all ER formats that file sources have been configured for in the company that you're currently signed in to.

Import data from Excel files that are in a SharePoint folder

1. In SharePoint, upload the Microsoft Excel file **1099import-data.xlsx** that contains vendor transactions to the **Files import source (main)** SharePoint folder that you created earlier.

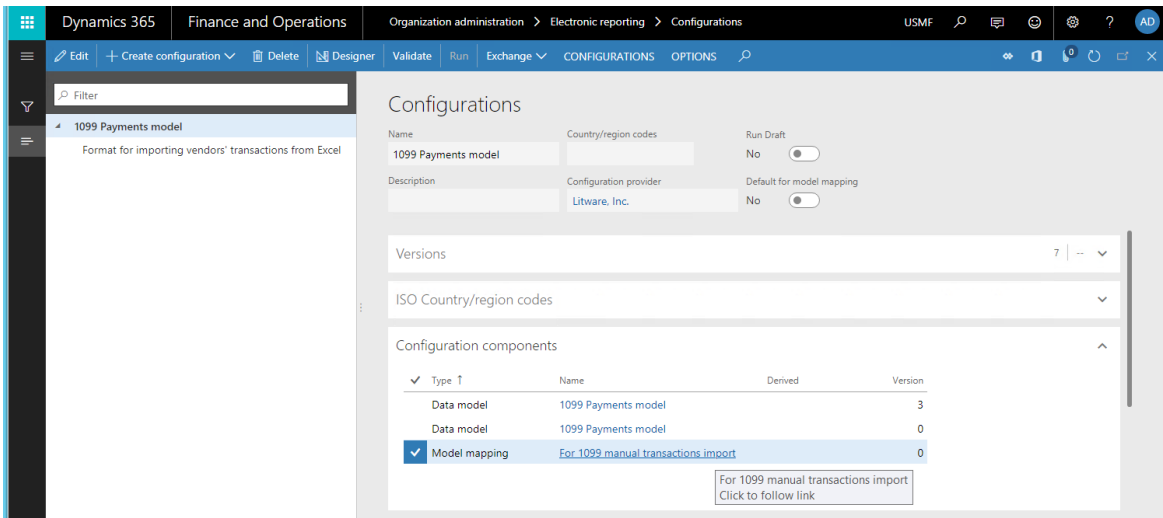

2. On the **File states for the sources** page, select **Refresh** to refresh the page. The Excel file that was uploaded to SharePoint appeared on this page with the status **Ready**. The following statuses are currently supported:
 - **Ready** – Assigned automatically for each new file in a SharePoint folder. This status means that the file is ready for import.
 - **Importing** – Assigned automatically by an ER report when the file will be locked by the import process to prevent its usage by other processes (if many of them are running simultaneously).
 - **Imported** – Assigned automatically by an ER report when the file import is successfully completed. This status means that the imported file has been deleted from the configured files source (SharePoint folder).

- **Failed** – Assigned automatically by an ER report when the file import completed with errors or exceptions.
- **On hold** – Assigned manually by user on this page. This status means that the file will not be imported for now. This status can be used to postpone the import of some files.

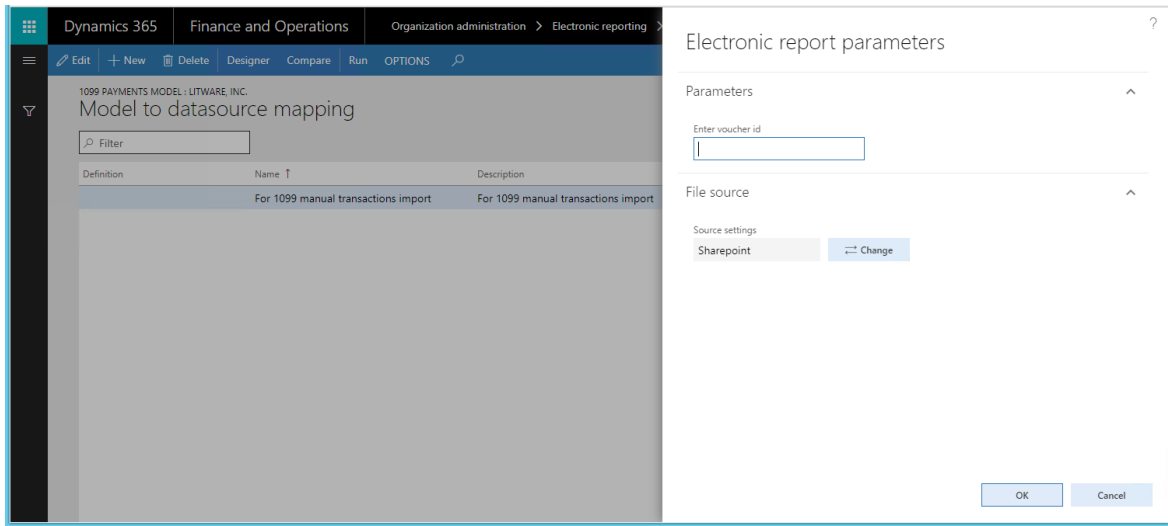

Import data from SharePoint files

1. Open the ER configurations tree, select the **1099 Payment model**, and expand the list of ER model components.
2. Select the name of the model mapping to open the list of model mappings of the selected ER model configuration.

3. Select **Run** to run the selected model mapping. Because you configured file sources for the ER format, you can change the setting of the **File source** option, if needed. If you keep the setting of this option, the .xlsx files are imported from the configured sources (the SharePoint folders, in this example).

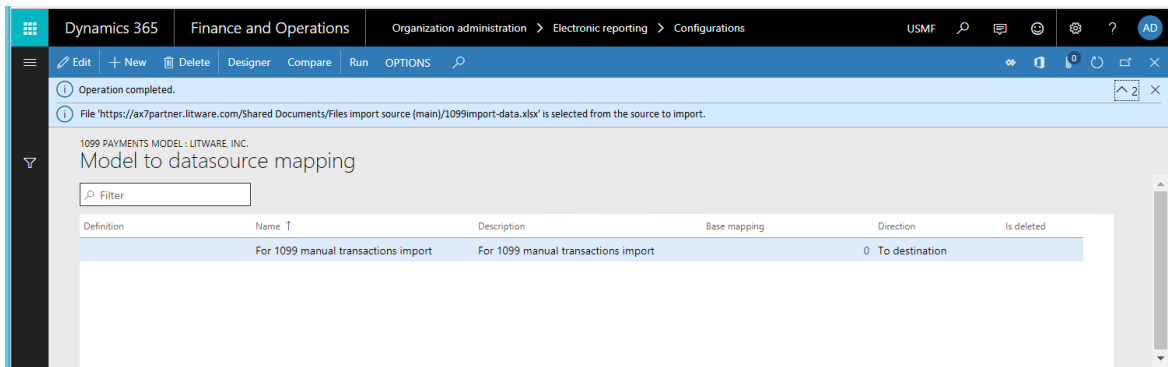

In this example, you're importing only one file. However, if there are multiple files, they are selected for importing in the order in which they were added to the SharePoint folder. Every run of an ER format imports a single selected file.

4. The model mapping can run **unattended** in batch mode. In this case, every time that a batch runs this ER format, a single file is imported from the configured file sources.

When a file is successfully imported from the SharePoint folder, it's deleted from that folder and moved to folder for successful imported files or to the folder to imported files with warnings. Otherwise it's moved to folder for failed files or stays in this folder if the folder for failed files isn't set up.

5. Enter the voucher ID, such as **V-00001**, and then select **OK**.

6. On the **File states for the sources** page, select **Refresh** to refresh the page.

7. In the **Files** section, review the list of files. The **Sources log for the import format** section provides the history of the Excel file import. Because this file was successfully imported, it's marked as **Deleted** in the SharePoint folder.

8. Review the **Files import source (main)** SharePoint folder. The Excel files that were successfully imported have been deleted from this folder.
9. Select **Accounts payable > Periodic tasks > Tax 1099 > Vendor settlement for 1099s**.
10. In the **From date** and **To date** fields, enter appropriate values. Then select **Manual 1099 transactions**.

The vendor transactions that were imported from the Excel files on SharePoint for voucher **V-00001**, are presented on the page.

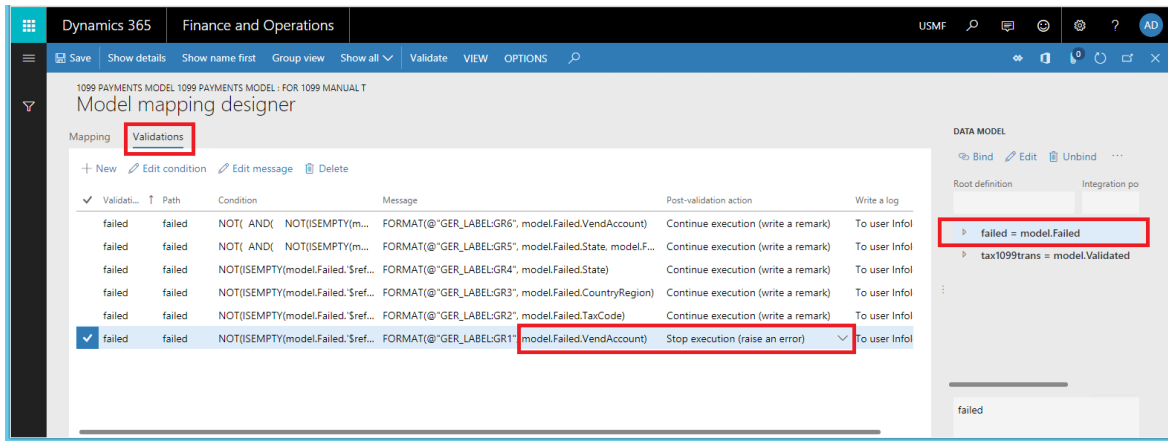

Vendor account	Date	Voucher	Invoice	Lot ID	Internal invoice	1099 box	Settled federal ...	State
US-101	3/25/2018	V-00001				MISC-01	3,000.00	WA
US-103	4/12/2018	V-00001				MISC-02	4,000.00	IL
US-105	5/1/2018	V-00001				MISC-03	450.00	CO

Prepare an Excel file for import

1. Open the Excel file that you previously used. In row 3 column 1, add a vendor code that doesn't exist in the application. Add additional false vendor information to the row.

	A	B	C	D	E	F	G	H	I	J	K	L	M	N
1	US-101	3/25/2018	MISC-01	3,000.00	USA	WA								
2	US-103	4/12/2018	MISC-02	4,000.00	USA	IL								
3	US-777	5/1/2018	MISC-03	450.00	USA	CO								

2. Upload the updated Excel file that contains vendors transactions to the **Files import source (main)** SharePoint folder.
3. Open the ER configurations tree, select the **1099 Payment model**, and expand the list of ER model components.
4. Select the name of the model mapping to update the model mapping so that the incorrect vendor code is considered an error during the data import process.
5. Select **Designer**.
6. On the **Validations** tab, you must change the post-validation action for the validation rule that was configured to evaluate whether the vendor account that is imported exists in the application. Update the value of the **Post-validation action** field to **Stop execution**, save your changes, and close the page.

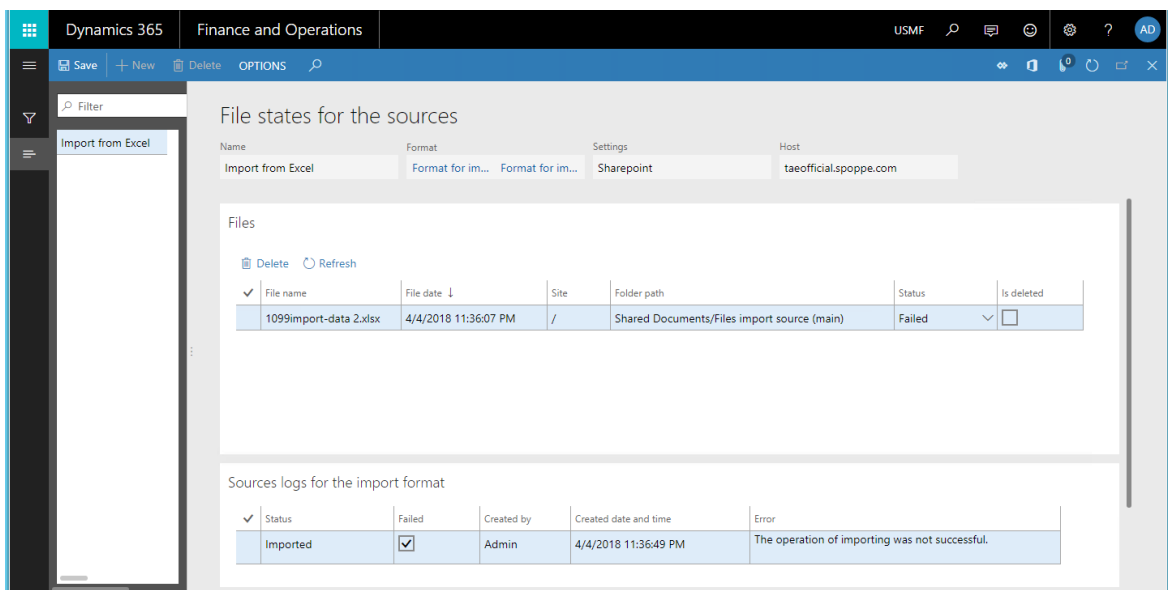

7. Save your changes, and close the ER model mapping designer.
8. Select **Run** to run the modified ER model mapping.
9. Enter the voucher ID, such as **V-00002**, and then select **OK**.

The Infolog contains a notification that there's a file in the SharePoint folder that contains incorrect vendor account and can't be imported.

10. On the **File states for the sources** page, select **Refresh**, and then, in the **Files** section, review the list of files.

The **Sources log** for the **import format** section indicates that the import process failed and that the file is in the Files error SharePoint folder (the **Is deleted** check box is not selected). If you fix this file on SharePoint by

adding the proper vendor code and then move it to the Files import source (main) SharePoint folder, you can import the file again.

11. Select **Accounts payable > Periodic tasks > Tax 1099 > Vendor settlement for 1099s**, enter appropriate values in the **From date** and **To date** fields, and then select **Manual 1099 transactions**.

Only transactions for voucher V-00001 are available. No transactions for voucher V-00002 are available even though the error for the last imported transaction has been found in the Excel file.

Limitations

The ER framework doesn't offer the capability to initiate a new batch job that will execute a model mapping in unattended mode for data import. To do this, you must develop new logic so that the configured ER model mapping can be called from the application user interface (UI) to import data from inbound files. Therefore, some engineering work is required.

To learn more about the relevant ER API, see the [Code to run a format mapping for data import](#) section in the [ER framework API changes for Application update 7.3](#) topic.

Review the code in the `BankImport_RU` class of the `Application Suite` model to see how your custom logic can be implemented. This class extends the `RunBaseBatch` class. In particular, review the `runER()` method where the `ERIModelMappingDestinationRun` object is created as the runner of an ER model mapping.

Import files in XML format with optional attributes

2/18/2021 • 3 minutes to read • [Edit Online](#)

You can design Electronic reporting (ER) formats to parse incoming electronic documents in XML format. Certain attributes of XML elements can be specified in designed ER format as optional. It will allow you to handle incoming files with and without such XML attributes properly. You can then use the content from these files to update application data.

To learn more about this feature, complete the steps in the topic, [\(RCS\) Import files in XML format with optional attributes](#), which is part of the 7.5.4.3 Acquire/Develop IT service/solution components (10677) business process. You can download this task guide and associated sample files from the [Microsoft Download Center](#).

CONTENT DESCRIPTION	FILE
Sample file in XML format	IncomingDocumentToLearnHowToHandleOptionalAttributes.xml
Task guide	RCS Import files in XML format with optional attributes.axtr

The following steps explain how a user in the System Administrator or Electronic Reporting Developer role can design ER format configuration to import files in XML format containing optional attributes. To complete these steps, you must first complete the steps in the procedure, [Create configuration providers and mark them as active](#). Before you begin, download and save locally the IncomingDocumentToLearnHowToHandleOptionalAttributes.xml file from Microsoft Download Center (<https://go.microsoft.com/fwlink/?linkid=874684>).

1. Go to **Organization administration > Workspaces > Electronic reporting**.
2. Make sure that the configuration provider for the sample company, Litware, Inc., is available and marked as **Active**. If you don't see this configuration provider, complete the steps in the topic, [Create configuration providers and mark them as active](#).
3. Click **Reporting configurations**.

Create a new data model configuration

1. Click **Create configuration** to open the drop dialog.
2. In the **Name** field, type 'Model to import xml file'.
3. Click **Create configuration**.
4. Click **Designer**.
5. Click **New** to open the drop dialog.
6. In the **Name** field, type 'Root'.
7. Click **Add**.
8. Click **New** to open the drop dialog.
9. In the **Name** field, type 'List'.
10. In the **Item type** field, select **Record list**.
11. Click **Add**.
12. Click **New** to open the drop dialog.
13. In the **Name** field, type 'Code'.
14. In the **Item type** field, select **String**.

15. Click **Add**.
16. Click **Save**.
17. Close the page.
18. Click **Change status**.
19. Click **Complete**.
20. Click **OK**.

Create a format for data import

1. Click **Create configuration** to open the drop dialog.
2. In the **New** field, enter 'Format based on data model Model to import xml file'.
3. In the **Name** field, type 'Format to import xml file'.
4. Select **Yes** in the **Supports data import** field.
5. Click **Create configuration**.

Design a format to parse incoming file in xml format

1. Click **Designer**.
2. Click **Add root** to open the drop dialog.
3. In the tree, select **XML\Element**.
4. In the **Name** field, type 'root'.
5. Click **OK**.
6. Click **Add** to open the drop dialog.
7. In the tree, select **XML\Element**.
8. In the **Name** field, type 'document'.
9. In the **Multiplicity** field, select **One many**.
10. Click **OK**.
11. In the tree, select **root\document**.
12. Click **Add** to open the drop dialog.
13. In the tree, select **XML\Attribute**.
14. In the **Name** field, type 'id'.
15. Click **OK**.
16. Click **Save**.

Design a format mapping to save parsed information to data model

1. Click **Map format to model**.
2. Click **New**.
3. In the **Definition** field, enter or select a value.
4. In the **Name** field, type 'Mapping'.
5. Click **Save**.
6. Click **Designer**.
7. In the tree, expand **format**.
8. In the tree, expand **format\root: XML Element(root)**.
9. In the tree, select **format\root: XML Element(root)\document: XML Element 1.. (document)***.
10. Click **Bind**.
11. In the tree, expand **format\root: XML Element(root)\document: XML Element 1.. (document)***.
12. In the tree, select *format\root: XML Element(root)\document: XML Element 1.. (document)\id**.

13. In the tree, expand **List = format.root.document**.
14. In the tree, select **List = format.root.document\Code**.
15. Click **Bind**.
16. Click **Save**.
17. Close the page.

Run format mapping

1. Click **Run**.
2. Click **Browse** and select the file, **IncomingDocumentToLearnHowToHandleOptionalAttributes.xml**.
3. Click **OK**.

NOTE

The selected file has not been imported as the format design assumes the existence of 'id' attribute for the 'document' element, but the imported file contains no such attribute.

Modify format structure to handle xml attribute as optional

1. Close the page.
2. In the tree, expand **root\document**.
3. In the tree, select **root\document\id**.
4. In the **Empty string for missing attribute** field, select **Yes**.
5. Click **Save**.

Run format mapping to test changes

1. Click **Map format to model**.
2. Click **Run**.
3. Click **Browse** and select the file, **IncomingDocumentToLearnHowToHandleOptionalAttributes.xml**.
4. Click **OK**.
5. Review the generated file. Note that same file has been imported as the format design now consider the 'id' attribute for the 'document' element as optional.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

(RCS) Import files in XML format with optional attributes

2/18/2021 • 3 minutes to read • [Edit Online](#)

The following steps explain how a user in the System Administrator or Electronic Reporting Developer role can design ER format configuration to import files in XML format containing optional attributes. To complete these steps, you must first complete the steps in the "Create a configuration provider and mark it as active" procedure. Before you begin, download and save locally the IncomingDocumentToLearnHowToHandleOptionalAttributes.xml file from [Microsoft Download Center](#).

1. Go to **All workspaces** > **Electronic reporting**.
2. Make sure that the configuration provider for the sample company, Litware, Inc., is available and marked as **Active**. If you don't see this configuration provider, complete the steps in the procedure [Create configuration providers and mark them as active](#).
3. Click **Reporting configurations**.

Create a new data model configuration

1. Click **Create configuration** to open the drop dialog.
2. In the **Name** field, type 'Model to import xml file'.
3. Click **Create configuration**.
4. Click **Designer**.
5. Click **New** to open the drop dialog.
6. In the **Name** field, type 'Root'.
7. Click **Add**.
8. Click **New** to open the drop dialog.
9. In the **Name** field, type 'List'.
10. In the **Item type** field, select **Record list**.
11. Click **Add**.
12. Click **New** to open the drop dialog.
13. In the **Name** field, type 'Code'.
14. In the **Item type** field, select **String**.
15. Click **Add**.
16. Click **Save**.
17. Close the page.
18. Click **Change status**.
19. Click **Complete**.
20. Click **OK**.

Create a format for data import

1. Click **Create configuration** to open the drop dialog.
2. In the **New** field, enter 'Format based on data model Model to import xml file'.
3. In the **Name** field, type 'Format to import xml file'.
4. Select **Yes** in the **Supports data import** field.

5. Click **Create configuration**.

Design a format to parse incoming file in xml format

1. Click **Designer**.
2. Click **Add root** to open the drop dialog.
3. In the tree, select **XML\Element**.
4. In the **Name** field, type 'root'.
5. Click **OK**.
6. Click **Add** to open the drop dialog.
7. In the tree, select **XML\Element**.
8. In the **Name** field, type 'document'.
9. In the **Multiplicity** field, select **One many**.
10. Click **OK**.
11. In the tree, select **root\document**.
12. Click **Add** to open the drop dialog.
13. In the tree, select **XML\Attribute**.
14. In the **Name** field, type 'ID'.
15. Click **OK**.
16. Click **Save**.

Design a format mapping to save parsed information to data model

1. Click **Map format to model**.
2. Click **New**.
3. In the **Definition** field, enter or select a value.
4. In the list, click the link in the selected row.
5. In the **Name** field, type 'Mapping'.
6. Click **Save**.
7. Click **Designer**.
8. In the tree, expand **format**.
9. In the tree, expand **format\root: XML Element(root)**.
10. In the tree, select **format\root: XML Element(root)\document: XML Element 1.. (document)***.
11. Click **Bind**.
12. In the tree, expand **format\root: XML Element(root)\document: XML Element 1.. (document)***.
13. In the tree, select *format\root: XML Element(root)\document: XML Element 1.. (document)\id**.
14. In the tree, expand **List = format.root.document**.
15. In the tree, select **List = format.root.document\Code**.
16. Click **Bind**.
17. Click **Save**.
18. Close the page.

Run format mapping

1. Click **Run**.
2. Click **Browse** and select **IncomingDocumentToLearnHowToHandleOptionalAttributes.xml**.
3. Click **OK**.

NOTE

The selected file has not been imported as the format design assumes the existence of 'id' attribute for the 'document' element, but the imported file contains no such attribute.

Modify format structure to handle xml attribute as optional

1. Close the page.
2. In the tree, expand **root\document**.
3. In the tree, select **root\document\id**.
4. Select **Yes** in the **Empty string for missing attribute** field.
5. Click **Save**.

Run format mapping to test changes

1. Click **Map format to model**.
2. Click **Run**.
3. Click **Browse** and select the **IncomingDocumentToLearnHowToHandleOptionalAttributes.xml** file.
4. Click **OK**.
5. Review the generated file.

NOTE

The same file has been imported as the format design now consider the 'id' attribute for the 'document' element as optional.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Split generated XML files based on file size and content quantity

2/18/2021 • 2 minutes to read • [Edit Online](#)

You can design Electronic reporting (ER) formats to generate outgoing documents in XML format. Sometimes, those documents can be accepted only when they meet specific criteria, such a maximum file size or a maximum number of some XML nodes. You can design ER formats to generate electronic documents that satisfy the requirements that the recipients of those documents specify.

- For the FILE format element, you can define a limit on the file size as an ER expression. If the defined limit is exceeded when an ER report is generated, ER finishes creating the current file and then moves on to create the next file.
- For any XML ELEMENT format, you can define a limit on the number of elements as an ER expression. If the number of XML nodes in the file that is generated exceeds the defined limit when an ER report is run, ER finishes creating the current file and then moves on to create the next file.
- For any XML SEQUENCE format element, you can define a limit on the number of child elements as an ER expression. If the number of nested XML nodes of the format element in the generated file exceeds the defined limit when an ER report is run, ER finishes creating the current file and then moves on to create the next file.
- You can mark any XML ELEMENT format element as non-breakable. In this way, you can keep the nested items of XML nodes that are generated under the format element in a single generated file.

In addition to using the XML ELEMENT and XML SEQUENCE format elements to add XML nodes to the generated file, you can use the RAW XML format element. However, nodes that you add by using the RAW XML format element aren't considered when the number of nodes is calculated to evaluate the limits on the number of elements.

If you configured file destinations for a FILE format element that has been configured to split the generated output whenever specific limits are exceeded, each piece of generated output is sent to the configured file destination as an individual file. To uniquely name the files that are created by splitting the output, you must configure an ER expression for the FILE format element. If you include an ER data source of the NUMBER SEQUENCE type, the number sequence will be incremented for each piece of the split output.

To learn more about this feature, play the **ER Split XML files based on the file size or content item quantity** task guide, which is part of the **7.5.4.3 Acquire/Develop IT service/solution components (10677)** business process and can be downloaded from the [Microsoft Download Center](#). This task guide walks you through the process of configuring an ER format to split generated files based on limits on the file size and content item quantity. To complete the task guide, you must download the following files:

- [ER model configuration - XmlFilesSplittingModel.xml](#)
- [ER format configuration - XmlFilesSplittingFormat.xml](#)

Support parameterized calls of ER data sources of the Calculated field type

2/18/2021 • 10 minutes to read • [Edit Online](#)

This topic explains how you can design an Electronic reporting (ER) data source by using the **Calculated field** type. This data source may contain an ER expression that, when executed, can be controlled by the values of the parameter arguments that are configured in a binding that calls this data source. By configuring parameterized calls of such a data source, you can reuse a single data source in many bindings, which reduces the total number of data sources that must be configured in ER model mappings or ER formats. It also simplifies the configured ER component, which reduces the maintenance costs and the cost of use by other consumers.

Prerequisites

To complete the examples in this topic, you must have the following access:

- Access to one of these roles:
 - Electronic reporting developer
 - Electronic reporting functional consultant
 - System administrator
- Access to Regulatory Configuration Services (RCS) that have been provisioned for the same tenant as Finance and Operations for one of the following roles:
 - Electronic reporting developer
 - Electronic reporting functional consultant
 - System administrator

You must also download and locally store the following files.

CONTENT	FILE NAME
Sample ER data model configuration	Model to learn parameterized calls.version.1.xml
Sample ER metadata configuration	Metadata to learn parameterized calls.version.1.xml
Sample ER model mapping configuration	Mapping to learn parameterized calls.version.1.1.xml
Sample ER format configuration	Format to learn parameterized calls.version.1.1.xml

Sign in to your RCS instance

In this example, you will create a configuration for the sample company, Litware, Inc. First, in RCS, you must complete the steps in the [Create configuration providers and mark them as active](#) procedure:

1. On the default dashboard, select **Electronic reporting**.
2. Select **Reporting configurations**.
3. Import the downloaded configurations to RCS in the following sequence: data model, metadata, model mapping, format. Complete the following steps for each ER configuration:

- a. Select **Exchange**.
- b. Select **Load from XML file**.
- c. Select **Browse**, and then select the required ER configuration in XML format.
- d. Select **OK**.

Review the provided ER solution

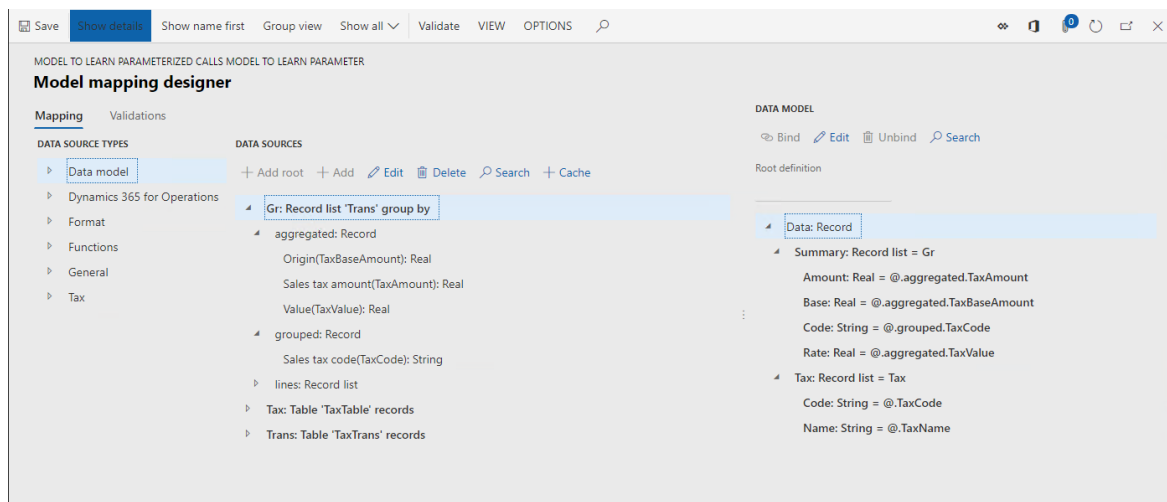

Review model mapping

1. In the configuration tree, expand the content of the **Model to learn parameterized calls** item.
2. Select **Mapping to learn parameterized calls**.
3. Select **Designer**.
4. Select **Designer**.

This ER model mapping is designed to do the following:

- Fetch the list of tax codes (**Tax** data source) residing in the **TaxTable** table.
- Fetch the list of tax transactions (**Trans** data source) residing in the **TaxTrans** table:
 - Group the list of fetched transactions (**Gr** data source) by tax code.
 - Calculate for grouped transactions following aggregated values per tax code:
 - Sum of tax base values.
 - Sum of tax values.
 - Minimum value of applied tax rate.

The model mapping in this configuration implements the base data model for any of the ER formats created for this model and executed in Finance and Operations. As a result, the content of the **Tax** and **Gr** data sources is exposed for ER formats such as abstract data sources.

5. Close the **Model mapping designer** page.
6. Close the **Model mapping** page.

Review format

1. In the configuration tree, expand the content of the **Model to learn parameterized calls** item.
2. Select **Format to learn parameterized calls**.
3. Select **Designer**. This ER format is designed to do the following:

- Generate a tax statement in XML format.
- Present the following levels of taxation in the tax statement: regular, reduced, and none.
- Present multiple details at each taxation level, having a different number of details in each level.

4. Select **Mapping**.

5. Expand the **Model**, **Data**, and **Summary** items.

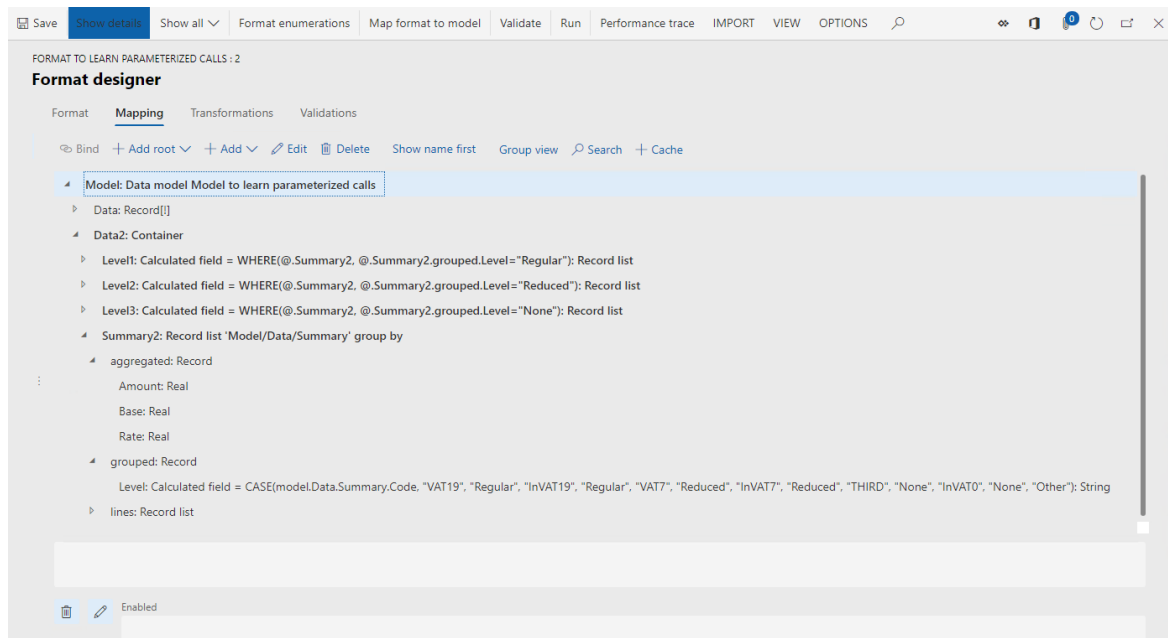

The calculated field **Model.Data.Summary.Level** contains the expression that returns the code of the taxation level (**Regular**, **Reduced**, **None**, or **Other**) as a text value for any tax code that can be retrieved from the **Model.Data.Summary** data source at run time.

6. Expand the **Model.Data2** item.

7. Expand the **Model.Data2.Summary2** item.

The **Model.Data2.Summary2** data source is configured to group the **Model.Data.Summary** data source transaction details by taxation level (returned by the **Model.Data.Summary.Level** calculated field) and compute the aggregations.

8. Review the calculated fields **Model.Data2.Level1**, **Model.Data2.Level2**, and **Model.Data2.Level3**. These calculated fields are used to filter the **Model.Data2.Summary2** records list and return only records that represent a particular taxation level.
9. Close the **Format designer** page.

Create a derived format

You can improve the provided format by adding one calculated field to filter the required taxation level instead of using the existing three fields: **Model.Data2.Level1**, **Model.Data2.Level2**, and **Model.Data2.Level3**. The required taxation level can be specified in the location where this new calculated field will be called.

1. In the configuration tree, expand the content of the **Model to learn parameterized calls** item.
2. Select **Format to learn parameterized calls**.
3. Select **Create configuration**.
4. Select **Derive from Name: Format to learn parameterized calls, Microsoft**.
5. In the **Name** field, enter **Format to learn parameterized calls (custom)**.
6. Select **Create configuration**.

Configure a parameterized calculated field that returns a list of records

Start adding a new calculated field

1. Select **Designer**.
2. Select **Expand/collapse** to expand all format items.
3. Select **Mapping**.
4. Expand the **Model** item.
5. Select the **Model.Data2** item.
6. Select **Add**.
7. Select **Functions\Calculated field**.
8. In the **Name** field, enter **Levels**.
9. Select **Edit formula**.

Define a parameter for adding a calculated field

1. Select **Parameters**.

2. Select **New**.
3. In the **Name** field, enter **Taxation Level**.
4. In the **Type** field, select **String**.

Only primitive data types can be used to specify the type of the parameter's argument. Therefore, **Record list**, **Record**, and **Enum** types cannot be used for this purpose.

The maximum number of parameters that can be specified for a single calculated field is 8.

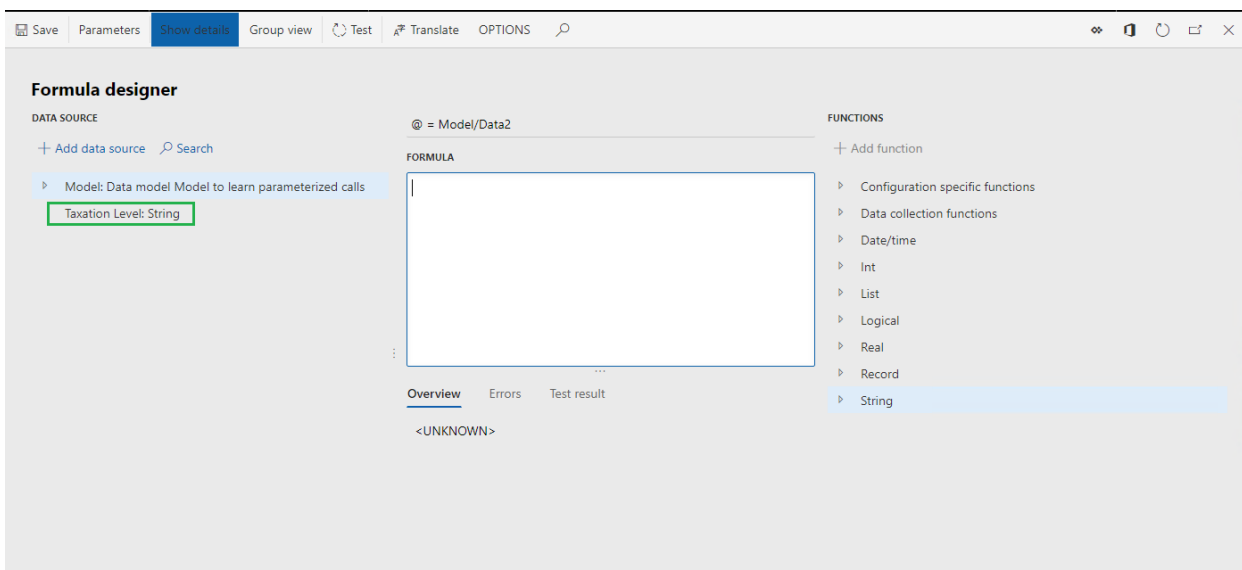

5. Select **OK**.

By adding this parameter, you specify the condition that must be in place to call this calculated field. When you call this calculated field, you need to specify the argument of the **Taxation Level** parameter as a value with **String** format.

Make sure that you define parameters only for those calculated fields that reside in a container (either **Record list**, **Record**, or **Container**).

The configured parameter is available in the list of data sources for this calculated field. You can add the parameter to the configured expression by selecting **Add data source**.

Define an expression for adding a calculated field

1. In the **Formula** field, enter:

WHERE(@.Summary2, @.Summary2.grouped.Level =

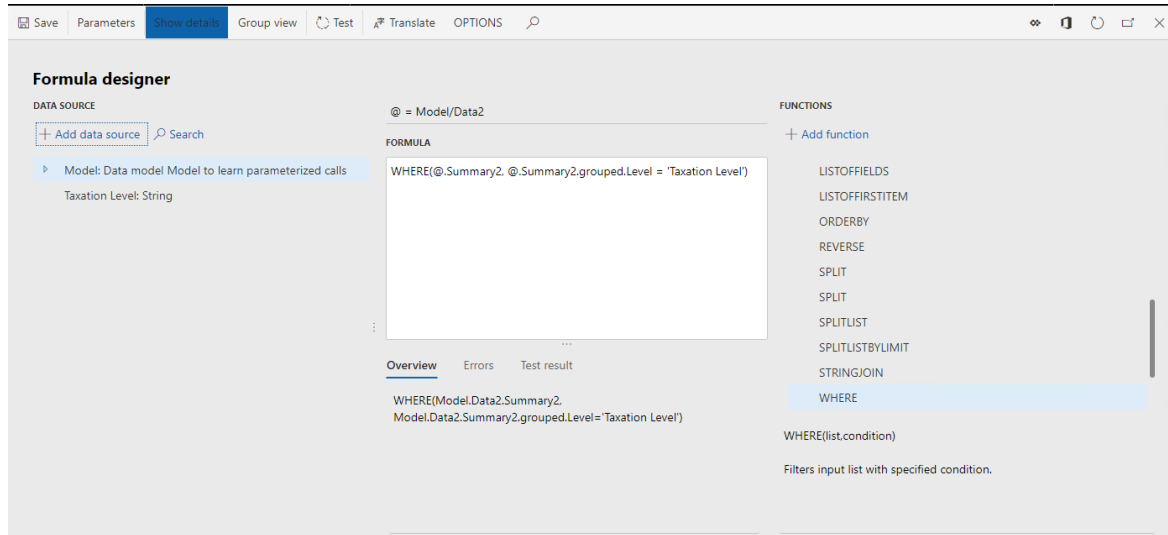

2. Select the **Taxation Level** parameter in the list of data sources.

3. Select **Add data source**.

4. In the **Formula** field, finalize the expression as:

WHERE(@.Summary2, @.Summary2.grouped.Level = 'Taxation Level')

5. Select **Save**.

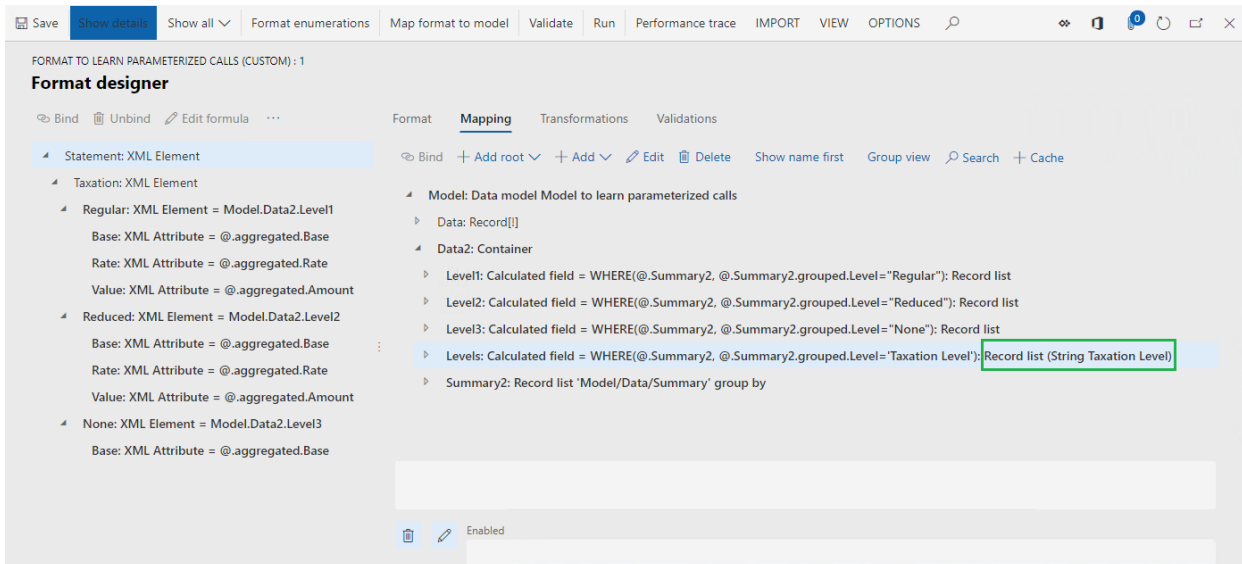

6. Close the **Formula designer** page.

Finish adding a new calculated field

- Select **OK**.

On the **Format designer** page, the configured parameterized calculated field **Levels** requires a **String** argument.

Use the configured calculated field for binding format elements

1. Select **Model.Data2.Levels** to select the configured calculated field.

2. Select the **Statement.Taxation.Regular** format element.

3. Select **Bind**.

4. Select **Yes** to confirm the replacement of the currently used data source, **Level1**, by the new data source, **Levels**, in all nested format elements of the selected format element.

Applied binding has been built as a call of the parameterized calculated field. By default, the name of the bound format element is used as an argument for parameterized calculated field under the following conditions:

- The calculated field is configured to use a single parameter.
- The data type of this parameter is defined as **String**.

When the name of the bound format element is blank, the data source name of this element is used in applied binding.

5. Select the **Statement.Taxation.Reduced** format element.
6. Select **Bind**.
7. Select **Yes** to confirm the replacement of the currently used data source, **Level2**, by the new data source, **Levels**, in all nested format elements under the selected format element.
8. Select the **Statement.Taxation.None** format element.
9. Select **Bind**.
10. Select **Yes** to confirm the replacement of the currently used data source, **Level3**, by the new data source, **Levels**, in all nested format elements under the selected format element.

When you specify the argument of the parameterized calculated field for the XML element representing taxation level (for example, **Model.Data2.Levels("Reduced")** as a text value), you don't need to do the same for nested XML attributes—their bindings will automatically inherit the value of the argument defined on the parent level (**Model.Data2.Levels.aggregated.Base**, not **Model.Data2.Levels("Reduced").aggregated.Base**).

Recurrent calls of any parameterized calculated field are not supported.

You can select **Edit formula**, and change the applied-by-default argument of the parameterized calculated field in the selected binding. If this argument is missing, it can cause errors at run time — users are informed about such a situation when the current format is validated.

The screenshot shows the 'Format designer' interface. At the top, a yellow banner displays the message 'Validation warnings exist'. The main workspace is divided into a tree view on the left and a mapping table on the right. The tree view shows a hierarchy: 'Statement: XML Element' > 'Taxation: XML Element' > 'None: XML Element = Model.Data2.Levels'. The mapping table shows two entries: 'Level3: Calculated field = WHERE(@.Summary2, @.Summary2.grouped.Level="None"): Record list' and 'Levels: Calculated field = WHERE(@.Summary2, @.Summary2.grouped.Level="Taxation Level"): Record list (String Taxation Level)'. Below the mapping table, a 'DETAILS' section shows 'Warnings (1)'. A table below this section lists the warning:

Description	Path	Resolutions
Value of mandatory parameter 1 is not provided in 'Model.Data2.Levels'	Binding: Statement: XML Element/Taxation: XML Element/None: XML Element	None

Configure a parameterized calculated field to return a record

When a parameterized calculated field returns a record, you need to support binding of individual fields of this record to format elements. In such cases there will be no parent binding that contains the value of an argument

to call a parameterized calculated field — this value must be defined in the binding of a single record's field.

Start adding a new calculated field

1. Select the **Model.Data2** item.
2. Select **Add**.
3. Select **Functions\Calculated field**.
4. In the **Name** field, enter **LevelRecord**.
5. Select **Edit formula**.

Define a parameter for adding a calculated field

1. Select **Parameters**.
2. Select **New**.
3. In the **Name** field, enter **Taxation Level**.
4. In the **Type** field, select **String**.
5. Select **OK**.

Define an expression for adding a calculated field

1. In the **Formula** field, enter the following:

```
FIRSTORNULL(@.Levels(
```

2. Select the **Taxation Level** parameter.

3. Select **Add data source**.

4. In the **Formula** field, append **'Taxation Level')**) to what you entered in Step 1 to finalize the expression to:

```
FIRSTORNULL(@.Levels('Taxation Level'))
```

5. Select **Save**.

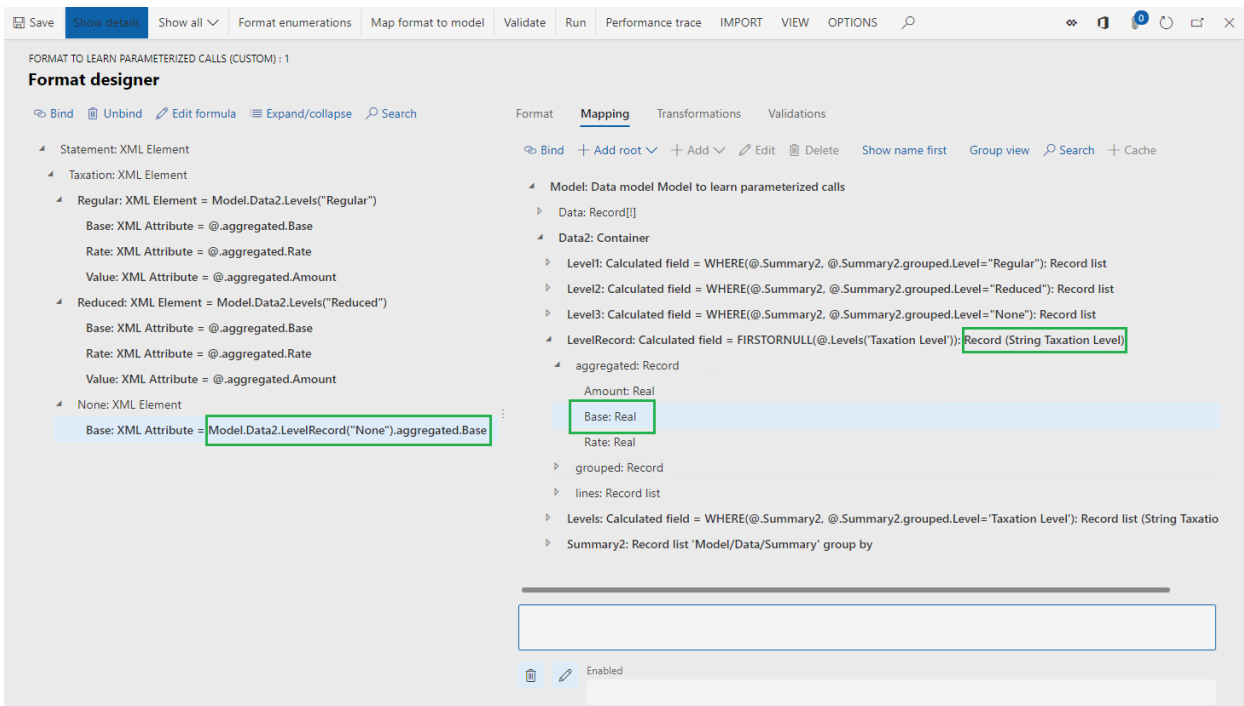

6. Close the **Formula designer** page.

Finish adding a new calculated field

- Select **OK**.

Use the configured calculated field to bind format elements

1. Expand **Model.Data2.LevelRecord** to select the configured calculated field.
2. Expand the **Model.Data2.LevelRecord.aggreated** container of the configured calculated field.
3. Select the **Model.Data2.LevelRecord.aggreated.Base** field.
4. Select the **Statement.Taxation.None** format element.
5. Select **Unbind**.
6. Select the **Statement.Taxation.None.Base** format element.
7. Select **Bind**.
8. Select **Edit formula**.
9. Change the expression to **Model.Data2.LevelRecord("None").aggreated.Base**.

Remove calculated fields that are not used

1. Select **Model.Data2.Level1**.
2. Select **Delete**.
3. Select **Model.Data2.Level2**.
4. Select **Delete**.
5. Select **Model.Data2.Level3**.
6. Select **Delete**.
7. Select **Save**.

NOTE

You reused the same calculated field **Model.Data2.Levels** several times in format bindings. It is much easier to use and maintain a single calculated field instead of doing this for multiple similar fields.

8. Close the **Format designer** page.

Complete adjusted version of a derived format

1. In the **Versions** FastTab, select **Change status**.
2. Select **Complete**.

Export completed version of a derived format

1. Select **Format to learn parameterized calls (custom)** format in the configurations tree.
2. In the **Versions** FastTab, select the completed version 1.1.1.
3. Select **Exchange**.
4. Select **Export as XML file**.
5. Store the downloaded configuration locally, in XML format.

Test ER formats

You can run the initial and improved ER formats to make sure that configured parameterized calculated fields work properly.

Import ER configurations

You can import reviewed configurations from RCS by using the ER repository of the RCS type. If you already went through the steps in the topic, [Import Electronic reporting \(ER\) configurations from Regulatory Configuration Services \(RCS\)](#), use the configured ER repository to import configurations discussed earlier in this topic to your environment. Otherwise, follow these steps:

1. Select the **DEMF** company and on the default dashboard, select **Electronic reporting**.
2. Select **Reporting configurations**.
3. Import the configurations from Microsoft Download Center in the following sequence: data model, model mapping, format. Complete the following steps for each ER configuration:
 - a. Select **Exchange**.
 - b. Select **Load from XML file**.
 - c. Select **Browse** to select the required ER configuration in XML format.
 - d. Select **OK**.
4. Import the exported from RCS completed version 1.1.1 of the **Format to learn parameterized calls (custom)** format:
 - a. Select **Exchange**.
 - b. Select **Load from XML file**.
 - c. Select **Browse** to select the locally stored **Format to learn parameterized calls (custom)** file in XML format.
 - d. Select **OK**.

Run ER formats

1. In the configuration tree, expand the content of the **Model to learn parameterized calls** item.
2. Select **Format to learn parameterized calls**.
3. Select **Run** on the top-most ribbon.
4. Save the locally generated output.
5. Select the **Format to learn parameterized calls (custom)** item.
6. Select **Run** on the top-most ribbon.
7. Save the generated output locally.
8. Compare the contents of the generated outputs.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Manage the Electronic reporting (ER) configuration lifecycle

2/18/2021 • 3 minutes to read • [Edit Online](#)

This topic describes how to manage the lifecycle of Electronic reporting (ER) configurations for Microsoft Dynamics 365 Finance.

Overview

Electronic reporting (ER) is an engine that supports statutory required and country-specific electronic documents. In general, ER assumes an ability to perform the following tasks for a single electronic document. For more details, see [Electronic reporting \(ER\) overview](#).

- Design a template for an electronic document:
 - Identify the required sources of data that can be presented in the document:
 - Underlying data, such as data tables, data entities, and classes.
 - Process-specific properties, such as execution date and time, and time zone.
 - User input parameters, specified by the end user at run time.
 - Define the required document elements and their topology to specify a final document format.
 - Configure the desired flow of data from selected data sources to defined document elements (via data source bindings to document format components), and specify process control logic.
- Make a template available so that it can be used in other instances:
 - Transform a document template that was created into an ER configuration, and export the configuration from the current application instance as an XML package that can be stored either locally or in LCS.
 - Transform an ER configuration into an application document template.
 - Import an XML package that is stored either locally or in LCS into the current instance.
- Customize the template of an electronic document:
 - Bring a template from LCS into the current instance as an ER configuration.
 - Design a custom version of an ER configuration, and keep a reference to the base version.
- Integrate a template with a particular business process, so that it's available in the application:
 - Configure settings so that the application starts to use an ER configuration, by referring to that configuration in a process-related parameter. For example, refer to the ER configuration in a specific Accounts payable payment method to generate an electronic payment message for processing invoices.
- Use a template in a specific business process:
 - Run an ER configuration in a specific business process. For example, to generate an electronic payment message for processing invoices when a payment method that references the ER configuration is selected.

Concepts

The following roles and related activities are associated with the ER configuration lifecycle.

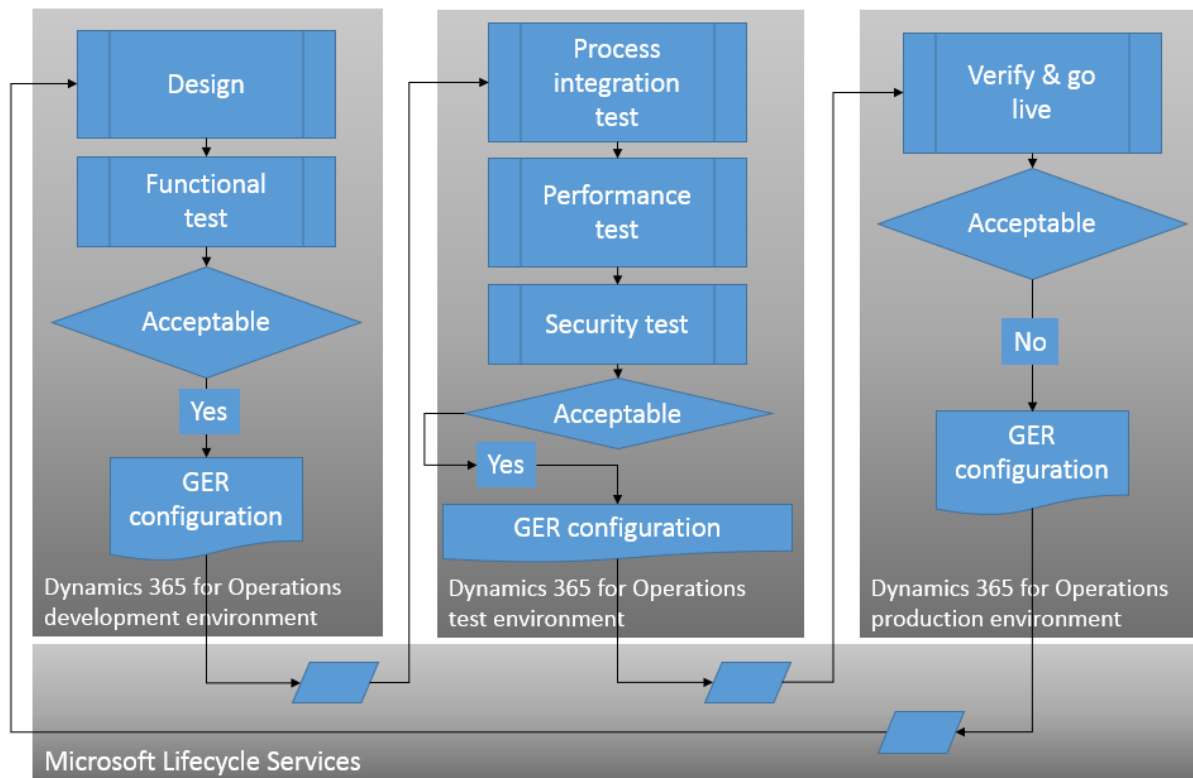

ROLE	ACTIVITIES	DESCRIPTION
Electronic reporting functional consultant	Create and manage ER components (models and formats).	A business person who designs ER domain-specific data models, designs the required templates for electronic documents, and binds them accordingly.
Electronic reporting developer	Create and manage data model mappings.	A specialist who selects the required Finance data sources and binds them to ER domain-specific data models.
Accounting supervisor	Configure process-related settings that reference ER artifacts.	For example, an Accounting supervisor role that allows the settings of an ER configuration to be used in a particular Accounts payable payment method to generate an electronic payment message for processing invoices.
Accounts payable payments clerk	Use ER artifacts in a specific business process.	For example, an Accounts payable payments clerk role that allows electronic payment messages to be generated for processing invoices, based on the ER format that is configured for a specific payment method.

ER configuration development lifecycle

For the following ER-related reasons, we recommend that you design ER configurations in the development environment, as a separate instance of Finance and Operations:

- Users in either the **Electronic reporting developer** role or the **Electronic reporting functional consultant** role can edit configurations and run them for testing purposes. This scenario can cause calls of methods of classes and tables that might harm business data and the performance of the instance.
- Calls of methods of classes and tables as ER data sources of ER configurations aren't restricted by entry points and logged company content. Therefore, users in either the **Electronic reporting developer** role or the **Electronic reporting functional consultant** role can access business-sensitive data.

ER configurations that are designed in the development environment can be uploaded to the test environment for the configuration evaluation (proper process integration, correctness of results, and performance) and quality assurance, such as correctness of role-driven access rights and segregation of duties. The features that enable ER configuration interchange can be used for this purpose. Finally, proven ER configurations can be uploaded either to LCS, where they can be shared with service subscribers, or to the production environment for internal use, such as shown in the following illustration.

[Electronic reporting \(ER\) overview](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Upload a configuration into Lifecycle Services

2/18/2021 • 4 minutes to read • [Edit Online](#)

This topic explains how a user in the System administrator or Electronic reporting developer role can create a new [Electronic reporting \(ER\) configuration](#) and upload it into the [project-level Asset library](#) in Microsoft Dynamics Lifecycle Services (LCS).

In this example, you will create a configuration and upload it into LCS for a sample company that is named Litware, Inc. These steps can be completed in any company, because ER configurations are shared among companies. To complete these steps, you must first complete the steps in [Create configuration providers and mark them as active](#). Access to LCS is also required.

1. Sign in to the application by using one of the following roles:
 - Electronic reporting developer
 - System administrator
2. Go to **Organization administration > Workspaces > Electronic reporting**.
3. Select **Litware, Inc.**, and mark it as **Active**.
4. Select **Configurations**.

NOTE

Make sure that the current Dynamics 365 Finance user is a member of the LCS project that contains the [Asset library](#) that is used to import ER configurations.

You can't access an LCS project from an ER repository that represents a different domain than the domain that is used in Finance. If you try, an empty list of LCS projects will be shown, and you won't be able to import ER configurations from the project-level Asset library in LCS. To access project-level Asset libraries from an ER repository that is used to import ER configurations, sign in to Finance by using the credentials of a user who belongs to the tenant (domain) that the current Finance instance has been provisioned for.

Create a new data model configuration

1. Go to **Organization administration > Electronic reporting > Configurations**.
2. On the **Configurations** page, select **Create configuration** to open the drop-down dialog box.

In this example, you will create a configuration that contains a sample data model for electronic documents. This data model configuration will be uploaded into LCS later.
3. In the **Name** field, enter **Sample model configuration**.
4. In the **Description** field, enter **Sample model configuration**.
5. Select **Create configuration**.
6. Select **Model designer**.
7. Select **New**.
8. In the **Name** field, enter **Entry point**.
9. Select **Add**.

10. Select **Save**.
11. Close the page.
12. Select **Change status**.
13. Select **Complete**.
14. Select **OK**.
15. Close the page.

Register a new repository

1. Go to **Organization administration > Workspaces > Electronic reporting**.
2. In the **Configuration providers** section, select the **Litware, Inc.** tile.
3. On the **Litware, Inc.** tile, select **Repositories**.

You can now open the list of repositories for the Litware, Inc. configuration provider.

4. Select **Add** to open the drop-down dialog box.

You can now add a new repository.

5. In the **Configuration repository enter** field, select **LCS**.
6. Select **Create repository**.
7. In the **Project** field, enter or select a value.

For this example, select the desired LCS project. You must have [access](#) to the project.

8. Select **OK**.

Complete a new repository entry.

9. In the list, mark the selected row.

For this example, select the **LCS** repository record.

Note that a registered repository is marked by the current provider. In other words, only configurations that are owned by that provider can be put in this repository and therefore uploaded into the selected LCS project.

10. Select **Open**.

You open the repository to view the list of ER configurations. If the selected project hasn't yet been used for ER configurations sharing, the list will be empty.

11. Close the page.
12. Close the page.

Upload a configuration into LCS

1. Go to **Organization administration > Electronic reporting > Configurations**.
2. On the **Configurations** page, in the configurations tree, select **Sample model configuration**.

You must select a created configuration that has been already completed.

3. In the list, find and select the desired record.

For this example, select the version of the selected configuration that has a status of **Completed**.

4. Select **Change status**.

5. Select **Share**.

The status of the configuration is changed from **Completed** to **Shared** when the configuration is published in LCS.

6. Select **OK**.

7. In the list, find and select the desired record.

For this example, select the configuration version that has a status of **Shared**.

Note that the status of the selected version was changed from **Completed** to **Shared**.

8. Close the page.

9. Select **Repositories**.

You can now open the list of repositories for the Litware, Inc. configuration provider.

10. Select **Open**.

For this example, select the **LCS** repository, and open it.

Notice that the selected configuration is shown as an asset of the selected LCS project.

11. Open LCS by going to <https://lcs.dynamics.com>.

12. Open a project that was used earlier for repository registration.

13. Open the Asset library of the project.

14. Select the **GER configuration** asset type.

The ER configuration that you uploaded should be listed.

Note that the uploaded LCS configuration can be imported into another instance if providers have access to this LCS project.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Import a configuration from Lifecycle Services

2/18/2021 • 3 minutes to read • [Edit Online](#)

This topic explains how a user in the System administrator or Electronic reporting developer role can import a new version of an [Electronic reporting \(ER\) configuration](#) from the [project-level Asset library](#) in Microsoft Dynamics Lifecycle Services (LCS).

In this example, you will select the desired version of the ER configuration and import it for a sample company that is named Litware, Inc. These steps can be completed in any company, because ER configurations are shared among companies. To complete these steps, you must first complete the steps in [Upload a configuration into Lifecycle Services](#). Access to LCS is also required.

1. Sign in to the application by using one of the following roles:
 - Electronic reporting developer
 - System administrator
2. Go to **Organization administration > Workspaces > Electronic reporting**.
3. Select **Configurations**.

NOTE

Make sure that the current Dynamics 365 Finance user is a member of the LCS project that contains the Asset library that the user wants to [access](#) to import ER configurations.

You can't access an LCS project from an ER repository that represents a different domain than the domain that is used in Finance. If you try, an empty list of LCS projects will be shown, and you won't be able to import ER configurations from the project-level Asset library in LCS. To access project-level Asset libraries from an ER repository that is used to import ER configurations, sign in to Finance by using the credentials of a user who belongs to the tenant (domain) that the current Finance instance has been provisioned for.

Delete a shared version of a data model configuration

1. On the **Configurations** page, in the configurations tree, select **Sample model configuration**.

You created the first version of a sample data model configuration and published it to LCS when you completed the steps in [Upload a configuration into Lifecycle Services](#). In this procedure, you will delete that version of the ER configuration. You will then import that version from LCS later in this topic.

2. In the list, find and select the desired record.

For this example, select the version of the configuration that has a status of **Shared**. This status indicates that the configuration has been published to LCS.

3. Select **Change status**.
4. Select **Discontinue**.

By changing the status of the selected version from **Shared** to **Discontinued**, you make the version available for deletion.

5. Select **OK**.
6. In the list, find and select the desired record.

For this example, select the version of the configuration that has a status of **Discontinued**.

7. Select **Delete**.

8. Select **Yes**.

Notice that the only draft version 2 of the selected data model configuration is now available.

9. Close the page.

Import a shared version of a data model configuration from LCS

1. Go to **Organization administration > Workspaces > Electronic reporting**.

2. In the **Configuration providers** section, select the **Litware, Inc.** tile.

3. On the **Litware, Inc.** tile, select **Repositories**.

You can now open the list of repositories for the Litware, Inc. configuration provider.

4. Select **Open**.

For this example, select the **LCS** repository, and open it. You must have **access** to the LCS project and to the Asset library that is accessed by the selected ER repository.

5. In the list, mark the selected row.

For this example, select the first version of **Sample model configuration** in the version list.

6. Select **Import**.

7. Select **Yes** to confirm the import of the selected version from LCS.

An informational message confirms that the selected version was successfully imported.

8. Close the page.

9. Close the page.

10. Select **Configurations**.

11. In the tree, select **Sample model configuration**.

12. In the list, find and select the desired record.

For this example, select the version of the configuration that has a status of **Shared**.

Notice that shared version 1 of the selected data model configuration is also available now.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

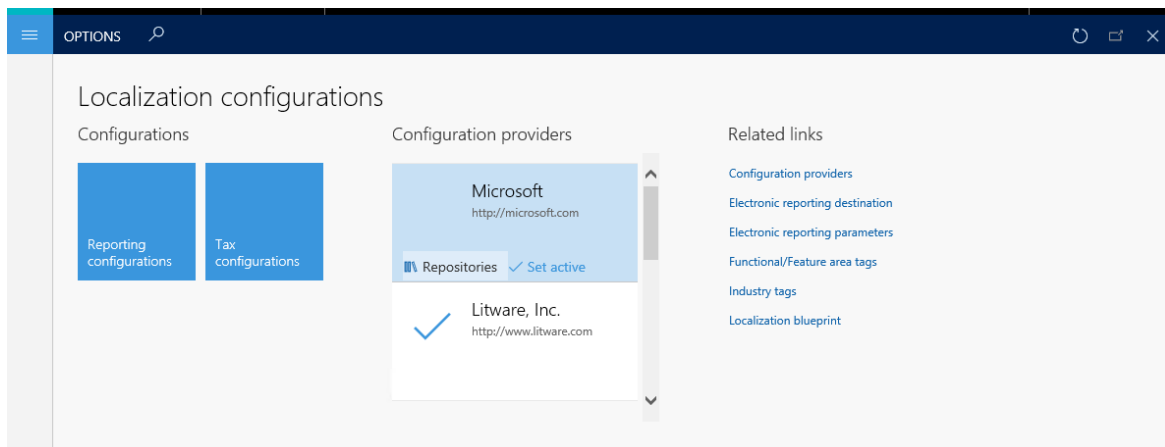

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Download Electronic reporting configurations from Lifecycle Services

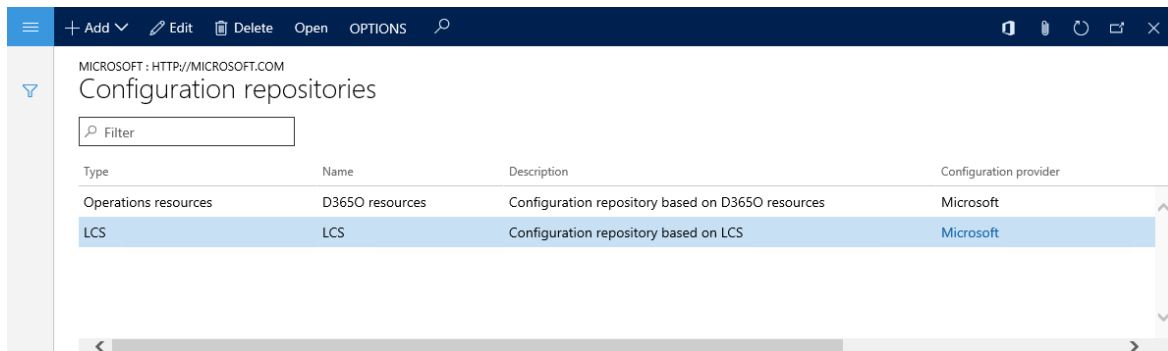

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic explains how to download the newest version of [Electronic reporting \(ER\) configurations](#) from the [Shared asset library](#) in Microsoft Dynamics Lifecycle Services (LCS).

1. Sign in to the application by using one of the following roles:
 - Electronic reporting developer
 - Electronic reporting functional consultant
 - System administrator
2. Go to **Organization administration > Workspaces > Electronic reporting**.
3. In the **Configuration providers** section, select the **Microsoft** tile.
4. On the **Microsoft** tile, select **Repositories**.

5. On the **Configuration repositories** page, in the grid, select the existing repository of the LCS type. If this repository doesn't appear in the grid, follow these steps:
 - a. Select **Add** to add a repository.
 - b. Select **LCS** as the repository type.
 - c. Select **Create repository**.
 - d. If you're prompted about authorization, follow the on-screen instructions.
 - e. Enter a name and description for the repository.
 - f. Select **OK** to confirm the new repository entry.
 - g. In the grid, select the new repository of the **LCS** type.
6. Select **Open** to view the list of ER configurations for the selected repository.

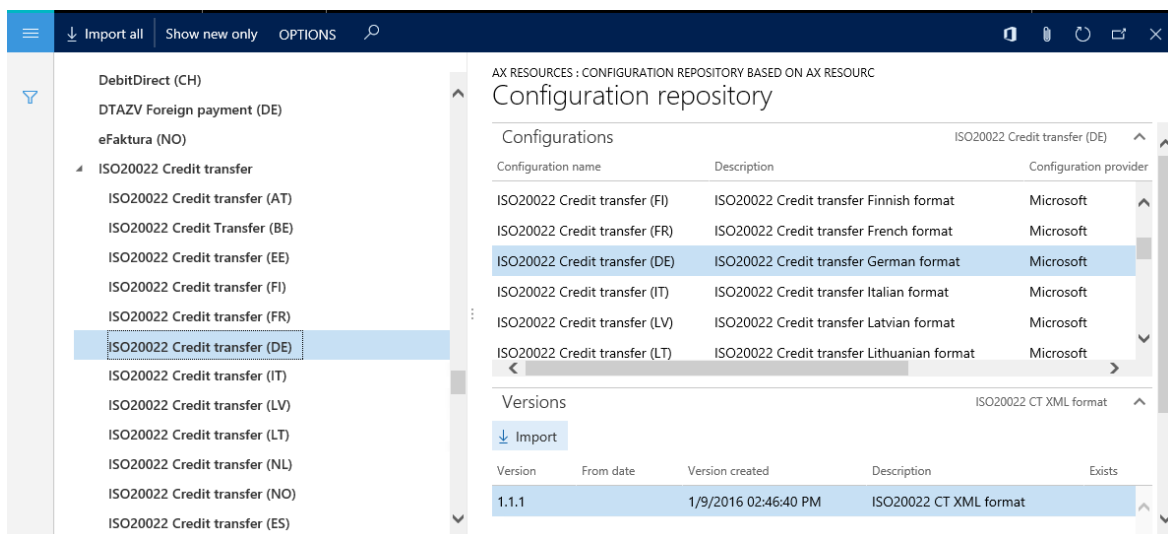

TIP

If you have trouble accessing the LCS repository to download configurations from the Shared asset library in LCS, you can download configurations from the [Global repository](#) instead.

7. In the configurations tree in the left pane, select the required ER configuration.
8. On the **Versions** FastTab, select the required version of the selected ER configuration.
9. Select **Import** to download the selected version from LCS to the current instance.

NOTE

The **Import** button is unavailable for ER configuration versions that are already present in the current instance.

NOTE

Depending on the ER settings, configurations are validated after they are imported. You might be notified about any inconsistency issues that are discovered. You must resolve those issues before you can use the imported configuration version. For more information, see the list of related topics for this topic.

Additional resources

Import Electronic reporting (ER) configurations

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic explains how to download Electronic reporting (ER) configurations from Microsoft Dynamics Lifecycle Services (LCS) to a local business data application. It also explains how to upload the ER configurations from an ER repository to the local business data (LBD) application.

1. Sign in to your local business data application by using one of the following roles:
 - Electronic reporting developer
 - Electronic reporting functional consultant
 - System administrator
2. Go to **Organization administration > Electronic reporting**.
3. In the **Configuration providers** section, select the card for the ER provider that is associated with your company.

NOTE

To learn how to register a new ER solution provider, play the **Create a configuration provider and mark it as active** task guide.

4. On the selected tile, click **Repositories**.
5. On the **Configuration repositories** page, in the grid, select the existing repository of the **File system** type. If the repository doesn't appear in the grid, follow these steps:
 - a. Click **Add** to add a new repository.
 - b. Select **FILE SYSTEM** as the repository type.
 - c. Click **Create repository**.
 - d. Enter a name and description for the repository.
 - e. Enter the path of the working directory for this repository. This path should point to a folder of the local file system where the ER configurations that belong to the repository will be stored.
 - f. Click **OK** to confirm and save the new repository.
 - g. In the grid, select the new repository of the **File system** type.
6. In your browser, open another tab, and sign in to LCS.
7. In the Shared asset library, select the **GER Configuration** asset type, and then click **Download all**.

NOTE

All the ER configurations will be put into a zip file for download.

8. Open the file, select all the ER configurations, and then copy them to the working directory for the repository of the **File system** type.
9. On the **ER repositories** page, on the **Dynamics 365 for Finance and Operations** tab, click **Open** to view the list of ER configurations for the selected repository.
10. In the **Configurations** tree in the left pane, select an ER configuration.

11. On the **Versions** FastTab, select the required version of the ER configuration.
12. Click **Import** to download the selected version from this repository to the current instance.

NOTE

The **Import** button is unavailable for existing ER configuration versions.

NOTE

Depending on the ER settings, configurations are validated after they are imported. You might be notified about inconsistencies or issues that are discovered. You must resolve these inconsistencies or issues before you can use the imported configuration version.

Frequently asked questions

Question: When I click **Download all** in the Shared asset library, I receive the following warning: "Zip generation is in progress, please try again in a few minutes." Why do I receive this warning?

Answer: You receive this warning because a new configuration is added to the Shared asset library, and the ER configuration is being archived.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Import Electronic reporting (ER) configurations from Regulatory Configuration Services (RCS)

2/18/2021 • 2 minutes to read • [Edit Online](#)

You can use Regulatory Configuration Services (RCS) to design Electronic reporting (ER) configurations. The ER tool provides access to the list of configurations that have been configured in each instance of RCS that has been provisioned for your company. You can use this feature to import configurations that you configured in an RCS instance into the current instance. After configurations are imported, they can be used to handle incoming documents or generate outgoing electronic documents.

To learn more about this feature, complete the example in this topic. Alternatively, play the **ER Import configurations from RCS** task guide, which is part of the 7.5.4.3 Acquire/Develop IT service/solution components (10677) business process. This task guide can be downloaded from the [Microsoft Download Center](#). It walks you through the process of importing ER configurations from an RCS instance into the current instance.

Example: Import an ER configuration from RCS

This example shows how a user in the System Administrator or Electronic Reporting Developer role can import a new version of an ER configuration from RCS. In this example, you select the desired version of the ER configuration that has been configured in an RCS instance, and you import that version into the current instance for a sample company that is named Litware, Inc. These steps can be completed in any company, because ER configurations are shared among companies.

To complete the steps in this example, you must first complete the steps in [Create configuration providers and mark them as active](#). You must also have access to an RCS instance that contains at least one ER configuration that has a status of either **Completed** or **Shared**.

1. Go to **Organization administration > Workspaces > Electronic reporting**.
2. On the **Localization configurations** page, in the **Configuration providers** section, make sure that the configuration provider for the Litware, Inc. sample company is listed, and that it's marked as **Active**. If you don't see this configuration provider, follow the steps in [Create configuration providers and mark them as active](#).
3. If no RCS environment has been provisioned for your company, in the **External Links** section, select **Regulatory services – Configuration**. Then follow the instructions to provision an RCS environment.
4. In the **Related links** section, select **Electronic reporting parameters**.
5. On the **Electronic reporting parameters** page, select the **RCS** tab.
6. Use the URLs on this tab to access the RCS environment has been provisioned for your company.
7. Close the **Electronic reporting parameters** page.

Register a new ER repository

1. On the **Localization configurations** page, select the **Litware, Inc.** configuration provider in the list.
2. Select **Repositories**.
3. Select **Add** to open the drop-down dialog box.
4. Select **RCS** as the configuration repository type, and then select **Create repository**.
5. In the **RCS environment display name** field, select the desired RCS instance. Note that you can have several instances.
6. Select **OK**.

Import ER configurations from an RCS-based repository

1. On the **Configuration repositories** page, select the **Show filters** button on the left side of the window.
2. For the **Name** filter, select **begins with** as the filter operator, and then enter **RCS** as the filter value.
3. Select the repository, and open it.
4. On the **Connect to Regulatory Configuration Services** page, select the **Click here to connect to Regulatory Configuration Services** link.
5. Select **Open**.
6. Select **Close**.
7. Select the desired version of the ER configuration, and then select **Import** to import that version.

Additional resource

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

(ER) Import configurations from RCS

2/18/2021 • 2 minutes to read • [Edit Online](#)

The following steps explain how a user in the System Administrator or Electronic Reporting Developer role can import a new version of an Electronic reporting (ER) configuration from Microsoft Regulatory Configuration Services (RCS). In this example, you will select the version of the ER configuration that has been configured in an RCS instance and import it into the current instance for sample company, Litware, Inc. These steps can be performed in any company because ER configurations are shared among companies. To complete these steps, you must first complete the steps in the topic, [Create configuration providers and mark them as active](#). To complete these steps, you must also have access to an RCS instance containing at least one ER configuration in either **Completed** or **Shared** status.

1. Go to **Organization administration > Workspaces > Electronic reporting**.
2. Make sure that the configuration provider for the sample company, Litware, Inc., is available and marked as **Active**. If you don't see this configuration provider, complete the steps in the topic, [Create configuration providers and mark them as active](#).
3. If you have no RCS environment provisioned to your company, select **Regulatory services – Configuration** external link and follow the instructions to provision an RCS environment.
4. Select **Electronic reporting parameters**.
5. Select the **RCS** tab.
6. If RCS environment has been already provisioned to your company, use presented on the page URLs to access it.
7. Close the page.

Register a new ER repository.

1. In the list, mark the selected row.
2. Select Litware, Inc. provider.
3. Select Repositories.
4. Select Add to open the drop dialog.
5. In the Configuration repository type field, enter 'RCS'.
6. Select Create repository.
7. In the RCS environment display name field, enter or select a value.
8. Select the desired RCS instance. You can have several of them.
9. Select OK.

Import ER configurations from RCS-based repository

1. Select **Show filters**.
2. Enter a filter value of "RCS" on the **Name** field using the **begins with** filter operator.
3. When you open the selected repository, on the **Connect to Regulatory Configuration Services** page, select **Select here to connect to Regulatory Configuration Services** link.
4. Select **Open**.
5. Select **Close**.
6. Select the desired version of ER configuration and select **Import** to bring it in the current instance.

NOTE

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Use JOIN data sources to get data from multiple application tables in Electronic reporting (ER) model mappings

2/18/2021 • 13 minutes to read • [Edit Online](#)

While configuring Electronic reporting (ER) model mappings or formats, you can [add](#) required data sources of the **Join** type. At design time, a **Join** data source is configured as a set of several data sources each of which returns a list of records. For every data source except the first one, you need to define necessary conditions to join records of the current and previous data sources. At runtime, a configured data source of **Join** type [returns](#) a single joined list of records containing fields from the records of nested data sources.

The following types of joins are currently supported:

- Outer (left) join:
 - Join all records of the first (left-most) data source and then any matching in accordance to configured conditions records of the second (right-most) data source.
- Inner (right) join:
 - Join only records of the first (left-most) data source and only records of the second (right-most) data source matching to each other in accordance to configured conditions.

In the configured **Join** data source, when all data sources are the **Table records** type, execution of the **Join** data source can be [performed at the database level](#) using a single SQL statement. This statement reduces the number of database calls, which improves model-mapping performance. Otherwise, execution of **Join data** source is performed in memory.

NOTE

Using the **VALUEIN** function in ER expressions that specify conditions for joining records in data sources of **Join** type is not supported yet. Visit the [Formula designer in Electronic reporting](#) page for more details about this function.

To learn more about this feature, complete the example in this topic.

Example: Use JOIN data sources in ER model mappings

The following steps explain how the System administrator or Electronic reporting developer can configure an Electronic reporting (ER) model mapping to get data from multiple application tables at once by using data sources of the **Join** type to improve data access performance. These steps can be performed for any company of Dynamics 365 Finance or Regulatory Configuration Services (RCS).

Prerequisites

To complete the examples in this topic, you must have access to one of the following depending on what service is used to complete these steps:

Access to Finance for one of the following roles:

- Electronic reporting developer
- Electronic reporting functional consultant
- System administrator

Access to RCS for one of the following roles:

- Electronic reporting developer
- Electronic reporting functional consultant
- System administrator

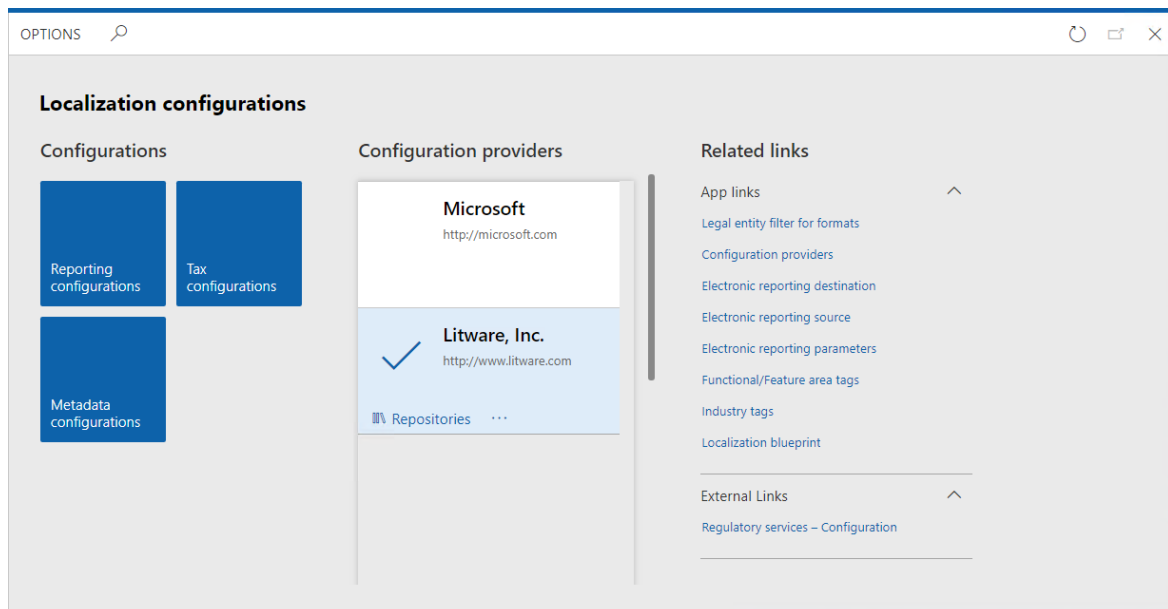

You also must first complete the steps in the [Create a configuration provider and mark it as active](#) procedure.

In advance, you must also download from [Microsoft Download Center](#) and save locally the following sample ER configuration files:

CONTENT DESCRIPTION	FILE NAME
Sample ER data model configuration file, which is used as the data source for the examples.	Model to learn JOIN data sources.version.1.1.xml
Sample ER model mapping configuration file, which implements the ER data model for the examples.	Mapping to learn JOIN data sources.version.1.1.xml
Sample ER format configuration file. This file describes the data to populate the ER format component for the examples.	Format to learn JOIN data sources.version.1.1.xml

Activate a configurations provider

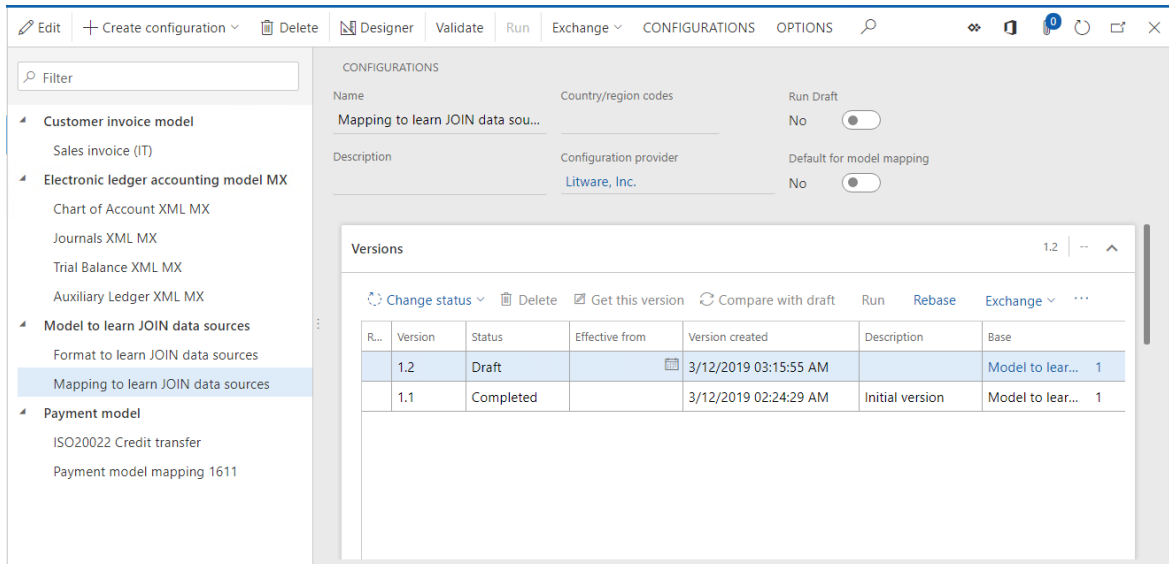

1. Access either Finance or RCS in the first session of your web browser.
2. Go to **Organization administration > Workspaces > Electronic reporting**.
3. On the **Localization configurations** page, in the **Configuration providers** section, make sure that the configuration provider for the [Litware, Inc.](#) sample company is listed, and that it's marked as **Active**. If you don't see this configuration provider, follow the steps in [Create a configuration provider and mark it as active](#) procedure.

Import sample ER configuration files

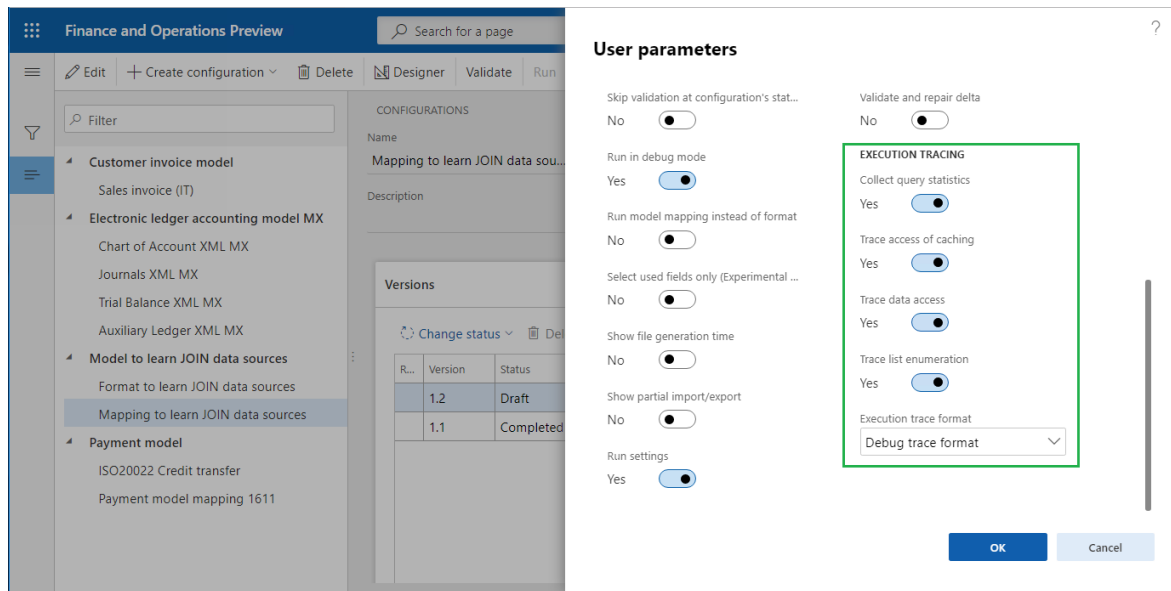

1. Select **Reporting configurations**.
2. Import the ER data model configuration file.
 - a. Select **Exchange**.
 - b. Select **Load from XML file**.

- c. Select **Browse** to find the **Model to learn JOIN data sources.version.1.1.xml** file.
 - d. Select **OK**.
3. Import the ER model-mapping configuration file.
 - a. Select **Exchange**.
 - b. Select **Load from XML file**.
 - c. Select **Browse** to find the **Mapping to learn JOIN data sources.version.1.1.xml** file.
 - d. Select **OK**.
 4. Import the ER format configuration file.
 - a. Select **Exchange**.
 - b. Select **Load from XML file**.
 - c. Select **Browse** to find the **Format to learn JOIN data sources.version.1.1.xml** file.
 - d. Select **OK**.
 5. In the configurations tree, expand the **Model to learn JOIN data sources** item as well as other model items (when available).
 6. Observe the list of ER configurations in the tree as well as version details on the **Versions** fast tab – they will be used as the source of data for your sample report.

Turn on execution trace options

1. Select **CONFIGURATIONS**.
2. Select **User parameters**.
3. Set execution trace parameters as shown on the screenshot below.

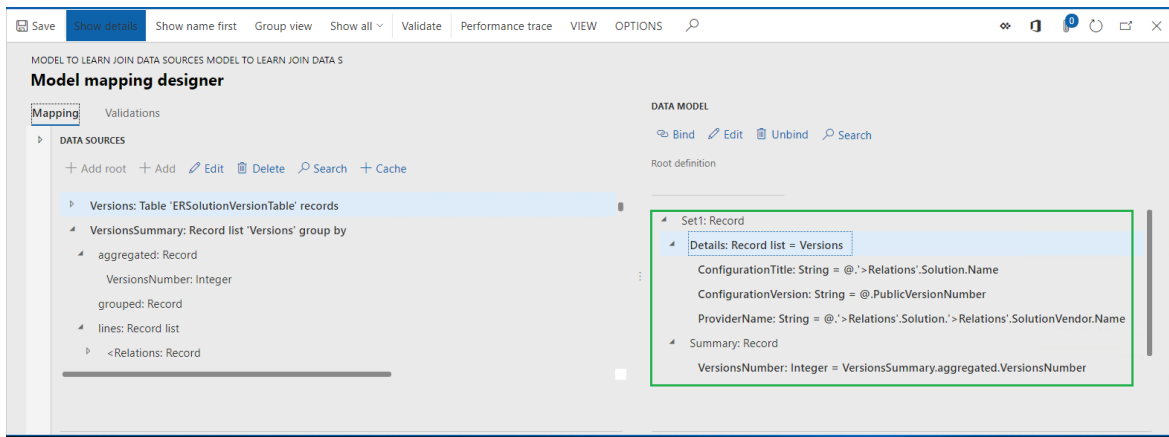

With these parameters turned on, for every execution of the imported ER format file, the execution trace will be generated. Using details of generated execution trace, you can analyze the execution of ER format and ER model-mapping components. Visit the [Trace execution of ER format to troubleshoot performance issues](#) page for more details about ER execution trace feature.

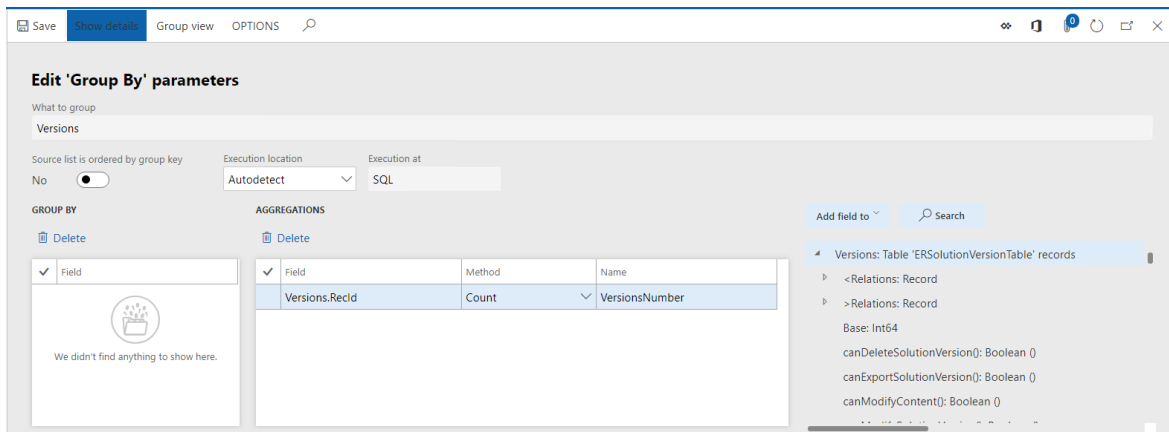

Review ER model mapping (part 1)

Review settings of the ER model-mapping component. The component is configured to access information about versions of ER configurations, details of configurations and configuration providers without using data sources of the **Join** type.

1. Select **Mapping to learn JOIN data sources** configuration.
2. Select **Designer** to open the list of mappings.
3. Select **Designer** to review the mapping details.
4. Select **Show details**.
5. In the configurations tree, expand the **Set1** and **Set1.Details** data model items:
 - a. Binding **Details: Record list = Versions** indicates that the **Set1.Details** item is bound to the **Versions** data source returning records of the **ERSolutionVersionTable** table. Each record of this table represents a single version of an ER configuration. The content of this table is presented in the **Versions** fast tab on the **Configurations** page.
 - b. Binding **ConfigurationVersion: String = @.PublicVersionNumber** means that the value of the public version of each ER configuration's version is taken from the **PublicVersionNumber** field of the **ERSolutionVersionTable** table and placed to the **ConfigurationVersion** item.
 - c. Binding **ConfigurationTitle: String = @.'>Relations'.Solution.Name** indicates that the name of an ER configuration is taken from the **Name** field of the **ERSolutionTable** table assessing by using the many-to-one relation ('>Relations') between the **ERSolutionVersionTable** and **ERSolutionTable** tables. Names of ER configurations of the current application instance are presented in the configurations tree on the **Configurations** page.
 - d. Binding **@.'>Relations'.Solution.'>Relations'.SolutionVendor.Name** means that the name of the configuration provider that owns the current configuration is taken from the **Name** field of the **ERVendorTable** table assessing by using the many-to-one relation between **ERSolutionTable** and **ERVendorTable** tables. Names of ER configuration providers are presented in the configurations tree on the **Configurations** page on the page header for each configuration. The entire list of ER configuration providers can be found on the **Organization administration > Electronic reporting > Configuration provider** table page.

6. In the configurations tree, expand the Set1.Summary data model item:
 - a. Binding **VersionsNumber: Integer = VersionsSummary.aggregated.VersionsNumber** indicates that the Set1.Summary.VersionsNumber item is bound to the VersionsNumber aggregation field of the VersionsSummary data source of the GroupBy type that was configured to return the number of records of the ERSolutionVersionTable table via the Versions data source.

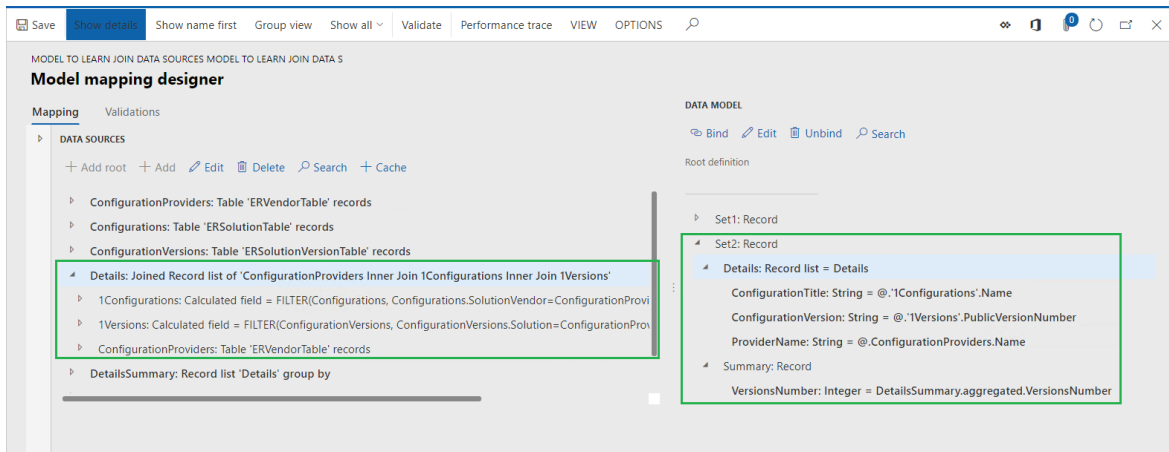

7. Close the page.

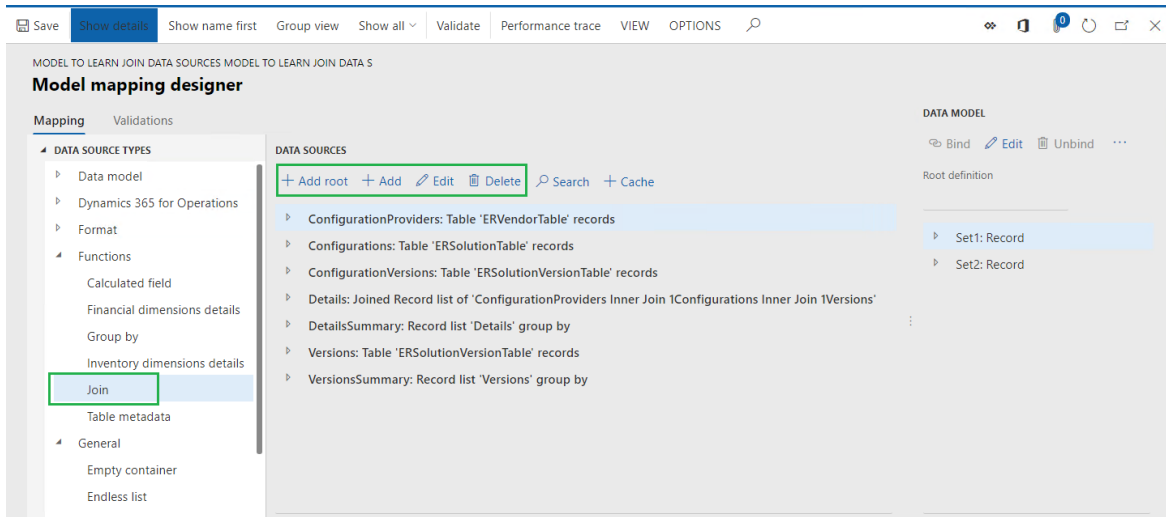

Review ER model mapping (part 2)

Review settings of the ER model-mapping component. The component is configured to access information about versions of ER configurations, details of configurations and configuration providers with using a data source of the Join type.

1. In the configurations tree, expand the Set2 and Set2.Details data model items. The binding **Details: Record list = Details** indicates that the Set2.Details item is bound to the Details data source configured as the data source of the Join type.

The Join data source can be added by selecting the Functions\Join data source:

2. Select **Details** data source.
3. Select **Edit** in the **Data sources** pane.
4. Select **Edit join**.
5. Select **Show details**.

This page is used to design the required data source of the **Join type**. At runtime, this data source will create a single joined list of records from the data sources in the **Joined list** grid. Join of records will start from the **ConfigurationProviders** data source that is in the grid as a first one (the **Type** column is blank for it). Records of every other data source will be joined consequently to records of the parent data source based on its order in this grid. Every joining data source must be configured as a data source nested under a target data source (**1Versions** data source is nested under **1Configurations** one; **1Configurations** data source is nested under **ConfigurationProviders** one). Each configured data source must contain the conditions for the join. In the data source for this particular **Join**, the following joins are defined:

- Each record of the **ConfigurationProviders** data source (referred to the **ERVendorTable** table) is joined with only records of the **1Configurations** one (referred to in the **ERSolutionTable** table) having the same value in the **SolutionVendor** and **ReclId** fields. The **Inner join** type is used for this join as well as the following conditions for matching records:

FILTER (Configurations, Configurations.SolutionVendor = ConfigurationProviders.ReclId)

- Each record of the **1Configurations** data source (referred to the **ERSolutionTable** table) is joined with the only records of the **1Versions** one (referred to the **ERSolutionVersionTable** table) having the same value in the **Solution** and **ReclId** fields. **Inner join** type is used for this join as well as the following conditions for matching records:

FILTER (ConfigurationVersions, ConfigurationVersions.Solution =

ConfigurationProviders.'1Configurations'.ReclId)

- **Execute** option is configured as **Query** meaning that this join data source will be executed at runtime on database level as a direct SQL call.

For joining records of data sources representing application tables, you can specify join conditions by using pairs of fields other than ones that describe existing in AOT relations between these tables. This type of join can be configured to execute at the database level as well.

6. Close the page.

7. Select **Cancel**.

8. In the configurations tree, expand the **Set2.Summary** data model item:

- Binding **VersionsNumber: Integer = DetailsSummary.aggregated.VersionsNumber** indicates that the **Set2.Summary.VersionsNumber** item is bound to the **VersionsNumber** aggregation field of the **DetailsSummary** data source of the **GroupBy** type that was configured to return the number of joined records of the **Details** data source of the **Join** type.
- The **Execution** location option is configured as **Query** meaning that this **GroupBy** data source will be run at runtime as a direct SQL call at the database level. This behavior is possible because the base data source **Details** of the **Join** type is configured as executed at the database level.

9. Close the page.

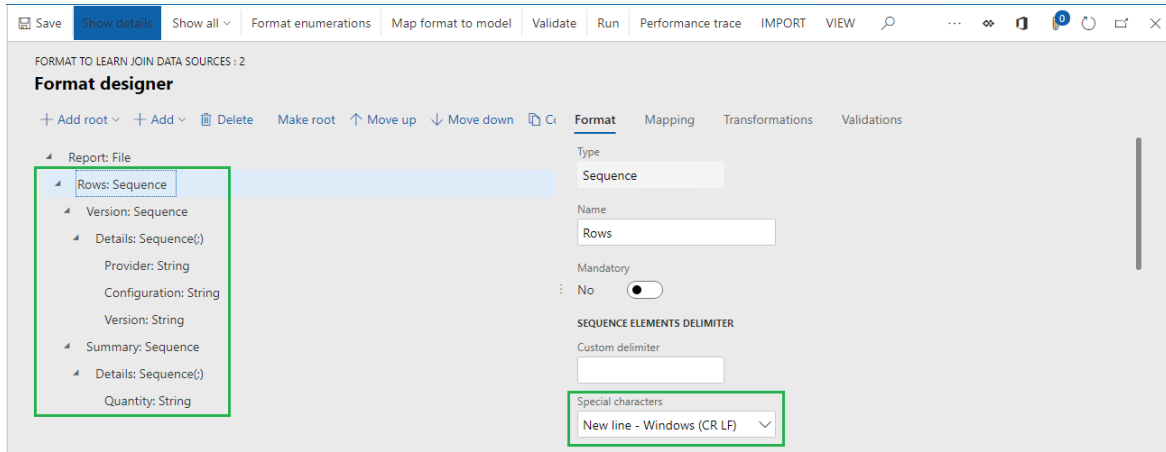

10. Select **Cancel**.

Execute ER format

1. Access Finance or RCS in the second session of your web browser using same credentials and company as in the first session.
2. Go to **Organization administration > Electronic reporting > Configurations**.
3. Expand **Model** to learn **JOIN data sources** configuration.
4. Select **Format** to learn **JOIN data sources** configuration.
5. Select **Designer**.
6. Select **Show details**.
7. Select **Mapping**.
8. Select **Expand/Collapse**.

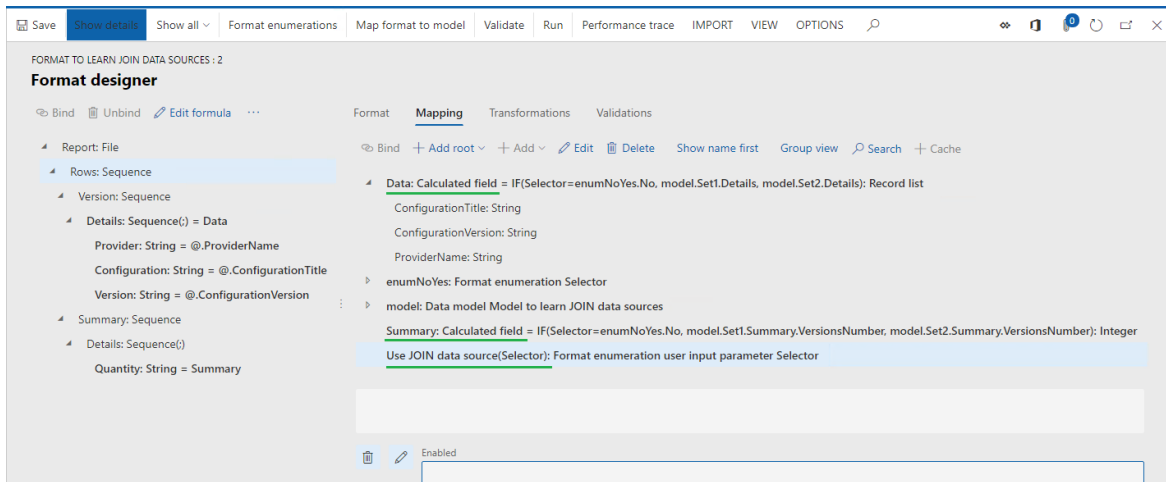

This format is designed to populate a generated text file with a new line for every version of an ER configuration (**Version** sequence). Each generated line will contain the name of a configuration provider owning the current configuration, the configuration name, and the configuration version separated by semicolon mark. The final line of generated file will contain the number of discovered versions of ER

configurations (Summary sequence).

The **Data** and **Summary** data sources are used to populate configuration version details to the generated file:

- Information from the **Set1** data model is used when you choose **No** for the **Selector** data source at runtime on the user dialog page when running ER format.
- Information from the **Set2** data model is used when you choose **Yes** for the **Selector** data source at runtime on the user dialog page.

9. Select **Run**.

10. On the dialog page, select **No** in the **Use JOIN data source** field.

11. Select **OK**.

12. Review generated file.

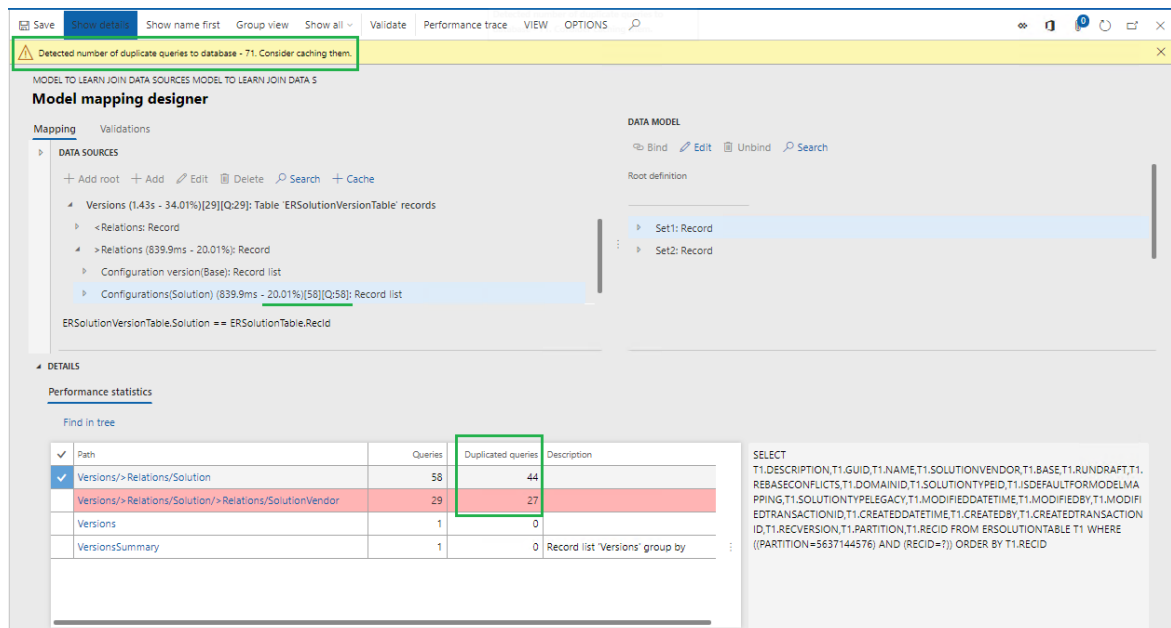

Analyze ER format execution trace

1. In the first session of Finance or RCS, select **Designer**.
2. Select **Performance trace**.
3. In the **Performance trace** grid, select the top-most record of the latest execution trace of an ER format that used the current model mapping component.
4. Select **OK**.

Execution statistics informs you about duplicated calls to application tables:

- **ERSolutionTable** has been called as many times as you have configuration version records in the **ERSolutionVersionTable** table, while the number of such calls could be reduced in times for performance improvement.
- **ERVendorTable** has been called twice for every configuration version record that was discovered in the **ERSolutionVersionTable** table, while the number of such calls could be reduced as well.

5. Close the page.

Execute ER format

1. Switch to your web browser tab with the second session of Finance or RCS.

2. Select **Run**.
3. On the dialog page, select **Yes** in the **Use JOIN data source** field.
4. Select **OK**.
5. Review generated file.

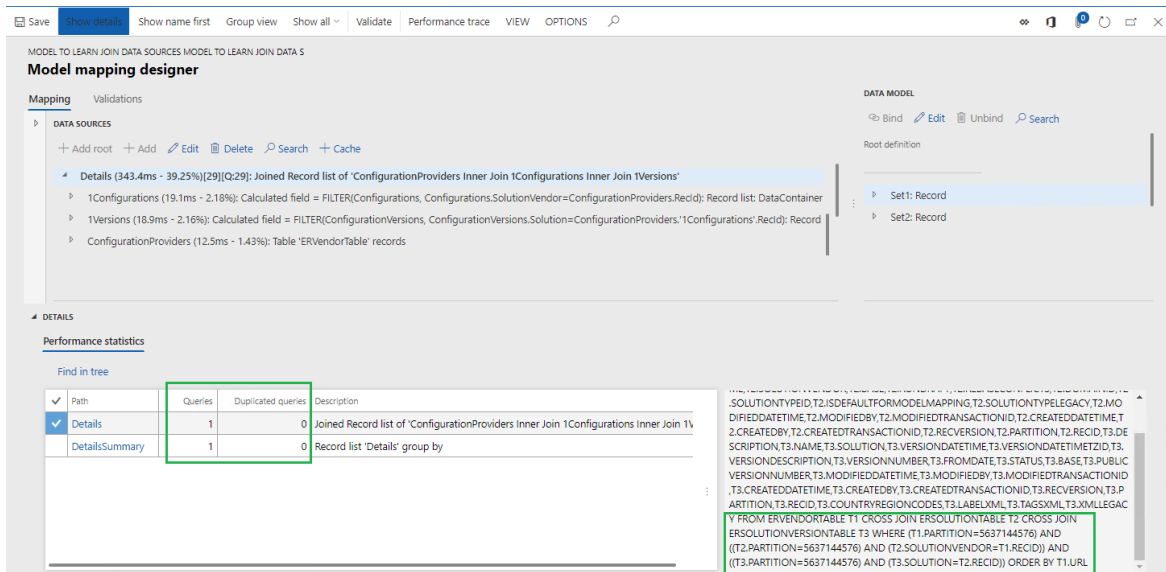

Analyze ER format execution trace

1. In the first session of Finance or RCS, select **Designer**.
2. Select **Performance trace**.
3. In the **Performance trace** grid, select top-most record representing the latest execution trace of an ER format that used the current model mapping component.
4. Select **OK**.

Statistics informs you about the following:

- Application database has been called once to get records from **ERVendorTable**, **ERSolutionTable**, and **ERSolutionVersionTable** tables to access required fields.

- Application database has been called once to calculate the number of configuration versions by using joins that were configured in the **Details** data source.

Limitations

As you can see from the example in this topic, the **JOIN** data source can be built from several data sources that describe the individual datasets of the records that must eventually be joined. You can configure those data sources by using the built-in ER **FILTER** function. When you configure the data source so that it's called beyond the **JOIN** data source, you can use company ranges as part of the condition for data selection. The initial implementation of the **JOIN** data source doesn't support data sources of this type. For example, when you call a **FILTER**-based data source within the scope of execution of a **JOIN** data source, if the called data source contains company ranges as part of the condition for data selection, an exception occurs.

In Microsoft Dynamics 365 Finance version 10.0.12 (August 2020), you can use company ranges as part of the condition for data selection in **FILTER**-based data sources that are called within the scope of execution of a **JOIN** data source. Because of the limitations of the application **query** builder, the company ranges are supported only for the first data source of a **JOIN** data source.

Example

For example, you must make a single call to the application database to get the list of foreign trade transactions of multiple companies and the details of the inventory item that is referred to in those transactions.

In this case, you configure the following artifacts in your ER model mapping:

- **Intrastat** root data source that represents the **Intrastat** table.
- **Items** root data source that represents the **InventTable** table.
- **Companies** root data source that returns the list of companies (**DEMF** and **GBSI** in this example) where transactions must be accessed. The company code is available from the **Companies.Code** field.
- **X1** root data source that has the expression `FILTER (Intrastat, VALUEIN(Intrastat.dataAreaId, Companies, Companies.Code))`. As part of the condition for data selection, this expression contains the definition of company ranges `VALUEIN(Intrastat.dataAreaId, Companies, Companies.Code)`.
- **X2** data source as a nested item of the **X1** data source. It includes the expression `FILTER (Items, Items.ItemId = X1.ItemId)`.

Finally, you can configure a **JOIN** data source where **X1** is the first data source and **X2** is the second data source. You can specify **Query** as the **Execute** option to force ER to run this data source on the database level as a direct SQL call.

When the configured data source is run while the ER execution is **traced**, the following statement is shown in the ER model mapping designer as part of the ER performance trace.

```
SELECT ... FROM INTRASTAT T1 CROSS JOIN INVENTTABLE T2 WHERE ((T1.PARTITION=?) AND (T1.DATAAREAID IN (N'DEMF',N'GBSI' ) ) ) AND ((T2.PARTITION=?) AND (T2.ITEMID=T1.ITEMID AND (T2.DATAAREAID = T1.DATAAREAID) AND (T2.PARTITION = T1.PARTITION))) ORDER BY T1.DISPATCHID,T1.SEQNUM
```

NOTE

An error occurs if you run a **JOIN** data source that has been configured so that it contains data selection conditions that have company ranges for additional data sources of the executed **JOIN** data source.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Configure country context dependent ER model mappings

2/18/2021 • 19 minutes to read • [Edit Online](#)

You can configure Electronic reporting (ER) model mappings so that they implement a generic ER data model but are specific to Dynamics 365 Finance. This topic explains how to design multiple ER model mappings for an ER data model to control how they are used by corresponding ER formats that are run from companies that have different country/region contexts.

Prerequisites

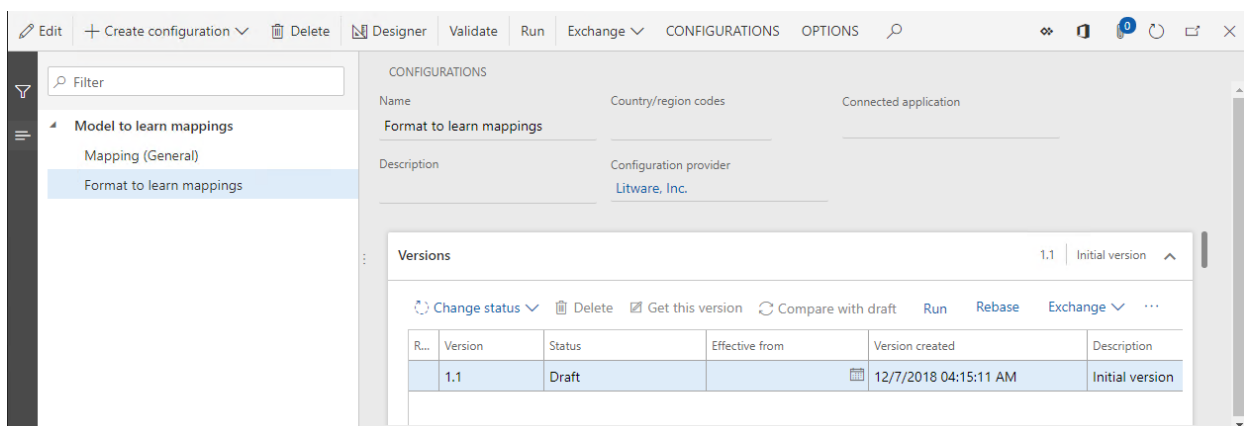

To complete the examples in this topic, you must have the following access:

- Access to Finance for one of the following roles:
 - Electronic reporting developer
 - Electronic reporting functional consultant
 - System administrator
- Access to the instance of Regulatory Configuration Services (RCS) that has been provisioned for the same tenant as Finance for one of the following roles:
 - Electronic reporting developer
 - Electronic reporting functional consultant
 - System administrator

Some steps in this topic require execution of an ER format. In some cases, execution of an ER format is affected by the country/region context of the company that you're currently signed in to. You can run an ER format in the current RCS instance if the company that has the required country/region context is available in RCS. Otherwise, you must upload a completed version of the ER model mapping and ER format configurations that use the ER data model to your Finance instance, and then run the ER format in that Finance instance. For information about how to import configurations that reside in RCS into a Finance instance, see [Import configurations from RCS](#).

Single model mapping case

Follow the steps in [Appendix 1](#) of this topic to design the required ER components. You now have the **Mapping (General)** model mapping configuration that contains the model mapping for the **Entry point 1** definition.

The screenshot shows the Dynamics 365 configuration interface. The left sidebar contains a filter and a tree view with 'Model to learn mappings' expanded, showing 'Mapping (General)' and 'Format to learn mappings'. The main area displays the configuration for 'Format to learn mappings' with fields for Name, Country/region codes, Connected application, Description, and Configuration provider (Litware, Inc.). Below this is a 'Versions' section with a table showing a single draft version (1.1) created on 12/7/2018.

R...	Version	Status	Effective from	Version created	Description
	1.1	Draft		12/7/2018 04:15:11 AM	Initial version

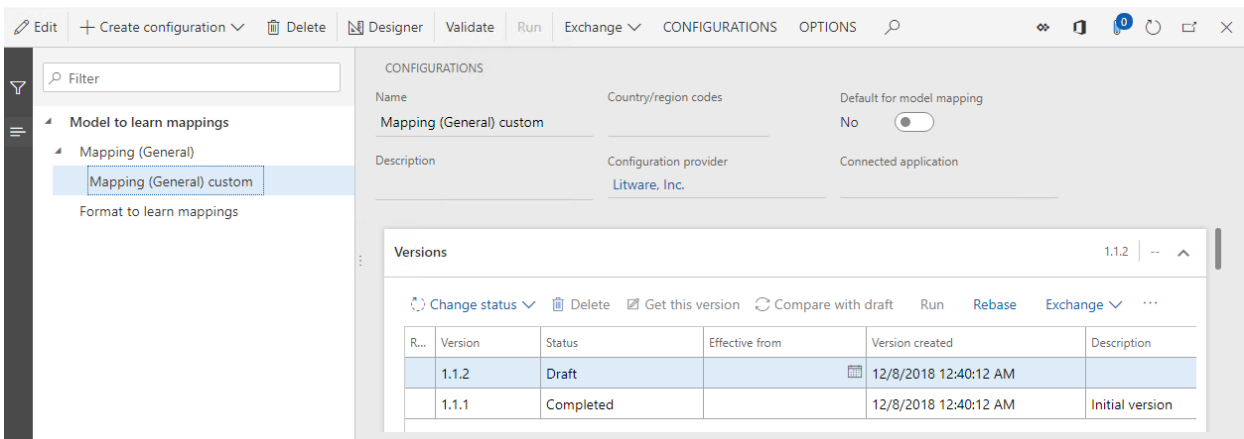

Run the configured format

1. On the **Configurations** page, on the **Versions** FastTab, select **Run**.
2. Select **OK**.

Notice that the web browser offers to download the text file that was generated by executed ER format. Because this format was configured to use the **Entry point 1** definition, and only a single model mapping is currently available for the base model that contains a mapping for this definition, the executed ER format used the **Mapping (General)** model mapping of the **Mapping (General)** configuration as a data source. Therefore, the downloaded file contains the **Generic functionality 1** text.

Multiple shared model mappings case

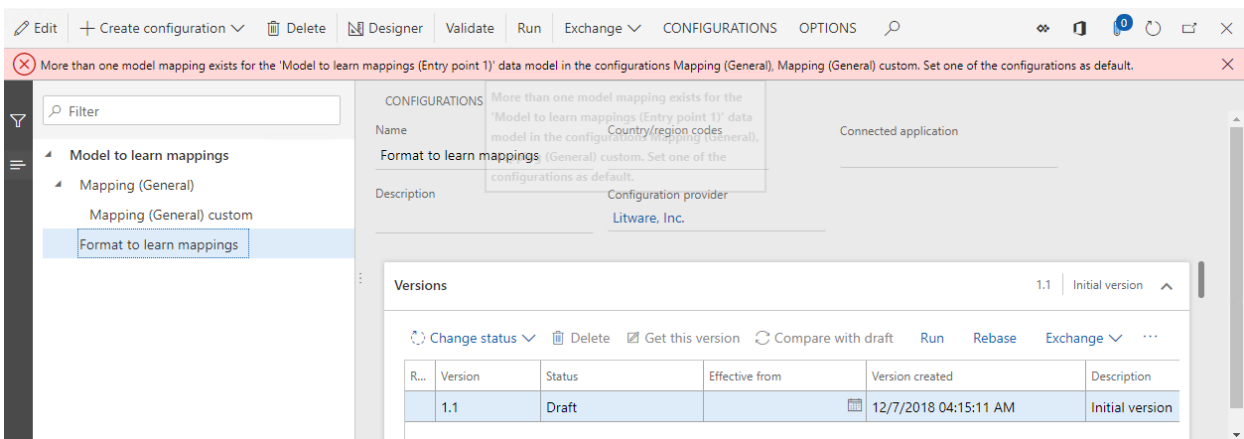

Follow the steps in [Appendix 2](#) of this topic to design the required ER components. You now have **Mapping (General)** and **Mapping (General) custom** model mapping configurations, each of which contains the model mapping for the **Entry point 1** definition.

Run the configured format

1. On the **Configurations** page, in the configurations tree, select **Format to learn mappings**.
2. On the **Versions** FastTab, select **Run**.
3. Select **OK**.

Notice that execution of the selected ER format is unsuccessful. An error message informs you that more than one model mapping exists for the **Model to learn mappings** model and the **Entry point 1** definition in the **Mapping (General)** and **Mapping (General) custom** model mapping configurations. The message also recommends that you select one of those configurations as the default configuration.

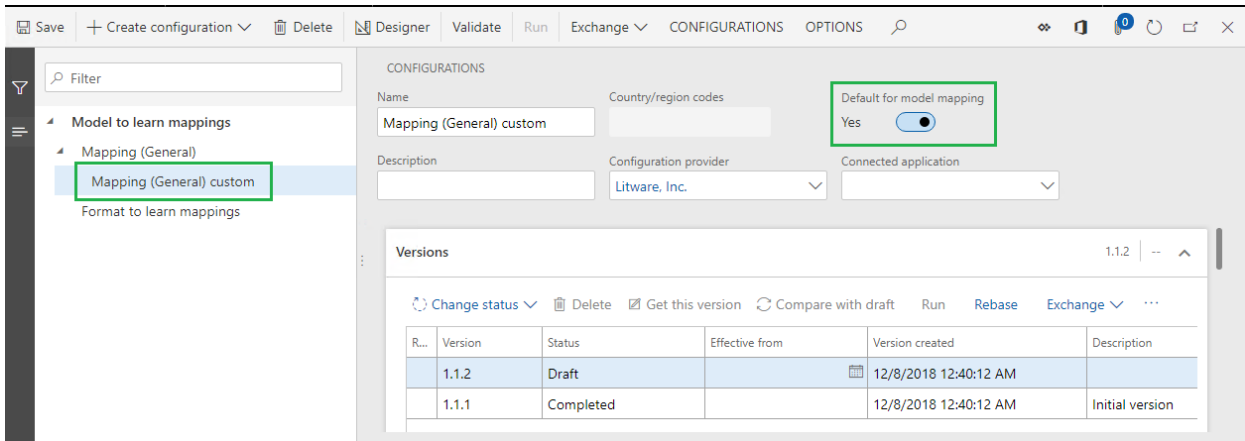

Define a default mapping configuration

Follow these steps to define the **Mapping (General) custom** model mapping configuration as the default configuration, so that its mappings can be used as data sources for the **Format to learn mappings** ER format.

1. On the **Configurations** page, in the configurations tree, select **Mapping (General) custom**.

2. As required, select **Edit** to make the current page ready for editing.
3. Set the **Default for model mapping** option to **Yes**.
4. Select **Save**.

Run the configured format

1. On the **Configurations** page, in the configurations tree, select **Format to learn mappings**.
2. On the **Versions** FastTab, select **Run**.
3. Select **OK**.

Notice that execution of the selected ER format succeeds. The web browser offers to download the text file that was generated by executed ER format. Because this format was configured to use the **Entry point 1** definition, and the **Mapping (General) custom** model mapping configuration was selected as the default configuration, the executed ER format used the **Mapping (General) copy** model mapping of the **Mapping (General) custom** configuration as a data source. Therefore, the downloaded file contains the **Generic functionality 1 custom** text.

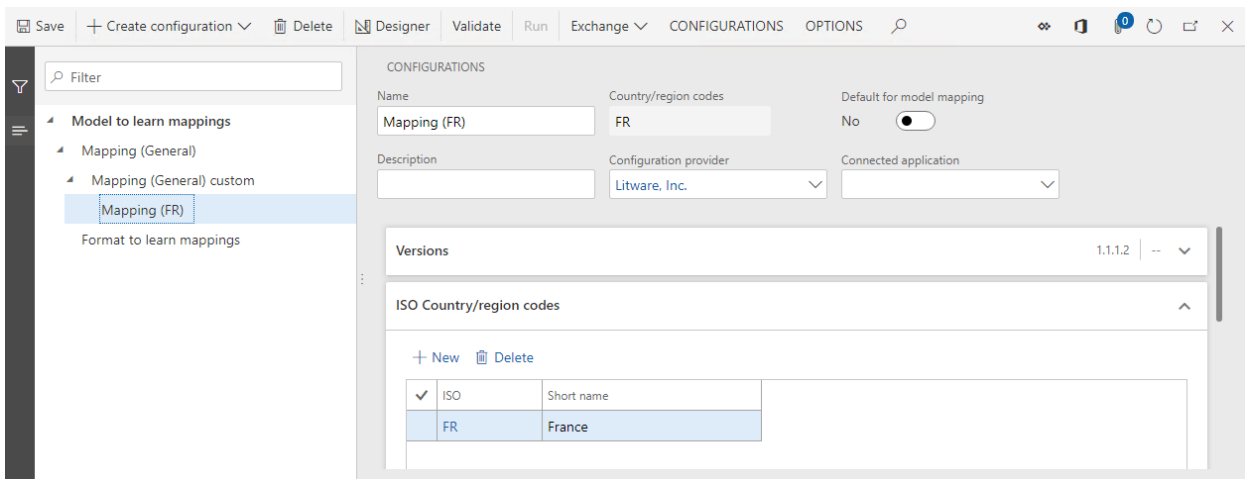

NOTE

If you change the company that you're currently signed in to and run this ER format again, you get the same content in the generated file, because the default ER model mapping configuration doesn't contain any company-dependent restrictions.

Multiple mixed model mappings case

Follow the steps in [Appendix 3](#) of this topic to design the required ER components. You now have **Mapping (General)**, **Mapping (General) custom**, and **Mapping (FR) model mapping** configurations that contain the model mapping for the **Entry point 1** definition.

Notice that version 1 of the **Mapping (FR) model mapping** configuration is configured so that it applies only to ER formats of the **Model to learn mappings** model that are run in Finance companies that have French country/region context.

Run the configured format

1. Change the company to FRSI.
2. On the **Configurations** page, in the configurations tree, select **Format to learn mappings**.
3. On the **Versions** FastTab, select **Run**.
4. Select **OK**.

Notice that execution of the selected ER format succeeds. The web browser offers to download the text file that was generated by the executed ER format. Because this format was configured to use the **Entry point 1** definition, and the **Mapping (General) custom** model mapping configuration was selected as the default configuration, the executed ER format used the **Mapping (General) copy** model mapping of the **Mapping (General) custom** configuration as a data source. Therefore, the downloaded file contains the **Generic functionality 1** custom text.

Define the France-specific mapping configuration as the default configuration

Follow these steps to define the custom **Mapping (FR)** model mapping configuration as the default configuration. Note that, because this mapping is specific to France, it will be considered the default mapping between all model mapping configurations that have the **FR** country code specified in the **ISO country/region codes** field.

1. On the **Configurations** page, in the configurations tree, select **Mapping (FR)**.
2. As required, select **Edit** to make the current page ready for editing.
3. Set the **Default for model mapping** option to **Yes**.
4. Select **Save**.

Run the configured format

1. On the **Configurations** page, in the configurations tree, select **Format to learn mappings**.
2. On the **Versions** FastTab, select **Run**.

3. Select **OK**.

Notice that execution of the selected ER format succeeds. The web browser offers to download the text file that was generated by the executed ER format. Because this format was configured to use the **Entry point 1** definition, and the **Mapping (FR)** model mapping configuration was selected as the default configuration, the executed ER format used the **Mapping (FR)** model mapping of the **Mapping (FR)** configuration as a data source. Therefore, the downloaded file contains the **FR functionality 1** text.

NOTE

If you change the company that you're currently signed in to and run this ER format again, the output will depend on the country/region context of the selected company.

Other model mapping cases

As you've seen, the selection of a model mapping for the execution of an ER format works in the following way:

- The model mapping definition that an ER format uses is specified (**Entry point 1** in the examples in this topic).
- All mapping configurations that contain a mapping that has the specified definition, and that satisfy any country/region context restrictions that are configured, can potentially be used to run the ER format (**Mapping (General)**, **Mapping (General) custom**, and **Mapping (FR)** in the examples in this topic).
- Any default model mapping that has country/region context restrictions has the highest priority for selection (**Mapping (FR)** in the examples in this topic).
- Any default model mapping that doesn't have country/region context restrictions has the next higher priority for selection (**Mapping (General) custom** in the examples in this topic).
- Any model mapping that has country/region context restrictions has higher priority for selection than a model mapping that doesn't have country/region context restrictions.

The following table provides information about the results of model mapping selection for all possible cases for model mapping settings:

- Column 1 indicates whether the first model mapping that doesn't have country/region context restrictions (for example, the shared **Mapping (General)** mapping) is presented and, if it is, whether the **Default for model mapping** option is set to **Yes** for it.
- Column 2 indicates whether the second model mapping that doesn't have country/region context restrictions (for example, the shared **Mapping (General) custom** mapping) is presented and, if it is, whether the **Default for model mapping** option is set to **Yes** for it.
- Column 3 indicates whether the first model mapping that has country/region A context restrictions (for example, the France-specific **Mapping (FR)** mapping) is presented and, if it is, whether the **Default for model mapping** option is set to **Yes** for it.
- Column 4 indicates whether the second model mapping that has country/region A context restrictions is presented and, if it is, whether the **Default for model mapping** option is set to **Yes** for it.
- Column 5 presents the result of a model mapping selection for execution of an ER format under the control of a company that has country/region A context.
- Column 6 presents the result of a model mapping selection for execution of an ER format under the control of a company that has country/region B context.

In the table, a plus sign (+) indicates the presence of a model mapping configuration in the current instance of the Microsoft Azure service that is used to run an ER format (either Finance or RCS).

CASE	MODEL MAPPING 1 WITHOUT COUNTRY/REGION CONTEXT (MM1)	MODEL MAPPING 2 WITHOUT COUNTRY/REGION CONTEXT (MM2)	MODEL MAPPING 1 WITH COUNTRY/REGION A CONTEXT (MM1A)	MODEL MAPPING 2 WITH COUNTRY/REGION A CONTEXT (MM2A)	RUN UNDER CONTROL OF A COMPANY THAT HAS COUNTRY/REGION A CONTEXT	RUN UNDER THE CONTROL OF A COMPANY THAT HAS COUNTRY/REGION B CONTEXT
	1	2	3	4	5	6
1					Error (missing mapping)	Error (missing mapping)
2	+				MM1	MM1
3	+	+			Error (multiple mappings)	Error (multiple mappings)
4	+		+		MM1A	MM1
5	+		+	+	Error (multiple mappings)	MM1
6	+	default	+	+	MM2	MM2
7	+		default		MM1A	MM1
8	+		default	+	MM1A	MM1
9	+		default	default	Error (multiple mappings)	MM1
10	default				MM1	MM1
11	default	+			MM1	MM1
12	default		+		MM1	MM1
13	default	default			Error (multiple mappings)	Error (multiple mappings)
14	default		default		MM1A	MM1
15	default		default	default	MM1A	MM2A
16			+	+	MM1A	MM2A
17			default	default	MM1A	MM2A

Learn what mapping was used in the execution of an ER format

Configure ER user parameters

1. On the **Configurations** page, on the Action Pane, on the **CONFIGURATIONS** tab, select **User parameters**.
2. Set the **Run in debug mode** option to **Yes**.

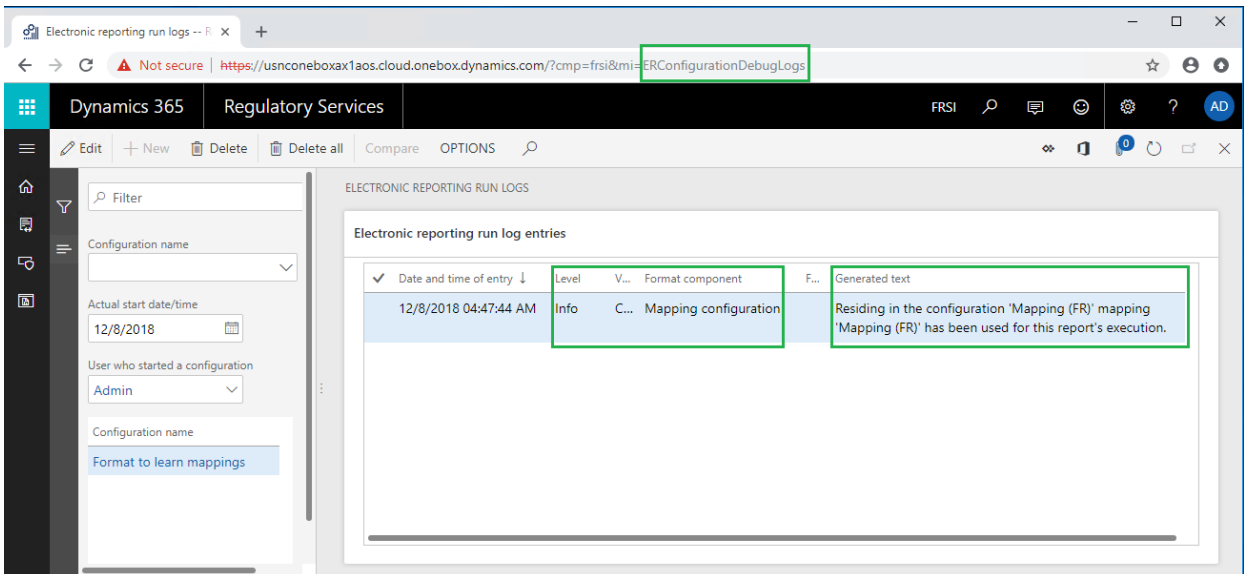

3. Select **Ok**.

Run the configured format

1. On the **Configurations** page, in the configurations tree, select **Format to learn mappings**.
2. On the **Versions** FastTab, select **Run**.
3. Select **Ok**.

Review the ER debug log

1. In the navigation pane, go to **Modules > Organization administration > Electronic reporting > Configuration debug log**.
2. Select the **Reload this page** button.

Notice that a new record has been added to the ER debug log for the executed ER format. Because the **Level** field of this record is set to **Info**, the record is informational. Because the **Format component** field is set to **Mapping configuration**, the record informs you about a model mapping that was used during execution of the **Format to learn mappings** ER format (selected in the **Configuration name** field). The content of the **Generated text** field informs you that the **Mapping (FR)** mapping component that resides in the **Mapping (FR)** configuration has been used to run this report.

Appendix 1

Configure a sample data model

Sign in to your RCS instance.

In this example, you will create a configuration for sample company, Litware, Inc. To complete these steps, you must first complete, in RCS, the steps in the [Create a configuration provider and mark it as active](#) procedure.

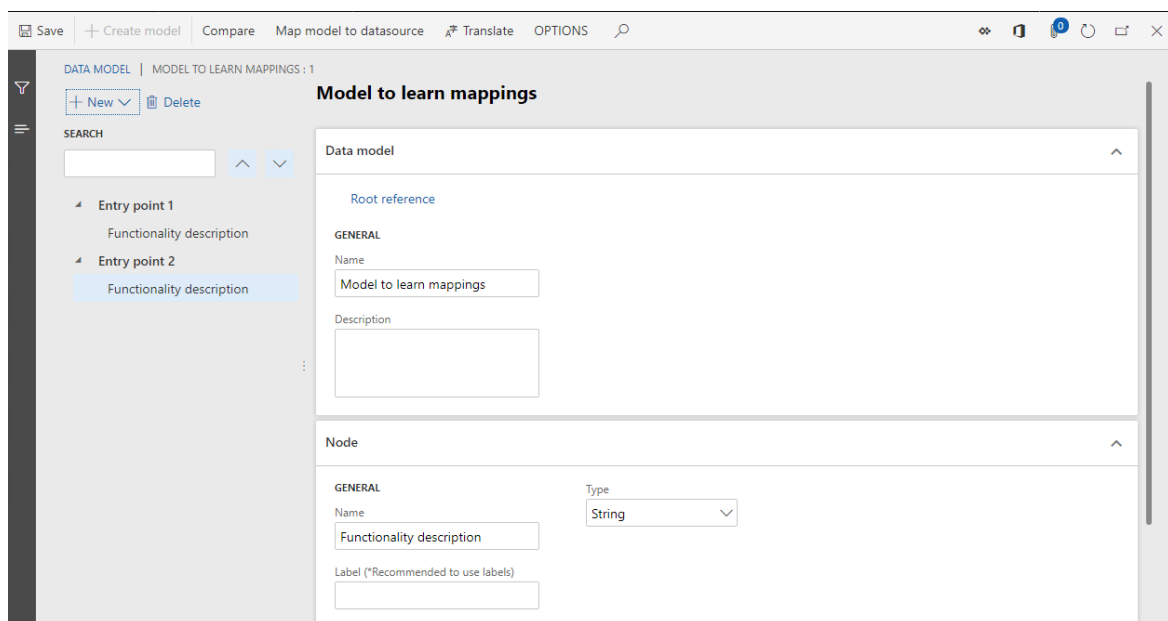

Create an ER data model configuration

1. On the default dashboard, select **Electronic reporting**.
2. Select the **Reporting configurations** tile.
3. On the **Configurations** page, select **Create configuration**.
4. In the drop-down dialog box, in the **Name** field, enter **Model to learn mappings**.
5. Select **Create configuration**.
6. Select the **Configuration components** FastTab.

Notice that draft version 1 of this ER configuration is ready for editing. This version contains the data model component.

Design a sample data model

1. On the **Configurations** page, select **Designer**.
2. Select **New**.
3. In the drop-down dialog box, in the **Name** field, enter **Entry point 1**.
4. Select **Add**.
5. Select **New**.
6. In the drop-down dialog box, in the **Name** field, enter **Functionality description**.
7. Select **Add**.
8. Select **New**.
9. In the drop-down dialog box, in the **New node** field group, select **Model root**.
10. In the **Name** field, enter **Entry point 2**.
11. Select **Entry point 2**.
12. Select **Add**.
13. Select **New**.
14. In the drop-down dialog box, in the **Name** field, enter **Functionality description**.
15. Select **Add**.

16. Select **Save**.
17. Close the page.

Complete the modified version of the model configuration

1. On the **Configurations** page, on the **Versions** FastTab, select **Change status**.

Change the status of designed model configuration from **Draft** to **Completed**, so that it can be used to design the required model mappings and formats.

2. Select **Complete**.
3. Select **OK**.

Notice that the configuration that you created is saved as completed version 1.

Configure a sample model mapping

Create an ER model mapping configuration

1. On the **Configurations** page, select **Create configuration**.
2. In the drop-down dialog box, in the **New** field group, select **Model mapping based on data model Model to learn mappings**.
3. In the **Name** field, enter **Mapping (General)**.
4. In the **Data model definition** field, select **Entry point 1**.
5. Select **Create configuration**.

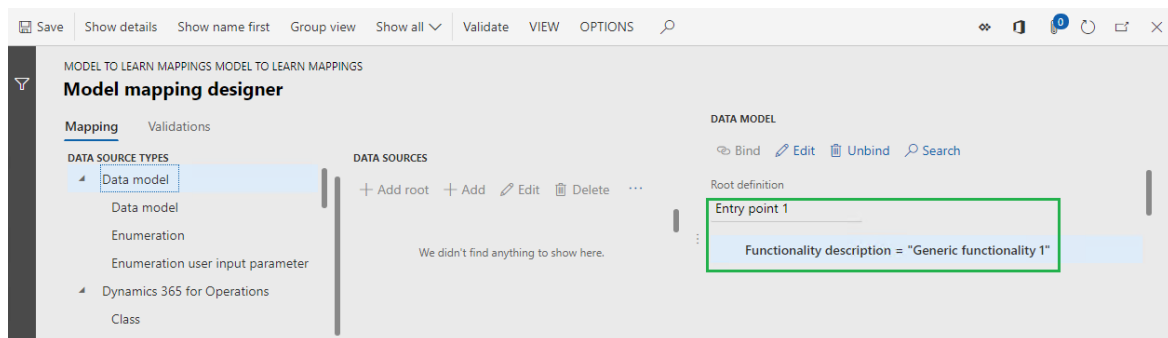

Notice that draft version 1 of this ER configuration is ready for editing. This version contains the model mapping component.

Design a sample model mapping

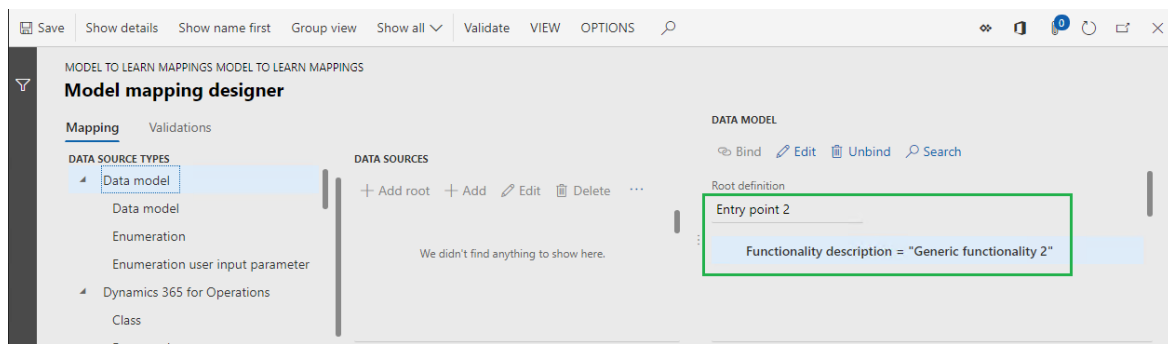

1. On the **Configurations** page, select **Designer**.

Notice that the model mapping of the **To model** direction type has been automatically added to this component for the **Entry point 1** definition.

2. Select **Designer** to start editing the added model mapping.
3. In the **Data model** section, select **Edit**.
4. In the **Formula** field, enter "**Generic functionality 1**".
5. Select **Save**.
6. Close the **Formula designer** page.

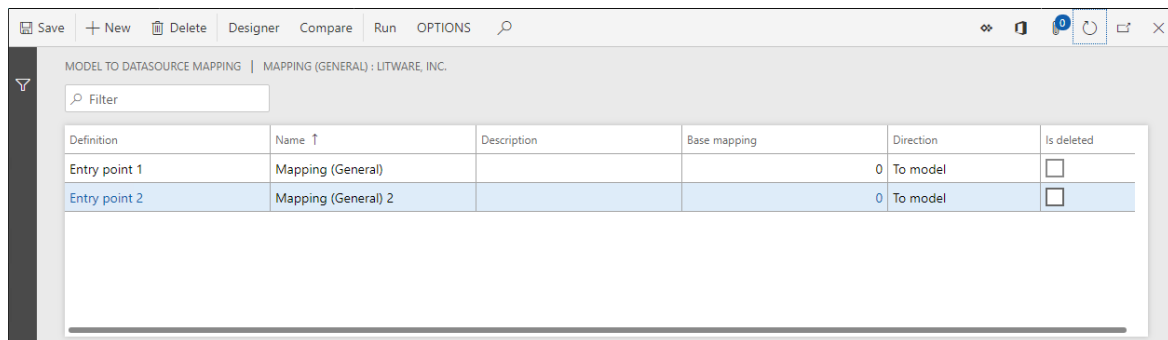

7. Select **Save**.
8. Close the **Model mapping designer** page.
9. Select **New**.
10. In the **Definition** field, select **Entry point 2**.
11. In the **Name** field, enter **Mapping (General) 2**.
12. Select **Designer**.
13. In the **Data model** section, select **Edit**.
14. In the **Formula** field, enter "**Generic functionality 2**".
15. Select **Save**.
16. Close the **Formula designer** page.

17. Select **Save**.

18. Close the **Model mapping designer** page.

19. Close the **Model mappings** page.

Complete the modified version of the model mapping configuration

1. On the **Configurations** page, on the **Versions** FastTab, select **Change status**.

Change the status of designed model mapping configuration from **Draft** to **Completed**, so that it can be used by ER formats.

2. Select **Complete**.

3. Select **OK**.

Notice that the configuration that is created is saved as completed version 1.

Configure a sample format

Create an ER format configuration

1. On the **Configurations** page, in the configurations tree, select **Model to learn mappings**.

2. Select **Create configuration**.

3. In the drop-down dialog box, in the **New** field group, select **Format based on data model Model to learn mappings**.

4. In the **Name** field, enter **Format to learn mappings**.

5. In the **Data model definition** field, select **Entry point 1**.

6. Select **Create configuration**.

Notice that draft version 1 of this ER configuration is ready for editing. This version contains the format component.

Design a sample format

1. On the **Configurations** page, select **Designer**.

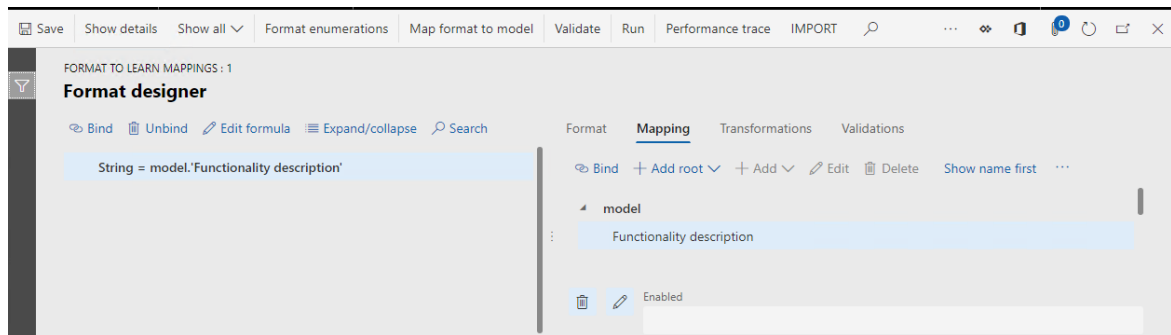

2. Select **Add root**.

3. In the **Text** group, select the **String** item.

4. Select **OK**.

Bind format elements to a data source

1. On the **Format designer** page, on the **Mapping** tab, expand the model data source.
2. Select the **Functionality description** field.
3. Select **Bind**.

4. Select **Save**.
5. Close the page.

Appendix 2

Configure a sample model mapping for general customization

You might want to customize a model mapping that a configuration provider (partner) provided to you, and then use the customized version as a data source for your ER formats. In this case, you must create a custom ER model mapping configuration to make the required changes in existing model mappings. The procedures in this appendix use the **Mapping (General)** model mapping as an example.

Create an ER model mapping configuration

1. On the **Configurations** page, in the configurations tree, select **Mapping (General)**.
2. Select **Create configuration**.
3. In the drop-down dialog box, in the **New** field group, select **Derive from Name: Mapping (General), Litware, Inc..**
4. In the **Name** field, enter **Mapping (General) custom**.
5. Select **Create configuration**.

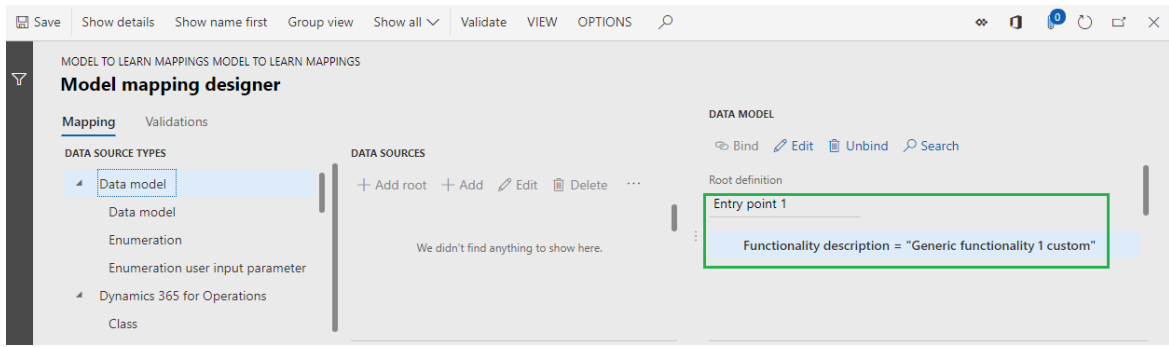

Notice that draft version 1 of this ER configuration is ready for editing.

Design a sample model mapping

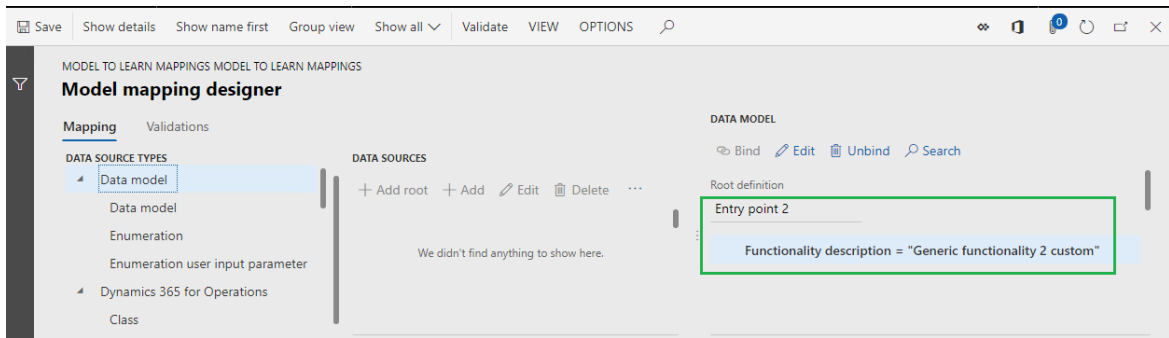

1. On the **Configurations** page, select **Designer**.

Notice that the model mappings of the base configuration have been automatically copied to this configuration.

2. Select the **Mapping (General) Copy** mapping.
3. Select **Designer**.
4. In the **Data model** section, select **Edit**.
5. In the **Formula** field, enter **"Generic functionality 1 custom"**.
6. Select **Save**.
7. Close the page.

8. Select **Save**.
9. Close the page.
10. Select the **Mapping (General) 2 Copy** mapping.
11. Select **Designer**.
12. In the **Data model** section, select **Edit**.
13. In the **Formula** field, enter "**Generic functionality 2 custom**".
14. Select **Save**.
15. Close the page.

16. Select **Save**.
17. Close the page.

18. Close the page.

Complete the modified version of the model mapping configuration

1. On the **Configurations** page, on the **Versions** FastTab, select **Change status**.

Change the status of designed model mapping configuration from **Draft** to **Completed**, so that it can be used by ER formats.

2. Select **Complete**.

3. Select **OK**.

Notice that the configuration that is created is saved as completed version 1.

Appendix 3

Configure a sample model mapping for country/region-specific customization

For some ER formats, there might be country/region-specific requirements for data preparation. In this case, you can manage a separate ER model mapping configuration and isolate the implementation of these country/region-specific requirements from the general implementation. The procedures in this appendix use the **Format to learn mappings** ER format and French-specific requirements as an example.

Create an ER model mapping configuration

First, create a new ER model mapping configuration to implement the country/region-specific requirements. Use your custom ER model mapping configuration as a base.

1. On the **Configurations** page, in the configurations tree, select **Mapping (General) custom**.
2. Select **Create configuration**.
3. In the drop-down dialog box, in the **New** field group, select **Derive from Name: Mapping (General) custom, Litware, Inc.**
4. In the **Name** field, enter **Mapping (FR)**.
5. Select **Create configuration**.

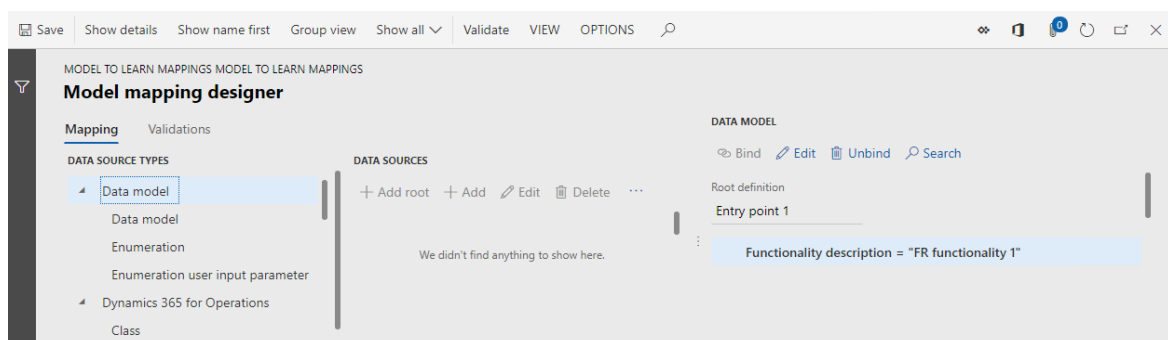

Notice that draft version 1 of this ER configuration is ready for editing.

Design a sample model mapping

1. On the **Configurations** page, select **Designer**.

Notice that model mappings of the base configuration have been automatically copied to this configuration.

2. Select the **Mapping (General) Copy Copy** mapping.
3. Rename it **Mapping (FR)**.
4. Select **Designer**.
5. In the **Data model** section, select **Edit**.
6. In the **Formula** field, enter **"FR functionality 1"**.
7. Select **Save**.
8. Close the page.

9. Select **Save**.
10. Close the page.

11. Select the **Mapping (General) 2 Copy Copy** mapping.
12. Rename it **Mapping (FR) 2**.
13. Select **Designer**.
14. In the **Data model** section, select **Edit**.
15. In the **Formula** field, enter "**FR functionality 2**".
16. Select **Save**.
17. Close the page.

18. Select **Save**.
19. Close the page.

20. Close the page.

Specify country/region context restrictions for use

1. On the **Configurations** page, on the **ISO Country/region codes** FastTab, select **New**.
2. In the **ISO** field, select **FR**.
3. Select **Save**.

Note that you must sign in to a specific company in Finance to run an ER format. Therefore, this company can be considered a party that controls both ER format execution and selection of the correct ER model mapping of the base ER data model. By adding the **FR** country code, you specify that this model mapping is available for selection by an ER format of the base data model only when that format is run under the control of a company that has French country/region context.

You can add multiple country/region codes for a single version of an ER model mapping configuration. In this way, model mappings that reside in that model mapping configuration can be used for an ER format that is run under the control of companies that have a different country/region context.

Note that the list of country/region codes is specified for each version of an ER model mapping configuration and can vary from version to version.

Complete the modified version of the model mapping configuration

1. On the **Configurations** page, on the **Versions** FastTab, select **Change status**.

Change the status of designed model mapping configuration from **Draft** to **Completed**, so that it

can be used by ER formats.

2. Select **Complete**.
3. Select **OK**.

Notice that the configuration that is created is saved as completed version 1.

[Apply country/region context](#)

Frequently asked questions

I configured two shared ER model mapping configurations in RCS and marked one of them as the default model mapping configuration. I successfully ran an ER format that was created for the same base ER data model configuration, to test model mappings. I then imported the whole ER solution (ER data model, two ER model mapping configurations, and ER format configuration) into Finance. Why do I receive an error message when I try to run the same ER format in Finance?

The default model mapping setting is environment-specific. It's configured in RCS but isn't exported to Finance. To successfully run this ER format, you must mark one of ER model mapping configurations as the default model mapping configuration in Finance too.

I configured one model mapping as a shared model mapping and completed the draft version of it. I then added a new model mapping configuration for same data model and configured it as French-specific. Why is the shared model mapping selected when I run an ER format, even though this ER format uses the correct root definition and execution is done under the control of the company that has French country/region context?

Make sure that the shared model mapping configuration isn't marked as the default model mapping configuration. Otherwise, it will have higher priority during mapping selection. Also make sure that the French-specific model mapping configuration is considered when a mapping is selected during ER format execution. An ER model mapping configuration is available for selection only if at least one of the following conditions is met:

- At least one version of the ER model mapping configuration has either **Completed** or **Shared** status. In this case, the version that has the highest version number will be used for ER format execution.
- The **Run draft** option for the ER model mapping configuration is turned on. In this case, the version that has **Draft** status will be used for ER format execution.

The **Run draft** option becomes available on the **Configurations** page for each ER model mapping configuration when the **Run setting** ER user parameter is turned on.

NOTE

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Configure ER formats to use parameters that are specified per legal entity

2/18/2021 • 13 minutes to read • [Edit Online](#)

Overview

In many of the Electronic reporting (ER) formats that you will design, you must filter data by using a set of values that are specific to each legal entity of your instance (for example, a set of tax codes to filter tax transactions). Currently, when filtering of this type is configured in an ER format, values that are dependent on the legal entity (for example, tax codes) are used in expressions of the ER format to specify data filtering rules. Therefore, the ER format is made legal entity-specific, and to generate the required reports, you must create derived copies of the original ER format for each legal entity where you have to run the ER format. Each derived ER format must be edited to bring legal entity-specific values into it, rebased whenever the original (base) version has been updated, exported from a test environment and imported into a production environment when it must be deployed for production use, and so on. Therefore, maintenance of this type of configured ER solution is quite complex and time-consuming for several reasons:

- The more legal entities there are, the more ER format configurations must be maintained.
- Maintenance of ER configurations requires that business users have ER knowledge.

The ER application-specific parameters feature lets power users configure data filtering in an ER format so that it's based on a set of abstract rules. This set of rules can be configured to use the data sources that are available in an ER format. Business users can then specify real rules beyond the ER framework by using the user interface (UI) that is automatically generated based on the settings of the corresponding ER format and the current legal entity data that will be accessed by the ER format's data sources. The set of rules that is specified for an ER format can be exported from the current legal entity of the Dynamics 365 Finance (Finance) instance. It can then be imported into another legal entity of either the same Finance instance or a different instance as a set of rules for the same ER format.

Prerequisites

To complete the examples in this topic, you must have access to the instance of Regulatory Configuration Services (RCS) that has been provisioned for the same tenant as Finance for one of the following roles:

- Electronic reporting developer
- Electronic reporting functional consultant
- System administrator

We recommend that you complete the steps in the [Support parameterized calls of ER data sources of CALCULATED FIELD type](#) topic. If you've already completed those steps, you can skip the steps in the **Import ER configurations into RCS** section that follows.

Import ER configurations into RCS

From [Microsoft Download Center](#), download the **Support parameterized calls of ER data sources of CALCULATED FIELD type** zip file. This zip file contains the following ER configurations that must be extracted and stored locally.

CONTENT DESCRIPTION	FILE NAME
Sample ER data model configuration file	Model to learn parameterized calls.version.1.xml
Sample ER metadata configuration file	Metadata to learn parameterized calls.version.1.xml
Sample ER model mapping configuration file	Mapping to learn parameterized calls.version.1.1.xml
Sample ER format configuration	Format to learn parameterized calls.version.1.1.xml

Next, sign in to your RCS instance.

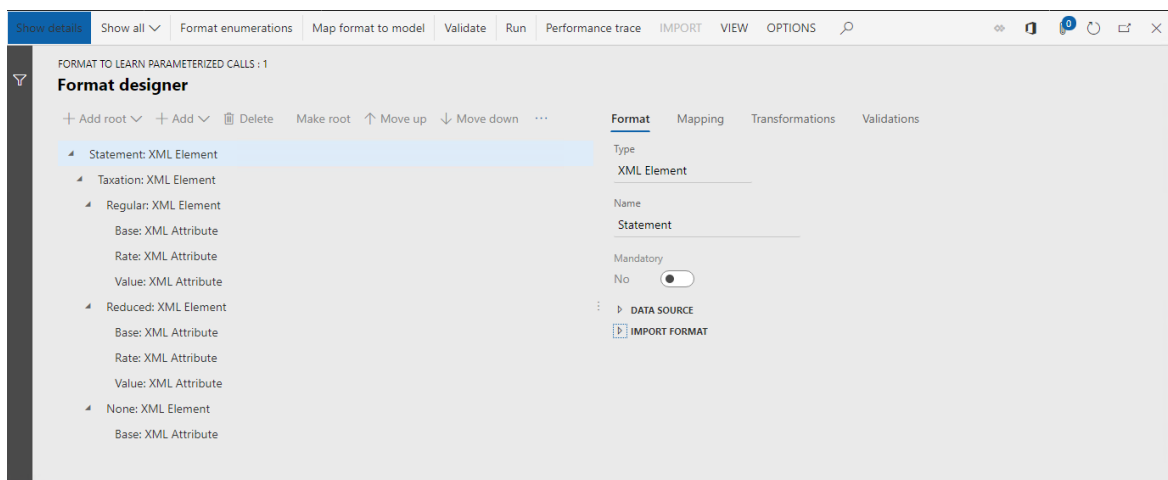

In this example, you will create a configuration for the Litware, Inc sample company. Before you can complete this procedure, you must complete the steps in the [Create a configuration provider and mark it as active](#) topic in RCS.

1. On the default dashboard, select **Electronic reporting**.
2. Select **Reporting configurations**.
3. Import the ER configurations that you downloaded earlier into RCS, in the following order: data model, metadata, model mapping, and format. For each ER configuration, follow these steps:
 - a. Select **Exchange**.
 - b. Select **Load from XML file**.
 - c. Select **Browse** to select the file for the required ER configuration in XML format.
 - d. Select **OK**.

Review the ER solution that is provided

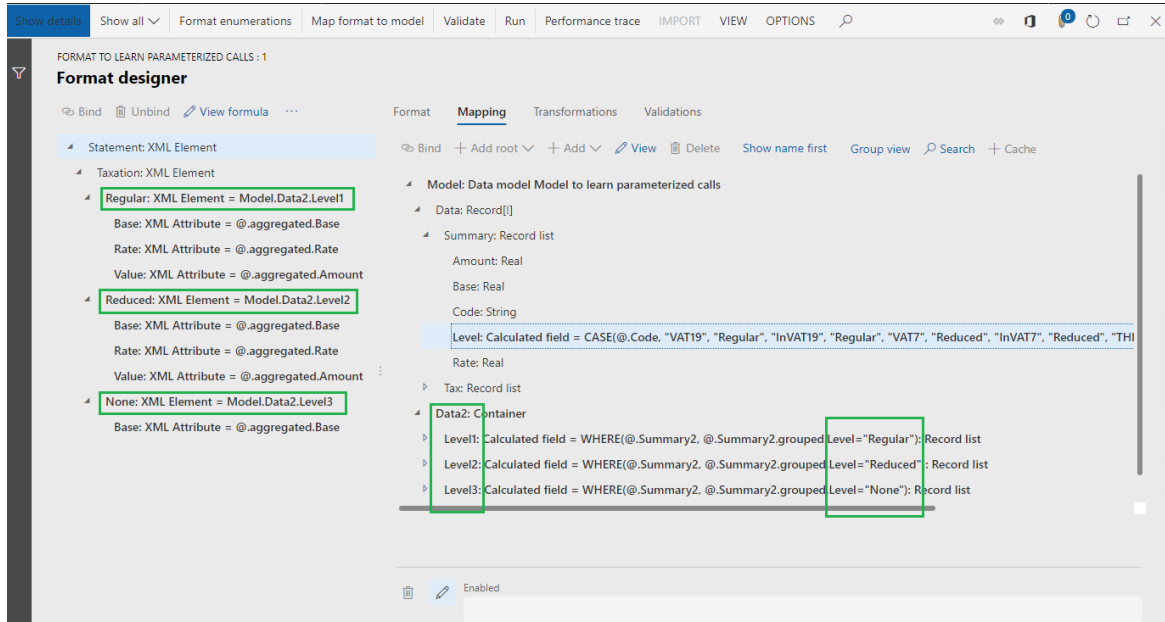

1. In the configuration tree, expand the contents of the **Model to learn parameterized calls** item.
2. Select the **Format to learn parameterized calls** item.
3. Select **Designer**.
4. Select **Expand/Collapse**.

The **Format to learn parameterized calls** ER format is designed to generate a tax statement in XML format that presents several levels of taxation (regular, reduced, and none). Each level has a different number of details.

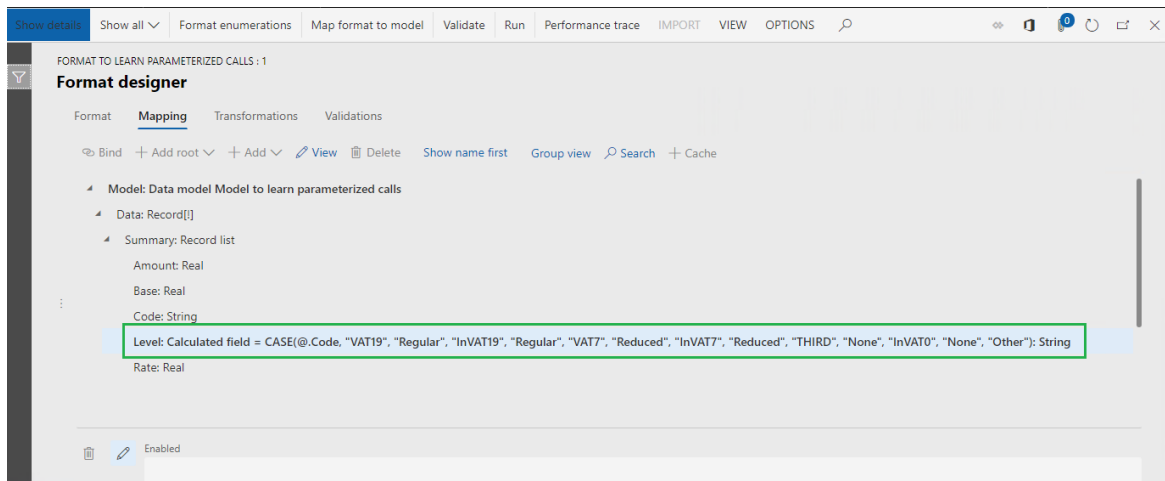

5. On the **Mapping** tab, expand the **Model**, **Data**, and **Summary** items.

The **Model.Data.Summary** data source returns the list of tax transactions. These transactions are summarized by tax code. For this data source, the **Model.Data.Summary.Level** calculated field has been configured to return the code for the taxation level of each summarized record. For any tax code that can be retrieved from the **Model.Data.Summary** data source at runtime, the calculated field returns the taxation level code (**Regular**, **Reduced**, **None**, or **Other**) as a text value. The **Model.Data.Summary.Level** calculated field is used to filter records of the **Model.Data.Summary** data source and enter the filtered data in each XML element that represents a taxation level by using the **Model.Data2.Level1**, **Model.Data2.Level2**, and **Model.Data2.Level3** fields.

The **Model.Data.Summary.Level** calculated field has been configured so that it contains an ER expression. Note that tax codes (**VAT19**, **InVAT19**, **VAT7**, **InVAT7**, **THIRD**, and **InVAT0**) are hardcoded into this configuration. Therefore, this ER format is dependent on the legal entity where these tax codes were configured.

To support a different set of tax codes for each legal entity, you must follow these steps:

- Create a derived version of the ER format for each legal entity.
- Update the tax codes in the **Model.Data.Summary.Level** calculated field, based on the legal entity setting.

6. Close the **Format designer** page.

Create a derived format

Next, you will use the ER application-specific parameters feature to support a different set of tax codes for each

legal entity in a single ER format.

1. In the configuration tree, expand the contents of the **Model to learn parameterized calls** item.
2. Select the **Format to learn parameterized calls** item.
3. Select **Create configuration**.
4. Select the **Derive from Name: Format to learn parameterized calls, Microsoft** option.
5. In the **Name** field, enter **Format to learn how to lookup LE data**.
6. Select **Create configuration**.

Configure a derived format

Add a format enumeration

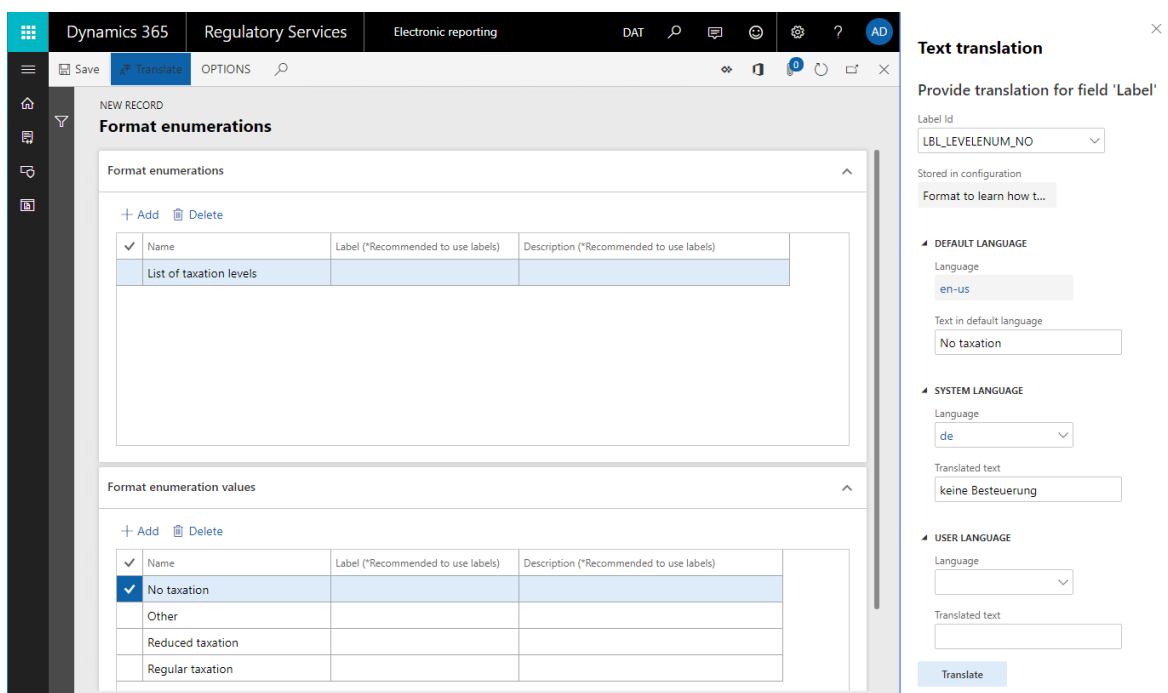

Next, you will add a new ER format enumeration. The values of this format enumeration will be presented to business users, who will specify legal entity–dependent sets of tax codes for the various taxation levels that are used in the ER format.

1. Select **Designer**.
2. Select **Format enumerations**.
3. Select **Add**.
4. In the **Name** field, enter **List of taxation levels**.
5. Select **Save**.
6. On the **Format enumeration values** tab, select **Add**.
7. In the **Name** field, enter **Regular taxation**.
8. Select **Add** again.
9. In the **Name** field, enter **Reduced taxation**.
10. Select **Add** again.
11. In the **Name** field, enter **No taxation**.
12. Select **Add** again.
13. In the **Name** field, enter **Other**.

Because the business users might use different languages to specify legal entity–dependent sets of tax codes, we recommend that you translate the values of this enumeration into the languages that are configured as the preferred languages for those users in Finance.

14. Select the **No taxation** record.
15. Click in the **Label** field.
16. Select **Translate**.
17. In the **Text translation** pane, in the **Label Id** field, enter **LBL_LEVELENUM_NO**.
18. In the **Text in default language** field, enter **No taxation**.
19. In the **Language** field, select **DE**.
20. In the **Translated text** field, enter **keine Besteuerung**.
21. Select **Translate**.

22. Select **Save**.

23. Close the **Format enumerations** page.

Add a new lookup data source

Next, you will add a new data source to specify how business users will specify legal entity–dependent rules to recognize the correct taxation level for each summarized transaction record.

1. On the **Mapping** tab, select **Add**.

2. Select **Format enumeration\Lookup**.

You just identified that each rule that business users specify for taxation level recognition will return a value of an ER format enumeration. Notice that the **Lookup** data source type can be accessed under the **Data model** and **Dynamics 365 for Operations** blocks in addition to the **Format enumeration** block. Therefore, ER data model enumerations and application enumerations can be used to specify the type of values that are returned for data sources of that type.

3. In the **Name** field, enter **Selector**.

4. In the **Format enumeration** field, select **List of taxation levels**.

You just specified that, for each rule that is specified in this data source, a business user must select one of the values of the **List of taxation levels** format enumeration as a returned value.

5. Select **Edit lookup**.

6. Select **Columns**.

7. Expand the **Model** item.

8. Expand the **Data** item.

9. Expand the **Tax** item.

10. Select the **Model.Data.Tax.Code** item.

11. Select the **Add** button (the right arrow).

You just specified that, for each rule that is specified in this data source for taxation level recognition, a business user must select one of the tax codes as a condition. The list of tax codes that the business user can select will be returned by the **Model.Data.Tax** data source. Because this data source contains the **Name** field, the name of the tax code will be shown for each tax code value in the lookup that is presented to the business user.

12. Select **OK**.

Business users can add multiple rules as records of this data source. Each record will be numbered by a line code. Rules will be evaluated in order of increasing line number.

Because you selected the **Tax code** field as a condition for rules in this lookup data source, and because **Tax code** is set up as a field of the **String** data type, each rule will be evaluated at runtime by comparing the tax code that is passed to the data source with the tax code that is defined in this record of the data source.

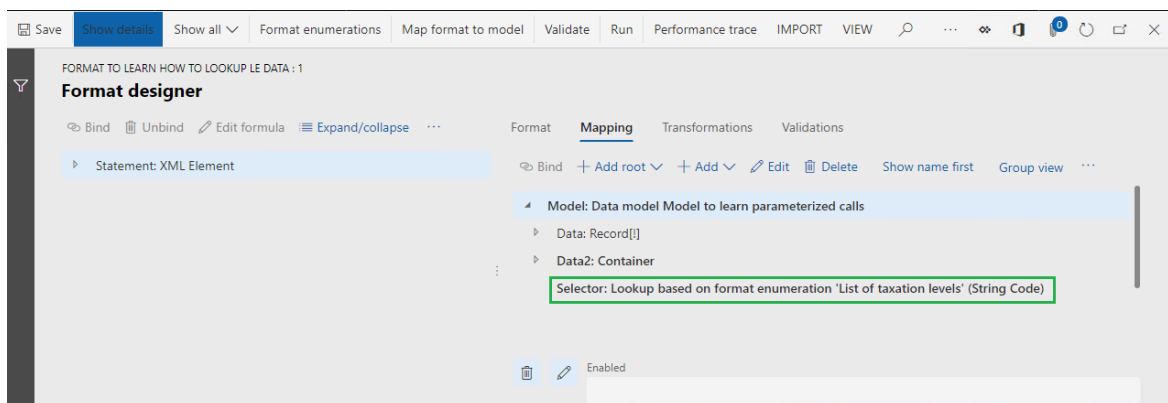

When a rule that satisfies the configured condition is found, this data source returns the lookup value of the rule that is defined in the **Lookup result** field. If no rule is found, an exception is thrown to notify the user that the current data source can't return a correct value.

13. Select **Save**.

14. Close the **Lookup designer** page.

15. Select **OK**.

Notice that you added a new data source that will return the taxation level as the value of the **List of taxation levels** format enumeration for any tax code that is passed to the data source as the argument of the **Code** parameter of the **String** data type.

Note that the evaluation of configured rules depends on the data type of the fields that have been selected to define conditions of those rules. When you select a field that is configured as a field of either the **Numeric** or **Date** data type, the criteria will differ from the criteria that were described earlier for the **String** data type. For **Numeric** and **Date** fields, the rule must be specified as a range of values. The condition of the rule will then be considered satisfied when a value that is passed to the data source is in the configured range.

The following illustration shows an example of this type of setup. In addition to the **Model.Data.Tax.Code** field of the **String** data type, the **Model.Tax.Summary.Base** field of the **Real** data type is used to specify conditions for a lookup data source.

Because the **Model.Data.Tax.Code** and **Model.Tax.Summary.Base** fields are selected for this lookup data source, each rule of this data source will be configured in the following way:

- In the list that is presented, the value of the **List of taxation levels** format enumeration must be selected as a returned value.
- The tax code must be entered as a condition of this rule. Only tax codes that are provided by the **Model.Data.Tax** data source are applicable.
- Minimum and maximum values of the tax base amount must be entered as conditions of this rule.

Here is how each rule of this data source will be evaluated at runtime:

- Does the code of the **String** data type that was passed to this data source equal the tax code of a rule?
- Does the value of the **Real** data type that was passed to this data source fall between specific minimum and maximum values?

A rule will be considered applicable when both conditions are satisfied.

Translate the label of the lookup data source that was added

Because business users might use different languages to specify legal entity–dependent sets of tax codes, we recommend that you translate the label of any lookup data source that you add, so that it's presented in each user's preferred language on the corresponding page.

1. Select the **Model.Data.Selector** data source.
2. Select **Edit**.
3. Click in the **Label** field.
4. Select **Translate**.
5. In the **Text translation** pane, in the **Label Id** field, enter **LBL_SELECTOR_DS**.
6. In the **Text in default language** field, enter **Select tax level by tax code**.
7. In the **Language** field, select **DE**.
8. In the **Translated text** field, enter **Steuerebene für Steuerkennzeichen auswählen**.
9. Select **Translate**.
10. Select **OK**.

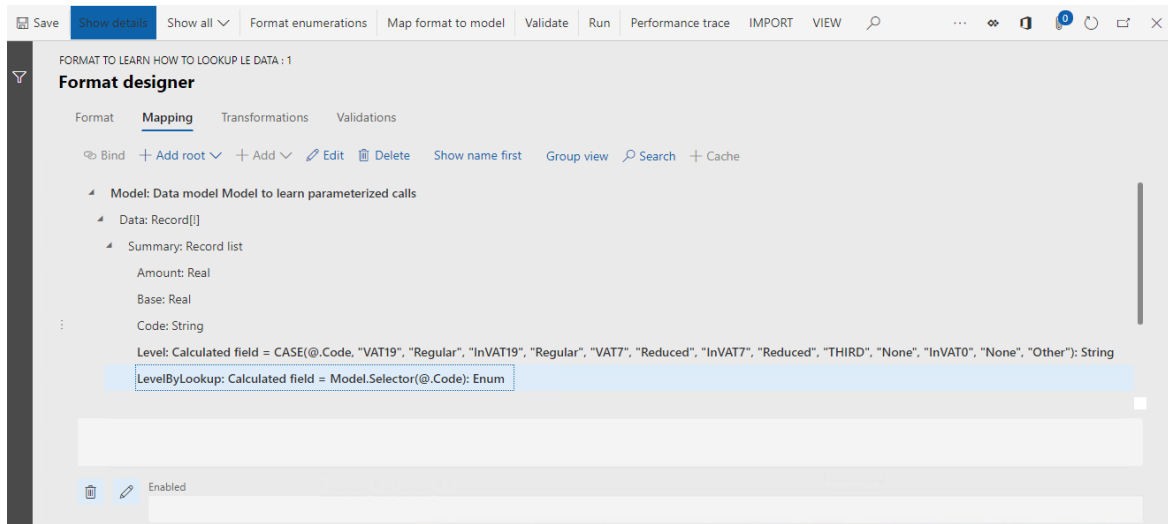

Add a new field to consume the configured lookup

1. Expand the **Model.Data** item.
2. Select the **Model.Data.Summary** item.
3. Select **Add**.
4. Select **Functions/Calculated field**.
5. In the **Name** field, enter **LevelByLookup**.
6. Select **Edit formula**.
7. In the **Formula** field, enter **Model.Selector(Model.Data.Summary.Code)**.
8. Select **Save**.

9. Close the **Formula editor** page.
10. Select **OK**.

Notice that the **LevelByLookup** calculated field that you added will return the taxation level as the value of the **List of taxation levels** format enumeration for each summarized tax transactions record. The tax code of the record will be passed to the **Model.Selector** lookup data source, and the set of rules for this data source will be used to select the correct taxation level.

Add a new format enumeration-based data source

Next, you will add a new data source that refers to the format enumeration that you added earlier. Values of this data source will be used in an ER format expression later.

1. Select **Add root**.
2. Select **Format enumerations\Enumeration**.
3. In the **Name** field, enter **TaxationLevel**.
4. In the **Format enumeration** field, select **List of taxation levels**.
5. Select **Save**.

Modify an existing field to start to use the lookup

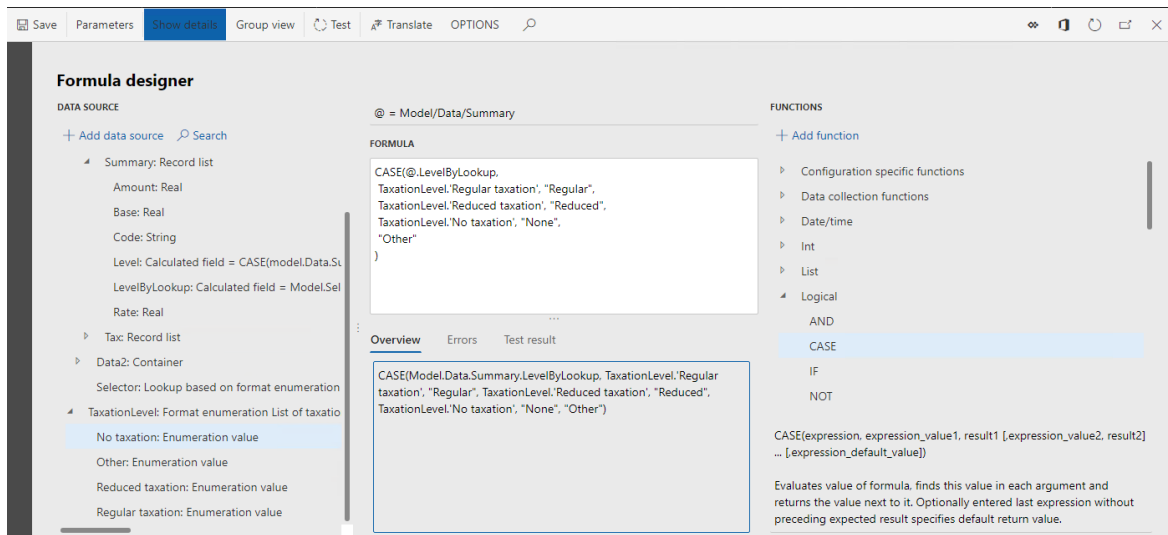

Next, you will modify the existing calculated field so that it uses the configured lookup data source to return the correct taxation level value, depending on the tax code.

1. Select the **Model.Data.Summary.Level** item.
2. Select **Edit**.
3. Select **Edit formula**.

Notice that the current expression of the **Model.Data.Summary.Level** field includes the following hard-coded tax codes:

```
CASE (@.Code, "VAT19", "Regular", "InVAT19", "Regular", "VAT7", "Reduced", "InVAT7", "Reduced", "THIRD", "None", "InVAT0", "None", "Other")
```

4. In the **Formula** field, enter **CASE(@.LevelByLookup, TaxationLevel.'Regular taxation', "Regular", TaxationLevel.'Reduced taxation', "Reduced", TaxationLevel.'No taxation', "None", "Other")**.

Notice that the expression of the **Model.Data.Summary.Level** field will now return the taxation level, based on the tax code of the current record and the set of rules that a business user configures in the **Model.Data.Selector** lookup data source.

5. Select **Save**.
6. Close **Formula designer** page.
7. Select **OK**.
8. Select **Save**.
9. Close **Format designer** page.

Complete the draft version of a derived format

1. On the **Versions** fast tab, select **Change status**.
2. Select **Complete**.
3. Select **OK**.

Export completed version of modified format

1. In the configuration tree, select the **Format to learn how to lookup LE data** item.
2. On the **Versions** fast tab, select the record that has a status of **Completed**.
3. Select **Exchange**.
4. Select **Export as XML file**.
5. Select **OK**.
6. The web browser downloads a **Format to learn how to lookup LE data.xml** file. Store this file locally.

Repeat steps in this section for parent items of the **Format to learn how to lookup LE data** format, and store the following files locally:

- **Format to learn parameterized calls.xml**
- **Mapping to learn parameterized calls.xml**
- **Model to learn parameterized calls.xml**

To learn how to use the configured **Format to learn how to lookup LE data** ER format to set up legal entity-dependent sets of tax codes to filter tax transactions by different taxation levels, complete the steps in the [Set up the parameters of an ER format per legal entity](#) topic.

Additional resources

[Formula designer in Electronic reporting](#)

[Set up the parameters of an ER format per legal entity](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Set up the parameters of an ER format per legal entity

2/18/2021 • 9 minutes to read • [Edit Online](#)

Prerequisites

To complete these steps, you must first complete the steps in the [Configure ER formats to use parameters that are specified per legal entity](#) topic.

To complete the examples in this topic, you must have access to Microsoft Dynamics 365 Finance (Finance) for one of the following roles:

- Electronic reporting developer
- Electronic reporting functional consultant
- System administrator

Import ER configurations

1. Sign in to your environment.
2. On the default dashboard, select **Electronic reporting**.
3. Select **Reporting configurations**.
4. Import, into the current instance of Finance, the configurations that you exported from Regulatory Configuration Services (RCS) while you were completing the steps in the [Configure ER formats to use parameters that are specified per legal entity](#) topic. Follow these steps for each Electronic reporting (ER) configuration, in the following order: data model, model mapping, and formats.
 - a. Select **Exchange > Load from XML file**.
 - b. Select **Browse** to select the file for the required ER configuration in XML format.
 - c. Select **OK**.

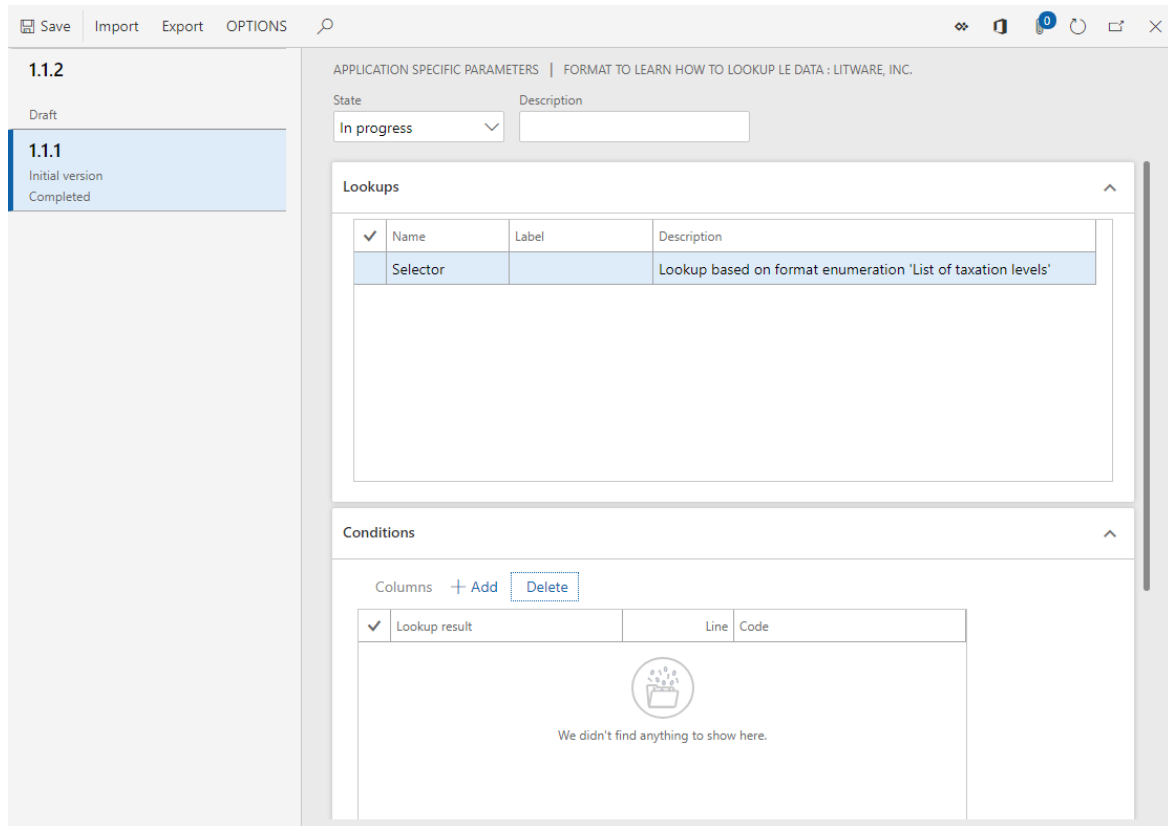

The following illustration shows the configurations that you must have when you've finished.

Set up parameters for the DEMF company

You can use the ER framework to set up application-specific parameters for an ER format.

1. Select the **DEMF** legal entity.
2. In the configurations tree, select the **Format to learn how to lookup LE data** format.
3. On the Action Pane, on the **Configurations** tab, in the **Application specific parameters** group, select **Setup**.

On the **Application specific parameters** page, you can configure the rules for the **Selector** data source of the **Format to learn how to lookup LE data** format.

If the base ER format will contain several data sources of the **Lookup** type, you must select the desired data source on the **Lookups** FastTab before you can start to configure the set of rules for the data source.

For each data source, you can configure separate rules for each version of the selected ER format.

The whole set of rules for all lookup data sources that are available in the selected version of the base ER format makes up the application-specific parameters for the ER format.

4. Select version **1.1.1** of the ER format.
5. On the **Conditions** FastTab, select **Add**.
6. In the **Code** field of the new record, select the drop-down arrow to open the lookup.

The lookup presents the list of tax codes for selection. This list is returned by the **Model.Data.Tax** data source that has been configured in the base ER format. Because this data source contains the **Name** field, the name of each tax code appears in the lookup.

7. Select the **VAT19** tax code.

8. In the **Lookup result** field of the new record, select the drop-down arrow to open the lookup. The lookup presents the list of values for the TaxationLevel format enumeration for selection.

Note that, if German is selected as the preferred language of the user that you're signed in as, the labels of the values in the lookup will be in German, provided that they have been translated in the base ER format. Additionally, if the label of a lookup data source has been translated, that label will appear in the user's preferred language on the **Lookups** tab.

9. Select the **Regular taxation** value.

By adding this record, you define the following rule: Whenever the **Selector** lookup data source is

requested, and the **VAT19** tax code is passed as an argument, **Regular taxation** will be returned as the requested taxation level.

10. Select **Add**, and then follow these steps:
 - a. In the **Code** field, select the **InVAT19** tax code.
 - b. In the **Lookup result** field, select the **Regular taxation** value.
11. Select **Add** again, and then follow these steps:
 - a. In the **Code** field, select the **VAT7** tax code.
 - b. In the **Lookup result** field, select the **Reduced taxation** value.
12. Select **Add** again, and then follow these steps:
 - a. In the **Code** field, select the **InVAT7** tax code.
 - b. In the **Lookup result** field, select the **Reduced taxation** value.
13. Select **Add** again, and then follow these steps:
 - a. In the **Code** field, select the **THIRD** tax code.
 - b. In the **Lookup result** field, select the **No taxation** value.
14. Select **Add** again, and then follow these steps:
 - a. In the **Code** field, select the **InVAT0** tax code.
 - b. In the **Lookup result** field, select the **No taxation** value.
15. Select **Add** again, and then follow these steps:
 - a. In the **Code** field, select the ***Not blank*** option.
 - b. In the **Lookup result** field, select the **Other** value.

By adding this last record, you define the following rule: Whenever the tax code that is passed as an argument doesn't satisfy any of the previous rules, the lookup data source will return **Other** as the requested taxation level.

1.1.2

Draft

1.1.1

Initial version

Completed

APPLICATION SPECIFIC PARAMETERS | FORMAT TO LEARN HOW TO LOOKUP LE DATA : LITWARE, INC.

State: In progress

Description:

Conditions

Lookup result	Line	Code
Regular taxation	1	VAT19
Regular taxation	2	InVAT19
Reduced taxation	3	VAT7
Reduced taxation	4	InVAT7
No taxation	5	THIRD
No taxation	6	InVAT0
Other	7	*Not blank*

16. In the **State** field, select **Completed**.

When you run an ER format version that has a status of either **Completed** or **Shared**, this set of rules must be in the **Completed** state. Otherwise, execution of the base ER format will be interrupted when the format tries to load data from this set of rules while the **Selector** lookup data source is being run.

When you run an ER format version that has a status of **Draft**, the base ER format can access this set of rules, regardless of its state.

17. Select **Save**.
18. Close the **Application specific parameters** page.

Run the ER format in the DEMF company

1. In the configurations tree, select the **Format to learn how to lookup LE data** format.
2. On the Action Pane, select **Run**.
3. In the dialog box that appears, select **OK**.
4. Download the statement that is generated and store it locally.

In the generated statement, notice that the summary of the **InVAT7** tax code has been put on the **Reduced** level, and the summaries of the **VAT19** and **InVA19** tax codes have been put on the **Regular** level. This behavior is determined by the configuration in the legal entity–dependent set of rules.

5. Go to **Tax > Indirect taxes > Sales tax > Sales tax codes**.
6. Select the **InVAT7** tax code.
7. On the Action Pane, on the **Sales tax code** tab, in the **Inquiries** group, select **Posted sales tax** to view information about the tax value and applied tax rate per tax code.

✓ Voucher ↑	Date	Source	Sales tax code	Sales tax direction	Transaction
PIV-110000004	1/4/2015	Purchase order	InVAT7	Sales tax receivable	EUR
PIV-110000018	3/1/2016	Purchase order	InVAT7	Sales tax receivable	EUR
PIV-110000027	12/3/2016	Purchase order	InVAT7	Sales tax receivable	EUR

```
<?xml version="1.0" encoding="UTF-8"?>
- <Statement>
- <Taxation>
  <Regular Value="-5073163.93" Rate="19" Base="-26700862.86"/>
  <Reduced Value="3623.2" Rate="7" Base="51760.0"/>
  <None Base="0"/>
</Taxation>
</Statement>
```

Total actual sales tax amount
3,623.20

8. Close the **Posted sales tax** page.

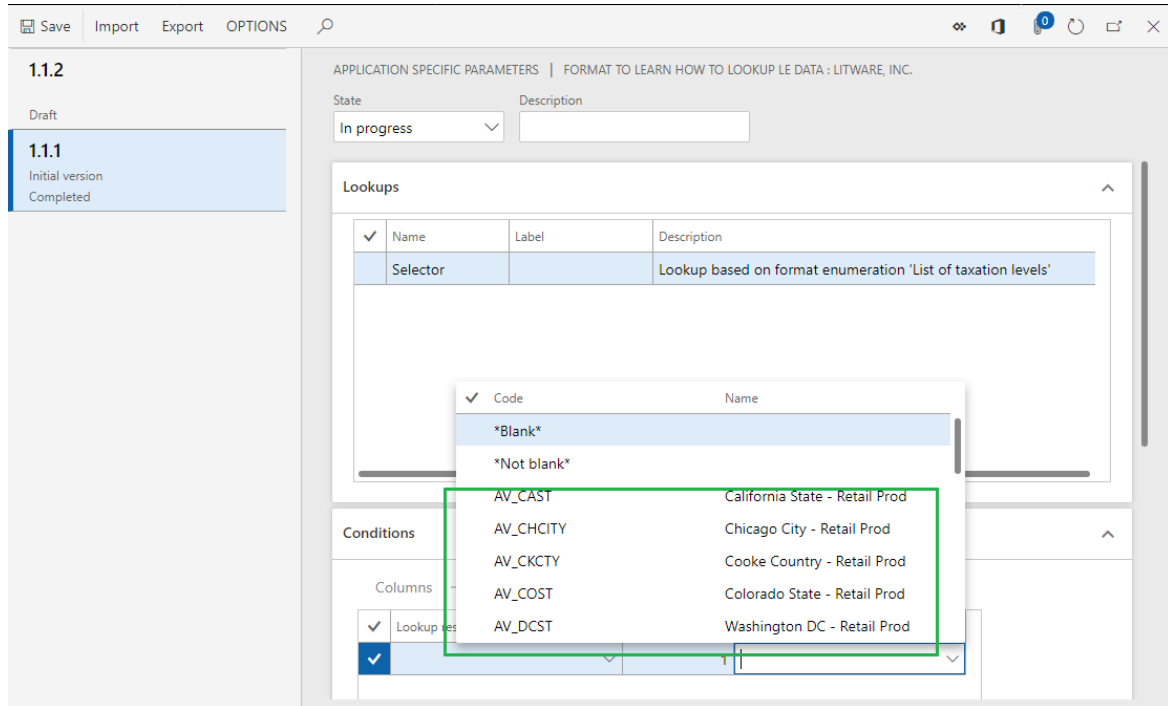

Set up parameters for the USMF company

1. Select the **USMF** legal entity.
2. Go to **Organization administration > Electronic reporting > Configurations**.
3. In the configurations tree, expand the **Model to learn parameterized calls** item, expand the **Format to learn parameterized calls** item, and select the **Format to learn how to lookup LE data** format.
4. On the Action Pane, on the **Configurations** tab, in the **Application specific parameters** group, select

Setup.

5. Select version **1.1.1** of the selected ER format.
6. On the **Conditions** FastTab, select **Add**.
7. In the **Code** field of the new record, select the drop-down arrow to open the lookup.

The lookup now presents the list of tax codes for the **USMF** company tax for selection.

8. Select the **EXEMPT** tax code.
9. In the **Lookup result** field of the new record, select the **No taxation** value.
10. Select **Add** again.
11. In the **Code** field of the new record, select the ***Not blank*** option.
12. In the **Lookup result** field of the new record, select the **Regular taxation** value.
13. In the **State** field, select **Completed**.
14. Select **Save**.

15. Close the **Application specific parameters** page.

Run the ER format in the USMF company

1. In the configurations tree, select the **Format to learn how to lookup LE data** format.
2. On the Action Pane, select **Run**.
3. In the dialog box that appears, select **OK**.
4. Download the statement that is generated and store it locally.

In the generated statement, notice that you've now reused the same ER format for a different legal entity, but without making any adjustments to the ER format.

Reuse legal entity–dependent parameters

Export parameters

1. Go to **Organization administration > Workspaces > Electronic reporting**.
2. Select **Reporting configurations**.
3. In the configurations tree, select the **Format to learn how to lookup LE data** format.
4. On the Action Pane, on the **Configurations** tab, in the **Application specific parameters** group, select **Setup**.
5. Select version **1.1.1** of the ER format.
6. On the Action Pane, select **Export**.
7. Download the file that is generated and store it locally.

The configured set of application-specific parameters has now been exported as an XML file.

Import parameters

1. Select version **1.1.2** of the ER format.
2. On the Action Pane, select **Import**.

3. Select **Yes** to confirm that you want to override the existing application-specific parameters for this format version.
4. Select **Browse** to find the file that contains the exported application-specific parameters for version 1.1.1.
5. Select **OK**.

Version 1.1.2 of the ER format now has the same application-specific parameters that you originally configured for version 1.1.1.

Note that the application-specific parameters of an ER format are legal entity–dependent. To reuse the application-specific parameters that were configured for one legal entity in a different legal entity, you must export them while you're signed in to the first legal entity and then import them after you sign in to the other legal entity.

You can also use this approach to transfer an ER format related application-specific parameters that were originally configured in one instance of Finance to another instance of Finance.

Be aware that if you configure application-specific parameters for one version of an ER format and import a higher version of the same format into the current Finance instance, the existing application-specific parameters won't be applied for the imported version.

Also be aware that, when you select a file for import, the structure of the application-specific parameters in that file is compared with the structure of the corresponding data source of the **Lookup** type in the ER format that is selected for import. The import is done when the structure of each application-specific parameter matches the structure of the corresponding data source in the ER format that is selected for import. If the structures don't match, you receive a warning message that states that the import can't be done. If you force the import to be done, the existing application-specific parameters for the selected ER format will be cleaned up, and you must set them up from the beginning.

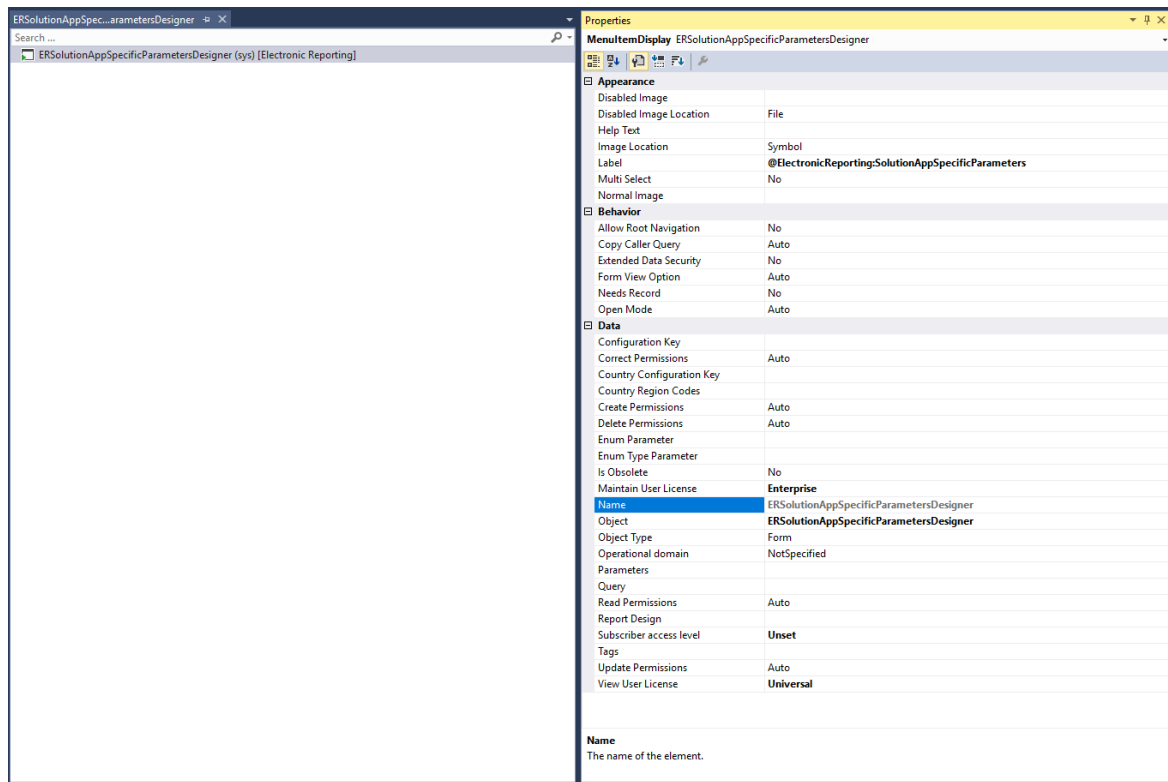

Relationship between application-specific parameters and an ER format

The relationship between an ER format and its application-specific parameters is established by the ER format's instance-independent unique identification code. Therefore, when you remove an ER format from Finance, the application-specific parameters that are configured for the ER format are kept in the current instance of Finance. They can be accessed whenever the base ER format is reimported into this instance of Finance.

Access application-specific parameters by using the ER framework

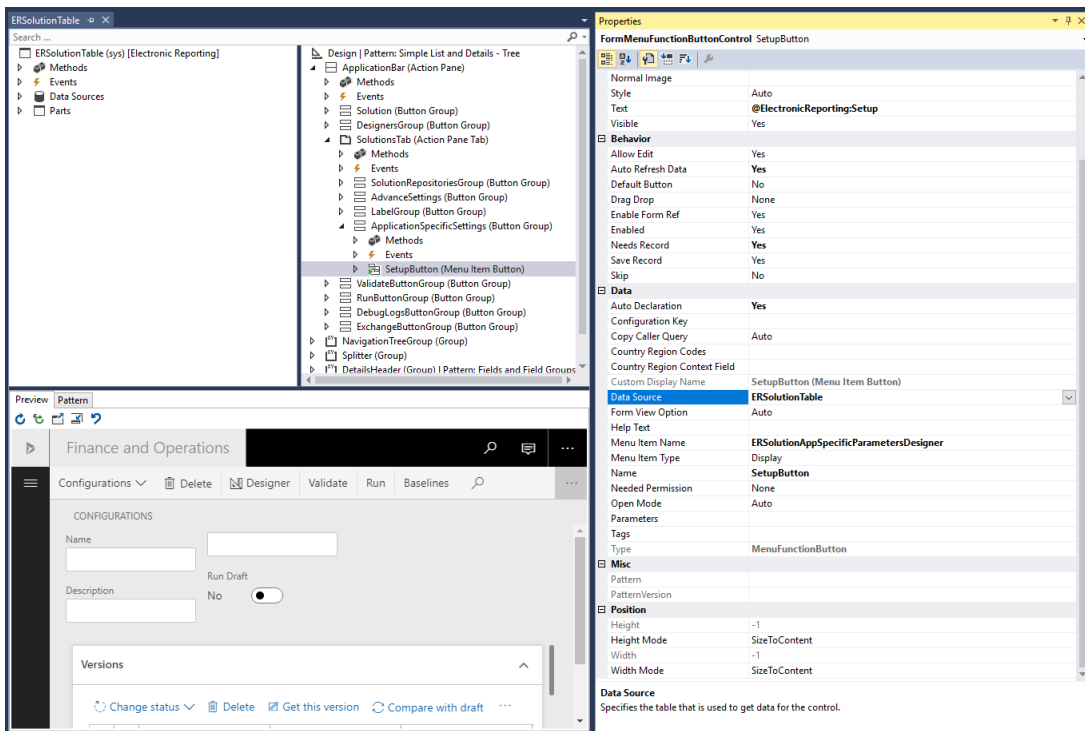

In the preceding example, you have accessed application-specific parameters of an ER format by using the ER framework. This approach doesn't let you restrict access to the application-specific parameters of a specific ER format. If you must apply such restrictions, follow these steps.

1. Either reuse an existing **ERSolutionAppSpecificParametersDesigner** menu item, or implement your own **ERSolutionAppSpecificParametersDesigner** menu item.

2. Follow one of these steps:

- a. Create a new menu item button, and link it to the corresponding record from the ERSolutionTable table by setting its Data Source property to ERSolutionTable.

- b. Create a simple button, and override the Clicked method as shown in the following example.

By using this approach, you can specify a unique solution ID (defined via the GUID value) to allow access to the application-specific parameters of only a specific ER format and descendant copies that have been derived from it.

```
public void clicked()
{
    super();

    ERSolutionTable solutionTableRecord = ERSolutionTable::findByGUID(str2Guid('ADACCB2F-
EFD1-4C90-877D-7E1E5D1AEE92'));

    Args args = new Args();
    args.record(solutionTableRecord);
    args.caller(this);

    new MenuFunction(menuItemDisplayStr(ERSolutionAppSpecificParametersDesigner),
MenuItemType::Display)
        .run(args);
}
```

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Defer the execution of sequence elements in ER formats

2/18/2021 • 11 minutes to read • [Edit Online](#)

Overview

You can use the Operations designer of the [Electronic reporting \(ER\)](#) framework to [configure](#) the [format component](#) of an ER solution that is used to generate outbound documents in a text format. The hierarchical structure of the configured format component consists of format elements of various types. These format elements are used to fill generated documents with the required information at runtime. By default, when you run an ER format, the format elements are run in the same order as they are presented in the format hierarchy: one by one, from top to bottom. However, at design time, you can change the execution order for any sequence elements of the configured format component.

By turning on the **Deferred execution** option for a sequence format element in the configured format, you can defer (postpone) the execution of that element. In this case, the element isn't run until all other elements of its parent have been run.

To learn more about this feature, complete the example in this topic.

Limitations

The **Deferred execution** option is supported only for sequence elements that are configured for an ER format that is used to generate **outbound** documents in text format.

The **Deferred execution** option isn't applicable to sequences that have been configured as trimmed sequences where the maximum length is limited.

Example: Defer the execution of a sequence element in an ER format

The following steps explain how a user in the System administrator or Electronic reporting functional consultant [role](#) can configure an ER format that contains a sequence element where order of execution differs from the order in the format hierarchy.

These steps can be performed in the **USMF** company in Microsoft Dynamics 365 Finance.

Prerequisites

To complete this example, you must have access to the **USMF** company in Finance for one of the following roles:

- Electronic reporting functional consultant
- System administrator

If you haven't yet completed the example in the [Defer the execution of XML elements in ER formats](#) topic, download the following [configurations](#) of the sample ER solution.

CONTENT DESCRIPTION	FILE NAME
ER data model configuration	Model to learn deferred elements.version.1.xml
ER model mapping configuration	Mapping to learn deferred elements.version.1.1.xml

Before you begin, you must also download and save the following configuration of the sample ER solution.

CONTENT DESCRIPTION	FILE NAME
ER format configuration	Format to learn deferred sequences.version.1.1.xml

Import the sample ER configurations

1. Go to **Organization administration > Workspaces > Electronic reporting**.
2. Select **Reporting configurations**.
3. On the **Configurations** page, if the **Model to learn deferred elements** configuration isn't available in the configuration tree, import the ER data model configuration:
 - a. Select **Exchange**, and then select **Load from XML file**.
 - b. Select **Browse**, find and select the **Model to learn deferred elements.1.xml** file, and then select **OK**.
4. If the **Mapping to learn deferred elements** configuration isn't available in the configuration tree, import the ER model mapping configuration:
 - a. Select **Exchange**, and then select **Load from XML file**.
 - b. Select **Browse**, find and select the **Mapping to learn deferred elements.1.1.xml** file, and then select **OK**.
5. Import the ER format configuration:
 - a. Select **Exchange**, and then select **Load from XML file**.
 - b. Select **Browse**, find and select the **Format to learn deferred sequences.1.1.xml** file, and then select **OK**.
6. In the configuration tree, expand **Model to learn deferred elements**.
7. Review the list of imported ER configurations in the configuration tree.

Activate a configurations provider

1. Go to **Organization administration > Workspaces > Electronic reporting**.
2. On the **Localization configurations** page, in the **Configuration providers** section, make sure that the **configuration provider** for the Litware, Inc. (<http://www.litware.com>) sample company is listed, and that it's marked as active. If this configuration provider isn't listed, or if it isn't marked as active, follow the steps in the [Create a configuration provider and mark it as active](#) topic.

Review the imported model mapping

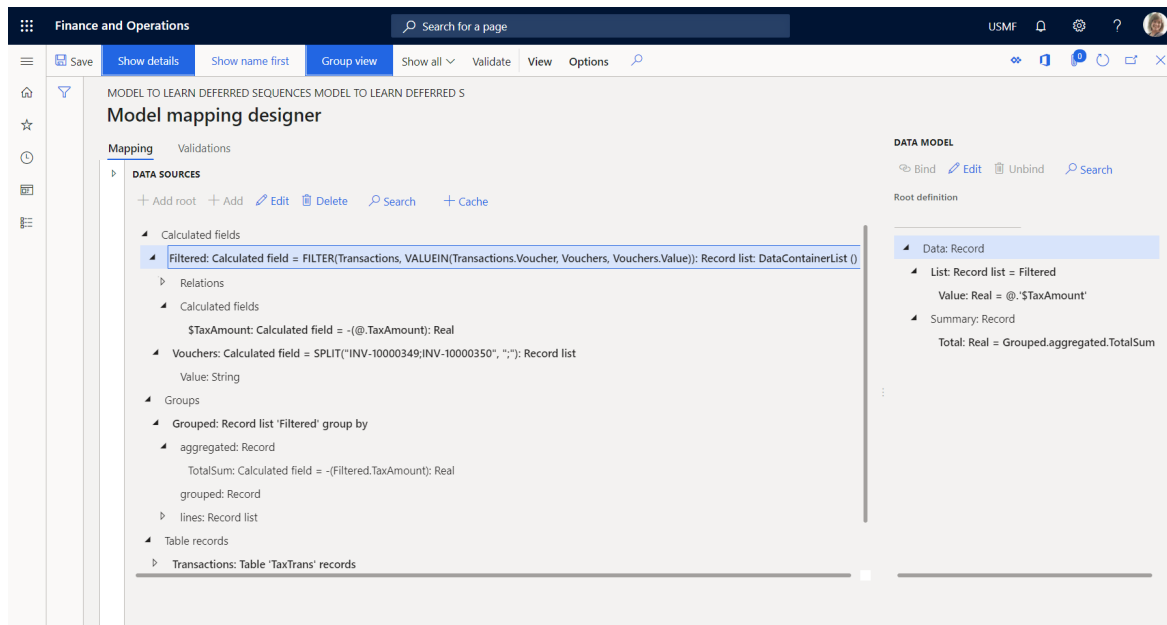

Review the settings of the ER model mapping component that is configured to access tax transactions and expose accessed data on request.

1. Go to **Organization administration > Workspaces > Electronic reporting**.
2. Select **Reporting configurations**.
3. On the **Configurations** page, in the configuration tree, expand **Model to learn deferred elements**.
4. Select the **Mapping to learn deferred elements** configuration.
5. Select **Designer** to open the list of mappings.
6. Select **Designer** to review the mapping details.
7. Select **Show details**.
8. Review the data sources that are configured to access tax transactions:
 - The **Transactions** data source of the *Table record* type is configured to access records of the **TaxTrans** application table.
 - The **Vouchers** data source of the *Calculated field* type is configured to return the required voucher codes (**INV-10000349** and **INV-10000350**) as a list of records.
 - The **Filtered** data source of the *Calculated field* type is configured to select, from the **Transactions** data source, only tax transactions of the required vouchers.
 - The **\$TaxAmount** field of the *Calculated field* type is added for the **Filtered** data source to expose the tax value that has the opposite sign.
 - The **Grouped** data source of the *Group By* type is configured to group filtered tax transactions of the **Filtered** data source.
 - The **TotalSum** aggregation field of the **Grouped** data source is configured to summarize values of the **\$TaxAmount** field of the **Filtered** data source for all filtered tax transactions of that data source.

9. Review how the configured data sources are bound to the data model, and how they expose accessed data to make it available in an ER format:

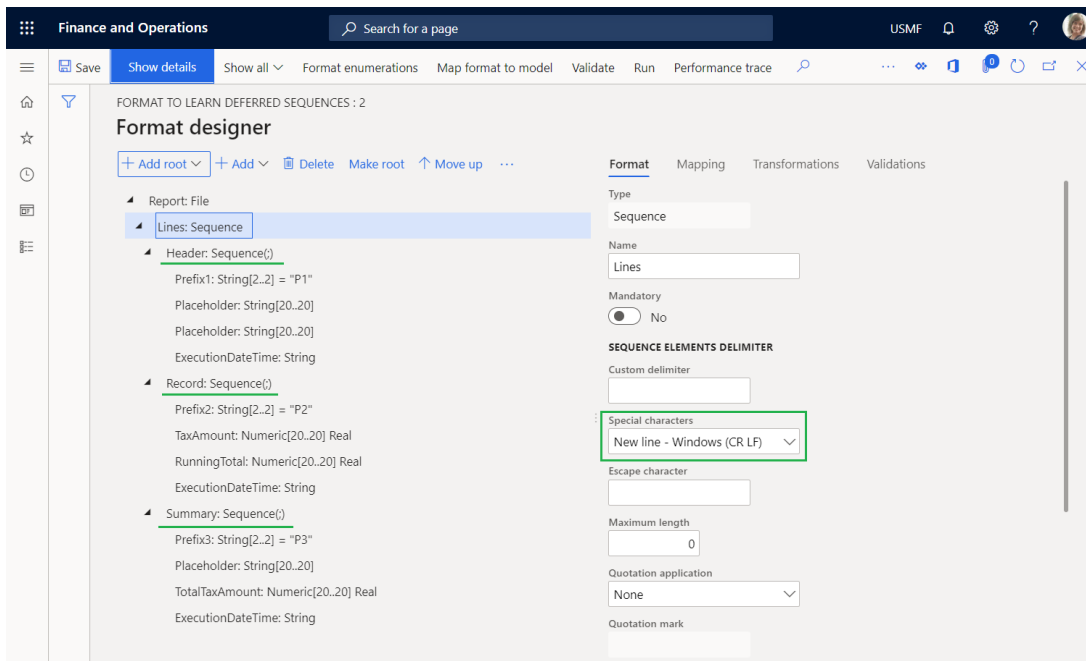

- The **Filtered** data source is bound to the **Data.List** field of the data model.
- The **\$TaxAmount** field of the **Filtered** data source is bound to the **Data.List.Value** field of the data model.
- The **TotalSum** field of the **Grouped** data source is bound to the **Data.Summary.Total** field of the data model.

10. Close the **Model mapping designer** and **Model mappings** pages.

Review the imported format

1. On the **Configurations** page, in the configuration tree, select the **Format to learn deferred sequences** configuration.
2. Select **Designer** to review the format details.
3. Select **Show details**.
4. Review the settings of the ER format components that are configured to generate an outbound document in text format that includes details of the tax transactions:
 - The **Report\Lines** sequence format element is configured to fill the outbound document with a single line that is generated from the nested sequence elements (**Header**, **Record**, and **Summary**).

- The **Report\Lines\Header** sequence format element is configured to fill the outbound document with a single header line that shows the date and time when the processing starts.
- The **Report \Lines\Record** sequence format element is configured to fill the outbound document with a single line that shows the details of individual tax transactions. These tax transactions are separated by a semicolon.

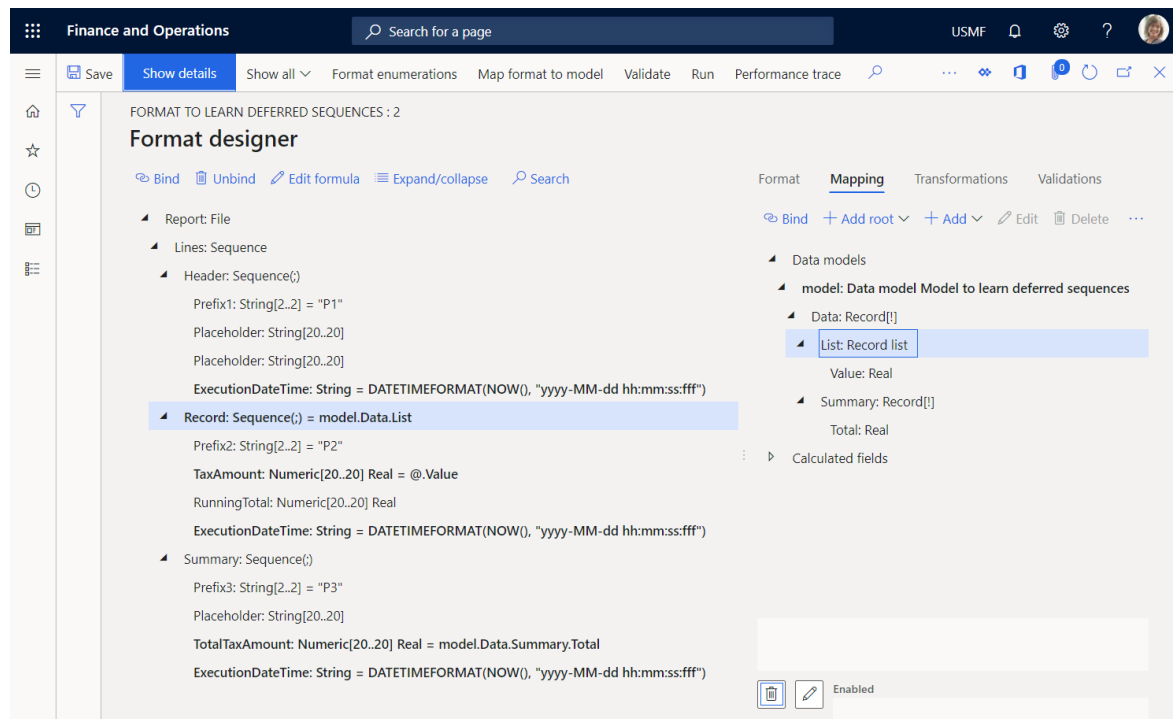

- The **Report\Lines\Summary** sequence format element is configured to fill the outbound document with a single summary line that includes the sum of the tax values from the processed tax transactions.

5. On the **Mapping** tab, review the following details:

- The **Report\Lines\Header** element doesn't have to be bound to a data source to generate a single line in an outbound document.
- The **Prefix1** element generates **P1** symbols to indicate that the line that is added is the report header line.
- The **ExecutionDateTime** element generates the date and time (including milliseconds) when the header line is added.

- The **Report\Lines\Record** element is bound to the **model.Data.List** list to generate a single line for every record from the bound list.
- The **Prefix2** element generates **P2** symbols to indicate that the line that is added is for the tax transaction details.
- The **TaxAmount** element is bound to **model.Data.List.Value** (which is shown as **@.Value** in the relative path view) to generate the tax value of the current tax transaction.
- The **RunningTotal** element is a placeholder for the running total of the tax values. Currently, this element has no output, because neither a binding nor a default value is configured for it.
- The **ExecutionDateTime** element generates the date and time (including milliseconds) when the current transaction is processed in this report.
- The **Report\Lines\Summary** element doesn't have to be bound to a data source to generate a single line in an outbound document.
- The **Prefix3** element generates **P3** symbols to indicate that the line that is added contains the total tax value.
- The **TotalTaxAmount** element is bound to **model.Data.Summary.Total** to generate the sum of the tax values of the processed tax transactions.
- The **ExecutionDateTime** element generates the date and time (including milliseconds) when the summary line is added.

Run the imported format

1. On the **Format designer** page, select **Run**.
2. Download the file that the web browser offers, and open it for review.

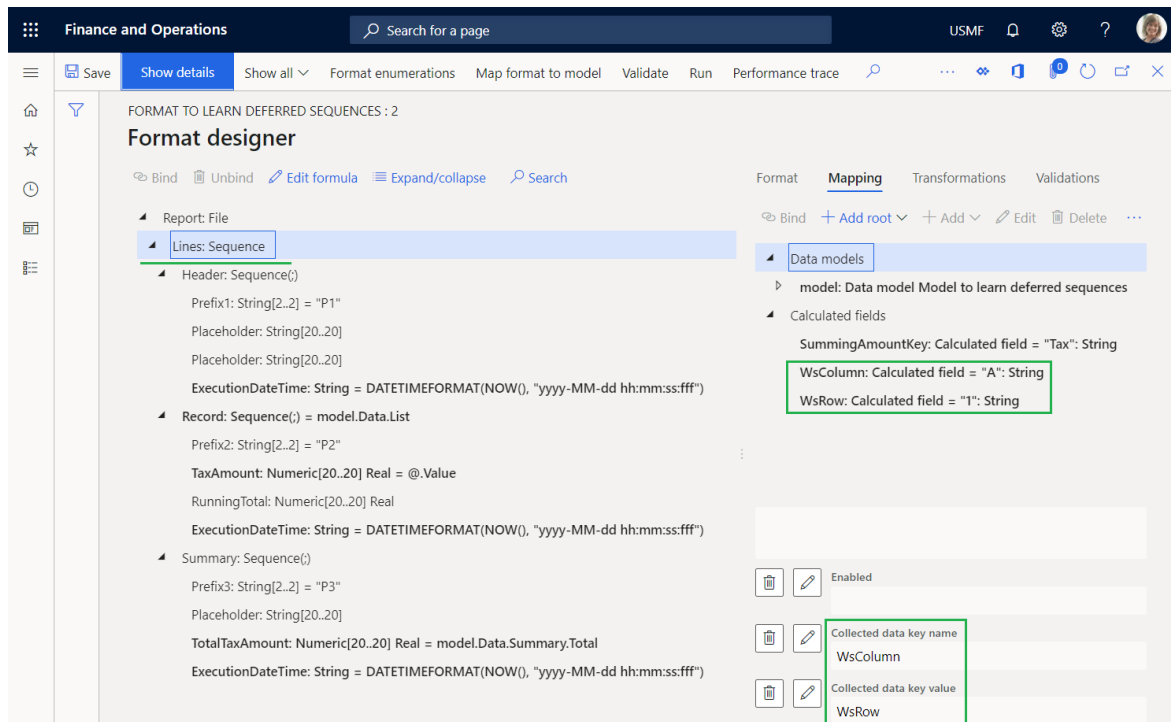

Notice that summary line 22 presents the sum of the tax values for the processed transactions. Because the format is configured to use the `model.Data.Summary.Total` binding to return this sum, the sum is calculated by calling the `TotalSum` aggregation of the `Grouped` data source of the `GroupBy` type that uses the model mapping. To calculate this aggregation, model mapping iterates over all transactions that have been selected in the `Filtered` data source. By comparing the execution times of lines 21 and 22, you can determine that calculation of the sum took 10 milliseconds (ms). By comparing the execution times of lines 2 and 21, you can determine that generation of all transactional lines took 7 ms. Therefore, a total of 17 ms was required.

Modify the format so that the summing is based on generated output

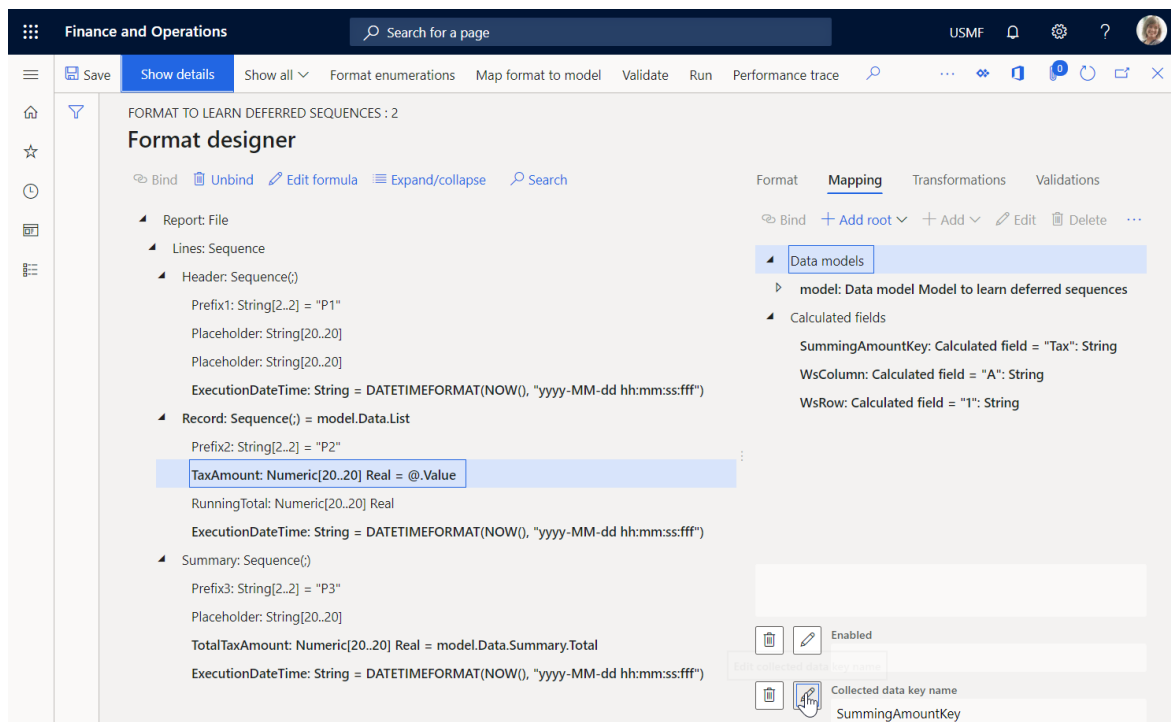

If the volume of transactions is much larger than the volume in the current example, the summing time might increase and cause performance issues. By changing the setting of the format, you can help prevent these performance issues. Because you access tax values to include them in the generated report, you can reuse this information to sum tax values. For more information, see [Configure format to do counting and summing](#).

1. On the **Format designer** page, on the **Format** tab, select the **Report** file element in the format tree.
2. Set the **Collect output details** option to **Yes**. You can now configure this format by using the content of an existing report as a data source that can be accessed by using the built-in ER functions in the **Data collection** category.
3. On the **Mapping** tab, select the **Report\Lines** sequence element.
4. Configure the **Collected data key name** expression as `WsColumn`.
5. Configure the **Collected data key value** expression as `WsRow`.

6. Select the **Report\Lines\Record\TaxAmount** numeric element.

7. Configure the **Collected data key name** expression as `SummingAmountKey`.

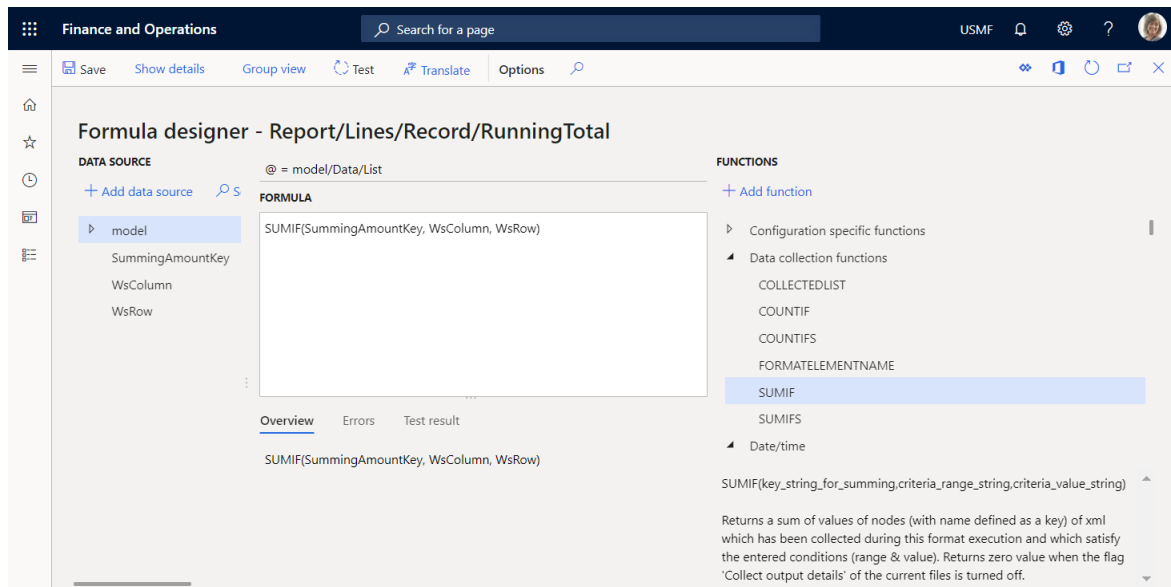

You can consider this setting the fulfillment of a virtual worksheet, where the value of cell A1 is appended with the value of the tax amount from every processed tax transaction.

8. Select the **Report\Lines\Record\RunningTotal** numeric element, and then select **Edit formula**.

9. Configure the `SUMIF(SummingAmountKey, WsColumn, WsRow)` expression by using the built-in **SUMIF** ER function.

10. Select **Save**.

11. Close the Formula designer page.
12. Select **Save**, and then select **Run**.
13. Download and review the file that the web browser offers.

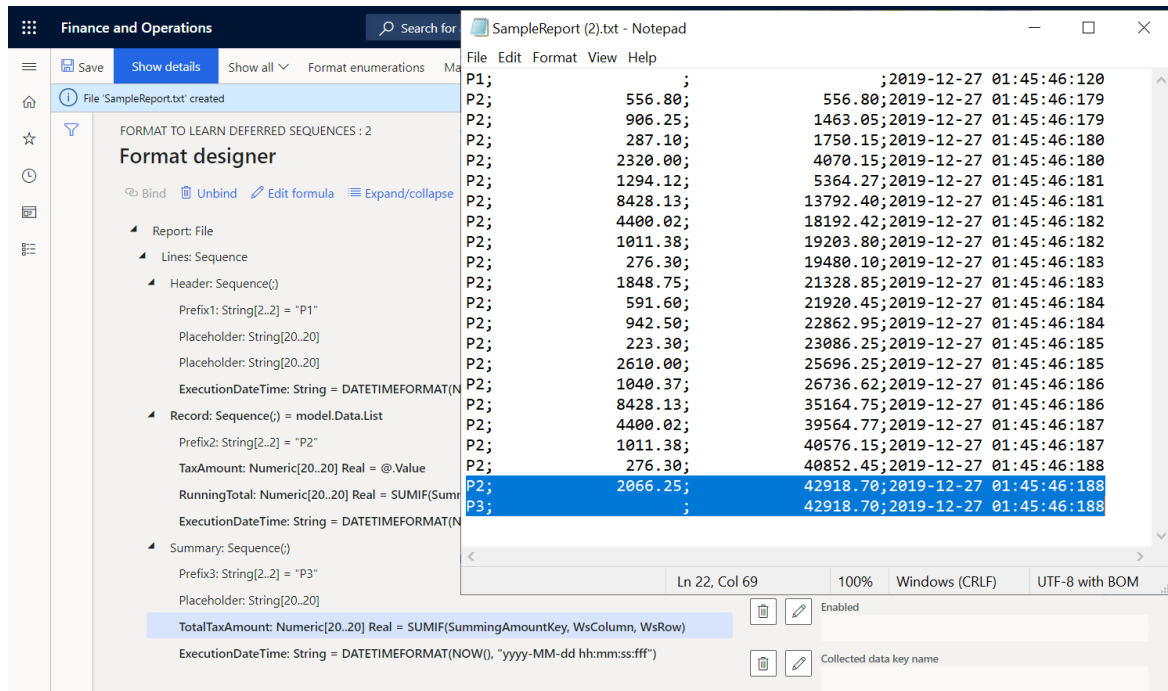

Line 21 contains the running total of tax values that is calculated for all processed transactions by using the generated output as a data source. This data source starts from the beginning of the report and continues through the last tax transaction. Line 22 contains the sum of the tax values for all processed transactions that are calculated in the model mapping by using the data source of the *GroupBy* type. Notice that these values are equal. Therefore, the output-based summing can be used instead of **GroupBy**. By comparing the execution times of lines 2 and 21, you can determine that generation of all the transactional lines and summing took 9 ms. Therefore, as far as the generation of detailed lines and the summing of tax values are concerned, the modified format is approximately two times faster than the original format.

14. Select the **Report\Lines\Summary>TotalTaxAmount** numeric element, and then select **Edit formula**.
15. Enter the `SUMIF(SummingAmountKey, WsColumn, WsRow)` expression instead of the existing expression.

16. Select **Save**, and then select **Run**.

17. Download and review the file that the web browser offers.

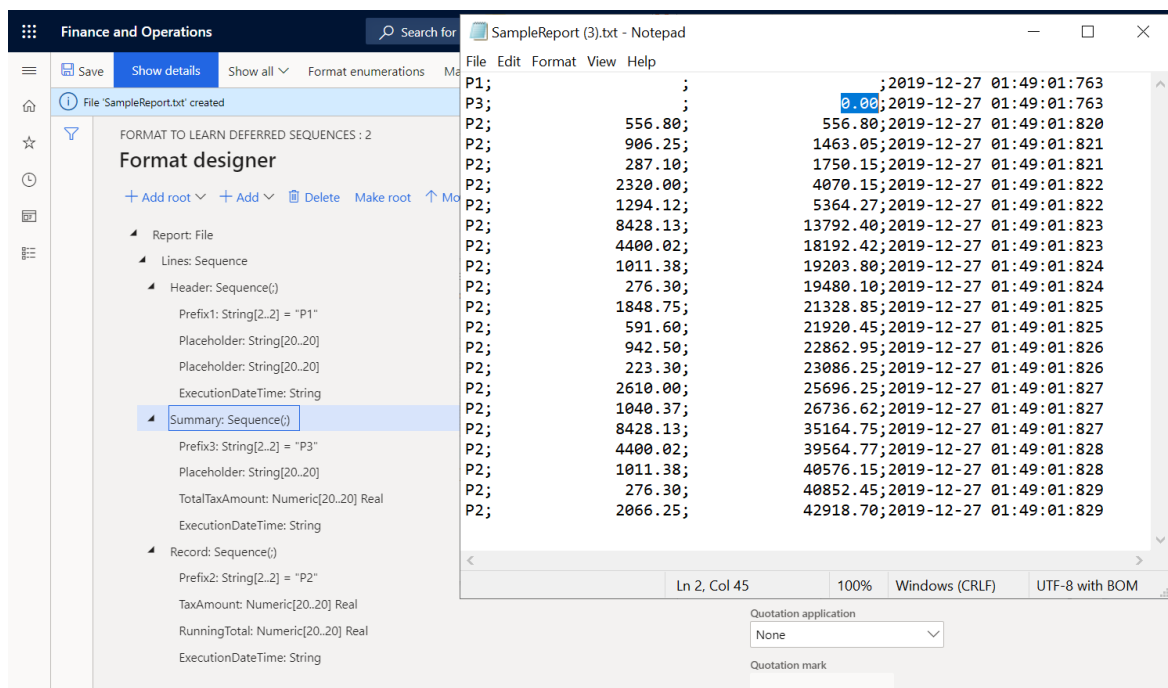

Notice that the running total of tax values on the last transaction details line now equals the sum on the summary line.

Put values of output-based summing in the report header

If, for example, you must present the sum of tax values in the header of your report, you can modify your format.

1. On the **Format designer** page, on the **Format** tab, select the **Report\Lines\Summary** sequence element.
2. Select **Move up**.
3. Select **Save**, and then select **Run**.
4. Download and review the file that the web browser offers.

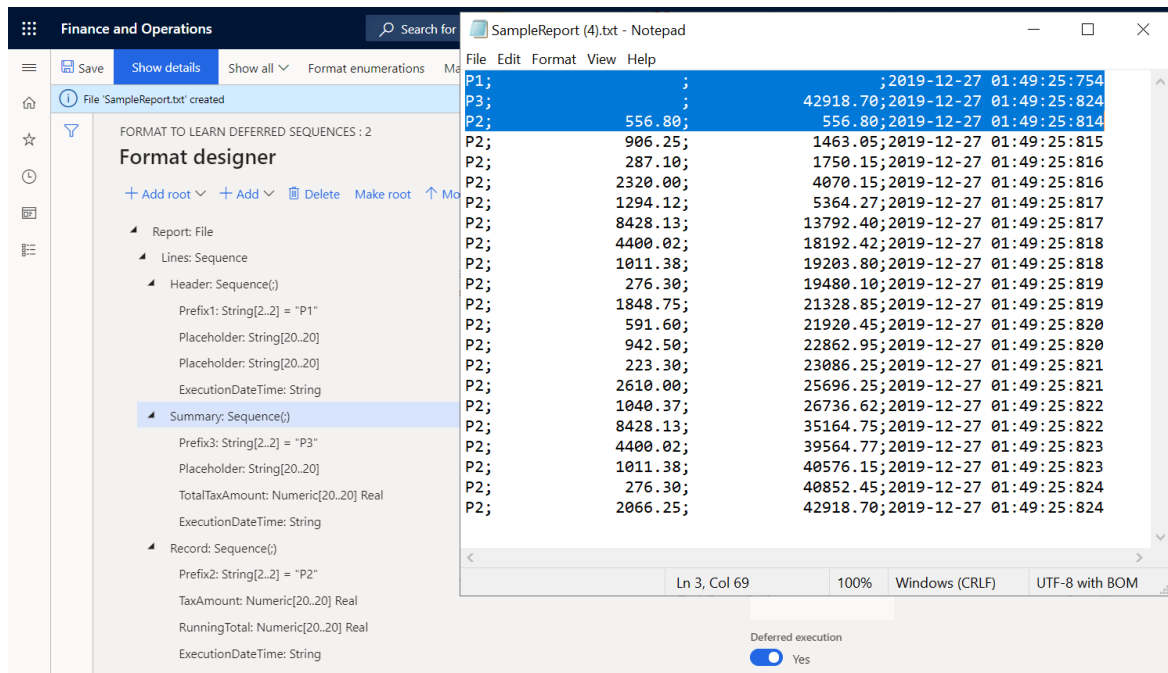

Notice that the sum of tax values on summary line 2 now equals 0 (zero), because this sum is now calculated based on the generated output. When line 2 is generated, the generated output doesn't yet contain lines that have transaction details. You can configure this format to defer the execution of the **Report\Lines\Summary** sequence element until the **Report\Lines\Record** sequence element has been run for all tax transactions.

Defer the execution of the summary sequence so that the calculated total is used

1. On the **Format designer** page, on the **Format** tab, select the **Report\Lines\Summary** sequence element.
2. Set the **Deferred execution** option to **Yes**.

3. Select **Save**, and then select **Run**.
4. Download and review the file that the web browser offers.

The **Report\Lines\Summary** sequence element is now run only after all other items that are nested under its parent element, **Report\Lines**, have been run. Therefore, it's run after the **Report\Lines\Record** sequence element has been run for all tax transactions of the model.Data.List data source. The execution times of lines 1, 2, and 3, and of the last line, 22, reveal this fact.

Defer the execution of XML elements in ER formats

2/18/2021 • 11 minutes to read • [Edit Online](#)

Overview

You can use the Operations designer of the [Electronic reporting \(ER\)](#) framework to [configure](#) the [format component](#) of an ER solution that is used to generate outbound documents in XML format. The hierarchical structure of the configured format component consists of format elements of various types. These format elements are used to fill generated documents with the required information at runtime. By default, when you run an ER format, the format elements are run in the same order as they are presented in the format hierarchy: one by one, from top to bottom. However, at design time, you can change the execution order for any XML elements of the configured format component.

By turning on the **Deferred execution** option for an XML element in the configured format, you can defer (postpone) the execution of that element. In this case, the element isn't run until all other elements of its parent have been run.

To learn more about this feature, complete the example in this topic.

Limitations

The **Deferred execution** option is supported only for XML elements that are configured for an ER format that is used to generate **outbound** documents in XML format.

The **Deferred execution** option is supported only for XML elements that reside in only one other XML element. Therefore, it isn't applicable to XML elements that reside in other types of format elements (for example, in an **XML sequence** element).

The **Deferred execution** option isn't supported for XML elements that reside in the **Common\File** format element when the **Split file** option is set to **Yes**. For more information about how to split XML files, see [Split generated XML files based on file size and content quantity](#).

Example: Defer the execution of an XML element in an ER format

The following steps explain how a user in the System administrator or Electronic reporting functional consultant [role](#) can configure an ER format that contains an XML element where the order of execution differs from the order in the format hierarchy.

These steps can be performed in the **USMF** company in Microsoft Dynamics 365 Finance.

Prerequisites

To complete this example, you must have access to the **USMF** company in Finance for one of the following roles:

- Electronic reporting functional consultant
- System administrator

If you haven't yet completed the example in the [Defer the execution of sequence elements in ER formats](#) topic, download the following [configurations](#) of the sample ER solution.

CONTENT DESCRIPTION	FILE NAME
ER data model configuration	Model to learn deferred elements.version.1.xml

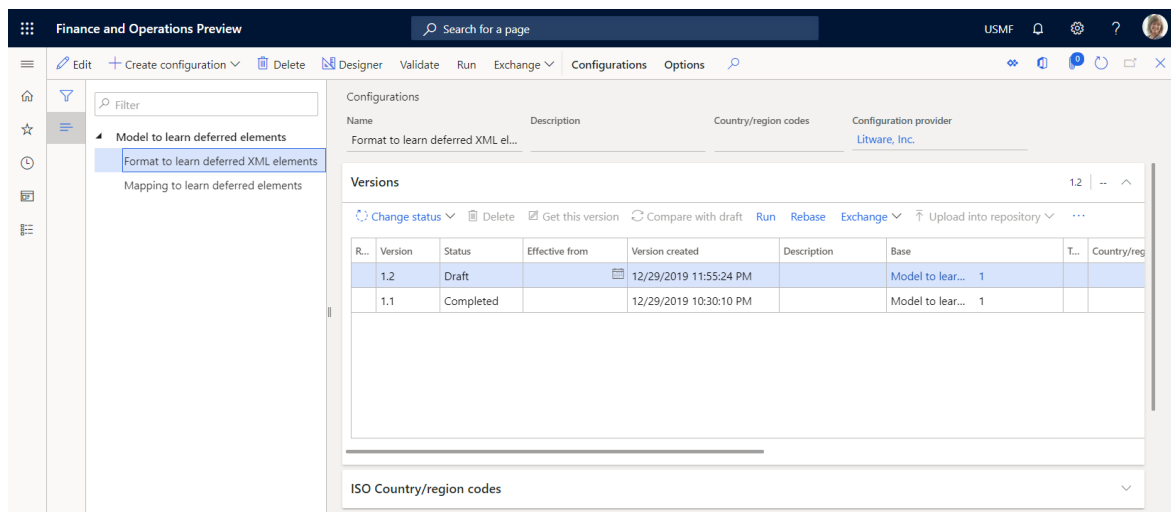

CONTENT DESCRIPTION	FILE NAME
ER model mapping configuration	Mapping to learn deferred elements.version.1.1.xml

Before you begin, you must also download and save the following configuration of the sample ER solution to your local computer.

CONTENT DESCRIPTION	FILE NAME
ER format configuration	Format to learn deferred XML elements.version.1.1.xml

Import the sample ER configurations

1. Go to **Organization administration > Workspaces > Electronic reporting**.
2. Select **Reporting configurations**.
3. On the **Configurations** page, if the **Model to learn deferred elements** configuration isn't available in the configuration tree, import the ER data model configuration:
 - a. Select **Exchange**, and then select **Load from XML file**.
 - b. Select **Browse**, find and select the **Model to learn deferred elements.1.xml** file, and then select **OK**.
4. If the **Mapping to learn deferred elements** configuration isn't available in the configuration tree, import the ER model mapping configuration:
 - a. Select **Exchange**, and then select **Load from XML file**.
 - b. Select **Browse**, find and select the **Mapping to learn deferred elements.1.1.xml** file, and then select **OK**.
5. Import the ER format configuration:
 - a. Select **Exchange**, and then select **Load from XML file**.
 - b. Select **Browse**, find and select the **Format to learn deferred XML elements.1.1.xml** file, and then select **OK**.
6. In the configuration tree, expand **Model to learn deferred elements**.
7. Review the list of imported ER configurations in the configuration tree.

Activate a configuration provider

1. Go to **Organization administration > Workspaces > Electronic reporting**.
2. On the **Localization configurations** page, in the **Configuration providers** section, make sure that

the [configuration provider](#) for the Litware, Inc. (<http://www.litware.com>) sample company is listed, and that it's marked as active. If this configuration provider isn't listed, or if it isn't marked as active, follow the steps in the [Create a configuration provider and mark it as active](#) topic.

Review the imported model mapping

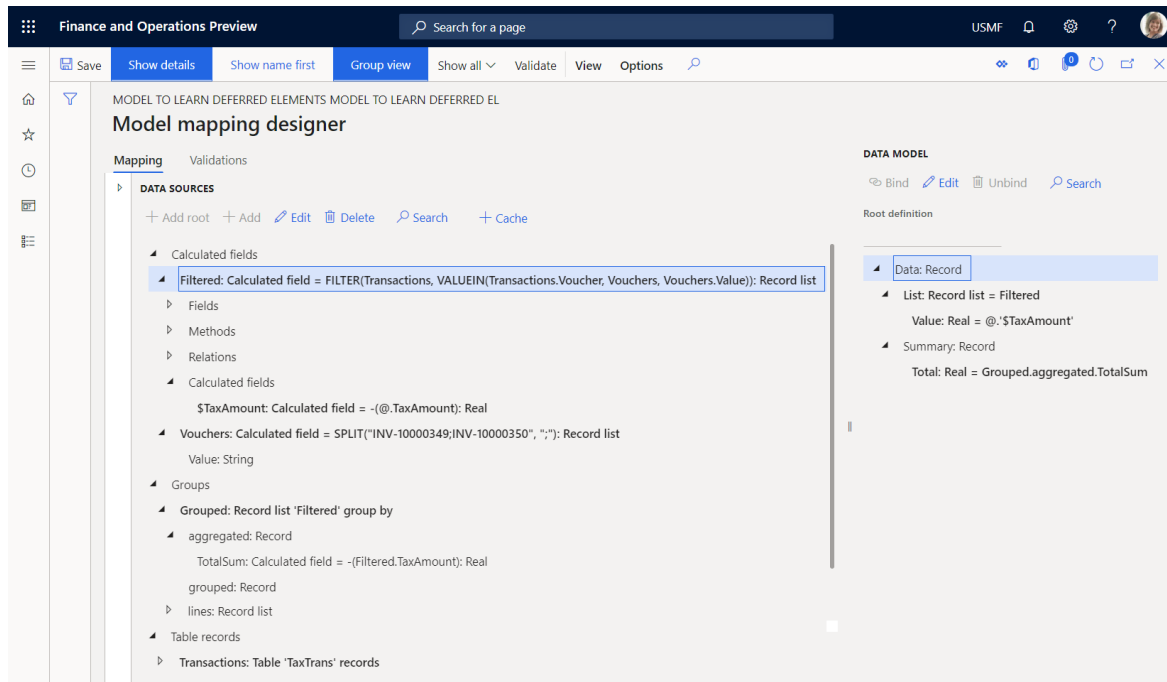

Review the settings of the ER model mapping component that is configured to access tax transactions and expose accessed data on request.

1. Go to **Organization administration > Workspaces > Electronic reporting**.
2. Select **Reporting configurations**.
3. On the **Configurations** page, in the configuration tree, expand **Model to learn deferred elements**.
4. Select the **Mapping to learn deferred elements** configuration.
5. Select **Designer** to open the list of mappings.
6. Select **Designer** to review the mapping details.
7. Select **Show details**.
8. Review the data sources that are configured to access tax transactions:
 - The **Transactions** data source of the *Table record* type is configured to access records of the **TaxTrans** application table.
 - The **Vouchers** data source of the *Calculated field* type is configured to return the required voucher codes (**INV-10000349** and **INV-10000350**) as a list of records.
 - The **Filtered** data source of the *Calculated field* type is configured to select, from the **Transactions** data source, only tax transactions of the required vouchers.
 - The **\$TaxAmount** field of the *Calculated field* type is added for the **Filtered** data source to expose the tax value that has the opposite sign.
 - The **Grouped** data source of the *Group By* type is configured to group filtered tax transactions of the **Filtered** data source.
 - The **TotalSum** aggregation field of the **Grouped** data source is configured to summarize values of the **\$TaxAmount** field of the **Filtered** data source for all filtered tax transactions of that data source.

9. Review how the configured data sources are bound to the data model, and how they expose accessed data to make it available in an ER format:

- The **Filtered** data source is bound to the **Data.List** field of the data model.
- The **\$TaxAmount** field of the **Filtered** data source is bound to the **Data.List.Value** field of the data model.
- The **TotalSum** field of the **Grouped** data source is bound to the **Data.Summary.Total** field of the data model.

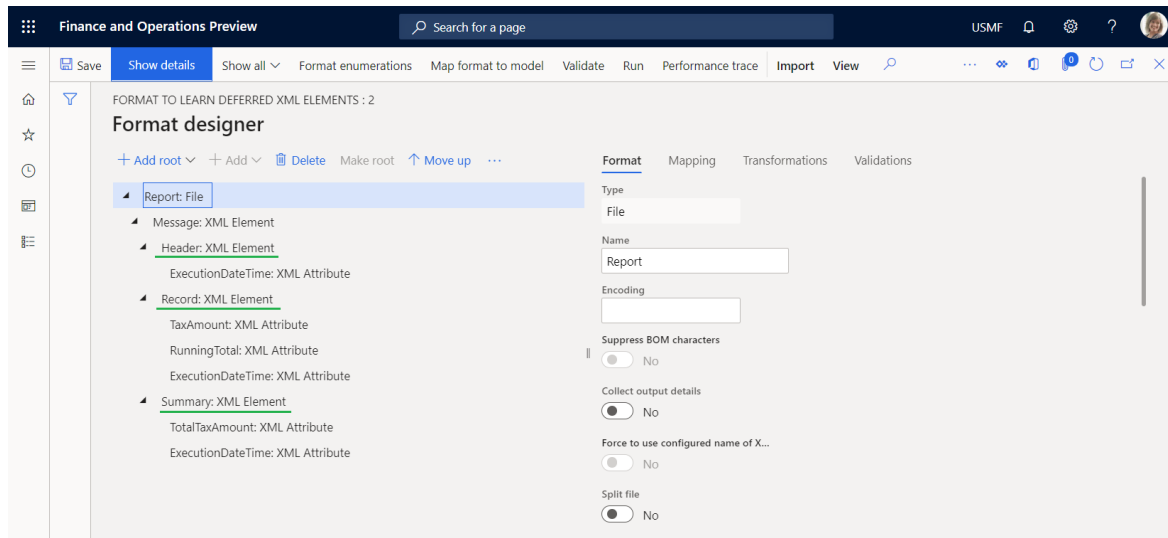

10. Close the **Model mapping designer** and **Model mappings** pages.

Review the imported format

1. On the **Configurations** page, in the configuration tree, select the **Format to learn deferred XML elements** configuration.
2. Select **Designer** to review the format details.
3. Select **Show details**.
4. Review the settings of the ER format components that are configured to generate an outbound document in XML format that includes details of the tax transactions:
 - The **Report\Message** XML element is configured to fill the outbound document with a single node that includes the nested XML elements (**Header**, **Record**, and **Summary**).
 - The **Report\Message\Header** XML element is configured to fill the outbound document with a

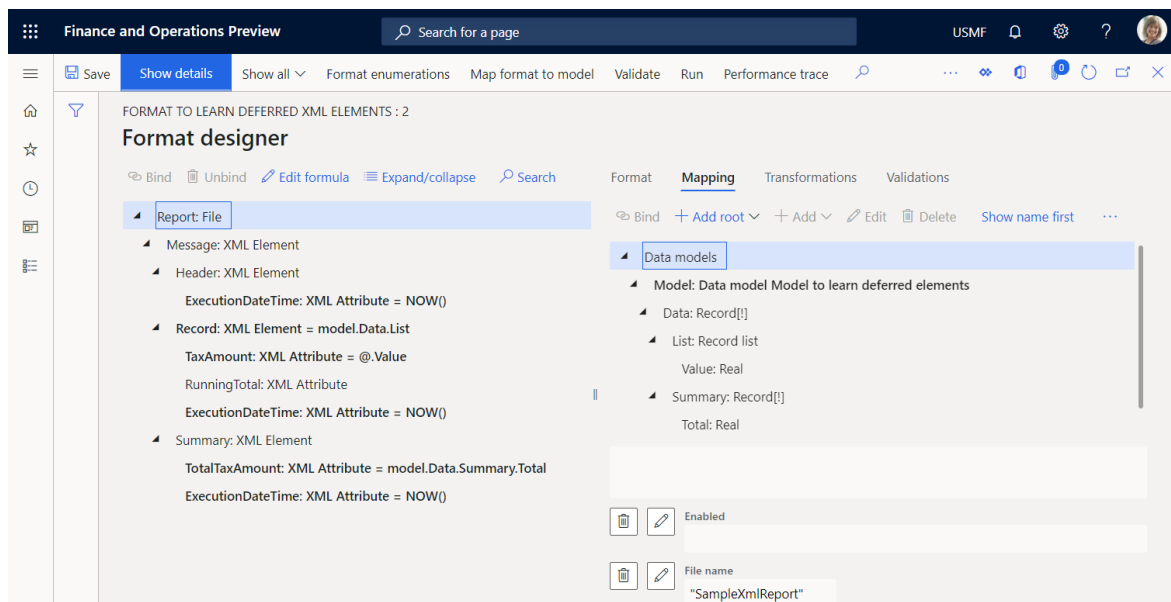

single header node that shows the date and time when the processing starts.

- The **Report \Message \Record** XML element is configured to fill the outbound document with a single record node that shows the details of a single tax transaction.
- The **Report \Message \Summary** XML element is configured to fill the outbound document with a single summary node that includes the sum of the tax values from the processed tax transactions.

5. On the **Mapping** tab, review the following details:

- The **Report \Message \Header** element doesn't have to be bound to a source to generate a single node in an outbound document.
- The **ExecutionDate** attribute generates the date and time (including milliseconds) when the header node is added.
- The **Report \Message \Record** element is bound to the **model.Data.List** list to generate a single record node for every record from the bound list.
- The **TaxAmount** attribute is bound to **model.Data.List.Value** (which is shown as **@.Value** in the relative path view) to generate the tax value of the current tax transaction.
- The **RunningTotal** attribute is a placeholder for the running total of the tax values. Currently, this attribute has no output, because neither a binding nor a default value is configured for it.
- The **ExecutionDate** attribute generates the date and time (including milliseconds) when the current transaction is processed in this report.
- The **Report \Message \Summary** element doesn't have to be bound to a data source to generate a single node in an outbound document.
- The **TotalTaxAmount** attribute is bound to **model.Data.Summary.Total** to generate the sum of the tax values of the processed tax transactions.
- The **ExecutionDate** attribute generates the date and time (including milliseconds) when the summary node is added.

Run the imported format

1. On the Format designer page, select Run.
2. Download the file that the web browser offers, and open it for review.

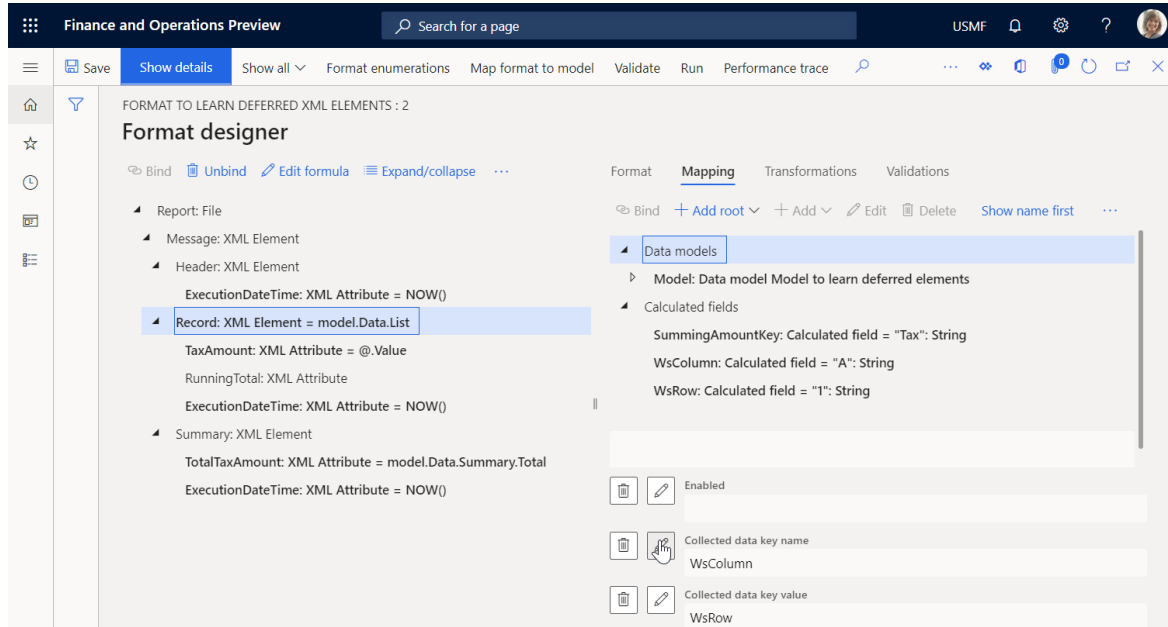

Notice that the summary node presents the sum of the tax values for the processed transactions. Because the format is configured to use the `model.Data.Summary.Total` binding to return this sum, the sum is calculated by calling the `TotalSum` aggregation of the `Grouped` data source of the `GroupBy` type in the model mapping. To calculate this aggregation, the model mapping iterates over all transactions that have been selected in the `Filtered` data source. By comparing the execution times of the summary node and the last record node, you can determine that calculation of the sum took 12 milliseconds (ms). By comparing the execution times of the first and last record nodes, you can determine that generation of all record nodes took 9 ms. Therefore, a total of 21 ms was required.

Modify the format so that the calculation is based on generated output

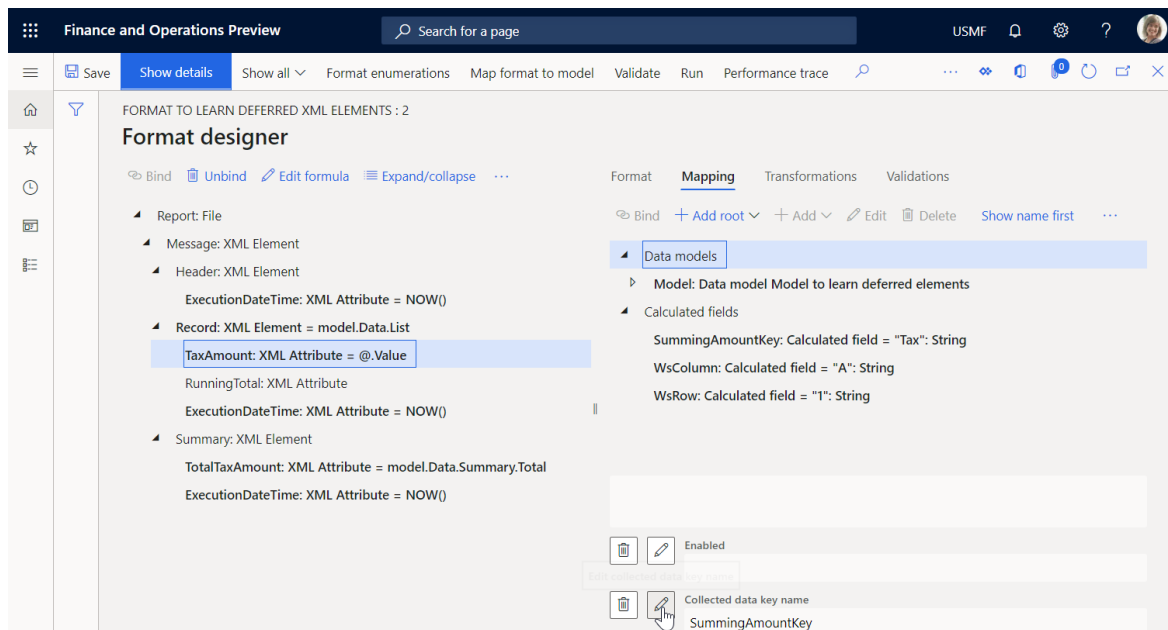

If the volume of transaction is much larger than the volume in the current example, the calculation time might increase and cause performance issues. By changing the setting of the format, you can help prevent these performance issues. Because you access tax values to include them in the generated report, you can reuse this information to calculate tax values. For more information, see [Configure format to do counting and summing](#).

1. On the Format designer page, on the Format tab, select the Report file element in the format tree.

- Set the **Collect output details** option to **Yes**. You can now configure this format by using the content of a generated report as a data source that can be accessed by using the built-in ER functions in the **Data collection** category.
- On the **Mapping** tab, select the **Report\Message\Record** XML element.
- Configure the **Collected data key name** expression as `WsColumn`.
- Configure the **Collected data key value** expression as `WsRow`.

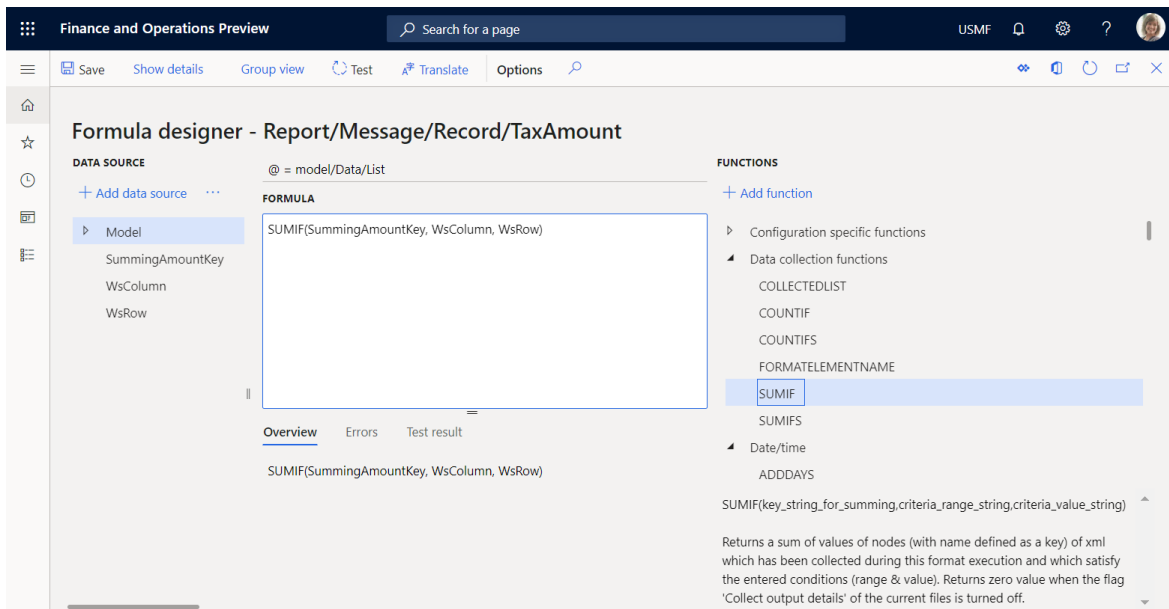

- Select the **Report\Message\Record\TaxAmount** attribute.
- Configure the **Collected data key name** expression as `SummingAmountKey`.

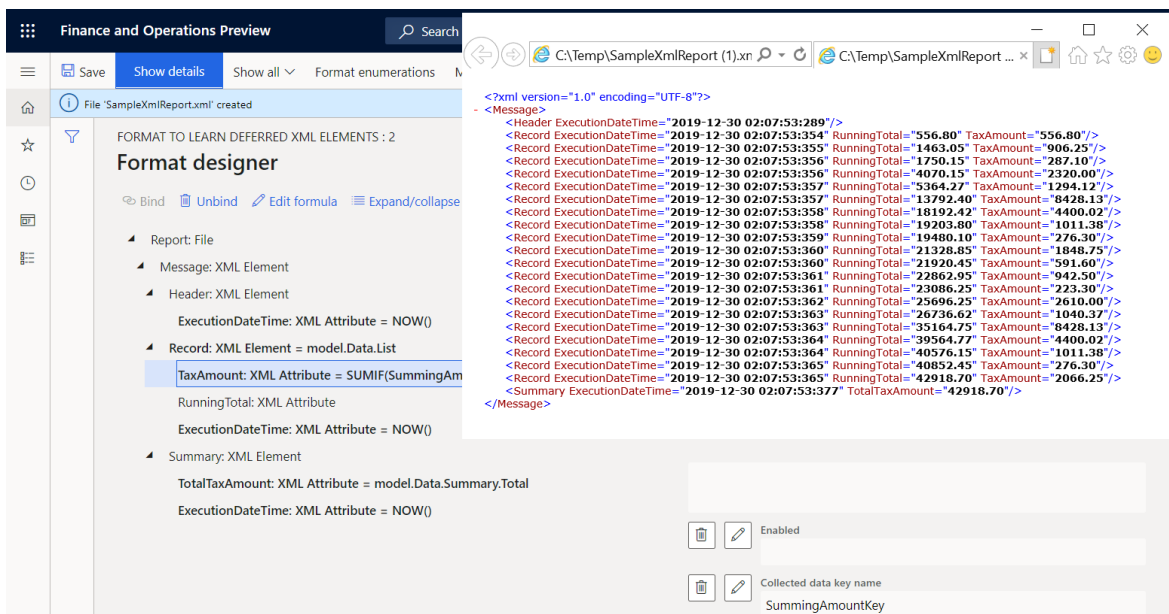

You can consider this setting the fulfillment of a virtual worksheet, where the value of cell A1 is appended with the value of the tax amount from every processed tax transaction.

- Select the **Report\Message\Record\RunningTotal** attribute, and then select **Edit formula**.
- Configure the `SUMIF(SummingAmountKey, WsColumn, WsRow)` expression by using the built-in **SUMIF** ER function, and then select **Save**.

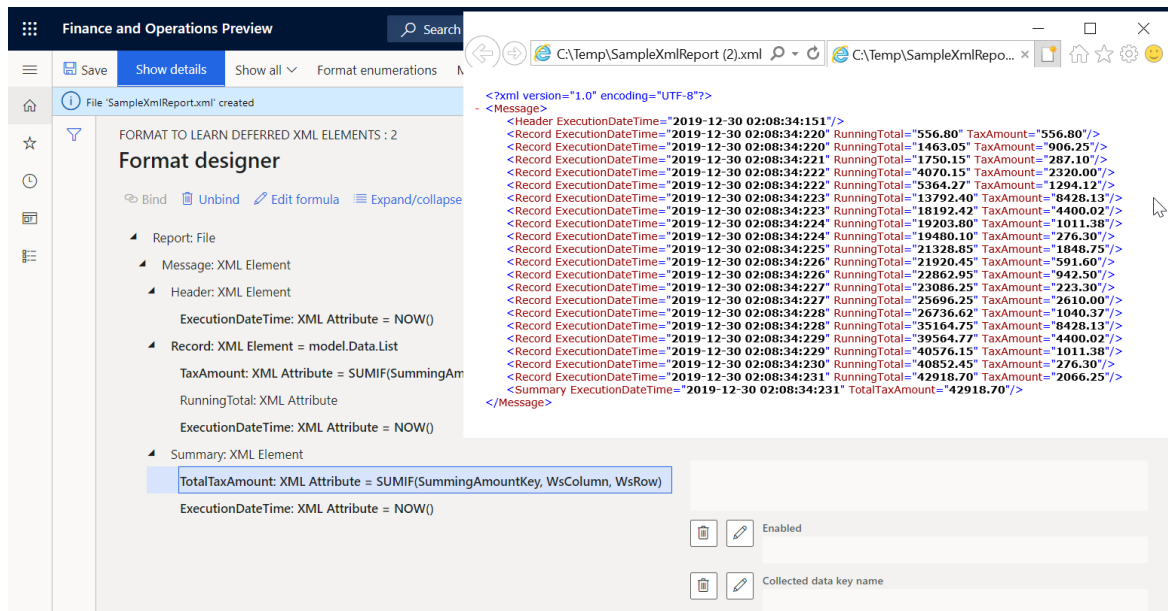

10. Close the Formula designer page.
11. Select **Save**, and then select **Run**.
12. Download and review the file that the web browser offers.

The last record node contains the running total of tax values that is calculated for all processed transactions by using the generated output as a data source. This data source starts from the beginning of the report and continues through the last tax transaction. The summary node contains the sum of the tax values for all processed transactions that are calculated in the model mapping by using the data source of the *GroupBy* type. Notice that these values are equal. Therefore, the output-based summing can be used instead of **GroupBy**. By comparing the execution times of the first record node and the summary node, you can determine that generation of all the record nodes and summing took 11 ms. Therefore, as far as the generation of record nodes and the summing of tax values are concerned, the modified format is approximately two times faster than the original format.

13. Select the **Report\Message\Summary\TotalTaxAmount** attribute, and then select **Edit formula**.
14. Enter the `SUMIF(SummingAmountKey, WsColumn, WsRow)` expression instead of the existing expression.
15. Select **Save**, and then select **Run**.
16. Download and review the file that the web browser offers.

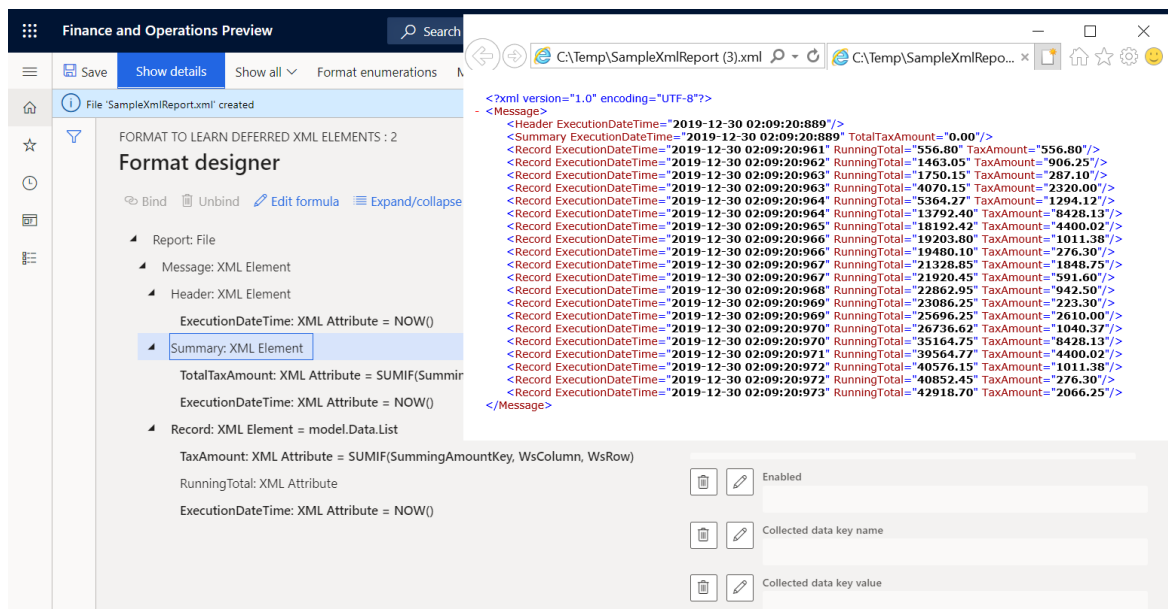

Notice that the running total of tax values in the last record node now equals the sum in the summary node.

Put values of output-based summing in the report header

If, for example, you must present the sum of tax values in the header of your report, you can modify your format.

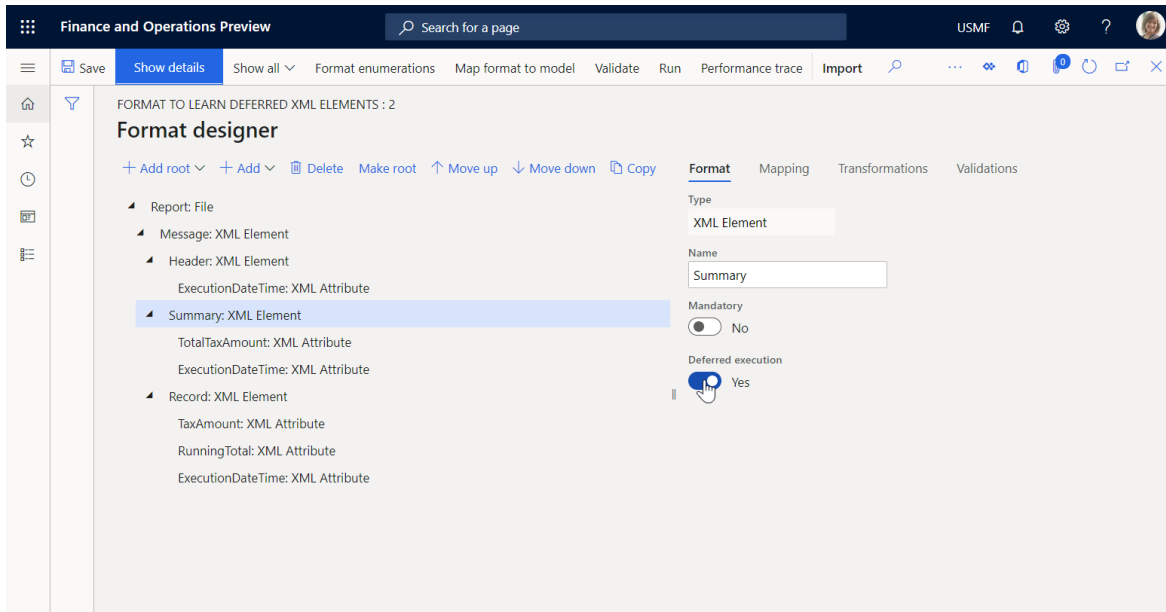

1. On the Format designer page, on the Format tab, select the Report\Message\Summary XML element.
2. Select **Move up**.
3. Select **Save**, and then select **Run**.
4. Download and review the file that the web browser offers.

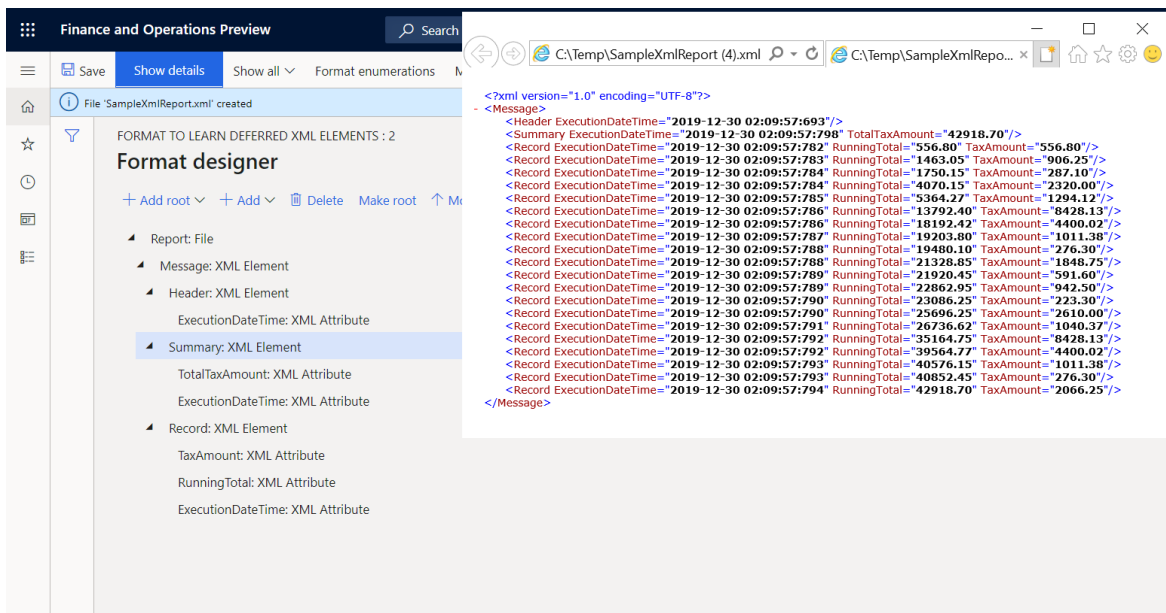

Notice that the sum of tax values in the summary node now equals 0 (zero), because this sum is now calculated based on the generated output. When the first record node is generated, the generated output doesn't yet contain record nodes that have transaction details. You can configure this format to defer the execution of the Report\Message\Summary element until the Report\Message\Record element has been run for all tax transactions.

Defer the execution of the summary XML element so that the calculated total is used

1. On the **Format designer** page, on the **Format** tab, select the **Report\Message\Summary** XML element.
2. Set the **Deferred execution** option to **Yes**.

3. Select **Save**, and then select **Run**.
4. Download and review the file that the web browser offers.

The **Report\Message\Summary** element is now run only after all other items that are nested under its parent element, **Report\Message**, have been run. Therefore, it's run after the **Report\Message\Record** element has been run for all tax transactions of the **model.Data.List** data source. The execution times of the first and last record nodes, and of the header and summary nodes, reveal this fact.

Configure the Electronic reporting (ER) framework

2/18/2021 • 7 minutes to read • [Edit Online](#)

This topic explains how to set up the basic functionality for Electronic reporting (ER). It also describes the steps that you must complete before you can set up ER.

Prerequisites for ER setup

Before you can set up ER, you must set up the required [document types](#) in Document management:

- A document type for Microsoft Office documents that are used as templates for ER reports.
- A document type that is used to store the output of ER reports in the jobs archive.
- A document type that is used to store the output of ER reports so that they can be viewed in other programs.
- A document type that is used to keep baselines of outputs of ER configurations.
- A document type that is used to handle files in the ER framework for all other purposes.

For each document type, the following attribute values can be selected.

ATTRIBUTE NAME	ATTRIBUTE VALUE
Class	Attach file
Group	File
Location	Azure storage or SharePoint

Set up ER

Use the following procedure to set up the basic functionality of ER for all legal entities.

1. Open the **Electronic reporting** workspace page.
2. Click **Electronic reporting parameters**.

Main parameters

On the **General** tab of the **Electronic reporting parameters** page, set the following ER parameters:

- **Enable design mode**
 - Set this option to **Yes** to enable embedded ER designers, so that users can create their own ER configurations.
 - Set this option to **No** to require that users access the functionality of ER designers by signing up for [Configuration service](#).
- **Disable tracing of ER performance in data handling**
 - Set this option to **No** to allow Microsoft Telemetry to collect information about the average time that is required to process a single incoming or outgoing record as an ER configuration. This information is tracked as a specific health metric of the environment, and it will help Microsoft quickly identify and address issues that affect customers who use the ER framework.
 - Set this option to **Yes** to stop collecting telemetry information.

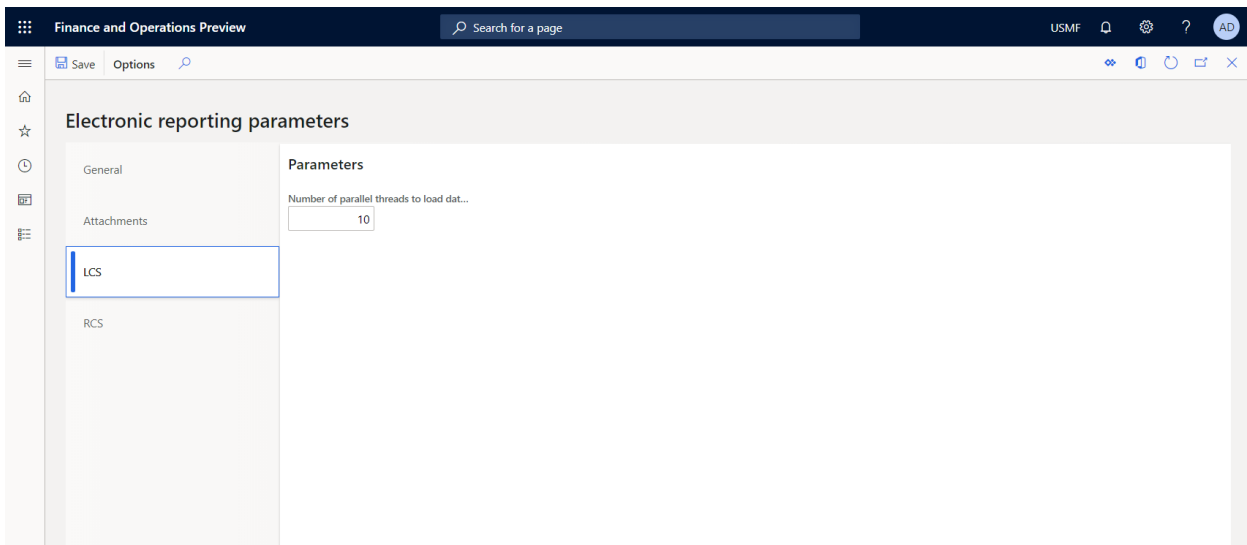

On the **Attachments** tab of the **Electronic reporting parameters** page, set the following ER parameters:

- **Configurations** – Select a document type to specify the storage of templates of ER formats. This document type is selected within the scope of a specific company. This document type will be used, regardless of the company that a user is signed in to while an ER format is being used.
 - **Job archive** – Select a document type to specify the storage of generated documents that are attached to the records of the ER jobs [archive](#). This document type is selected as a company-specific document type. You must make sure that the selected document type is configured for every company that you plan to run ER formats for, and then store the results in the ER jobs archive.
 - **Temporary** – Select a document type to specify the storage of generated documents that are used for other purposes. For example, documents might be generated for [preview](#) by other services. This document type is selected as a company-specific document type. You must make sure that the selected document type is configured for every company that you plan to run ER formats for, and then store the results in the ER jobs archive.
 - **Baseline** – Select a document type to specify the storage of documents that are used as [baselines](#) during the automated testing of ER configurations. This document type is selected as a company-specific document type. You must make sure that the selected document type is configured for every company that you plan to run ER formats for, and then store the results in the ER jobs archive.
 - **Others** – Select a document type to specify the storage of generated documents that are used for all other purposes. This document type is selected as a company-specific document type. You must make sure that the selected document type is configured for every company that you plan to run ER formats for, and then store the results in the ER jobs archive.
 - **Stop making backup copies of templates**
 - Set this option to **No** to automatically create a backup copy of any ER format configuration template and store the copy in the database storage.
 - Set this option to **Yes** to stop making backup copies of ER formation configuration templates.
- For more information, see [Backup storage of ER templates](#).

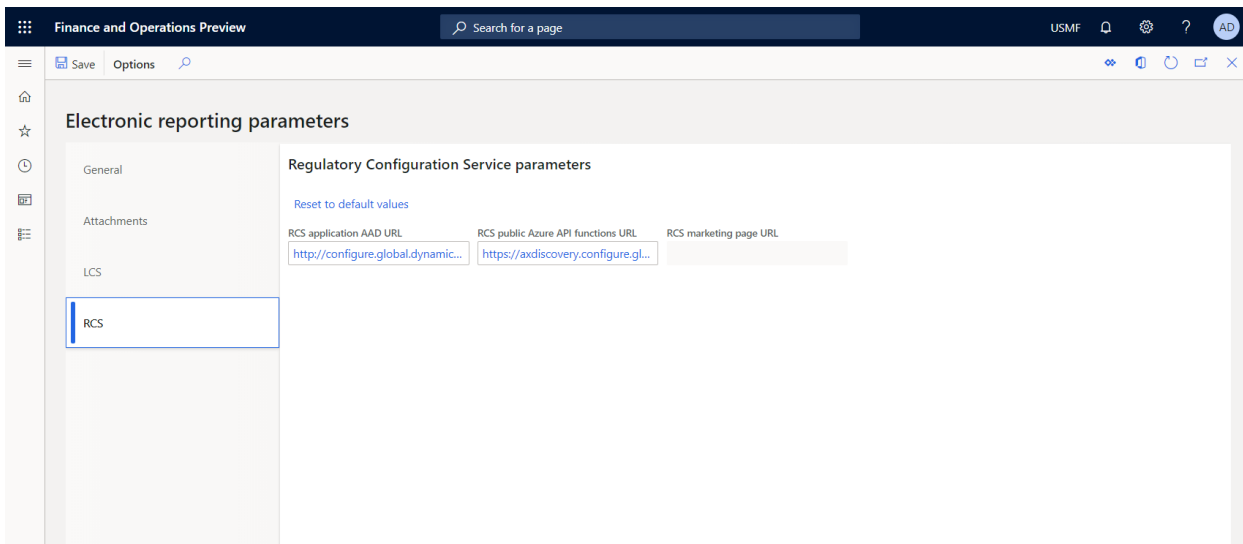

LCS parameters

On the LCS tab of the **Electronic reporting parameters** page, define the number of parallel threads that should be used to load an ER configuration from repositories in Microsoft Dynamics Lifecycle Services (LCS), so that the configurations are loaded in the most efficient manner. The value can vary from 1 through 15, depending on the available resources of the current program. Based on this setting and the number of other tasks and their priorities, the real number of threads will be defined automatically.

RCS parameters

On the RCS tab of the **Electronic reporting parameters** page, sign up for [Configuration service](#).

Active ER configurations provider

On the **Configuration provider** table page, create ER provider records. Each provider can be **marked** as **Active**. The active provider's name and internet address are stored in an ER configuration, as attributes of the configuration owner.

Optional setup for ER

In addition to the basic functionality, ER has other functionality that you can set up.

- On the **Electronic reporting destination** page, define the ER output destinations for each file output of each ER format configuration. Use the **document types** of the Document management framework that you set up earlier. You can also use this page to set up the optional ER functionality for each legal entity. For more information, see **Electronic reporting (ER) destinations**.
- When you add new Application Object Tree (AOT) artifacts or update existing AOT artifacts that are used as data sources (tables, views, or data entities) in ER, use the **Rebuild table references** menu item (**Organization administration** > **Electronic reporting** > **Rebuild table references**) to bring your AOT changes into the ER metadata.

Frequently asked questions

Question: What is the optimal number of parallel threads to use to load an ER configuration from LCS?

Answer: To calculate the optimal number of parallel threads, use the following empirical formula: $\text{Cores} \div 2 + 1(2)$. For example, if the program runs on a virtual machine (VM) that has two CPUs, and each CPU contains four cores, the optimal number is five or six parallel threads.

Question: I have added a custom table to the AOT. I created a new ER model mapping configuration for my ER data model. During the design of the model mapping, I tried to add a new data source type, **Table records**, that refers to my table. I could manually add my table name to the **Table** lookup, and the ER model mapping accepted it without errors or warnings. However, my table's name isn't included in the list of available choices that the **Table** lookup of this data source offers. How do I include the name of my table?

Answer: To include the name of your custom table in the **Table** lookup, use the **Rebuild table references** menu item as described in the "Optional setup for ER" section earlier in this topic.

Question: Why can't I mark the Microsoft provider as **Active** in the **Electronic reporting** workspace in my production environment?

Answer: The Microsoft provider is used to mark ER configurations that have been designed and maintained by

Microsoft. We expect that Microsoft will release new versions of the configurations in the future. We recommend that you not mark the Microsoft provider as **Active**. Otherwise, you can update the configurations. (For example, you can change the content and register new versions.) These updates will cause issues in the future, when Microsoft provides new versions of the configurations, and those new versions must be imported and adopted. Instead, register a new ER provider for your company, and use it for your ER configurations maintenance. To reuse a Microsoft configuration, select it as the base for your derived copy. To incorporate changes that are provided by Microsoft, rebase your configuration to a new version of the Microsoft configuration when it becomes available.

Question: I successfully ran an ER format in one company. However, when I ran the same ER format in another company and used the same settings, I received the following error message: "The provided document type is not a File type." Why?

Answer: Most likely, the second company doesn't contain document types that have been selected in the **Job archive, Temporary, Baseline, and Others ER parameters**. To fix this issue, configure these document types in the second company.

- [Electronic reporting \(ER\) overview](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Backup storage of ER templates

2/18/2021 • 5 minutes to read • [Edit Online](#)

The [Electronic reporting \(ER\) overview](#) lets business users configure formats for outbound documents according to the legal requirements of various countries and regions. Configured ER formats can use predefined templates to generate outbound documents in various formats, such as Microsoft Excel workbooks, Microsoft Word documents, or PDF documents. The templates are filled with data that the configured dataflow for generated documents requires.

Each configured format can be published as part of an ER solution. Each ER solution can be exported from one instance of Finance and Operations and imported into another instance.

The ER framework uses the [Configure document management](#) to keep the required templates for the current Finance and Operations instance. Depending on the settings of the ER framework, Microsoft Azure Blob storage or a Microsoft SharePoint folder can be selected as the physical primary storage location for templates. (For more information, see [Configure the Electronic reporting \(ER\) framework](#).) The DocuValue table holds an individual record for each template. In each record, the **AccessInformation** field stores the path of a template file that is located in the configured storage location.

When you manage your Finance and Operations instances, you might decide to migrate the current instance to another location. For example, you might migrate your production instance to a new sandbox environment. If you configured the ER framework to store templates in Blob storage, the DocuValue table in the new sandbox environment refers to the instance of Blob storage in the production environment. However, this instance can't be accessed from the sandbox environment, because the migration process doesn't support the migration of artifacts in Blob storage. Therefore, if you try to run an ER format that uses a template to generate business documents, an exception occurs, and you're notified about the missing template. You're also guided to use the ER cleanup tool to delete and then re-import the ER format configuration that contains the template. Because you might have several ER format configurations, this process can be time consuming.

The Backup storage of ER templates feature can help you make your templates so that they are always available to generate business documents.

NOTE

This feature can be used only when Blob storage has been selected as the physical storage location for ER templates.

Automated recovery and notification

For this feature, every template of a new ER format configuration in the current environment is automatically saved to the backup storage location for templates (the ERDocuDatabaseStorage database table) when the following events occur:

- You import a new ER format configuration that contains a template.
- You complete the draft version of an ER format configuration that contains a template.

Backup copies of templates are migrated to a new instance of Finance and Operations as part of the application database.

If a template of an ER format is required for generation of outbound documents, to process vendor payments including generation of payment advice and control reports, for example, but the required template isn't found in the primary storage location, the following events occur:

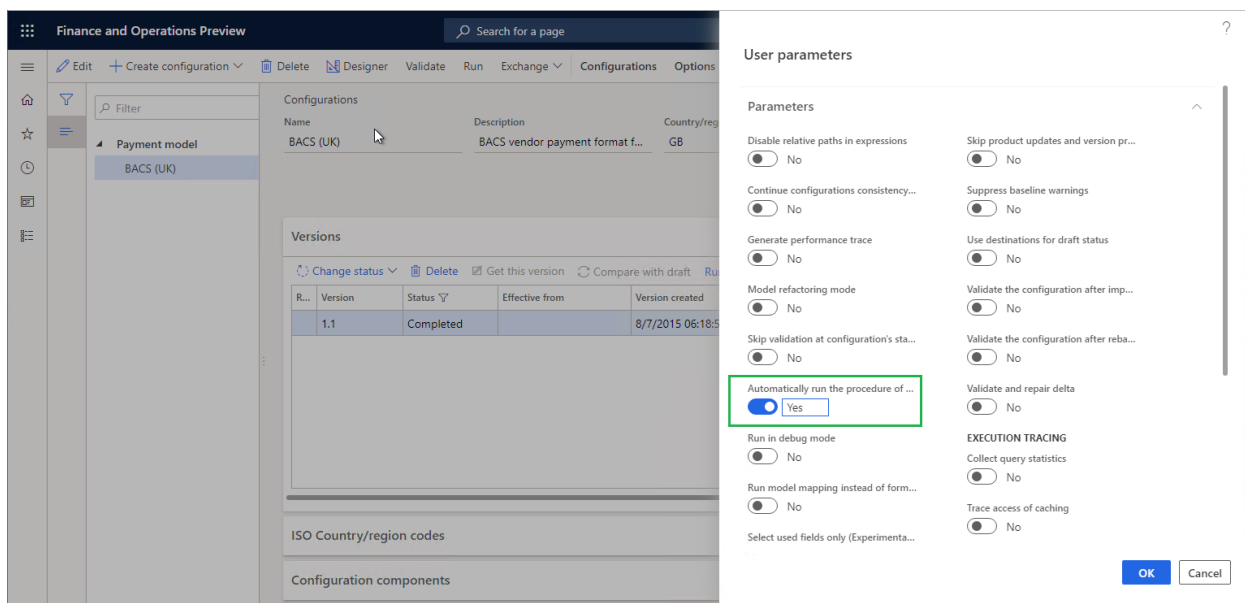

- If the template is available in the backup storage location, it is automatically taken from the backup storage location, restored to the primary storage location, and used for the current execution.
- Every user who is assigned to the **Electronic reporting developer** or **System administrator** role is notified about the missing template issue through the Action center. The message that appears depends on the value of the **Automatically run the procedure of restoring the broken templates in batch** parameter:
 - If this parameter is set to **Off**, the message recommends that you start the batch process to automatically fix similar issues for other ER format configuration templates. The message includes a link that you can use to start the batch process.
 - If this parameter is set to **On**, the message notifies you that a missing templates issue has been discovered, and that a new batch process, **Restore broken templates from internal database backup**, has been automatically scheduled. This batch process will automatically fix similar issues for other templates.

To set up the **Automatically run the procedure of restoring the broken templates in batch** parameter, complete the following steps:

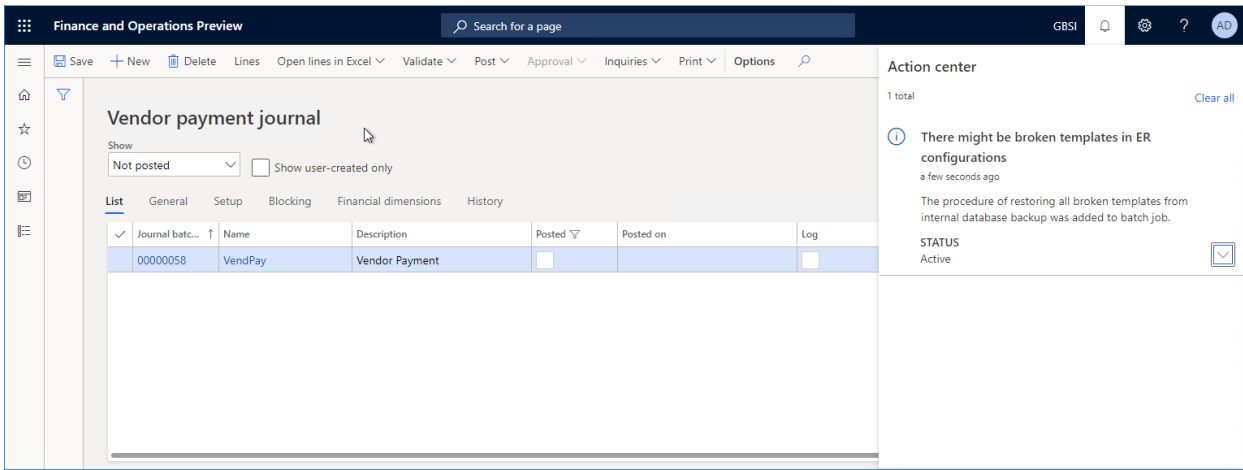

1. In Finance and Operations, open the **Organization administration > Electronic reporting > Configurations** page.
2. On the **Configurations** page, on the Action Pane, on the **Configurations** tab, in the **Advanced settings** group, select **User parameters**.
3. In the **User parameters** dialog box, set the required value for the **Automatically run the procedure of restoring the broken templates in batch** parameter.

NOTE

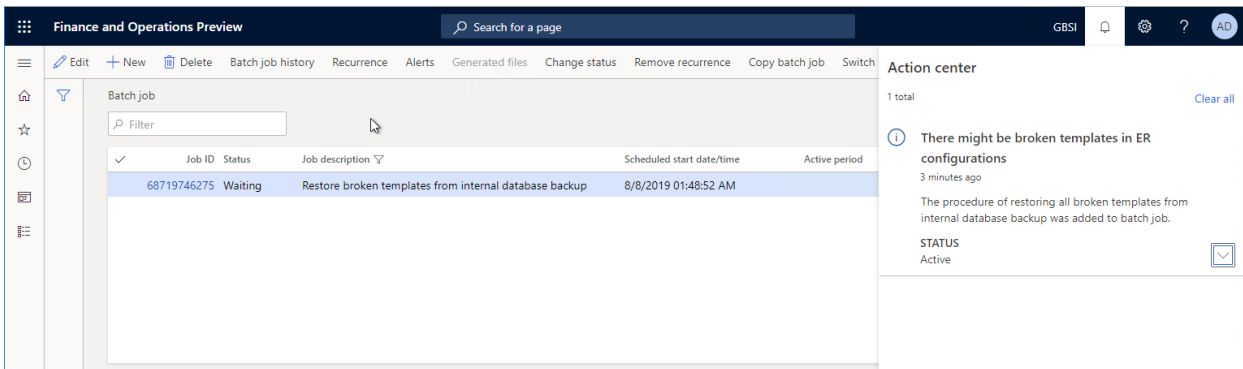

This parameter is defined as application user and logged company specific.

The following illustration shows an example of the message that appears when the **Automatically run the procedure of restoring the broken templates in batch** parameter is set to **On**.

The following illustration shows the **Restore broken templates from internal database backup** batch process on the **Batch job** page.

The execution log of the completed **Restore broken templates from internal database backup** batch process includes information about the templates that have been restored from the backup storage location to the primary storage location.

By default, the process of automatically creating backup copies of templates that reside in ER format configurations is turned on. To stop making backup copies of templates, set the **Stop making backup copies of template** option to **Yes** on the **Attachments** tab of the **Electronic reporting parameters** page. You can open this page from the **Electronic reporting** workspace.

If you set the **Stop making backup copies of templates** option to **Yes** and don't want to keep the backup copies that were previously made of templates, select **Clean up backup storage** on the **Electronic reporting parameters** page.

If you upgraded your environment to Finance and Operations version 10.0.5 (October 2019) and want to migrate to a new environment that includes ER format configurations that can be run, select **Fill in backup storage** on the **Electronic reporting parameters** page before the migration occurs. This button starts the process of making backup copies of all available templates, so that they can be stored in the ER backup storage location for templates.

Manual recovery

Go to **Organization administration > Electronic reporting > Restore broken templates** to manually initiate the process of restoring ER templates from the backup storage location to the primary storage location. Before you start this process, on the **Restore broken templates** page you can specify whether it will be performed interactively, or the batch process will be scheduled for this.

Supported deployments

In Finance and Operations version 10.0.5, the Backup storage of ER templates feature is available only in cloud deployments.

Additional resources

[Electronic reporting \(ER\) overview](#)

Create configuration providers and mark them as active

2/18/2021 • 2 minutes to read • [Edit Online](#)

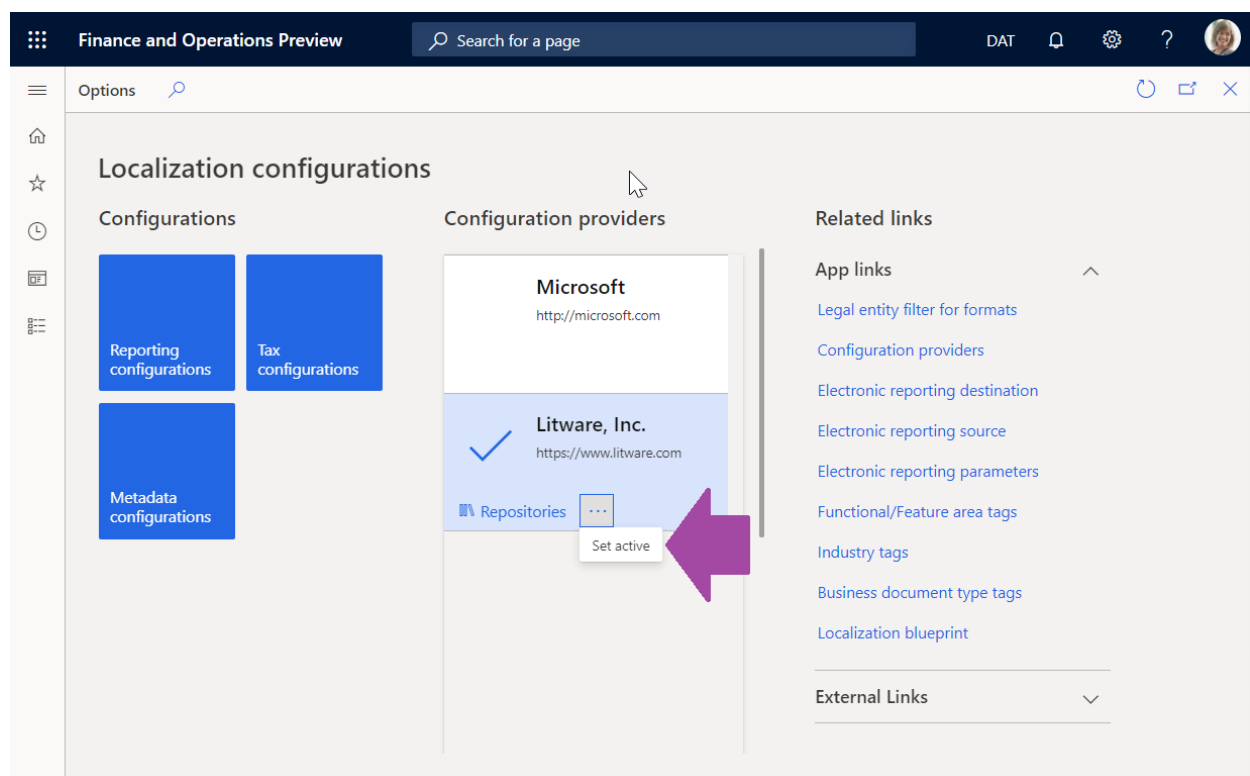

This topic explains how a user assigned to the System Administrator or Electronic Reporting Developer role can create a configuration provider for Electronic reporting (ER). Each ER configuration will refer to the provider as the author of the configuration. In this example, you will create a configuration provider for sample company, Litware, Inc. These steps can be performed in any company as ER configuration providers are shared among all companies.

Create a provider

1. Go to the **navigation pane** in the upper left corner and select **Organization administration**.
2. Go to **Workspaces > Electronic reporting**.
3. Go to **Related links > Configuration providers**.
4. Select **New**.
 - A provider record has a unique name and URL. Review the content of this page and skip this procedure if a record for Litware, Inc. (<https://www.litware.com>) already exists.
5. In the Name field, type `Litware, Inc.`.
6. In the Internet address field, type `https://www.litware.com`.
7. Select **Save**.
8. Close the page.

Select as an active provider

1. Select the Litware, Inc. provider.
2. Select **Set active**.

The screenshot shows the Dynamics 365 interface for 'Localization configurations'. The 'Configuration providers' section is active, displaying two providers: 'Microsoft' (http://microsoft.com) and 'Litware, Inc.' (https://www.litware.com). The 'Litware, Inc.' provider is selected, indicated by a blue checkmark and a blue background. A purple arrow points to the 'Set active' button located below the 'Litware, Inc.' provider. The interface also shows 'Reporting configurations', 'Tax configurations', and 'Metadata configurations' on the left, and 'Related links' on the right.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Electronic reporting (ER) destinations

2/18/2021 • 12 minutes to read • [Edit Online](#)

You can configure a destination for each Electronic reporting (ER) format configuration and its output component (a folder or a file). Users who have appropriate access rights can also modify destination settings at runtime. This topic explains ER destination management, the types of destinations that are supported, and security considerations.

ER format configurations usually contain at least one output component: a file. Typically, configurations contain multiple file output components of different types (for example, XML, TXT, XLSX, DOCX, or PDF) that are grouped into either a single folder or multiple folders. ER destination management lets you preconfigure what occurs when each component is run. By default, when a configuration is run, a dialog box appears that lets you save or open the file. The same behavior also occurs when you import an ER configuration and don't configure any specific destinations for it. After a destination is created for a main output component, that destination overrides the default behavior, and the folder or file is sent according to the destination's settings.

Availability and general prerequisites

The functionality for ER destinations isn't available in Microsoft Dynamics AX 7.0 (February 2016). Therefore, you must install Microsoft Dynamics 365 for Operations version 1611 (November 2016) or later to use the following destination types:

- [Email](#)
- [Archive](#)
- [File](#)
- [Screen](#)
- [Power BI](#)

Alternatively, you can install one of the following prerequisites. However, be aware that these alternatives provide a more limited ER destination experience.

- Microsoft Dynamics AX application version 7.0.1 (May 2016)
- [Electronic reporting destination management application hotfix](#)

There is also a [Print](#) destination type. To use it, you must install Microsoft Dynamics 365 Finance version 10.0.9 (April 2020).

Overview

You can set up destinations only for ER configurations that have been [imported](#) into the current Finance instance, and for the formats that are available on the [Electronic reporting configurations](#) page. The functionality for ER destination management is available at **Organization administration > Electronic reporting > Electronic reporting destination**.

Default behavior

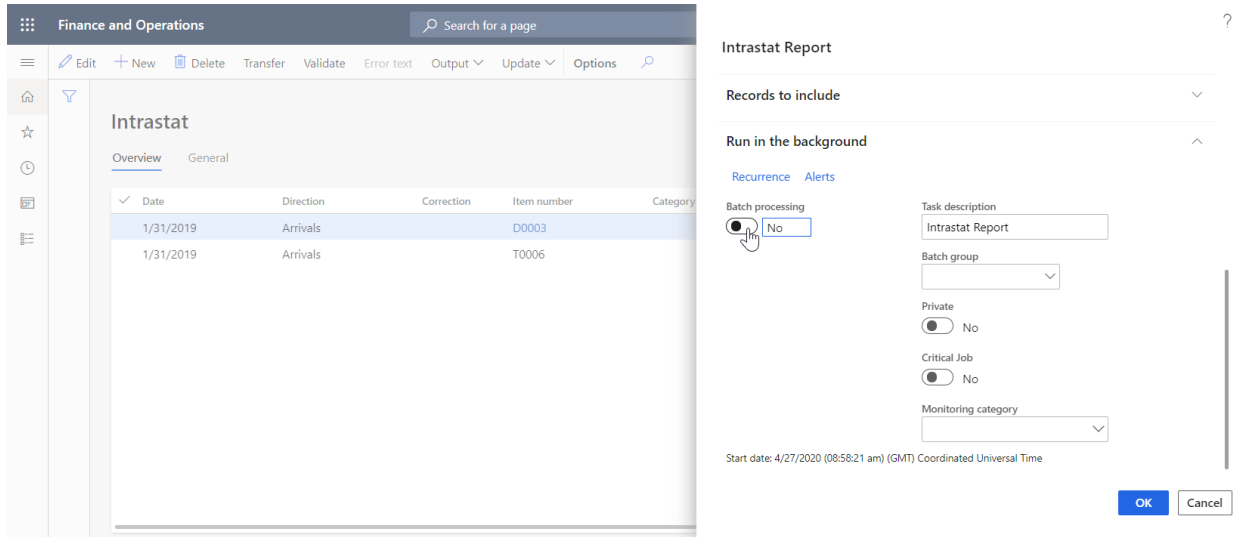

The default behavior for an ER format configuration depends on the execution type that you specify when an ER format starts.

In the **Intrastat Report** dialog box, on the **Run in the background** FastTab, if you set the **Batch processing** option to **No**, an ER format is run immediately in interactive mode. When this execution is successfully completed, a generated outbound document is made available for download.

If you set the **Batch processing** option to **Yes**, an ER format is run in **batch** mode. The appropriate batch job is created, based on the parameters that you specify on the **Run in the background** tab of the ER parameters dialog box.

NOTE

The job description informs you about the run of an ER format mapping. It also contains the name of the ER component that is run.

You can find information about this job in several places:

- Go to **Common > Inquiries > Batch jobs > My batch jobs** to check the status of the scheduled job.
- Go to **Organization administration > Electronic reporting > Electronic reporting jobs** to check the status of the scheduled job and the execution results of the completed job. When job execution is successfully completed, select **Show files** on the **Electronic reporting jobs** page to get a generated outbound document.

NOTE

This document is stored as an attachment of the current job record and is controlled by the **Document management** framework. The **document type** that is used to store ER artifacts of this type is configured in the **ER parameters**.

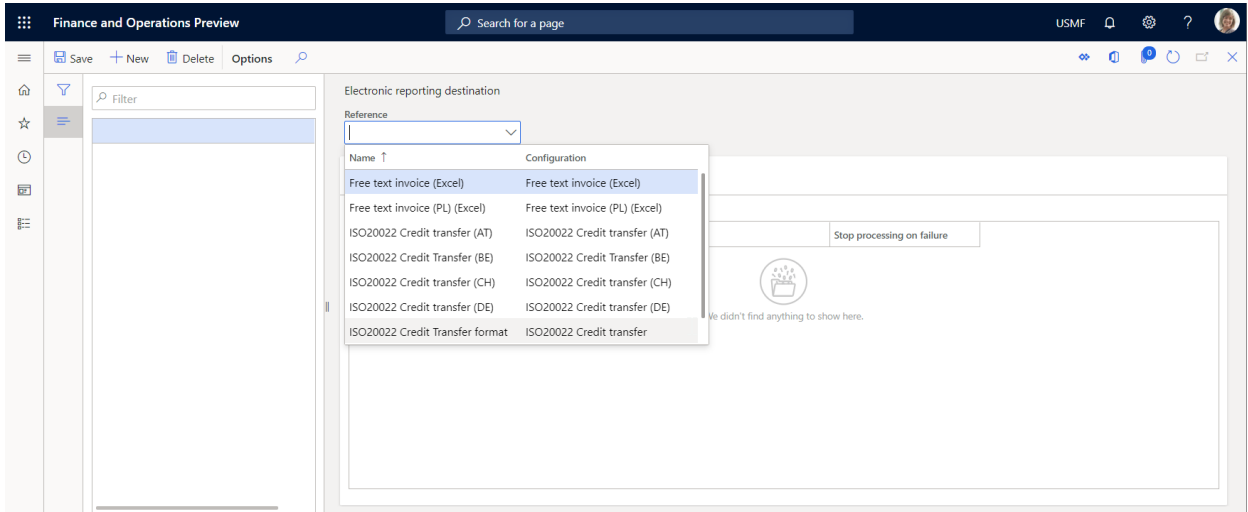

- On the **Electronic reporting jobs** page, select **Show files** to view the list of any errors and warnings that were generated during job execution.

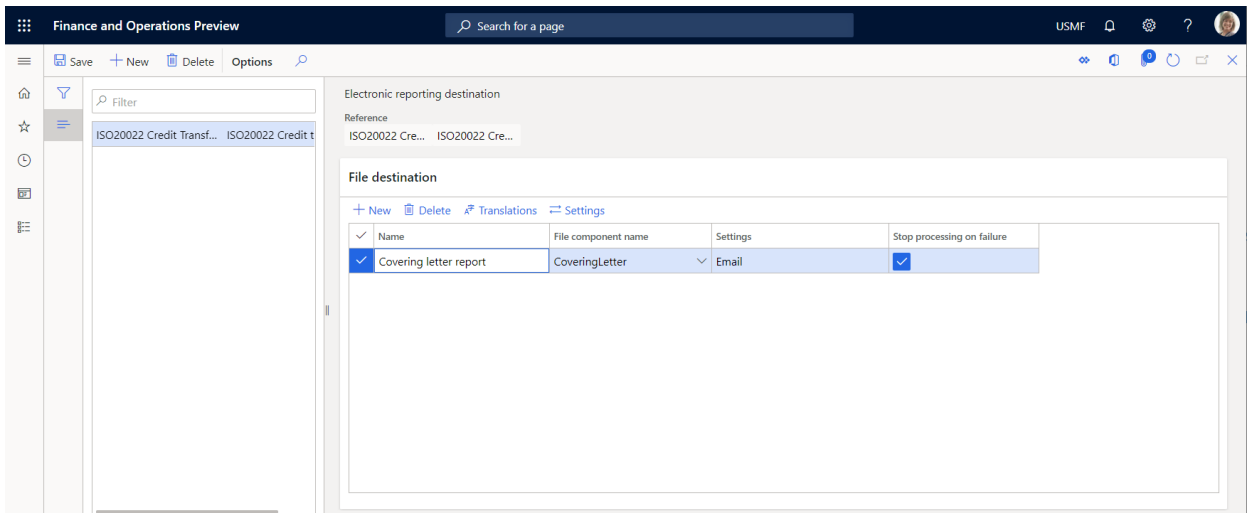

User-configured behavior

On the **Electronic reporting destination** page, you can override the default behavior for a configuration. Imported configurations aren't shown on this page until you select **New** and then, in the **Reference** field, select

a configuration to create destination settings for.

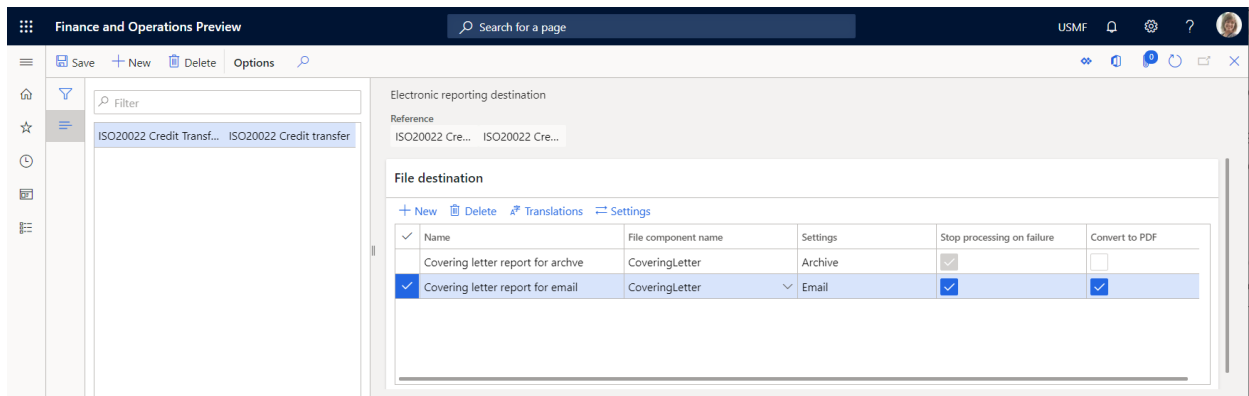

After you create a reference, you can create a file destination for each **Folder** or **File** output component of the referenced ER format.

Next, in the **Destination settings** dialog box, you can enable and disable individual destinations for the file destination. The **Settings** button is used to control all the destinations for a selected file destination. In the **Destination settings** dialog box, you can control each destination separately by setting the **Enabled** option for it.

In versions of Finance **before version 10.0.9**, you can create **one file destination** for each output component of the same format, such as a folder or a file that is selected in the **File Name** field. However, in **version 10.0.9 and later**, you can create **multiple file destinations** for each output component of the same format.

For example, you can use this capability to configure file destinations for a file component that is used to generate an outbound document in Excel format. One destination (**Archive**) can be configured to store the original Excel file in the ER jobs archive, and another destination (**Email**) can be configured to simultaneously **convert** the Excel file to PDF format and send the PDF file by email.

When you run an ER format, all destinations that were configured for components of the format are always run. In addition, in Finance **version 10.0.17 and later**, the ER destinations functionality has been improved and now lets you configure different sets of destinations for a single ER format. This configuration marks each set as configured for a particular user action. The ER API has been [extended](#) so that an action can be provided that the user performs by running an ER format. The action code that is provided is passed to ER destinations. You can run different destinations of an ER format, depending on the action code that is provided. For more information, see [Configure action-dependent ER destinations](#).

Destination types

The following destinations are currently supported for ER formats. You can disable or enable all types at the same time. In this way, you can either do nothing or send the component to all configured destinations.

- [Email](#)
- [Archive](#)
- [File](#)
- [Screen](#)
- [Power BI](#)
- [Print](#)

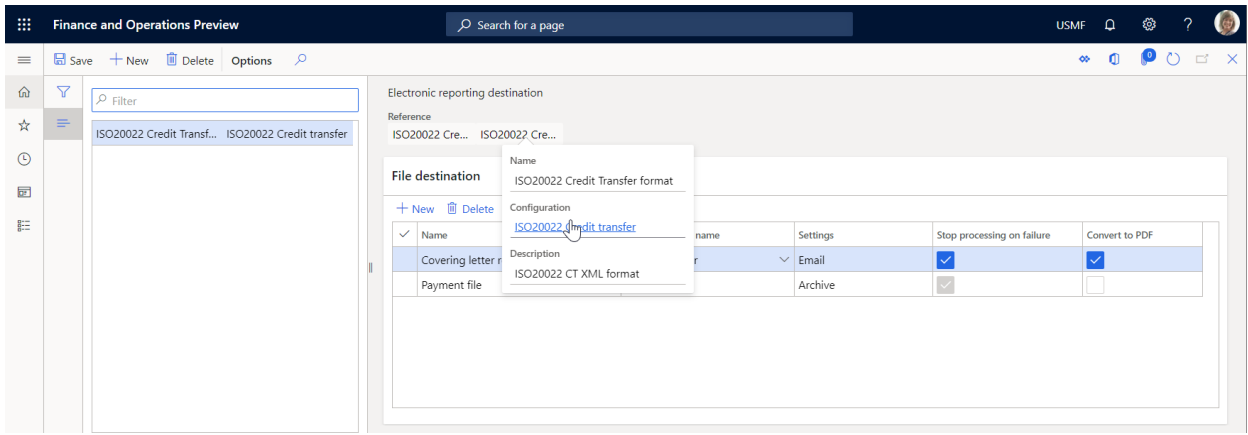

Applicability

You can set up destinations only for ER configurations that have been imported, and for the formats that are available on the [Electronic reporting configurations](#) page.

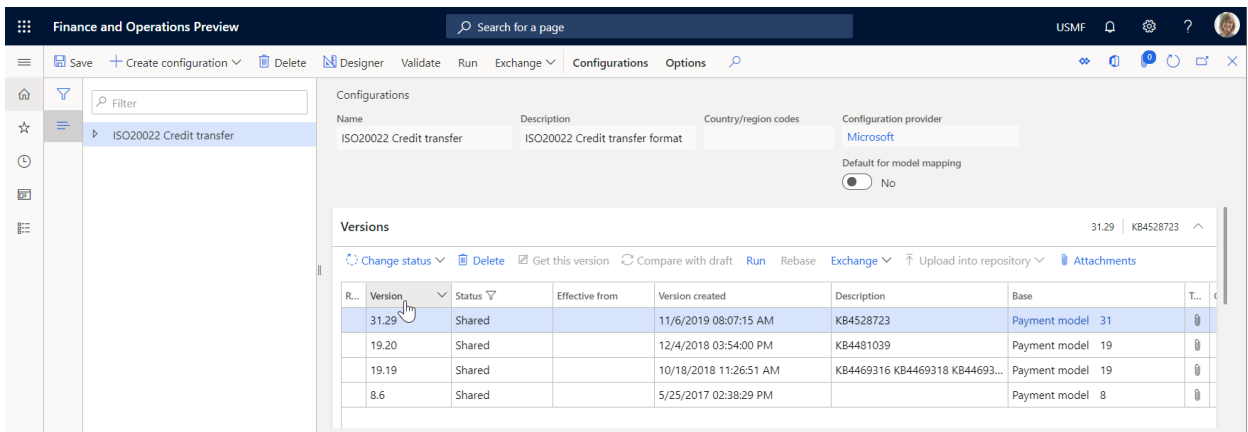

NOTE

Configured destinations are company-specific. If you plan to use an ER format in different companies of the current Finance instance, you must configure destinations for that ER format for each of those companies.

When you configure file destinations for a selected format, you configure them for the whole format.

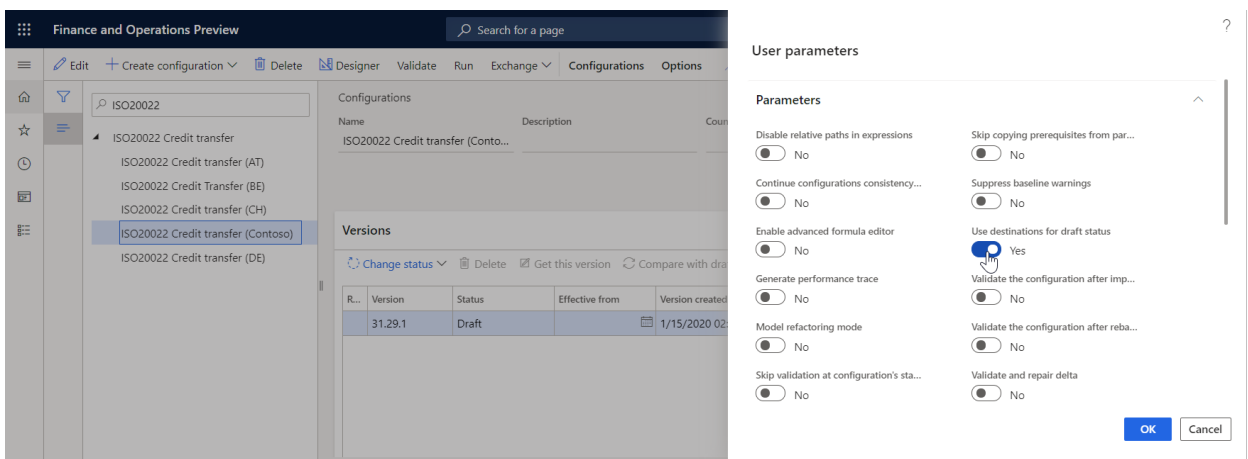

At the same time, you might have multiple **versions** of the format that have been imported into the current Finance instance. You can view them if you select the **Configuration** link that is offered when you select the **Reference** field.

By default, configured destinations are applied only when you run an ER format version that has a status of either **Completed** or **Shared**. However, you must sometimes use configured destinations when the draft version of an ER format is run. For example, you modify a draft version of your format, and you want to use configured destinations to test how generated output will be delivered. Follow these steps to apply destinations for an ER format when the draft version is run.

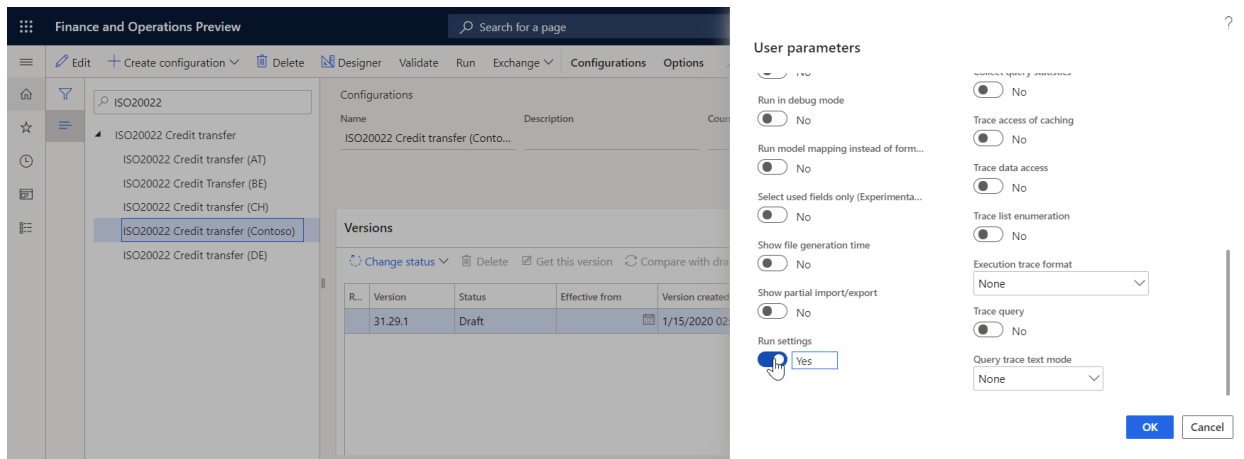

1. Go to **Organization administration > Electronic reporting > Configurations**.
2. On the **Configurations** page, on the Action Pane, on the **Configurations** tab, in the **Advanced settings** group, select **User parameters**.
3. Set the **Use destinations for draft status** option to **Yes**.

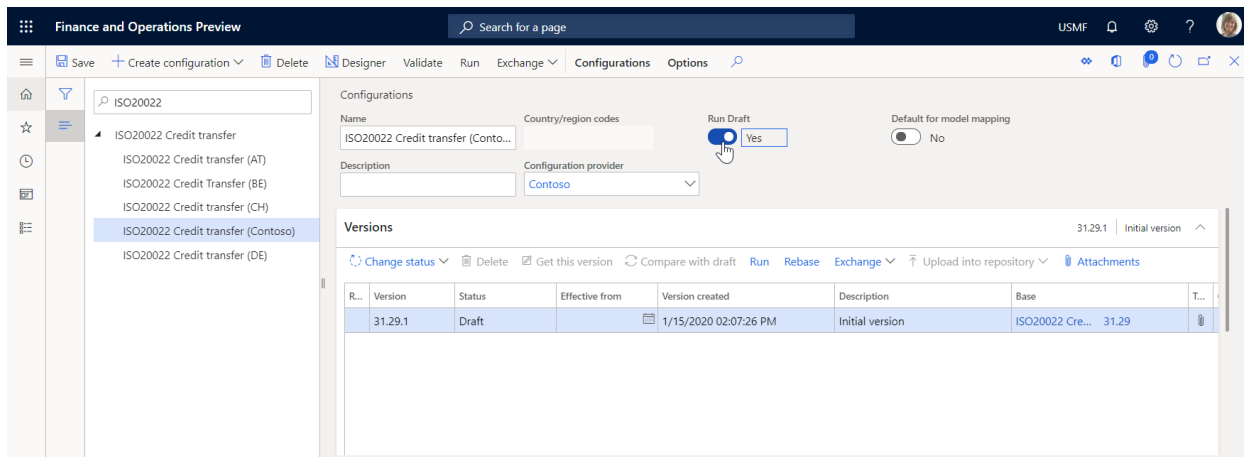

To use the draft version of an ER format, you must mark the ER format accordingly.

1. Go to **Organization administration > Electronic reporting > Configurations**.

- On the **Configurations** page, on the Action Pane, on the **Configurations** tab, in the **Advanced settings** group, select **User parameters**.
- Set the **Run setting** option to **Yes**.

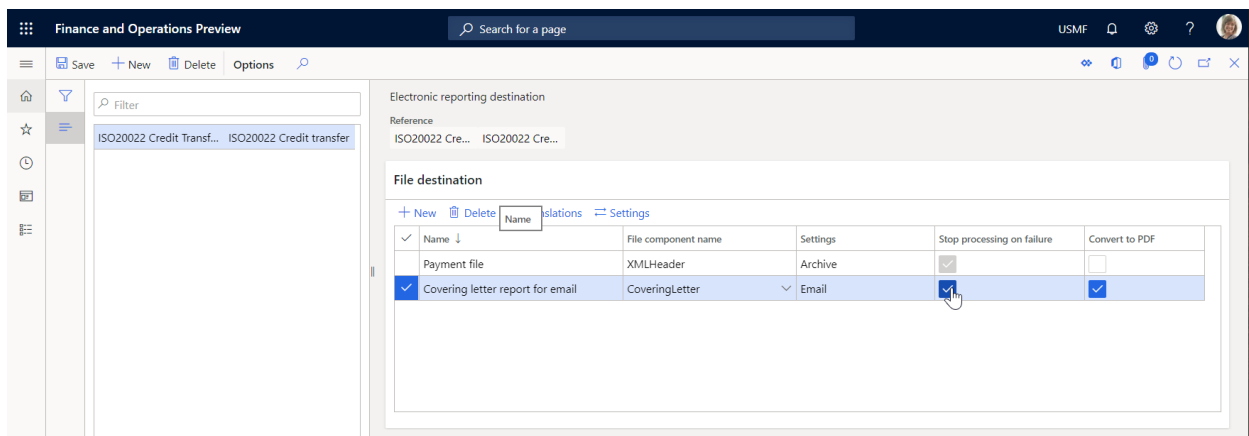

After you complete this setup, the **Run draft** option becomes available for ER formats that you modify. Set this option to **Yes** to start to use the draft version of the format when the format is run.

Destination failure handling

Usually, an ER format is run within the scope of a specific business process. However, the delivery of an outbound document that is generated during execution of an ER format must sometimes be considered part of that business process. In this case, if delivery of a generated outbound document to a configured destination is unsuccessful, execution of the business process must be canceled. To configure the appropriate ER destination, select the **Stop processing on failure** option.

For example, you configure vendor payment processing so that the **ISO20022 Credit Transfer** ER format is run to generate the payment file and supplementary documents (for example, the covering letter and control report). If a payment should be considered successfully processed only if the covering letter is successfully delivered by email, you must select the **Stop processing on failure** check box for the **CoveringLetter** component in the appropriate file destination, as shown in the following illustration. In this case, the status of the payment that is selected for processing will be changed from **None** to **Sent** only when the covering letter that is generated is successfully accepted for delivery by an email provider that is configured in the Finance instance.

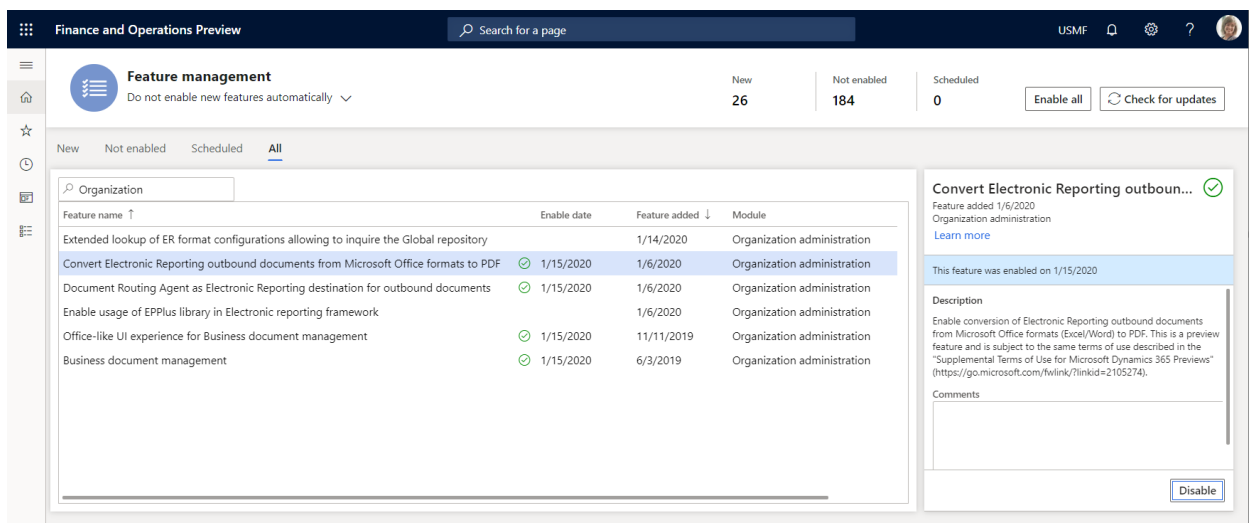

If you clear the **Stop processing on failure** check box for the **CoveringLetter** component in the destination, a payment will be considered successfully processed even if the covering letter isn't successfully delivered by email. The status of the payment will be changed from **None** to **Sent** even if the covering letter can't be sent because, for example, the email address of the recipient or sender is missing or incorrect.

Output conversion to PDF

You can use the PDF conversion option to convert output in Microsoft Office (Excel or Word) format to PDF format.

Make PDF conversion available

To make the PDF conversion option available in the current Finance instance, open the **Feature management** workspace, and turn on the **Convert Electronic Reporting outbound documents from Microsoft Office formats to PDF** feature.

Applicability

The PDF conversion option can be turned on only for file components that are used to generate output in Office (Excel or Word) format (**Excel file**). When this option is turned on, output that is generated in Office format is automatically converted to PDF format.

Limitations

The PDF conversion option is available only for cloud deployments.

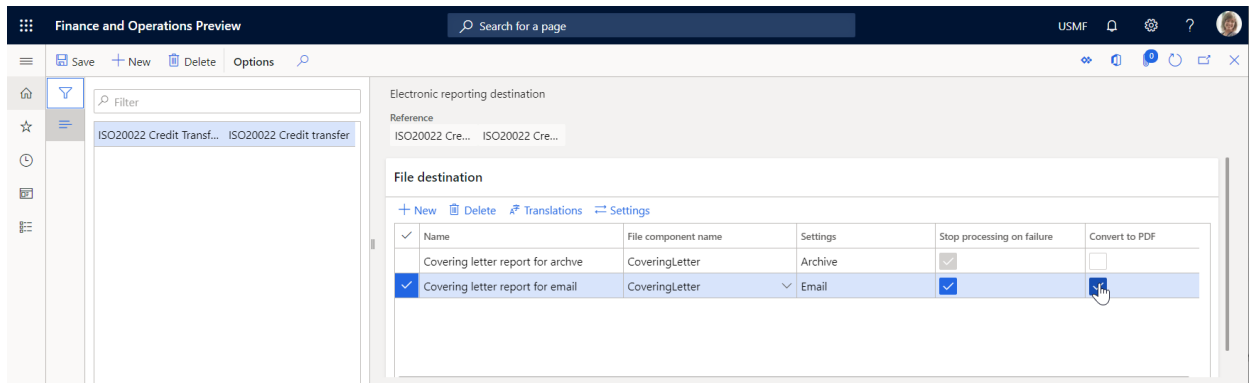

The PDF document that is produced is limited to a maximum length of 300 pages.

In Finance **version 10.0.9**, only landscape page orientation is supported in the PDF document that is produced from Excel output. In Finance **version 10.0.10 (May 2020) and later**, you can [specify the page orientation](#) of the PDF document that is produced from Excel output while you configure an ER destination.

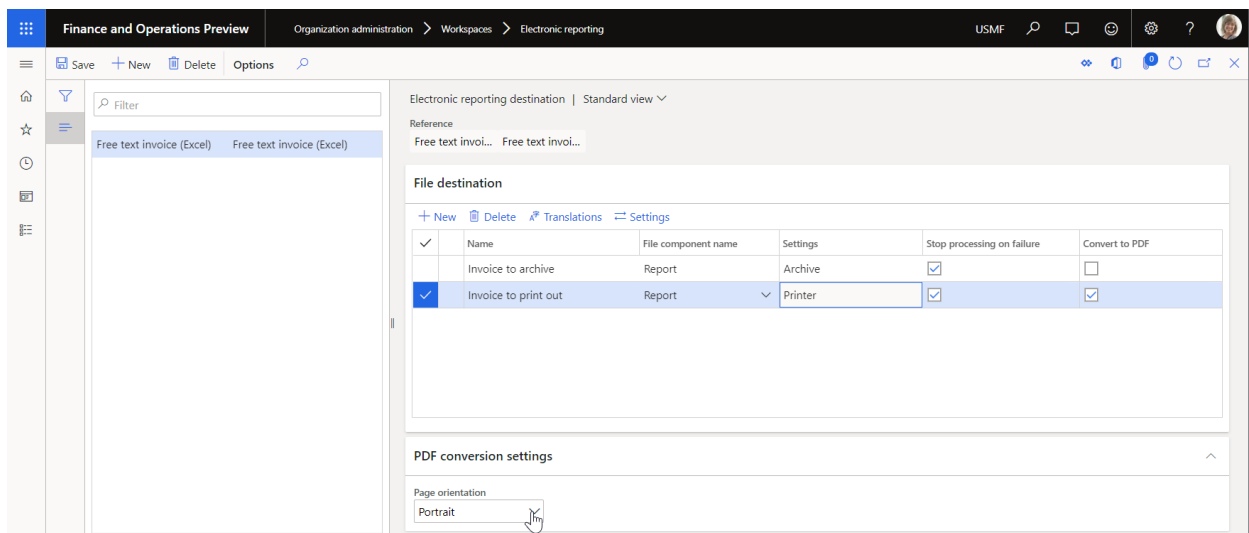

Only the common system fonts of the Windows operating system are used to convert output that contains no embedded fonts.

Use the PDF conversion option

To turn on PDF conversion for a file destination, select the **Convert to PDF** check box.

If you generate an ER configuration in Excel format and want to convert it to PDF format, you can specify the page orientation of the PDF document. When you select the **Convert to PDF** check box to turn on PDF conversion for a file destination that produces an output file in Excel format, the **Page orientation** field becomes available on the **PDF conversion settings** FastTab. In the **Page orientation** field, select the preferred orientation.

NOTE

To have the option to select the PDF page orientation, you must install Finance version 10.0.10 or later.

The selected page orientation is applied to all ER configurations that are generated in Excel format and then converted to PDF format.

If an ER configuration in Word format is converted to PDF format, the page orientation of the PDF document is taken from the Word document.

Security considerations

Two types of privileges and duties are used for ER destinations. One type controls a user's overall ability to maintain the destinations that are configured for a legal entity (that is, it controls access to the **Electronic reporting destinations** page). The other type controls an application user's ability to override, at runtime, the destination settings that an ER developer or ER functional consultant has configured.

ROLE (AOT NAME)	ROLE NAME	DUTY (AOT NAME)	DUTY NAME
ERDeveloper	Electronic reporting developer	ERFormatDestinationConfigure	Configure electronic reporting format destination
ERFunctionalConsultant	Electronic reporting functional consultant	ERFormatDestinationConfigure	Configure electronic reporting format destination
PaymAccountsPayablePaymentsClerk	Accounts payable payments clerk	ERFormatDestinationRuntimeConfigure	Configure electronic reporting format destination during runtime
PaymAccountsReceivablePaymentsClerk	Accounts receivable payments clerk	ERFormatDestinationRuntimeConfigure	Configure electronic reporting format destination during runtime

NOTE

Two privileges are used in the preceding duties. These privileges have the same names as the corresponding duties: `ERFormatDestinationConfigure` and `ERFormatDestinationRuntimeConfigure`.

Frequently asked questions

I have imported electronic configurations, and I see them on the Electronic reporting configurations page. But why don't I see them on the Electronic reporting destinations page?

Make sure that you select **New** and then select a configuration in the **Reference** field. The **Electronic reporting destinations** page shows only configurations that destinations have been configured for.

Is there any way to define which Microsoft Azure Storage account and Azure Blob storage are used?

No. The default Microsoft Azure Blob storage that is defined and used for the document management system is used.

What is the purpose of the File destination in the destination settings? What does that setting do?

The **File** destination is used to control a dialog box of your web browser when you run an ER format in interactive mode. If you enable this destination, or if no destination is defined for a configuration, an open or save dialog box appears in your web browser after an output file is created.

Can you give an example of the formula that refers to a vendor account that I can send email to?

The formula is specific to the ER configuration. For example, if you use the ISO 20022 Credit Transfer configuration, you can use `'$PaymentsForCoveringLetter'.Creditor.Identification.SourceID` or `model.Payments.Creditor.Identification.SourceID` to get an associated vendor account.

One of my format configurations contains multiple files that are grouped into one folder (for example, Folder1 contains File1, File2, and File3). How do I set up destinations so that Folder1.zip isn't created at all, File1 is sent by email, File2 is sent to SharePoint, and I can open File3 immediately after the configuration is run?

Your format must first be available in the ER configurations. If this prerequisite is met, open the **Electronic reporting destination** page, and create a new reference to the configuration. You must then have four file destinations, one for each output component. Create the first file destination, give it a name such as **Folder**, and select a file name that represents a folder in your configuration. Then select **Settings**, and make sure that all the destinations are disabled. For this file destination, the folder won't be created. By default, because of hierarchical dependencies between files and parent folders, the files will behave in the same way. In other words, they won't

be sent anywhere. To override that default behavior, you must create three more file destinations, one for each file. In the destination settings for each, you must enable the destination that the file should be sent to.

Additional resources

[Electronic reporting \(ER\) overview](#)

[Configure action-dependent ER destinations](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

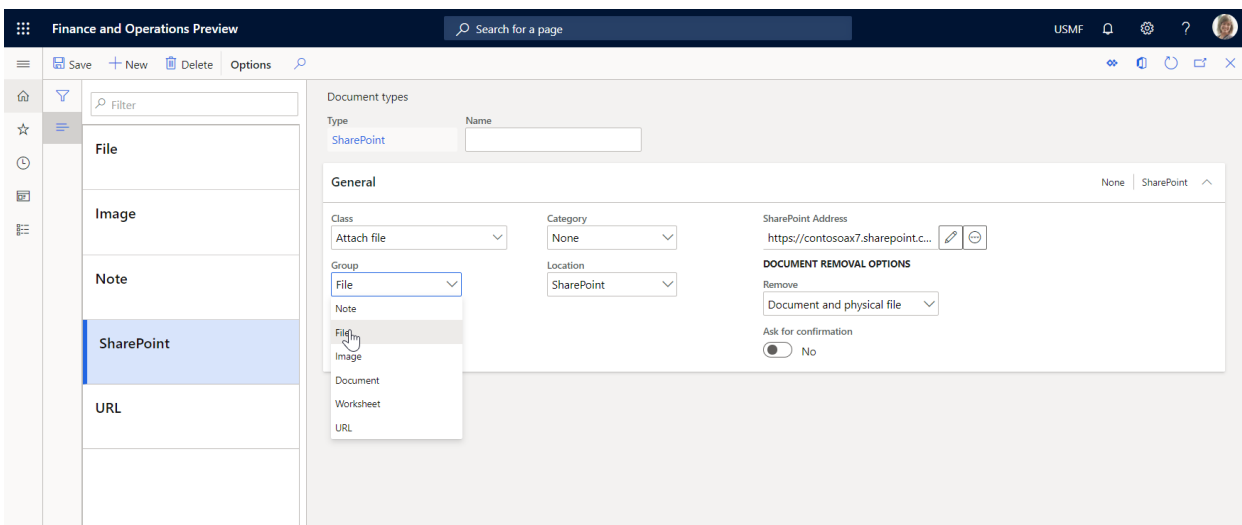

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Archive ER destination type

2/18/2021 • 2 minutes to read • [Edit Online](#)

You can configure an archive destination for each **Folder** or **File** component of an Electronic reporting (ER) format that is configured to generate outbound documents. Based on the destination setting, a generated document is stored as an attachment of a record of the ER jobs list. To view the results, go to **Organization administration > Electronic reporting > Electronic reporting jobs**.

You can use this option to send the generated document to a Microsoft SharePoint folder or Microsoft Azure Storage. Set **Enabled** to **Yes** to send output to a destination that is defined by the selected document type. Only document types where the group is set to **File** are available for selection. You define document **types** at **Organization administration > Document management > Document types**. The configuration for ER destinations is the same as the configuration for the document management system.

The location determines where the file is saved. After the **Archive** destination is enabled, the results can be saved in the Job archive. You can view the results at **Organization administration > Electronic reporting > Electronic reporting archived jobs**.

NOTE

Select a document type for the Job archive by navigating to **Organization administration > Workspaces > Electronic reporting > Electronic reporting parameters**. For more information, see [Configure the Electronic reporting \(ER\) framework](#).

SharePoint

You can save a file in a designated SharePoint folder. To define the default SharePoint server, go to **Organization administration > Document management > Document management parameters**. On the **SharePoint** tab, configure the SharePoint folder. Then, you can select it as the folder where the ER output will be saved. The **SharePoint** location must be selected in this document type.

Azure Storage

When the document type location is set to **Azure storage**, you can save a file to Azure Storage.

NOTE

The ER framework permanently stores files in Azure Blob storage unlike the Data management framework that applies the seven-day retention policy for documents that must be processed. For more information, see [API for getting message status](#) and [Status check API](#). The ER-related files will be stored in Azure Blob storage as attachments of application table records as long as necessary. A single file will be deleted from Azure Blob storage along with the application table record that this file was attached to.

Email ER destination type

2/18/2021 • 7 minutes to read • [Edit Online](#)

When an Electronic reporting (ER) format is run, one or more outbound documents can be generated. **Folder** or **File** format components are used in ER formats to specify the structure of outbound documents. You can configure an email destination for these types of components to send outbound documents as email attachments.

You can configure an email destination for each **Folder** or **File** component of an ER format. In this case, **each outbound document is emailed individually**. Based on this destination setting, a generated document is delivered as an attachment of an email.

NOTE

If no document is generated, because the **Enabled** expression for the relevant **File** component has been configured to return a **False** Boolean value, no email is sent, even if an email destination is configured and enabled for the component.

You can also **group** several **Folder** or **File** components together, and then configure an email destination for all the components in the group. In this case, all outbound documents that are generated by components that belong to the group **are sent as multiple attachments of a single email**. Based on this destination setting, each generated document is delivered as an attachment of a single email.

NOTE

If at least one document is generated by a **File** component in a group of components, an email is sent. If no document is generated by grouped components, because the **Enabled** expression for each **File** component has been configured to return a **False** Boolean value, no email is sent, even if an email destination is configured and enabled for that group of components.

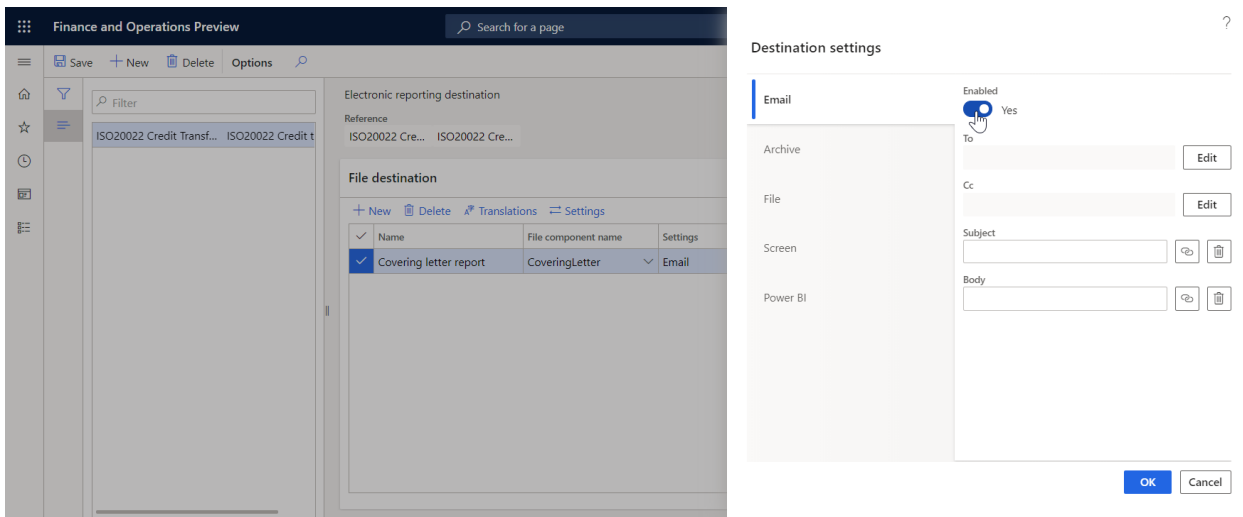

Email is the only destination that can be configured for a group of components. To deliver a document that is emailed based on the email destination setting for a group, add one more destination record, select the component that you want, and then configure another destination for this record.

Multiple groups of components can be configured for a single ER format configuration. In this way, you can configure an email destination for every group of components and an email destination for every component.

Configure an email destination

To send an output file or several output files by email, on the **Electronic reporting destination** page, on the **File destination** FastTab, select a component or group of components in the grid, and then select **Settings**. In the **Destination settings** dialog box that appears, on the **Email** tab, set the **Enabled** option to **Yes**. You can then specify email recipients, and edit the subject and body of the email message. You can either set up constant text for the email subject and body, or use ER [formulas](#) to dynamically create email texts.

You can configure email addresses for ER in two ways. The configuration can be completed in the same way that the Print Management feature completes it, or you can resolve an email address by using a direct reference to the ER configuration through a formula.

Email address types

If you select **Edit** next to the **To** or **Cc** field in the **Destination settings** dialog box, the **Email to** dialog box appears. Select **Add**, and then select the type of email address to use. Two types are currently supported: **Print Management email** and **Configuration email**.

Print Management email

If you select **Print Management email** as the email address type, you can enter fixed email addresses in the **Email to** dialog box by setting the following fields:

- In the **Email source** field, select **None**.
- In the **Additional email addresses, separated by ";"** field, enter the fixed email addresses.

Alternatively, you can obtain email addresses from the contact details of the party that you generate an outbound document for. To use email addresses that aren't fixed, in the **Email source** field, select the **role** of the party for a file destination. The following roles are supported:

- Customer
- Vendor
- Prospect
- Contact
- Competitor
- Worker
- Applicant
- Prospective vendor

- Disallowed vendor

For example, to configure an email destination for an ER format that is used to process vendor payments, select the **Vendor** role.

After you select the desired role, select the **Bind** button (chain symbol) next to the **Email source account** field to open the [Formula designer](#) page. You can then use this page to configure a formula that returns, at runtime, the account number of the party that is assigned to the configured role from the processed document to the email destination.

NOTE

Formulas are specific to the ER configuration.

On the **Formula designer** page, in the **Formula** field, enter a document-specific reference to a supported role. Instead of typing the reference, in the **Data source** pane, find and select the data source node that represents an account of the configured role, and then select **Add data source** to update the formula. For example, if you configure the email destination for the **ISO 20022 Credit Transfer** configuration that is used to process vendor payments, the node that represents a vendor account is

```
'$PaymentsForCoveringLetter'.Creditor.Identification.SourceID
```

The screenshot shows the 'Destination settings' dialog box in Microsoft Dynamics 365 Finance and Operations. The 'Email to' section is selected, and the 'Vendor' role is chosen from the 'Email source' dropdown. The 'Email source account' and 'Company of email source' fields are empty. The 'To' field is empty with an 'Edit' button next to it. The 'OK' and 'Cancel' buttons are at the bottom right.

If the account numbers of the configured role are unique for the whole instance of Microsoft Dynamics 365 Finance, the **Company of email source** field in the **Email to** dialog box can remain blank.

Alternatively, you might have a situation where different parties in the [Global address book](#) have been registered in different companies ([legal entities](#)) in such a way that they all use the same account number to fill the configured role. In this case, account numbers for the configured role aren't unique for the whole Finance instance. Therefore, to explicitly select a party, you can't specify only an account number. You must also specify the company that the party has been registered in the scope of to fill the configured role. Select the **Bind** button (chain symbol) next to the **Company of email source** field in the **Email to** dialog box to open the [Formula designer](#) page. You can then use this page to configure a formula that returns, at runtime, the code of the company that the desired source must be found in the scope of.

TIP

If you must use the company code to run an ER format, but the ER format doesn't provide any data source that the company code can be obtained from, configure the `GetCurrentCompany()` formula by using the built-in `GETCURRENTCOMPANY` ER function.

NOTE

Formulas are specific to the ER configuration.

To specify the type of email addresses that must be used at runtime, in the **Email to** dialog box, select **Edit** next to the **To** field to open the **Assign email address** drop-down dialog box. Then set the following fields:

- In the **Purpose** field, select the desired purposes. Only email addresses of the selected purposes from contacts of the discovered party will be used.
- Set the **Primary contact** option to **Yes** to use an email address that is configured for the discovered party as the primary email address.

NOTE

If purposes are selected in the **Purpose** field and the **Primary contact** option is set to **Yes** at the same time, every email that satisfies at least one configured criterion will be used at runtime.

Configuration email

Select **Configuration email** as the email address type if the configuration that you use has a node in the data sources that returns either a single email address or multiple email addresses that are separated by semicolons (;). You can use [data sources](#) and [functions](#) in the formula designer to get a correctly formatted email address or correctly formatted email addresses that are separated by semicolons. For example, if you use the **ISO 20022 Credit Transfer** configuration, the node that represents the primary email address of a vendor from the vendor contact details that the covering letter should be sent to is

```
'$PaymentsForCoveringLetter'.Creditor.ContactDetails.Email
```

Group format components

To group format components, on the **Electronic reporting destination** page, on the **File destination** FastTab, select the components in the grid, and then select **Group**.

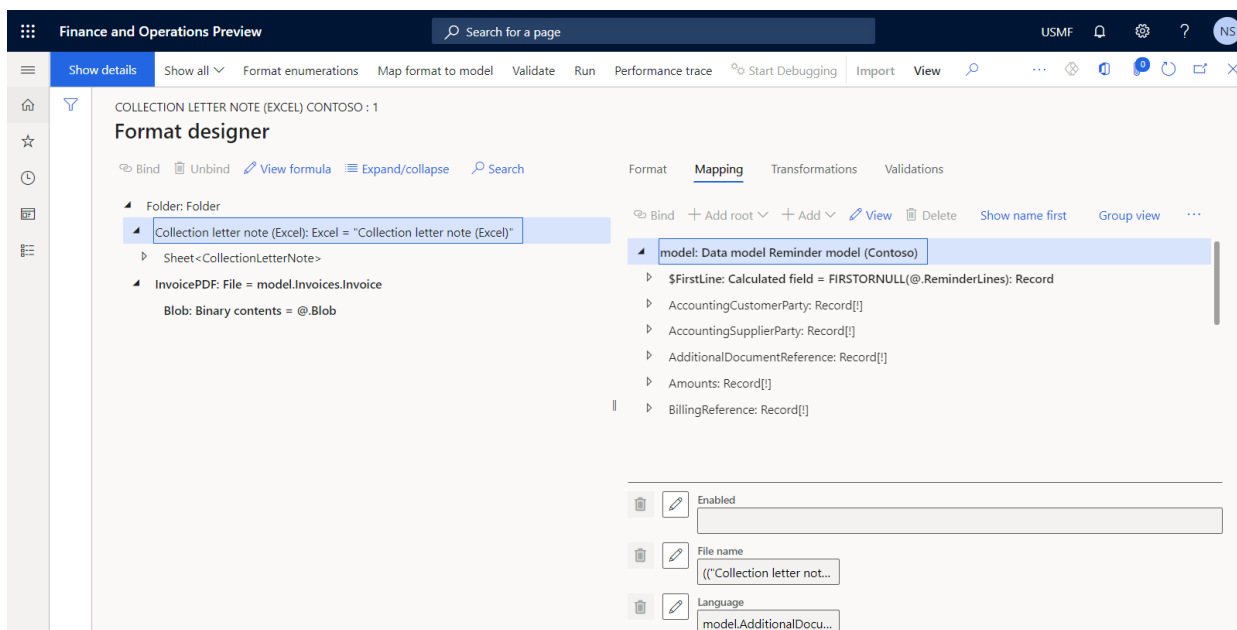

Email is the only previously configured destination that is still available for the selected components. No other previously configured destinations are available, because they are considered unsupported for a group of components. You will be notified about these changes as appropriate.

The record that you previously added is considered the header of the group that is created. This header record holds the email destination settings for the group. Other records are group members that will use the email destination settings of the group's header record.

To ungroup format components, on the **File destination** FastTab, select a record that belongs to the group, and then select **Ungroup**.

- If you select a header record, the whole group will be ungrouped.
- If you select a member record, and it's the last member record in a group, the whole group will be ungrouped.
- If you select a member record that isn't the last member record in a group, that record will be excluded from the current group.

The following illustration shows the structure of an ER format that was configured to produce a zipped outbound file that contains a collection letter note and appropriate customer invoices in PDF format.

The following illustration shows the process, as described in this topic, of grouping individual components and enabling the **Email** destination for the new group, so that a collection letter note is sent together with appropriate customer invoices as email attachments.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

File destination

2/18/2021 • 2 minutes to read • [Edit Online](#)

You can configure a file destination for each FOLDER or FILE component of an Electronic reporting (ER) format that is configured to generate outbound documents. Based on the setting of the destination, a generated document is available for download from the web browser.

On the **Destination settings** page, if you set **Enabled** to **Yes**, an open or save dialog box opens when the configuration has finished running.

Power BI destination

2/18/2021 • 2 minutes to read • [Edit Online](#)

You can configure a Microsoft Power BI destination for each folder or file component of an Electronic reporting (ER) format that is configured to generate outbound documents. Based on the setting of the destination, a generated document is stored in a previously configured SharePoint folder.

Set **Enabled** to **Yes** to use your ER configuration to arrange the transfer of data from your Dynamics 365 Finance instance to Microsoft Power BI services. The transferred files are stored on a Microsoft SharePoint Server instance that must be configured for that purpose. For more information, see [Configure Electronic reporting \(ER\) to pull data into Power BI](#).

Additional resources

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Printer destination

2/18/2021 • 2 minutes to read • [Edit Online](#)

You can send a generated document directly to a network printer for direct printing.

Prerequisites

Before you begin, you must install and configure the Document Routing Agent, and then register the network printers. For more information, see [Install the Document Routing Agent to enable network printing](#).

Make the Printer destination available

To make the **Printer** destination available in the current instance of Microsoft Dynamics 365 Finance, go to the **Feature management** workspace, and turn on the following features, in this order:

1. Convert Electronic Reporting outbound documents from Microsoft Office formats to PDF
2. Document Routing Agent as Electronic Reporting destination for outbound documents

Feature name ↑	Enable date	Feature added ↓	Module
Extended lookup of ER format configurations allowing to inquire the Global repository		1/14/2020	Organization administration
Convert Electronic Reporting outbound documents from Microsoft Office formats to PDF		1/6/2020	Organization administration
Document Routing Agent as Electronic Reporting destination for outbound documents		1/6/2020	Organization administration
Enable usage of EPPlus library in Electronic reporting framework		1/6/2020	Organization administration
Office-like UI experience for Business document management	1/15/2020	11/11/2019	Organization administration
Business document management	1/15/2020	6/3/2019	Organization administration

Document Routing Agent as Electronic...

Feature added 1/6/2020
Organization administration
[Learn more](#)

You cannot enable this feature. Please first enable the "Convert Electronic Reporting outbound documents from Microsoft Office formats to PDF" feature.

Description
Enable Document Routing Agent in Electronic Reporting framework to support network printing scenarios for outbound documents. This is a preview feature and is subject to the same terms of use described in the "Supplemental Terms of Use for Microsoft Dynamics 365 Previews" (<https://go.microsoft.com/fwlink/?linkid=2105274>).

Comments

[Schedule](#) [Enable now](#)

Applicability

The **Printer** destination can be configured only for file components that are used to generate output in either printable PDF format (PDF Merger or PDF file format elements) or Microsoft Office Excel/Word format (Excel file). When output is generated in PDF format, it's sent to a printer. When output is generated in Microsoft Office format, it's automatically converted to PDF format and then sent to a printer.

Limitations

This feature is a preview feature and is subject to the terms of use that are described in [Supplemental Terms of Use for Microsoft Dynamics 365 Previews](#).

The **Printer** destination is implemented only for cloud deployments.

Use the Printer destination

1. Set the **Enabled** option to **Yes** to send a generated document to a printer.
2. In the **Printer** name field, select the required network printer.
3. Set the **Save in print archive?** option to **Yes** to store the generated output in the print archive, so that it's available for further printing. To access archived output later, go to **Organization administration** > **Inquiries and reports** > **Report archive**.

NOTE

The **Convert to PDF** option doesn't have to be turned on when you configure the **Printer** destination. The PDF conversion for printing purposes will occur even if the option is turned off.

To use a specific [page orientation](#) when you print an outbound document in Excel format, you must turn on the **Convert to PDF** option. When you set the **Convert to PDF** option to **Yes**, the **Page orientation** field becomes available. In the **Page orientation** field, you can select a page orientation.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Screen destination

2/18/2021 • 2 minutes to read • [Edit Online](#)

You can configure a screen destination for each folder or file component of an Electronic reporting (ER) format that is configured to generate outbound documents. Based on the setting of the destination, a generated document is opened for preview in a separate browser tab.

If you set **Enabled** to **Yes**, a preview of the output is created. You can view some file types, such as XML, TXT, or PDF, directly in a browser window. For other file types, such as Microsoft Excel or Word, the Microsoft Office Online service is used.

ER Configure destinations

2/18/2021 • 2 minutes to read • [Edit Online](#)

This procedure demonstrates how to set up and use different destinations for Electronic reporting (ER) output components, such as a folder or a file. The demo data company used to create this procedure is DEMF. Germany is the country\region of the legal entity's primary address, however you can use any legal entity for this procedure.

The format used in this example is ISO20022 Credit transfer, but you can use any format that you have already imported. Note, this procedure is an example of a single file and a single destination setup. More information about Electronic reporting destination management can be found in the Dynamics 365 Finance Help.

1. Go to Organization administration > Electronic reporting > Electronic reporting destination.
2. Click New to create a new set of destinations for a format.
3. In the Reference field, select a format for which you want to configure destinations.
 - If you don't have a value to select, it means that you have not imported any Electronic reporting format configurations. You must import a format configuration before setting up destinations.
4. Click New to create a new file destination.
 - Note, you can create one file destination for each output component of the same format, such as a folder or a file. You will be able to enable and disable destinations separately in the settings.
5. In the Name field, enter the user-friendly name of output component.
 - We recommend that you use meaningful names, such as "Payment file" or "Control report". These names will be presented to users at configuration runtime along with the destination settings.
6. In the File name, select a file or folder that is specific to the format.
7. Click Settings.
8. Select Yes in the Enabled field.
 - The Enabled check box on each tab enables and disables each destination separately. In this example, you'll enable sending an output file to a mail recipient when the file is generated.
9. Click Edit, to set up email recipients.
10. Click Add.
11. Click Print Management email.
12. In the Email source field, select an option.
 - You can select different email source types, such as a customer or a vendor type. This defines the type of argument that will be returned by the Email source account formula. The Email source account formula, described in a following step, is the place where you bind an email source. Select Vendor if your formula will return a vendor account. Use Vendor if you are using the ISO 20022 Credit Transfer configuration example.
13. Click Email source bind button.
14. In the Formula, enter a document-specific reference to a party type that you selected earlier.
 - Instead of typing, you can find a data source node that represents the party account, and click the Add data source button to update the formula. For example, if you use the ISO 20022 Credit Transfer configuration, the node representing a vendor account is '\$PaymentsForCoveringLetter'.Creditor.Identification.SourceID. Otherwise, enter any string value, such as "DE-001", to save a formula.
15. Click Save.
16. Close the page.
17. Click Edit to configure contact details for the party.

18. Select Yes in the Primary contact field.

- You may use different options to indicate what contact type of the party should be used as an email address for this destination. We use primary contact in this example.

19. Click OK.

20. Click OK.

21. In the Subject field, type a value.

22. Click OK.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Allow users to set up an ER format reference inquiring a format from the Global repository

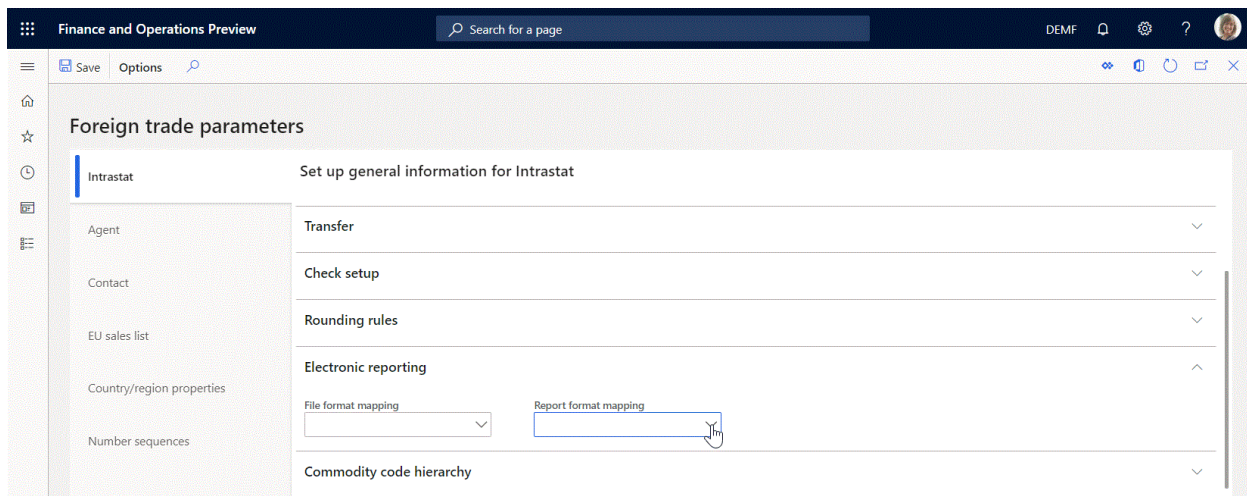

2/18/2021 • 4 minutes to read • [Edit Online](#)

You can use the [Electronic reporting](#) (ER) framework to configure [formats](#) for outbound documents in accordance to the legal requirements of various countries/regions. You can also use the ER framework to configure [formats](#) for parsing inbound documents and use the information from those documents to append or update application data. Each of these formats can be used in your Dynamics 365 Finance instance for handling inbound or outbound business documents as part of a certain business process.

Usually, you must specify what ER format must be used in a certain business process. To do that, select a single ER format in a lookup field that is configured as part of business process-specific parameters. These lookup fields are usually implemented by using the appropriate API of the ER framework. For more information, see [ER framework API - code to display a format mapping lookup](#).

For example, when you configure [foreign trade parameters](#), you need to set up the references to individual ER formats that will be used to generate the Intrastat declaration and the Intrastat declaration control report. The screenshots below show how the ER formats lookup field looks like in the **Foreign trade parameters** page.

If the current Finance instance contains no Intrastat business process-related ER formats, this lookup field will be empty.

If the current Finance instance contains Intrastat business process related ER formats, this lookup field offers the ER formats.

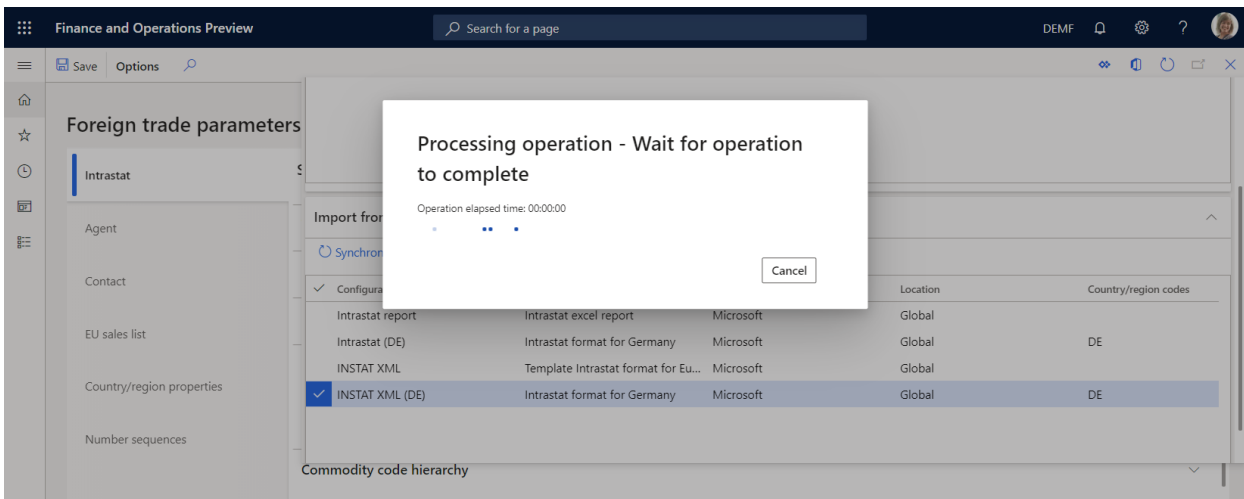

This lookup offers only the ER formats that have already been imported to the current Finance instance. To [import](#) ER solutions to the current Finance instance, you need to have permissions to run the appropriate function of the ER framework that supports the [lifecycle](#) of ER solutions that contain ER formats.

Starting in the Finance version 10.0.9 (April 2020 release), the user interface of the ER format lookup that is implemented by using the ER framework API, has been extended. You can still select the existing ER formats, which on the **Select format configuration** FastTab. In addition, the extended lookup offers the new option to search the Global repository (GR) to locate specific ER formats. All ER formats of the GR are offered on the **Import from Global repository** FastTab.

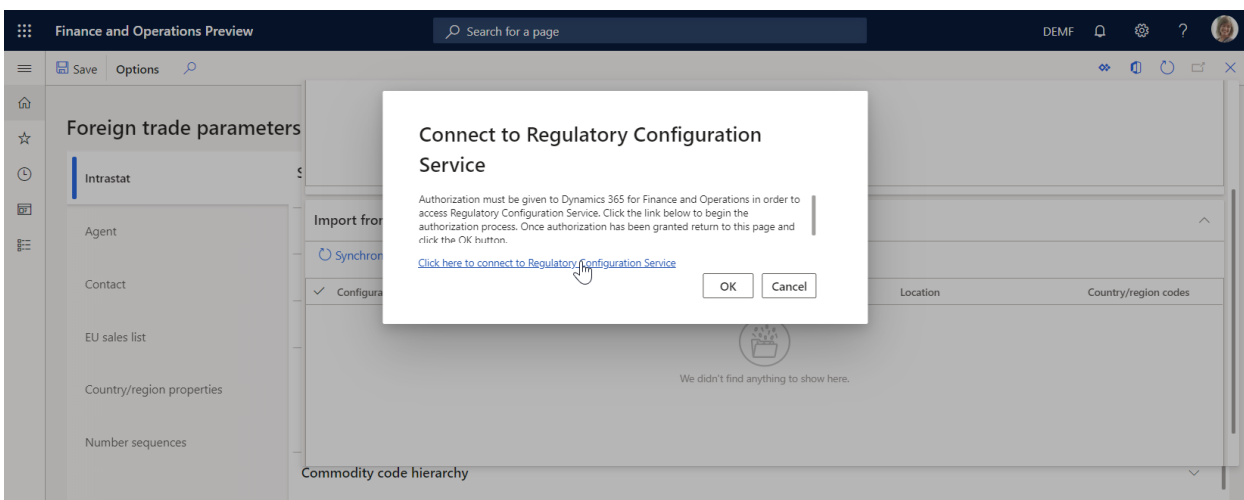

Similar to the **Select format configuration** FastTab, the **Import from Global repository** FastTab shows only the ER formats that are applicable to the business process for which an ER format is selected in this lookup field. In this example, the generation of Intrastat declaration. The ER format is applicable for the company to which the user is currently signed in, depending on the company country context.

When you select an ER format on the **Import from Global repository** FastTab, the selected ER format [configuration](#) is imported from the GR to the current Finance instance.

Then, if the import completes successfully, the reference to the imported ER format is stored in this lookup field. When you access the GR for the first time, you need to follow the link provided to sign up for the [Regulatory Configuration Service \(RCS\)](#) that is used to manage access to the GR storage.

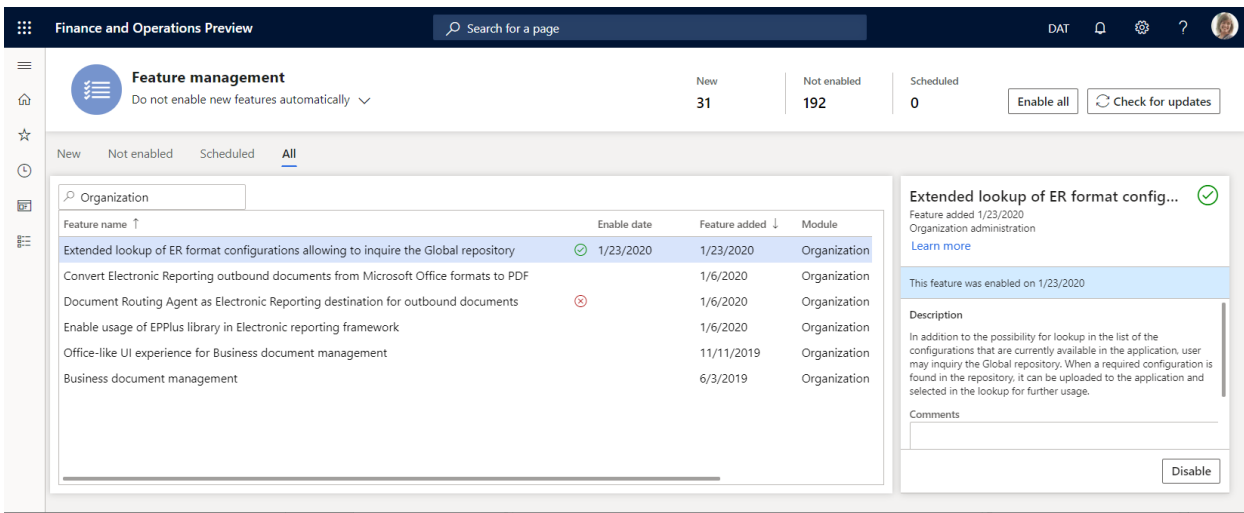

By default, the **Import from Global repository** FastTab presents the list of ER formats from the temporary storage that is automatically created based on the GR content for performance improvements. This happens when the **Import from Global repository** FastTab is opened the first time, which may take several seconds.

If you do not see the required ER format in the **Import from Global repository** FastTab, but you are sure that this ER format is stored in the GR, select the **Synchronize** option. This option will update the temporary storage and synchronize it with the current content of the GR.

Feature activation

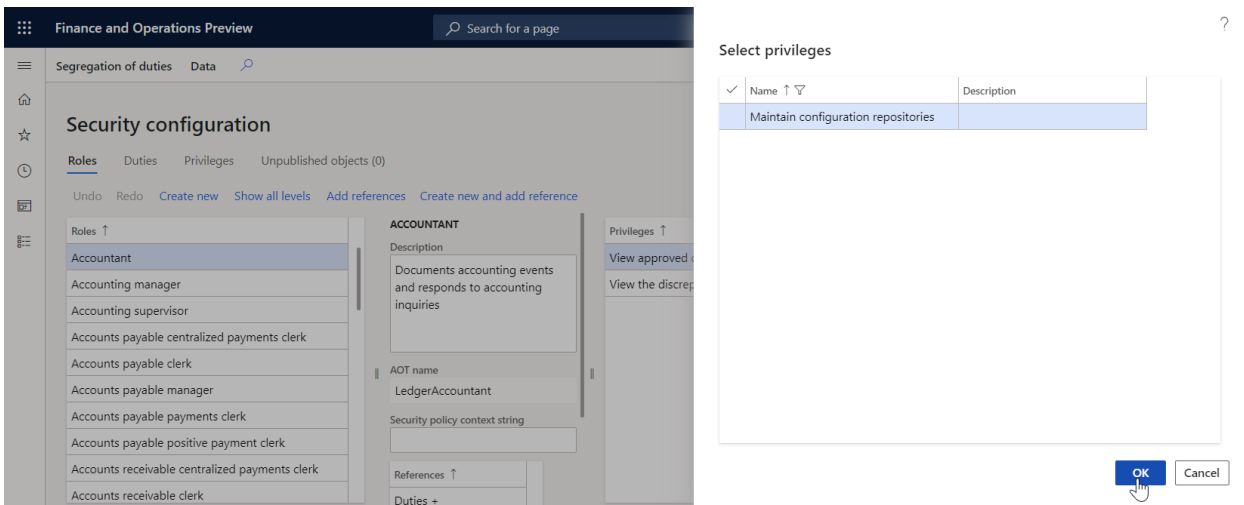

The availability of this functionality is controlled by the feature **Extended lookup of ER format configurations allowing to inquire the Global repository** in the **Feature management**. This feature is enabled by default.

Security considerations

The **Maintain configuration repositories (ERMaintainSolutionRepositories)** privilege controls access to the GR for a user opening the ER format lookup with the enabled **Import from Global repository** FastTab. To allow users to access the GR content from the ER format lookups, you need to change the security settings by granting the **ERMaintainSolutionRepositories** privilege to users either directly or by using already assigned roles and duties.

The following screenshot shows how this privilege can be granted to users who are assigned to the **Accountant** role. This role allows users to configure foreign trade parameters and set up references to the ER formats in the **File format mapping** and **Report format mapping** fields on the **Foreign trade parameters** page.

Limitations

Access to the GR in the ER format lookup is currently only supported for the selection of ER formats that are used to generate outbound documents.

Frequently asked questions

Why can't I access the Global repository from the ER format lookup?

If you have enabled the **Extended lookup of ER format configurations allowing to inquire the Global repository** feature on the **Feature management** page, but users can't see ER formats on the **Import from Global repository** FastTab and the **Synchronize** option is visible but disabled, make sure that the **Maintain configuration repositories (ERMaintainSolutionRepositories)** privilege has been granted to the user. Contact your system administrator to receive this privilege.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Trace generated report results and compare them with baseline values

2/18/2021 • 8 minutes to read • [Edit Online](#)

You can trace the results of Electronic reporting (ER) formats that generate outgoing electronic documents. When trace generation is turned on (by using the **Run in debug mode** ER user parameter), a new trace record is generated in the ER format execution log every time that an ER report is run. The following details are stored in each trace that is generated:

- All warnings that were generated by validation rules
- All errors that were generated by validation rules
- All generated files that are stored as attachments of the trace record

You can store individual baseline application files for any ER format. Files are considered baseline files when they describe the expected results of reports that are run. If a baseline file is available for an ER format that is run while trace generation is turned on, the trace stores, in addition to the details that were mentioned earlier, the result of the comparison of the generated electronic document with the baseline file. In one click, you can also get the generated electronic document and its baseline file in a single zip file. You can then do detailed comparison by using an external tool such as WinDiff.

You can evaluate the trace to analyze whether the electronic documents that are generated include the expected content. You can do this evaluation in a user acceptance testing (UAT) environment when the code base has been changed (for example, when you migrated to a new instance of the application, installed hotfix packages, or deployed code modifications). In this way, you can make sure that the evaluation doesn't affect the execution of ER reports that are used. For many ER reports, the evaluation can be done in unattended mode.

To learn more about this feature, play the **ER Generate reports and compare results (Part 1)** and **ER Generate reports and compare results (Part 2)** task guides, which are part of the **7.5.4.3 Test IT services/solutions (10679)** business process and can be downloaded from the [Microsoft Download Center](#). These task guides walk you through the process of configuring the ER framework to use baseline files to evaluate generated electronic documents.

Example: Trace generated report results and compare them with baseline values

This procedure explains how to configure the ER framework to collect information about ER format executions and then evaluate the results of those executions. As part of that evaluation, generated documents are compared with their baseline files. In this example, you will create the required ER configurations for the Litware, Inc. sample company. This procedure is intended for users who have the System administrator or Electronic reporting developer role assigned to them. These steps can be completed by using any data set.

To complete the steps in this example, you must first complete the steps in [Create configuration providers and mark them as active](#).

1. Go to **Organization administration > Workspaces > Electronic reporting**.
2. On the **Localization configurations** page, in the **Configuration providers** section, verify that the configuration provider for the Litware, Inc. sample company is listed, and that it's marked as **Active**. If you don't see this configuration provider, follow the steps in [Create configuration providers and mark them as active](#).

Configure document management parameters

1. Go to **Organization administration > Document management > Document types**, and create a new document type to store baseline files.
2. In the **Class** field, enter **Attach file**.
3. In the **Group** field, enter **File**.

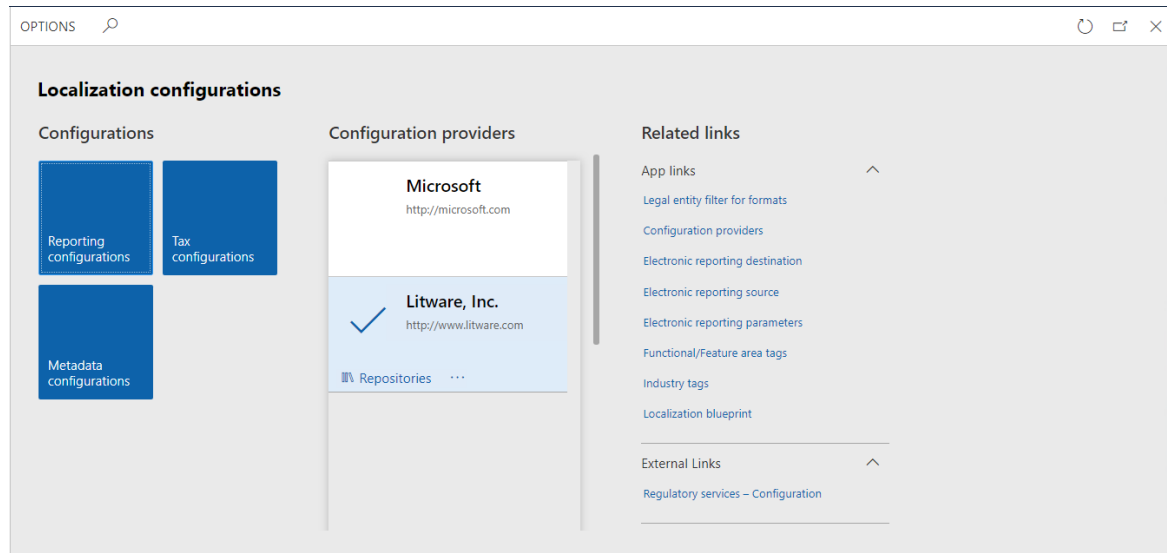

NOTE

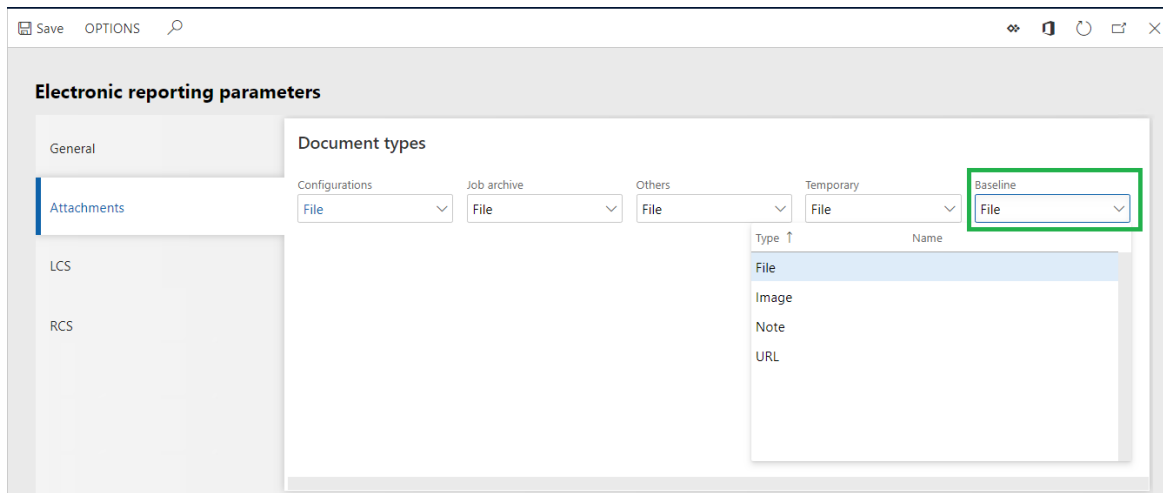

A new document type that has the same name must be configured for each data set where you plan to use the ER baseline feature.

Configure ER parameters to start to use the baseline feature

1. In the **Electronic reporting workspace**, in the **Related links** section, select **Electronic reporting parameters**.

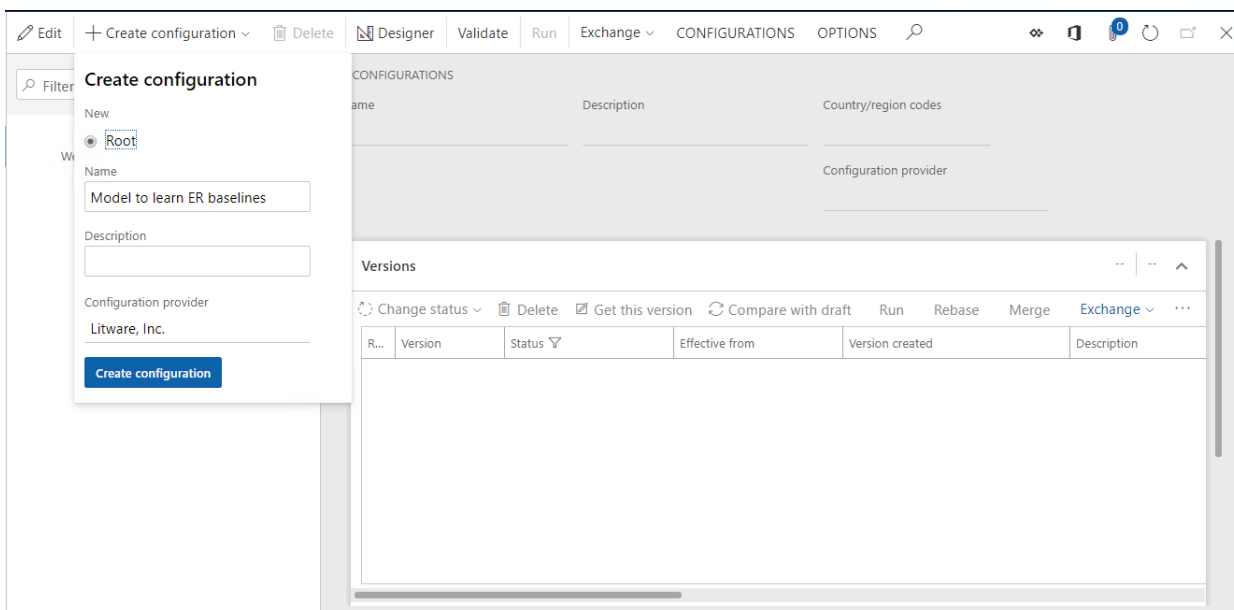

2. On the **Attachments** tab, in the **Baseline** field, enter or select the document type that you just created.

3. Select **Save**, and then close the **Electronic reporting parameters** page.

Add a new ER model configuration

1. In the **Electronic reporting workspace**, in the **Configurations** section, select the **Reporting configurations** tile.
2. On the **Action Pane**, select **Create configuration**.
3. In the drop-down dialog box, in the **Name** field, enter **Model to learn ER baselines**.
4. Select **Create configuration** to confirm the creation of a new ER data model entry.

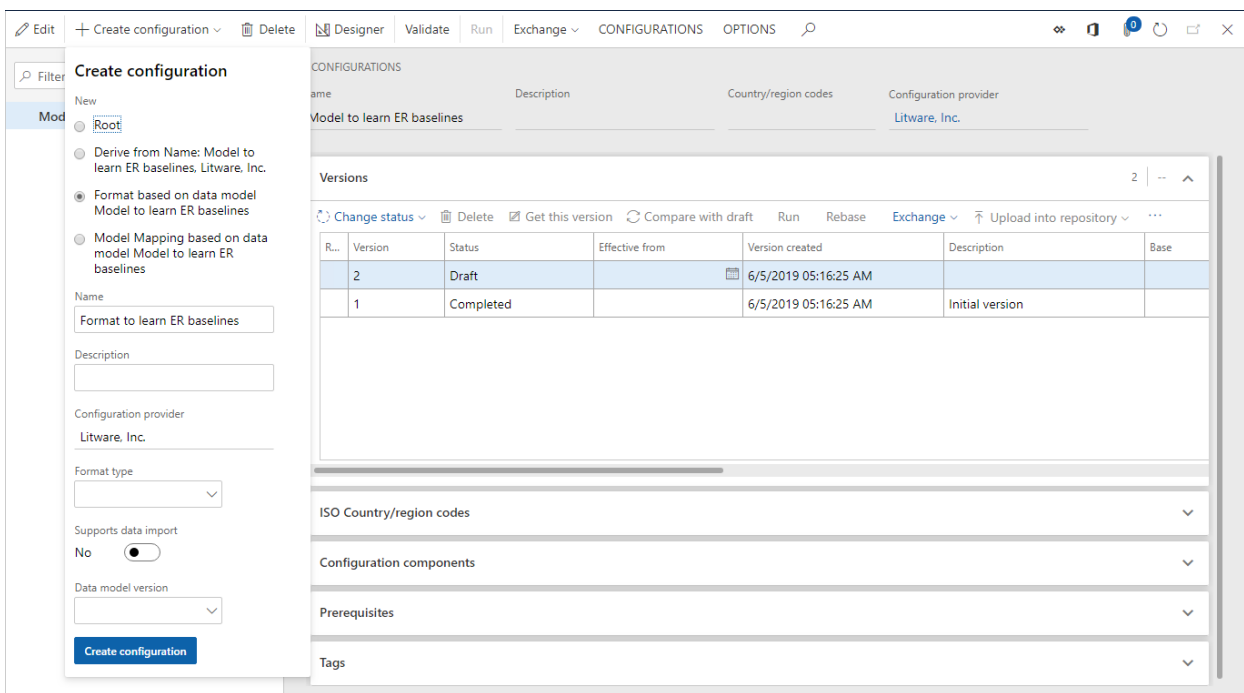

Design a data model

1. On the **Configurations** page, on the **Action Pane**, select **Designer**.
2. Select **New**.
3. In the drop-down dialog box, in the **Name** field, enter **Root**.
4. Select **Add**.
5. Select **Root reference**.
6. Select **OK**, and then select **Save**.
7. Close the **Model designer** page.
8. Select **Change status**.
9. Select **Complete**, and then select **OK**.

Add a new ER format configuration

1. On the **Configurations** page, on the Action Pane, select **Create configuration**.
2. In the drop-down dialog box, in the **New** field group, select **Format based on data model Model to learn ER baselines**.
3. In the **Name** field, enter **Format to learn ER baselines**.
4. Select **Create configuration** to confirm the creation of a new ER format entry.

Design a format

For this example, you will create a simple ER format to generate XML documents.

1. On the **Configurations** page, on the Action Pane, select **Designer**.
2. Select **Add root**.
3. In the drop-down dialog box, follow these steps:
 - a. In the tree, select **Common\File**.
 - b. In the **Name** field, enter **Output**.
 - c. Select **OK**.

4. Select **Add**.
5. In the drop-down dialog box, follow these steps:
 - a. In the tree, select **XML\Element**.
 - b. In the **Name** field, enter **Document**.
 - c. Select **OK**.
6. In the tree, select **Output\Document**.
7. Select **Add**.
8. In the drop-down dialog box, follow these steps:
 - a. In the tree, select **XML\Attribute**.
 - b. In the **Name** field, enter **ID**.
 - c. Select **OK**.

9. On the **Mapping** tab, select **Delete**.
10. Select **Add root**.
11. In the drop-down dialog box, in the tree, select **General\User input parameter**, and then follow these steps:
 - a. In the **Name** field, enter **ID**.
 - b. In the **Label** field, enter **Enter ID**.
 - c. Select **OK**.
12. In the tree, select **Output\Document\Id**.
13. Select **Bind**, and then select **Save**.

Based on the designed structure, the configured format will generate an XML file. This XML contains the Root element that has the ID attribute that is set to the value that the user enters in the ER runtime dialog box.

Generate a new baseline file for a designed ER format

1. On the Configurations page, on the Versions FastTab, select Run.
2. In the Enter ID field, enter 1.
3. Select OK.

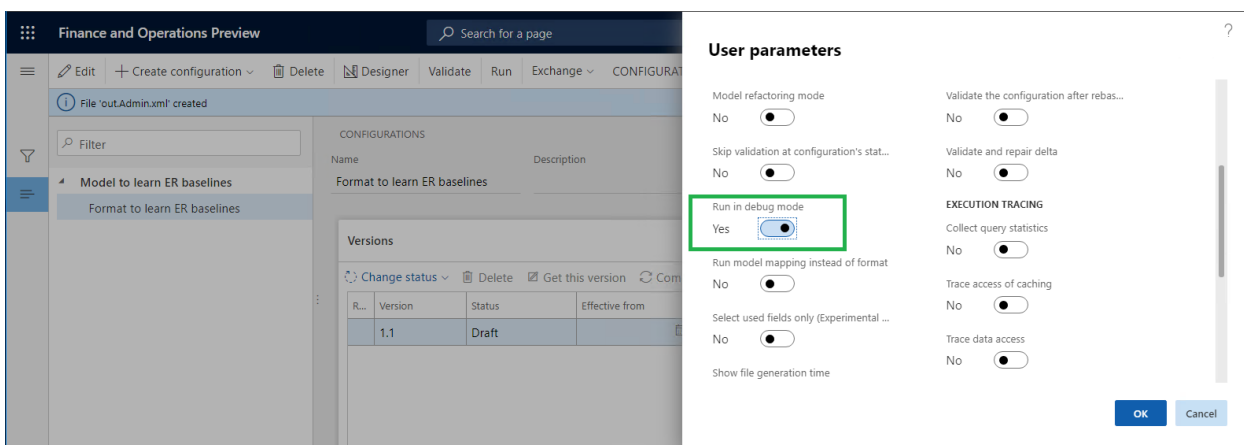

4. Save a local copy of the out.Admin.xml file that is generated, so that you can use it later as a baseline for this ER format.

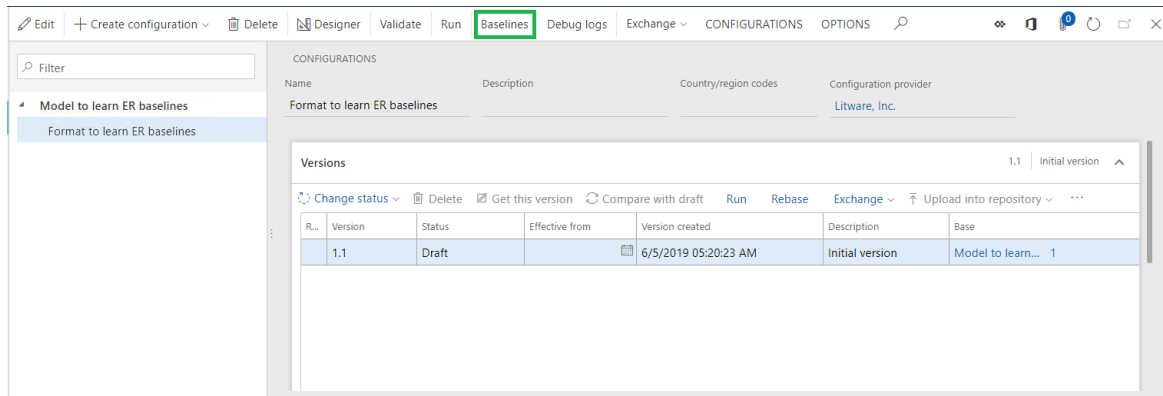

Configure ER parameters to use the baseline feature

1. On the Configurations page, on the Action Pane, on the Configurations tab, select User parameters.
2. Set the Run in debug mode option to Yes.
3. Select OK.

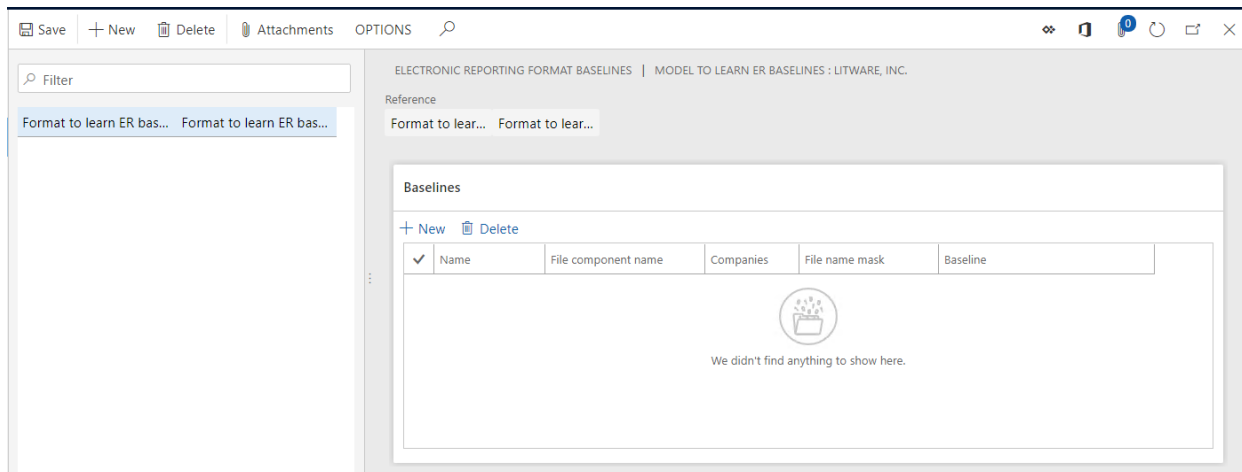

Add a new baseline for designed ER format

1. Go to **Organization administration > Electronic reporting > Configurations**.
2. On the Action Pane, select **Baselines**.

3. On the Action Pane, select **New**.
4. Select the **Format to learn ER baselines** ER format that you designed earlier.
5. Select **Save**.

The baseline is added for the **Format to learn ER baselines** format.

Configure a baseline rule for the added baseline

1. On the **Electronic reporting format baselines** page, on the Action Pane, select the **Attachments** button (the paper clip symbol).
2. On the Action Pane, select **New > File**. In the ER parameters, the **File** document type should have been previously selected as the document type that is used to store baseline files.
3. Select **Browse**, and select the **out.Admin.xml** file that was generated when you ran the configured ER format earlier.

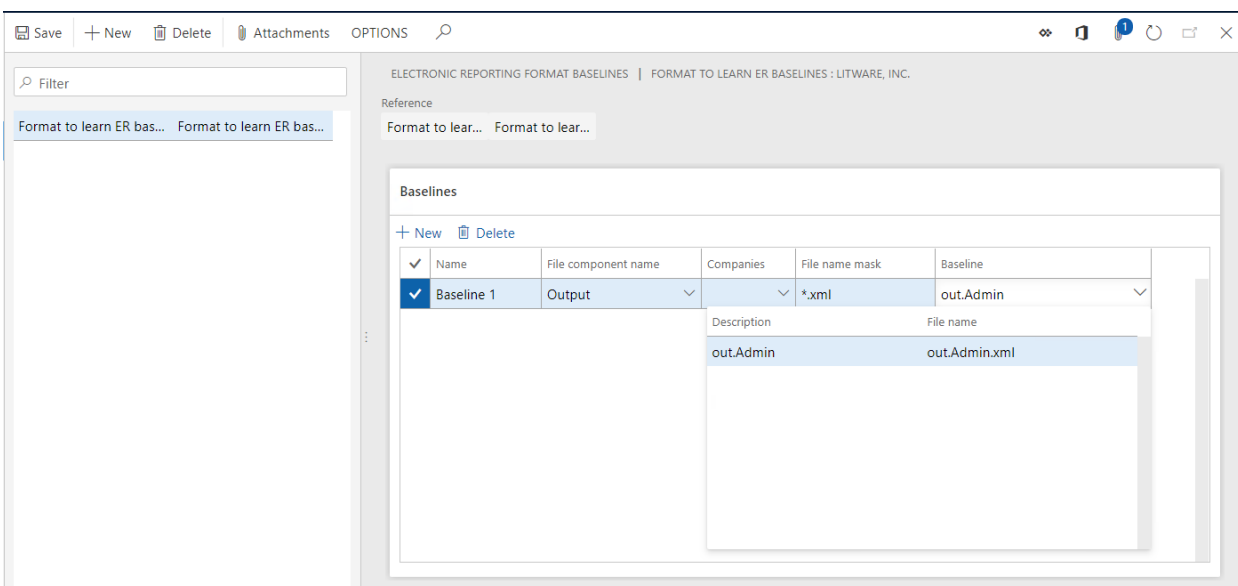

4. Close the **Attachments** page.
5. On the **Baselines** FastTab, select **New**.
6. In the **Name** field, enter **Baseline 1**.
7. In the **File component name** field, enter or select **Output**. This value indicates that the configured baseline will be compared with a file that is generated by using the **Output** format element.
8. In the **File name mask** field, enter ***.xml**.

NOTE

You can define the file name mask. When the file name mask is defined, the baseline record will be used to evaluate the generated output only when the name of the output file that is generated satisfies that mask.

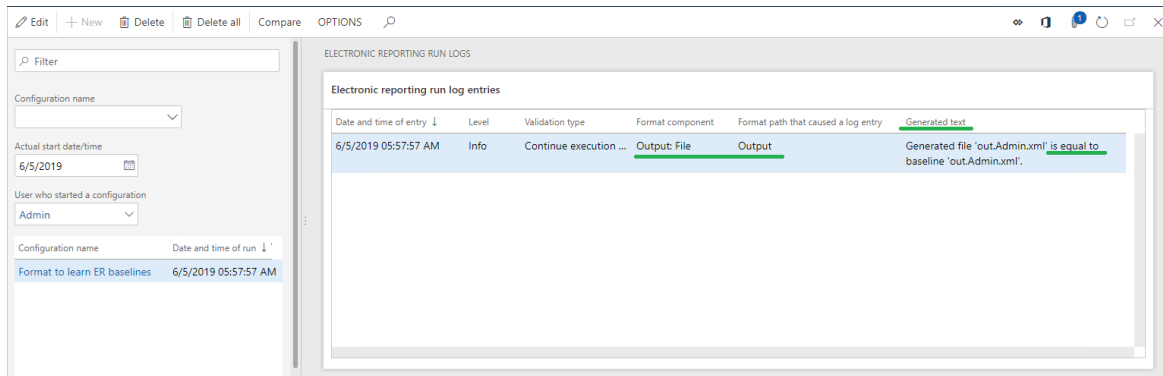

9. If the configured baseline should be used only when the **Format to learn ER baselines** ER format is run by users who are signed in to specific companies, select those companies in the **Companies** field.
10. In the **Baseline** field, enter or select the **out.Admin** attachment.
11. Select **Save**.

Run the designed ER format and review the log to analyze the results

1. Go to **Organization administration > Electronic reporting > Configurations**.

- In the tree, expand **Model to learn ER baselines**, and then select **Model to learn ER baselines\Format to learn ER baselines**.
- On the **Versions** FastTab, select **Run**.
- In the **Enter ID** field, enter **1**.
- Select **OK**.
- Go to **Organization administration > Electronic reporting > Configuration debug logs**.

NOTE

The execution log contains information about the results of the comparison of the generated file with the configured baseline. In this example, the log indicates that the generated file and the baseline are equal.

- Select **Delete all**.

Run the designed ER format and review the log to analyze the results

- Go to **Organization administration > Electronic reporting > Configurations**.
- In the tree, expand **Model to learn ER baselines**, and then select **Model to learn ER baselines\Format to learn ER baselines**.
- On the **Versions** FastTab, select **Run**.
- In the **Enter ID** field, enter **2**.
- Select **OK**.
- Go to **Organization administration > Electronic reporting > Configuration debug logs**.

NOTE

The execution log contains information about the results of the comparison of the generated file with the configured baseline. In this example, the log indicates that the generated file and the baseline differ.

7. Select **Compare**.

NOTE

The generated file and the baseline file are offered as a zip file. You can use external comparison tools such as WinDiff to compare the files and review the differences.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Improvements in tracing the results of generated ER reports and comparing them with baseline values

2/18/2021 • 7 minutes to read • [Edit Online](#)

This topic describes the first set of improvements that have been made to the baseline feature of the Electronic reporting (ER) framework. These improvements are available in Microsoft Dynamics 365 for Finance and Operations version 10.0.3 (June 2019) and later.

Automate the setting of baseline rules

The [Trace generated report results and compare them with baseline values](#) topic explains how to configure the ER framework to collect information about ER format executions and evaluate the results of those executions. The example in this topic shows the steps that must be completed.

Here are some of the steps:

- Run an ER format to generate an outbound file, and store the file locally.
- Add the locally stored file as an attachment of the baseline that was added for an ER format.
- Configure the baseline rule for the added baseline. This configuration includes the following steps:
 - Specify an ER format element that is used to generate an outbound file.
 - Select the attachment that refers to the generated outbound file.

NOTE

These steps must be done manually, even though the new ER capabilities enable them to be automated. To learn more about this feature, complete the following example.

Example: Automate the setting of baseline rules

To complete the steps in this example, you must first complete the steps in the example in the [Trace generated report results and compare them with baseline values](#) topic, up through the "Add a new baseline for a designed ER format" section.

Review added baseline

1. Go to **Organization administration > Electronic reporting > Configurations**.
2. Select **Baselines**.

NOTE

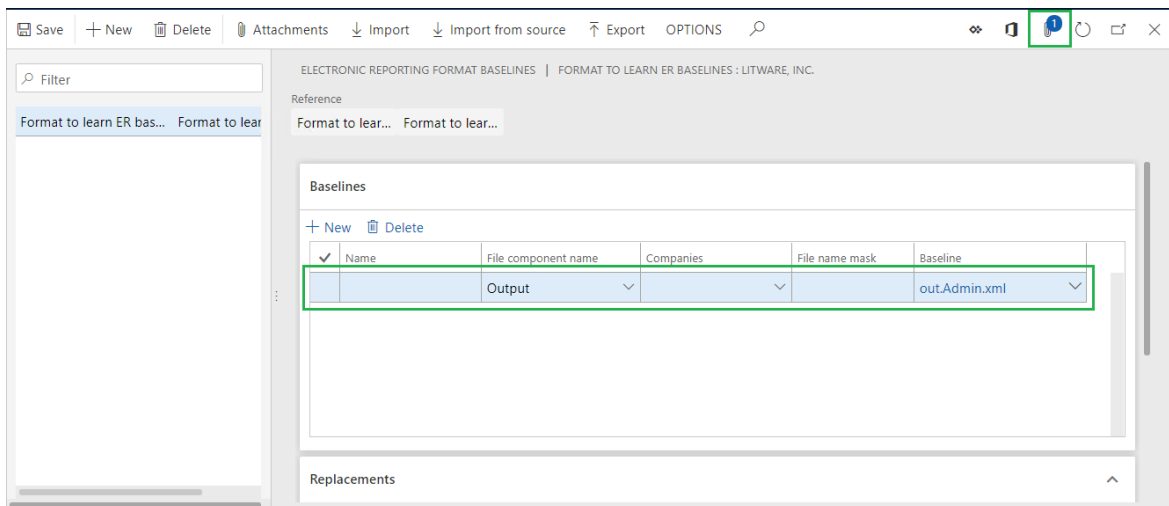

The **Baselines** button on the Action Pane is available only when the **Run in debug mode** ER user parameter is turned on for the current company.

The baseline has been added for the selected **Format to learn ER baselines** format, but the baseline rules haven't yet been added for this baseline.

Make a new baseline rule

1. Go to **Organization administration > Electronic reporting > Configurations**.
2. In the tree, expand **Model to learn ER baselines**.
3. In the tree, select **Model to learn ER baselines\Format to learn ER baselines**.
4. On the **Versions** FastTab, select **Run**.
5. In the **Enter Id** field, enter **1**.
6. Set the **Make baseline files** option to **Yes**.
7. Select **OK**.
8. Select **Baselines**.

The generated outbound file has been automatically attached to the baseline of the executed ER format. The baseline rule has been automatically added to this baseline and also contains the reference to the attached file.

9. In the **Name** field, enter **Baseline 1**.
10. In the **File name mask** field, enter **.xml**.
11. Select **Save**.

Run the format

You're now ready to complete the remaining steps in the example in the [Trace generated report results and compare them with baseline values](#) topic, starting from the "Run the designed ER format and review the log to

analyze the results" section.

NOTE

When you delete the automatically added baseline rule on the **Baselines** FastTab, the referenced attachment isn't automatically deleted.

Configure the baseline so that it ignores constantly changing parts of the ER output

When an ER format has been designed to contain information that is changed when the format is run, the format must be required to use the ER baseline feature to compare the generated results with baseline values. For example, the information might be the processing date and time or the unique identifier of a generated document in different formats (globally unique identifier [GUID], and so on). The new ER capabilities let you configure the baseline rule so that it ignores changeable elements of an ER format when the format is run with the purpose of comparing baseline values with the results of the format's execution. To learn more about this feature, complete the following example.

Example: Configure the baseline so that it ignores constantly changing parts of the ER output

To complete the steps in this example, you must first complete the steps in the example in the [Trace generated report results and compare them with baseline values](#) topic.

Modify a configured ER format

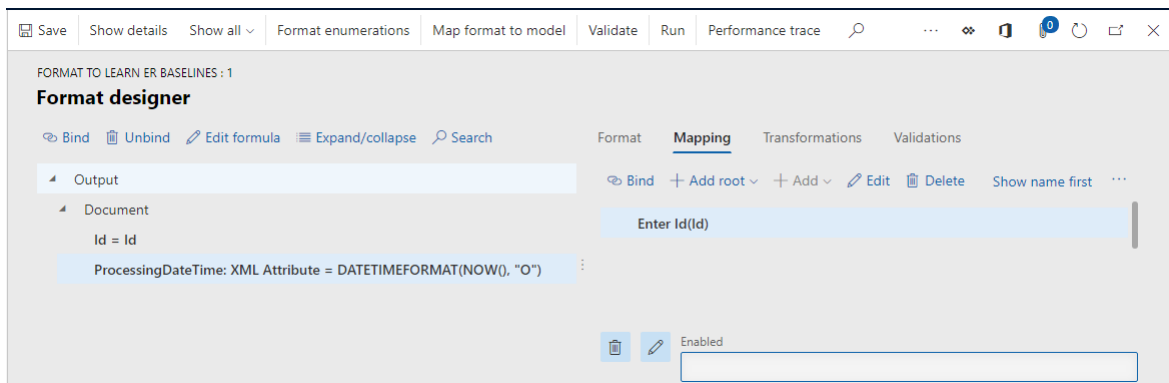

1. Go to **Organization administration > Electronic reporting > Configurations**.
2. In the tree, expand **Model to learn ER baselines**.
3. In the tree, select **Model to learn ER baselines\Format to learn ER baselines**.
4. Select **Designer**.
5. In the tree, select **Output\Document**.
6. Select **Add**.
7. In the drop-down dialog box, in the tree, select **XML\Attribute**.
8. In the **Name** field, enter **ProcessingDateTime**.
9. Select **OK**.
10. On the **Mapping** tab, in the tree, select **Output\Document\ProcessingDateTime**.
11. Select **Edit formula**.
12. In the **Formula** field, enter the following expression: `DATETIMEFORMAT(NOW(), "O")`
13. Select **Save**, and then select **Test**.
14. Select **Test** again to retest the configured expression.

NOTE

The **Test result** tab shows that the configured expression returns a different date and time value whenever it's called.

15. Close the Formula designer page, and then select **Save**.

16. Close the Format designer page.

Remove an existing baseline rule

1. Go to **Organization administration > Electronic reporting > Configurations**.
2. Select **Baselines**.
3. In the list of baselines, select the baseline that is configured for the **Format to learn ER baselines** format.
4. On the **Baselines** FastTab, select **Delete** to remove the baseline rule that you configured earlier.

Define replacements for bindings of designed ER format

1. On the **Configurations** page, on the **Replacements** FastTab, select **Select components**.
2. In the format components tree, expand **Output**, expand **Output\Document**, and then select the check box for **Output\Document\ProcessingDateTime**.
3. Select **OK**.

The selected ER format component has been added to the list of components on the **Replacements** FastTab. When the base ER format is run in debug mode, the format's binding for each component will be replaced by the binding that is shown in the **Binding** column. To change the default binding for a component that is listed on the **Replacements** FastTab, select **Edit**.

Make a new baseline rule

Follow the steps in the "Example: Automate the setting of baseline rules" section earlier in this topic. A notification warns you that the outbound file has been generated by using baseline settings, and that a forced replacement of the format bindings has occurred.

Suppress warnings about the replacement of format bindings

By setting specific ER parameters, you can suppress notifications that warn about the replacement of format bindings. This suppression can be useful when format bindings are replaced in an unattended mode by using the Regression Suite Automation Tool. In this case, the warning can be considered a failure of the test case that is running.

1. On the **Configurations** page, on the Action Pane, on the **Configurations** tab, select **User parameters**.
2. Set the **Suppress baseline warnings** option to **Yes**, and then select **OK**.

Review the generated baseline file

1. Go to **Organization administration > Electronic reporting > Configurations**.
2. Select **Baselines**.
3. Select **Attachments**.

NOTE

The generated file contains the processing date and time text ("##") from the binding that was configured in the added baseline rule, not from the format's binding.

4. Close the **Attachments** page.

Run the designed ER format and review the log to analyze the results

1. Go to **Organization administration > Electronic reporting > Configurations**.
2. In the tree, expand **Model to learn ER baselines**.
3. In the tree, select **Model to learn ER baselines\Format to learn ER baselines**.
4. On the **Versions** FastTab select **Run**.
5. In the **Enter Id** field, type **1**.
6. Select **OK**.
7. Go to **Organization administration > Electronic reporting > Configuration debug logs**.

The execution log contains information about the results of the comparison of the generated file with the configured baseline. The log indicates that the generated file and the baseline are equal, even though the executed format contains the binding to enter a constantly changing date and time value in the outbound file.

NOTE

Although the outbound file has been generated by using baseline settings that force the replacement of the format's bindings, you don't receive any warnings about the replacement.

Exchange baseline settings between environments

Export baseline settings

The new ER capabilities let you export baseline settings for the selected ER format from the current environment and store them as XML files.

To export baseline settings, on the **Electronic reporting format baselines** page, select **Export**.

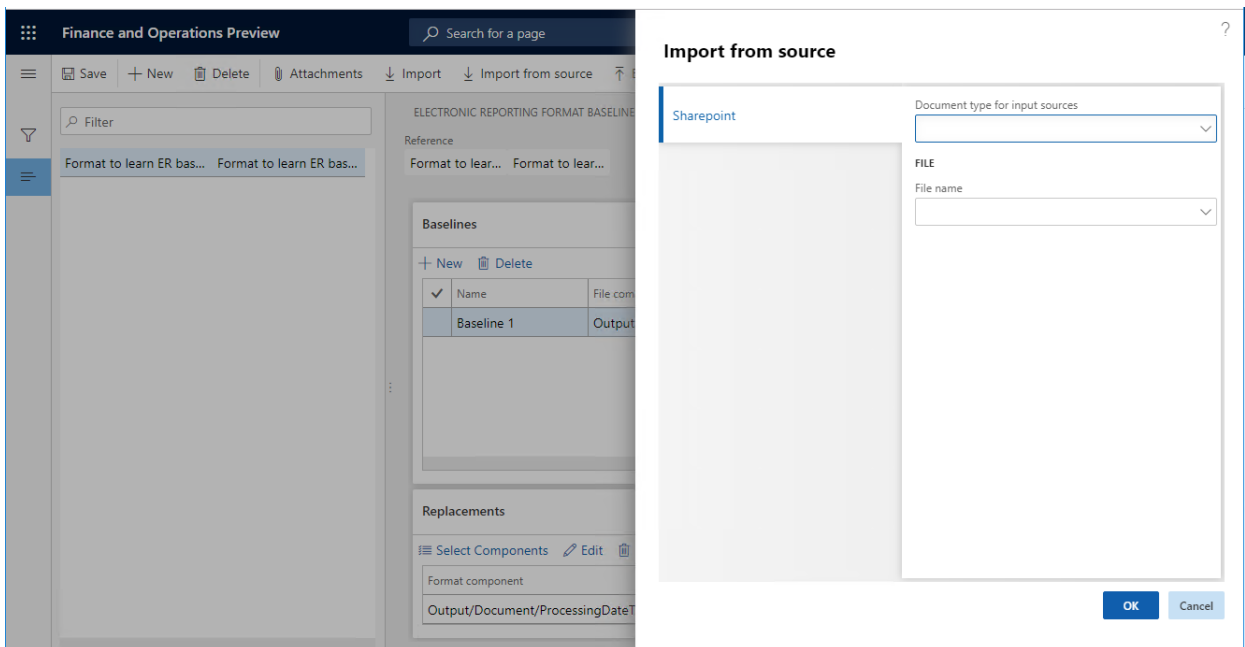

Import baseline settings

Exported baseline settings can be imported into a different environment. The environment must first be imported as an ER format. You can then import the baseline settings.

To import baseline settings from a locally stored XML file, on the **Electronic reporting format baselines** page, select **Import**, and then select **Browse** to select the XML file.

To import baseline settings from an XML file that is stored on the Microsoft SharePoint Server, based on the current Document management settings and the selected document type, on the **Electronic reporting format baselines** page, select **Import from source**. Then select the document type and the XML file. The required document type to access the SharePoint folder must be configured in advance.

NOTE

You can use Task recorder to record the steps for selecting the required document type and the file name in the **Import from source** dialog box. In this way, you can keep required baseline settings on SharePoint Server and then automatically import them by playing a task recording when you run automated tests by using the Regression Suite Automation Tool.

Additional resources

- [Trace generated report results and compare them with baseline values](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Automate testing with Electronic reporting

2/18/2021 • 13 minutes to read • [Edit Online](#)

This topic explains how you can use the Electronic reporting (ER) framework to automate testing of some functionality. The example in this topic shows how to automate the testing of vendor payment processing.

The application uses the ER framework to generate payment files and corresponding documents during vendor payment processing. The ER framework consists of a data model, model mappings, and format components that support payment processing for different payment types and the generation of documents in different formats. These components can be downloaded from Microsoft Dynamics Lifecycle Services (LCS) and imported into the instance.

You also can customize each Microsoft component and use it as the basis of your own custom component. By creating a custom version, you can make changes that support specific requirements. For example, you can adjust the ER data model and ER model mapping to access customer-specific application data, or you can change an ER format to modify the layout of a generated document.

You can use customized ER formats to process payment files that generate vendor payments and also to process control reports. Versioning is supported in ER components. Therefore, Microsoft can provide updated versions of ER solutions for vendor payment processing, and you can automatically merge the updated version with your customized component by rebasing it. However, you must test the rebased version to make sure that it works as you expect.

ER data models and ER model mappings are common for many ER formats that are used to process payments of different types and to generate country/region-specific payment documents. Therefore, it's highly desirable to automate user acceptance and integration testing so that it's automatically done in multiple companies but considers the country/region context of each target company, uses different datasets, and so on.

For more information about how to create a custom version of a format that is based on the format that you received from a configuration provider, see [ER Upgrade your format by adopting a new, base version of that format](#).

Key concepts

Functional power users can author user acceptance and integration testing without having to write source code.

- Use the ER baseline feature to compare generated documents to master copies. For more information, see [Trace generated report results and compare them with baseline values](#).
- Use Task recorder to record test cases, and include baseline assessment. For more information, see [Task recorder resources](#).
- Group test cases for required test scenarios. For more information, see [Create and automate user acceptance tests](#).
 - Use Business process modeler (BPM) in LCS to make libraries for user acceptance tests.
 - Use BPM test libraries to create a test plan and test suites in Microsoft Azure DevOps Services (Azure DevOps).

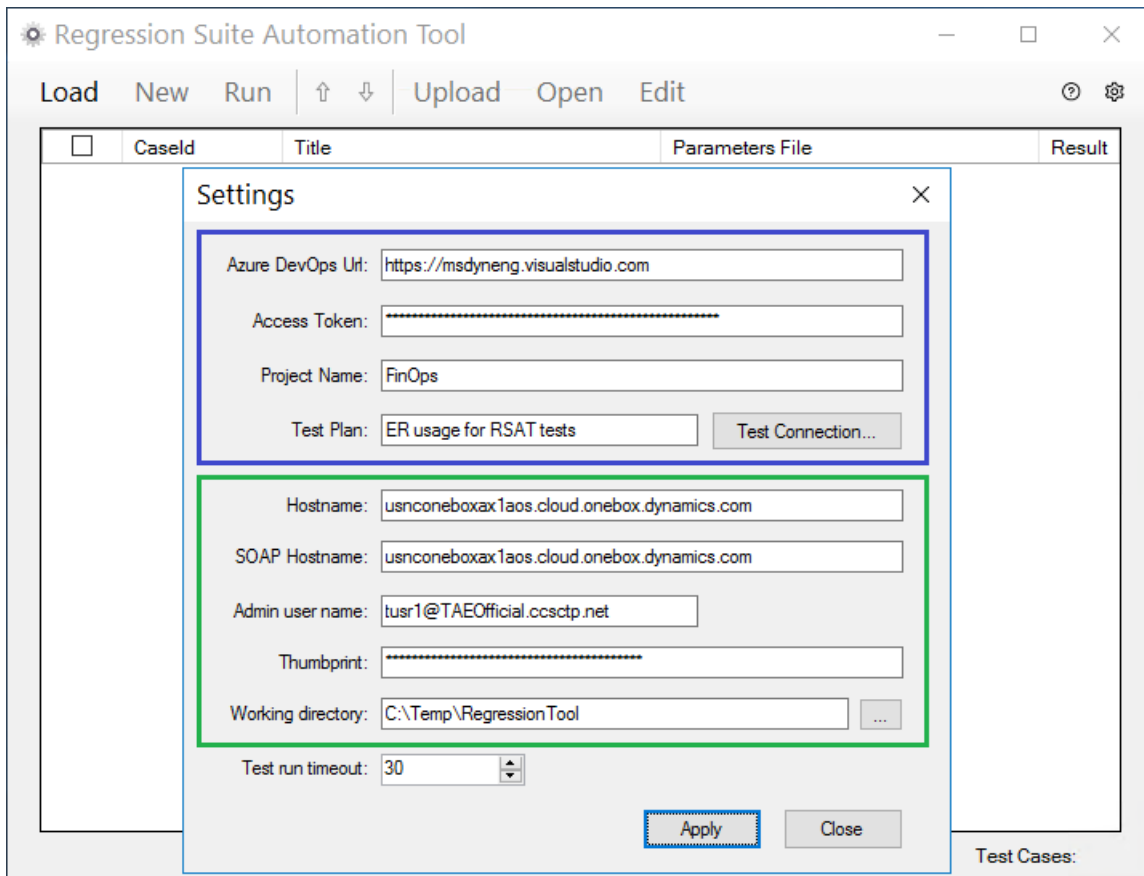

Functional power users can run user acceptance and integration tests.

- Use Regression suite automation tool (RSAT) to run test cases of the desired test suite.
- Report the results of the testing to Azure DevOps, and use this service to investigate those results.

Prerequisites

Before you can complete the tasks in this topic, you must complete the following prerequisites:

- Deploy a topology that supports test automation. You must have access to the instance of this topology for the **System administrator** role. This topology must contain the demo data that will be used in this example. For more information, see [Deploy and use an environment that supports continuous build and test automation](#).
- To run user acceptance and integration tests automatically, you must install RSAT in the topology that you're using and configure it in the appropriate manner. For information about how to install and configure RSAT and configure it to work with Finance and Operations apps and Azure DevOps, see [Regression Suite Automation Tool](#). Pay attention to the prerequisites for using the tool. The following illustration shows an example of the RSAT settings. The blue rectangle encloses the parameters that specify access to Azure DevOps. The green rectangle encloses the parameters that specify access to the instance.

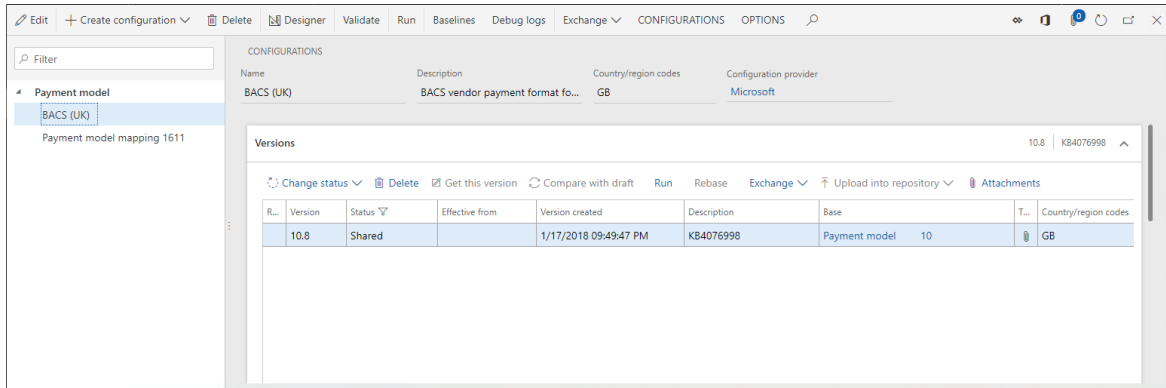

- To organize test cases in suites to help guarantee the correct execution sequence, so that you can collect logs of test executions for further reporting and investigation, you must have access to Azure DevOps from the deployed topology.
- To complete the example in this topic, we recommend that you download [ER usage for RSAT tests](#). This zip file contains the following task guides:

CONTENT	FILE NAME AND LOCATION
Sample task recording to prepare data for testing	Prepare\Recording.xml
Sample task recording to process vendor payment	Process\Recording.xml

Prepare the Accounts payable module to process vendor payments

1. Sign in to your instance.
2. Download the following ER configurations from LCS. For instructions, see [ER Import a configuration from Lifecycle Services](#).
 - **Payment model** ER model configuration
 - **Payment model mapping 1611** ER model mapping configuration
 - **BACS (UK)** ER format configuration

3. Select the GBSI demo data company, which has a country/region context in Great Britain.
4. Configure Accounts payable parameters:
 - a. Go to **Accounts payable > Payment setup > Methods of payment**.
 - b. Select the **Electronic** method of payment.
 - c. Configure the selected method of payment so that it uses the **BACS (UK)** ER format that you downloaded earlier for vendor payment processing:
 - a. On the **File formats** FastTab, set the **Generic electronic Export format** option to **Yes**.
 - b. In the **Export format configuration** field, select **BACS (UK)**.

NOTE

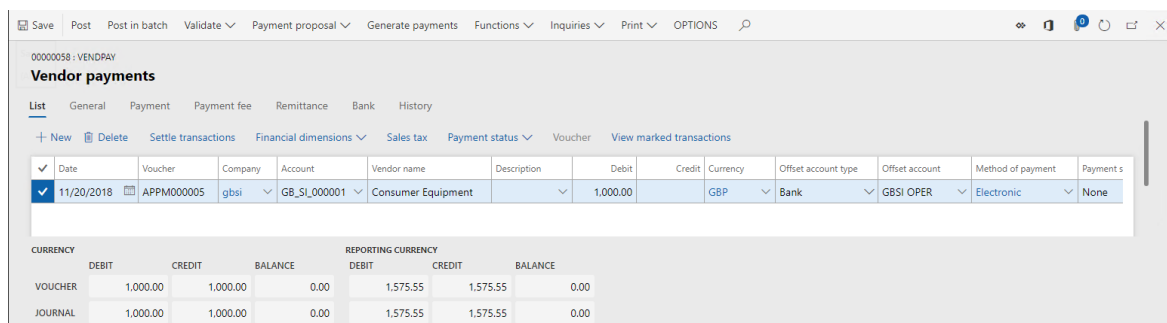

If you have the derived version of this ER format that was created to support customizations, you can select this configuration in the **Electronic** method of payment.

5. Create an example vendor payment:
 - a. Go to **Accounts payable > Payments > Payment journal**.
 - b. Make sure that you haven't posted the payment journal.

c. Select Lines, and enter a line that has the following information.

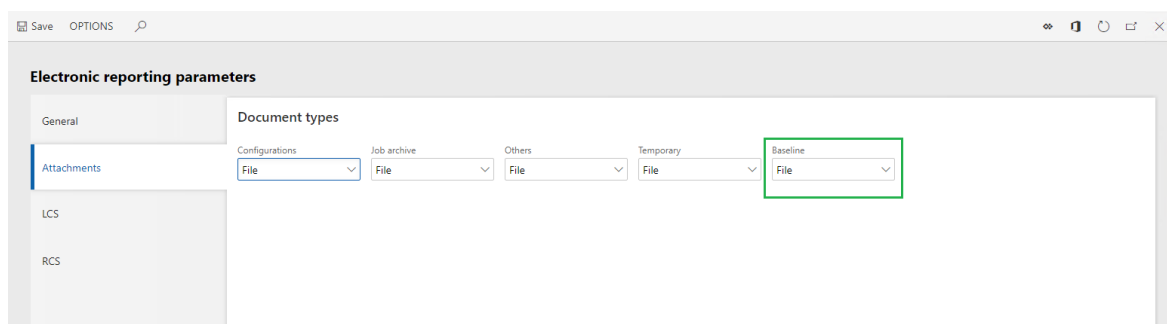

FIELD	EXAMPLE VALUE
Vendor name	GB_SI_000001
Debit	1,000.00
Currency	GBP
Offset account type	Bank
Offset account	GBSI OPER
Method of payment	Electronic

Prepare the ER framework to test vendor payment processing

Configure ER parameters

1. Go to **Organization administration > Electronic reporting > Electronic reporting parameters**.
2. On the **Attachments** tab, in the **Baseline** field, select **File** as the document type that the Document management (DM) framework uses to keep documents that are related to the baseline feature as DM attachments.

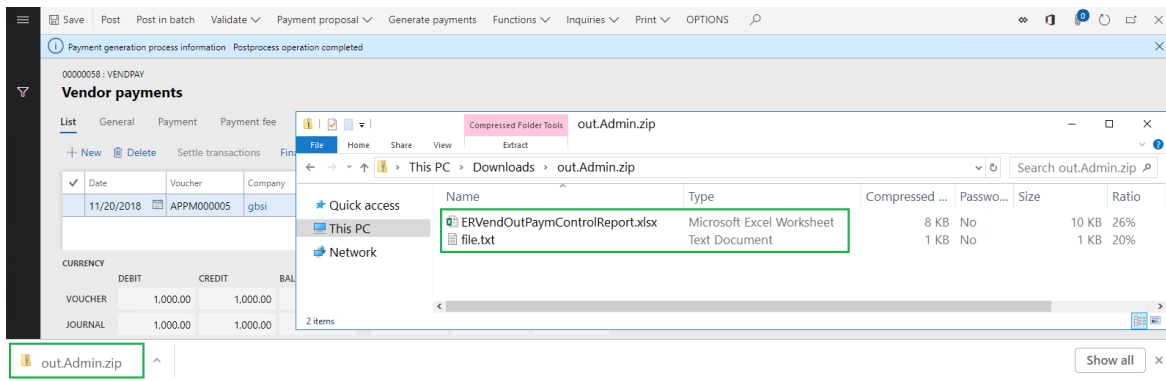

Generate baseline copies of vendor payment-related documents

1. Go to **Accounts payable > Payments > Payment journal**.

2. Select **Lines**.
3. Select **Generate payments**.
4. Select the **Electronic** method of payment.
5. Select the **GBSI OPER** bank account.
6. Set the **Print control report** option to **Yes**.
7. Download the generated output as a zip file.
8. Open the downloaded file.
9. Extract following files from the downloaded file:

- **File payment file in text format**
- **ERVendOutPaymControlReport control report file in XLSX format**

Turn on the ER baseline feature

1. Go to **Organization administration > Electronic reporting > Configurations**.
2. On the Action Pane, on the **Configurations** tab, select **User parameters**.
3. Set the **Run in debug mode** option to **Yes**.

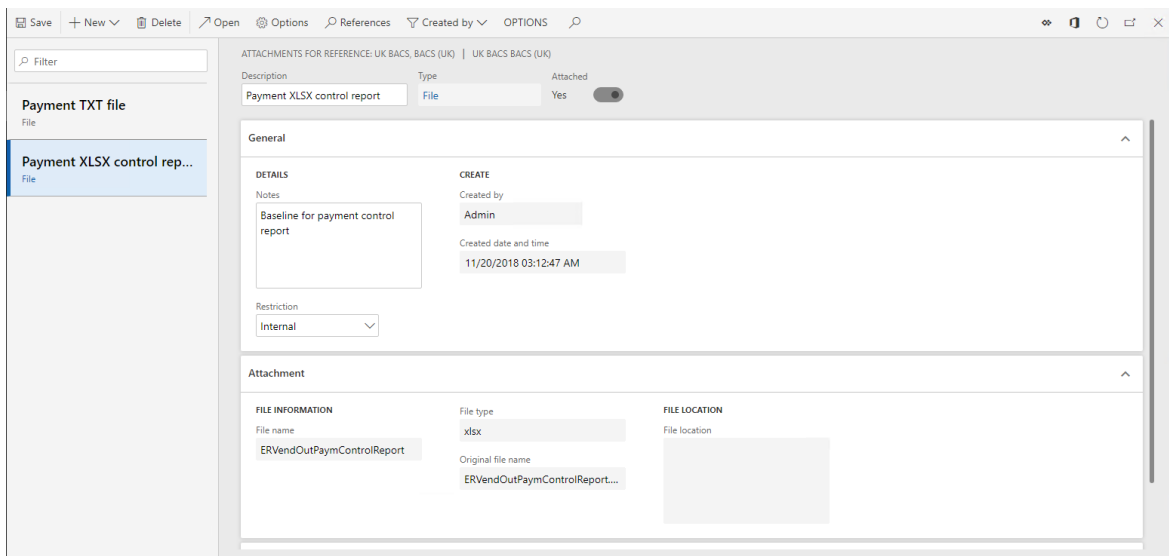

By turning on the **Run in debug mode** parameter, you force the ER framework to perform the following actions after the execution of any ER format that generates outgoing documents:

1. Determine whether a baseline was configured for any of components of the executed ER format.
2. Determine whether each configured baseline is applicable in the current conditions (company code of the signed-in company, file name and file name extension of the generated output, and so on).
3. For each applicable baseline, perform the following actions:
 - a. Compare the output that is generated during execution of the ER format with the corresponding baseline.
 - b. Store the results of the comparison in the ER configurations debug log.

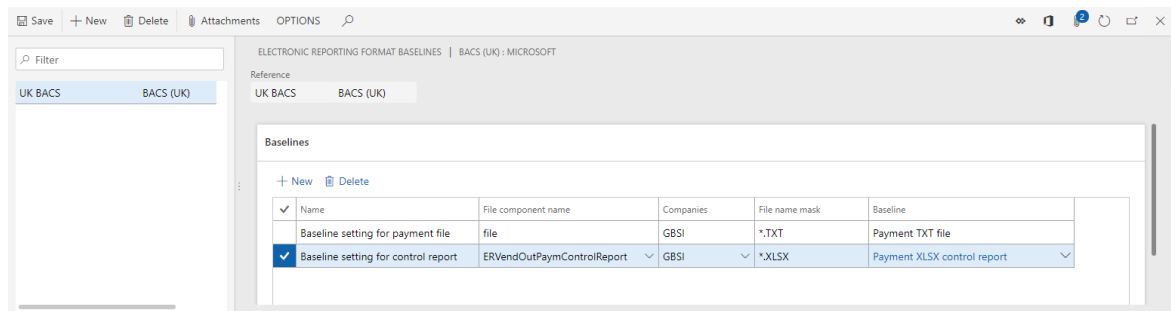

Configure ER baselines for vendor payment processing

1. Go to **Organization administration > Electronic reporting > Configurations**.
2. Select **Baselines**.
3. Select **New**.
4. In the **Reference** field, select the **BACS (UK)** format.
5. Select **Attachments**.
6. Add a new baseline for the vendor payment file:

- a. Select **New**.
 - b. In the **Type** field, select the **File DM** document type that you configured in the ER parameters to store baseline artifacts.
 - c. Browse to select the locally saved **File** payment file in text format.
 - d. In the **Description** field, enter **Payment TXT file**.
7. Add a new baseline for the control report for the vendor payment:
- a. Select **New**.
 - b. In the **Type** field, select the **File DM** document type that you configured in the ER parameters to store baseline artifacts.
 - c. Browse to select the locally saved **ERVendOutPaymControlReport** control report file in XLSX format.
 - d. In the **Description** field, enter **Payment XLSX control report**.

8. Close the page.
9. On the **Baselines** FastTab, select **New** to configure a baseline for the payment file:
 - a. Name the line **Baseline setting for payment file**.
 - b. In the **File component name** field, select **file** to apply this baseline to the ER format output that generates the payment file in BACS (UK) text format.
 - c. In the **Companies** field, select **GBSI** to apply this baseline when the **BACS (UK)** ER format is run in the GBSI company.
 - d. In **File name mask** field, enter ***.TXT** to apply this baseline only to outputs of the file format component that have the **.txt** file name extension.
 - e. In the **Baseline** field, select **Payment TXT file** so that this baseline is used for comparison with the generated output.
10. Select **New** to configure a baseline for the control report:
 - a. Name the line **Baseline setting for control report**.
 - b. In the **File component name** field, select **ERVendOutPaymControlReport** to apply this baseline to the ER format output that generates the control report.
 - c. In the **Companies** field, select **GBSI** to apply this baseline when the **BACS (UK)** ER format is run in the GBSI company.
 - d. In **File name mask** field, enter ***.XLSX** to apply this baseline only to outputs of the **ERVendOutPaymControlReport** format component that have the **.xlsx** file name extension.
 - e. In the **Baseline** field, select **Payment XLSX control report** so that this baseline is used for comparison with the generated output.

Record tests to validate vendor payment processing

As a functional power user, you can record your own steps to test vendor payment processing. We recommend that you play (and edit, as required) the **Prepare\Recording.xml** task recording that you downloaded earlier. This recording is used to set all testing data to the correct state. That step is required because the testing can be done many times, and every test must use data that is in the same state.

Reset user settings

1. Open the default dashboard.
2. Select the **Settings** button (the gear symbol).
3. Select **User options**.
4. Select **Usage data**.
5. Select **Reset**.
6. Select **Yes** to confirm that you want to reset usage data.
7. Close the page.

Record the steps to prepare data for testing

1. Select the **Settings** button (the gear symbol).
2. Select **Task recorder**.
3. Select **Playback recording**.
4. Select **Open from this PC**.
5. Select **Browse**, and select the locally save **Prepare\Recording.xml** file.
6. Select **Start**.
7. Keep selecting **Play next pending step** until all the steps in the recording have been played.

This task recording performs the following actions:

1. Set the status of the processed payment line to **None**.

13	Go to Organization administration > Electronic
14	Click Delete all.
15	Click Yes.

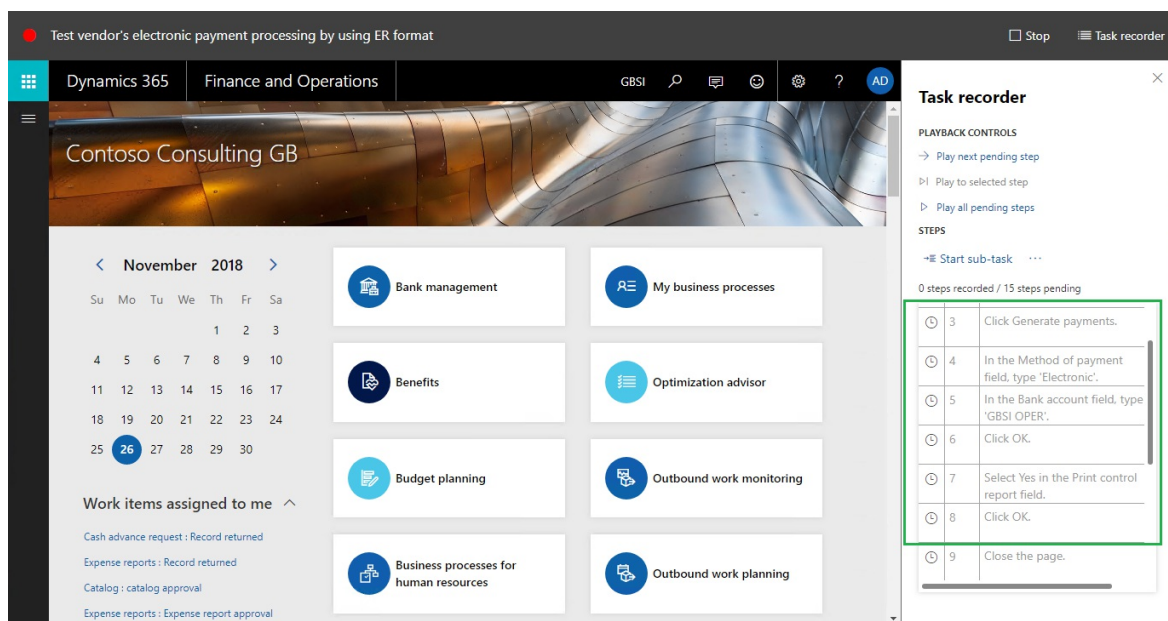

Record the steps to test vendor payment processing

We recommend that you play (and edit, as required) the **Process\Recording.xml** task recording that you downloaded earlier. This recording is used to process vendor payments and validate the results of the comparison of generated documents to corresponding baselines.

1. Select the **Settings** button (the gear symbol).
2. Select **Task recorder**.
3. Select **Playback recording**.
4. Select **Open from this PC**.
5. Select **Browse**, and select the locally saved **Process\Recording.xml** file.
6. Select **Start**.
7. Keep selecting **Play next pending step** until all the steps in the recording have been played.

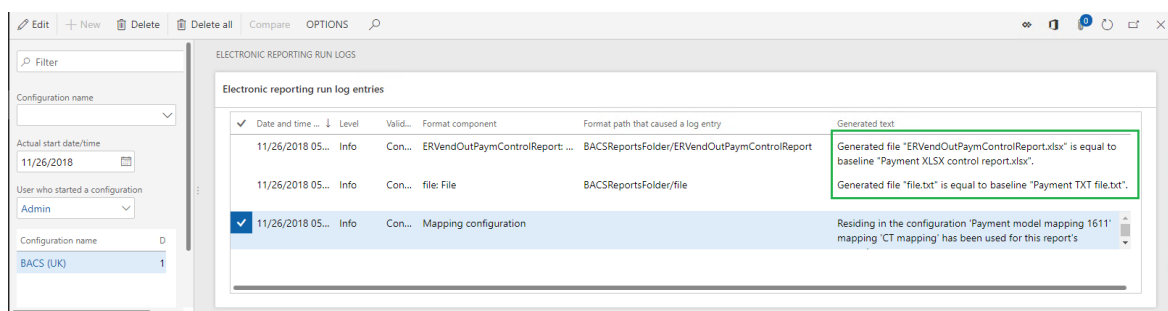

This task recording performs the following actions:

1. Start vendor payment processing.
2. Select the correct runtime parameters, and turn on generation of a control report.

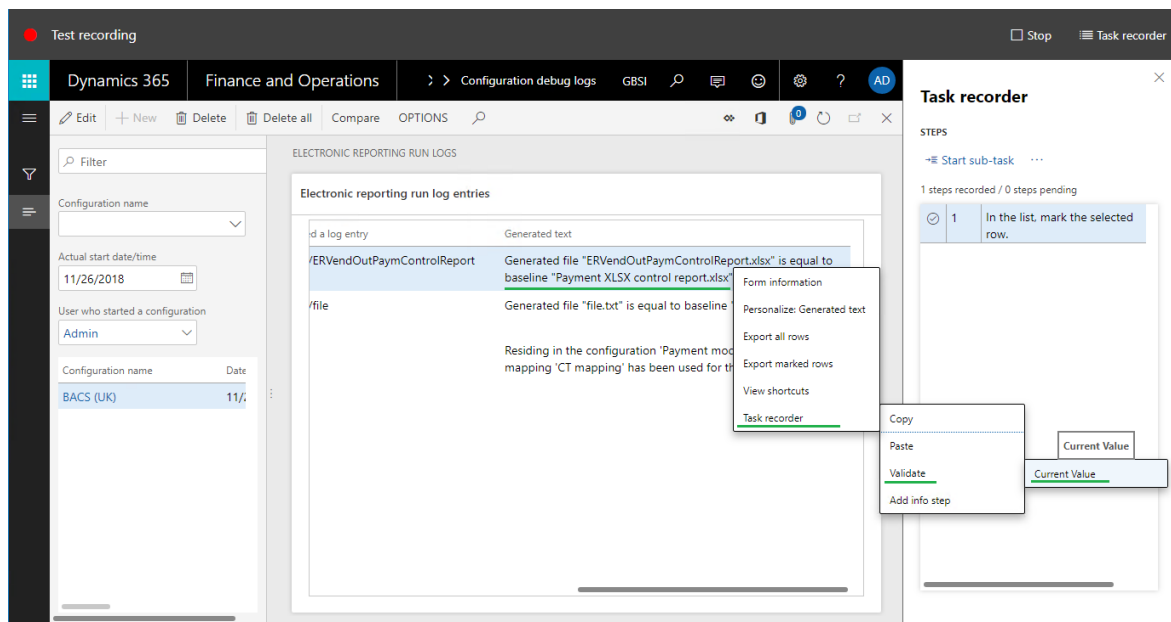

3. Access the ER debug log to record the results of the comparison of generated outputs to corresponding baselines.

In the ER debug log, the results of the comparison appear in the **Generated text** field. The **Format component** and **Format path that caused a log entry** fields refer to the file component for which the generated output has been compared to the baseline.

4. The comparison of the current output to the baseline is recorded by using the **Validate** Task recorder option and selecting **Current Value**.

The following illustration shows what the recorded validation steps look like in the task recording.

Add the recorded tests to Azure DevOps

1. Open the Azure DevOps environment.
2. Select the project that you defined in the RSAT parameters when you [configured the tool](#).
3. Select the test plan that you defined in the RSAT parameters when you [configured the tool](#).
4. Create a new test case for the selected test plan:
 - a. Name the test case **Prepare data to test processing of vendor's electronic payment**.
 - b. Attach the **Recording.xml** file from the **Prepare** folder that you downloaded earlier.
5. Create a new test case for the selected test plan:
 - a. Name the test case **Test processing of vendor payments by using ER format BACS (UK)**.
 - b. Attach the **Recording.xml** file from the **Process** folder that you downloaded earlier.

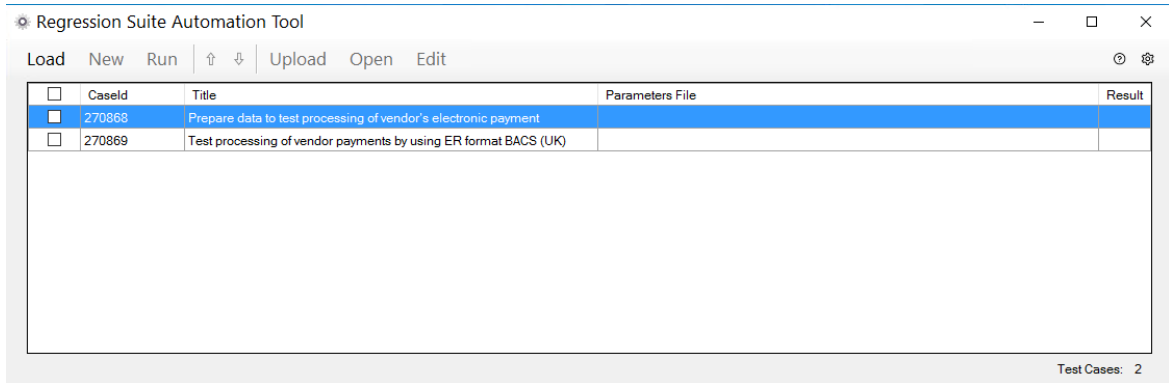

NOTE

Pay attention to the correct execution order of the tests that are added.

Prepare RSAT to run the recorded tests

Load the tests from Azure DevOps to RSAT

1. Open the local RSAT application in the current topology.
2. Select **Load** to load the tests that currently reside in Azure DevOps into RSAT.

Create automation and parameters files

1. In RSAT, select the tests that you loaded from Azure DevOps.
2. Select **New** to create RSAT automation and parameters files.

Modify the parameters files

1. In RSAT, select the **Prepare data to test processing of vendor's electronic payment** test case.
2. Select **Edit**.
3. In the Microsoft Excel workbook that is opened, on the **General** worksheet, change the company code to **GBSI**, because this company will be used for test execution.

- In RSAT, select the **Test processing of vendor payments by using ER format BACS (UK)** test case.
- Select **Edit**.
- In the Excel workbook that is opened, on the **General** worksheet, change the company code to **GBSI**.
- On the **ERFormatMappingRunLogTable** worksheet, notice that cells A:3 and C:3 contain the text of the fields in the ER debug log table that are used to validate the results of the comparison of the output to the baseline. These texts will be used to evaluate ER debug log records that are created during test execution.

Run the tests and analyze the results

Run the tests in RSAT

- In RSAT, select the loaded tests.
- Select **Run**.

Notice that test cases are automatically run in the application by using a web browser.

Analyze the results of test execution

The results of the test execution are stored in RSAT. Notice that both tests were passed.

Notice that the results of the test execution are also sent to Azure DevOps so that you can do further analysis.

Simulate a situation where tests fail

This test suite must fail when at least one of the generated outputs doesn't match the corresponding baseline. To

achieve this situation, you can use your derived version of the **BACS (UK)** format that will generate a payment file that has different content than the corresponding baseline. To simulate this situation, you can use the same **BACS (UK)** format but change the payment amount on the processed payment line.

1. Open the application and go to **Accounts payable > Payments > Payment journal**.
2. Select **Lines**.
3. Select the payment line, and then select **Payment status > None**.
4. In the **Debit** field, change the value from **1,000.00** to **2,000.00**.
5. Select **Save** to save your changes.

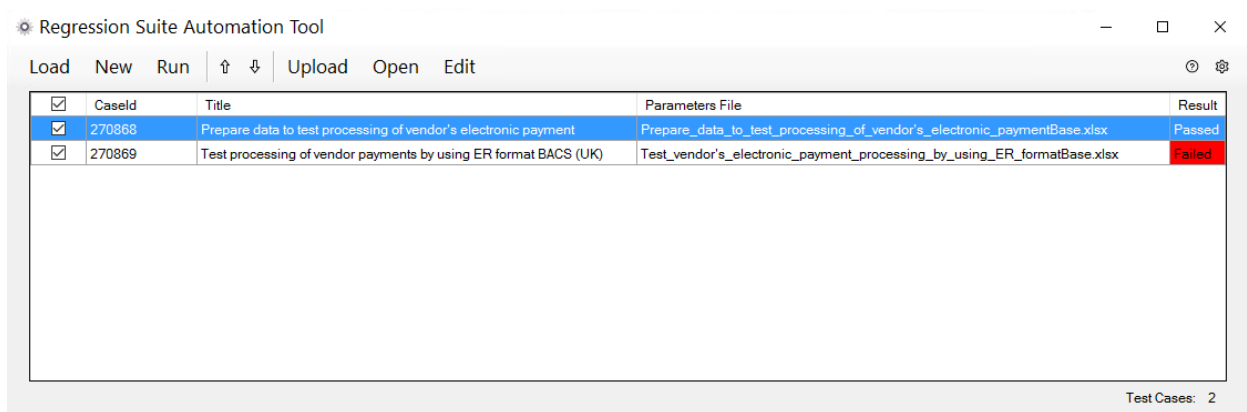

Run the tests in RSAT

1. In RSAT, select the loaded tests.
2. Select **Run**.

Notice that test cases are automatically run in the application by using a web browser.

Analyze the results of test execution

The results of the test execution are stored in RSAT. Notice that the second test failed during the second execution.

The screenshot shows the Regression Suite Automation Tool (RSAT) interface. At the top, there are menu options: Load, New, Run, Upload, Open, Edit. Below the menu is a table with the following data:

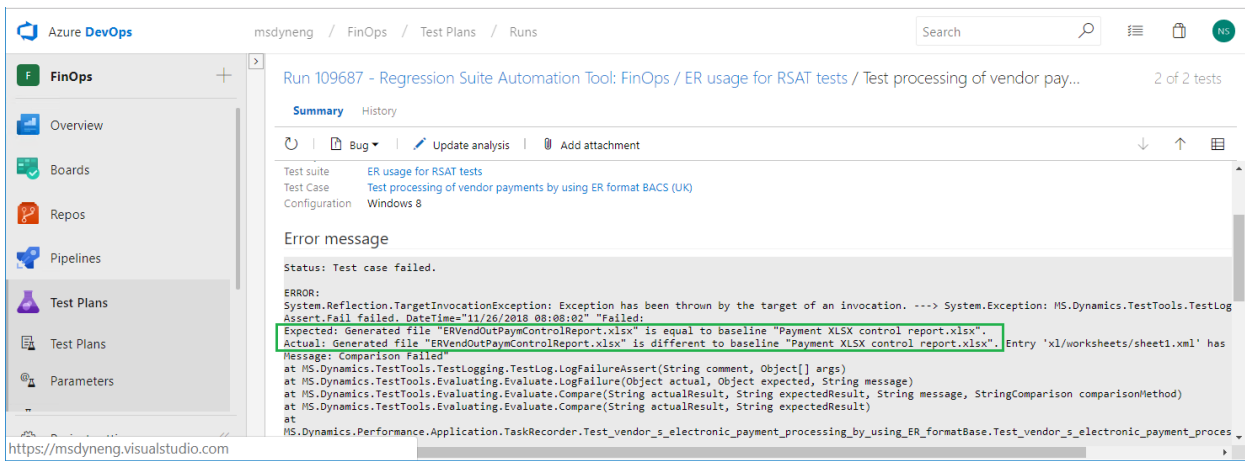

CaseId	Title	Parameters File	Result
270868	Prepare data to test processing of vendor's electronic payment	Prepare_data_to_test_processing_of_vendor's_electronic_paymentBase.xlsx	Passed
270869	Test processing of vendor payments by using ER format BACS (UK)	Test_vendor's_electronic_payment_processing_by_using_ER_formatBase.xlsx	Failed

At the bottom right of the window, it says "Test Cases: 2".

Notice that the results of the test execution are also sent to Azure DevOps so that you can do further analysis.

You can access the status of each test. You can also access the execution log so that you analyze the reasons for any failure. In the following illustration, the execution log shows that the failure occurred because of the difference in content between the generated payment file and its baseline.

Therefore, as you've seen, the functioning of any ER format can be evaluated automatically by using RSAT as the testing platform and by using Task recorder-based test cases that use the ER baseline feature.

Configure Electronic reporting (ER) to pull data into Power BI

2/18/2021 • 8 minutes to read • [Edit Online](#)

This topic explains how you can use your Electronic reporting (ER) configuration to arrange the transfer of data from your instance to Power BI services. As an example, this topic uses Intrastat transactions as business data that must be transferred. The Power BI map visualization uses this Intrastat transaction data to present a view for analysis of company import/export activities on the Power BI report.

Overview

Microsoft Power BI is a collection of software services, apps, and connectors that work together to turn external sources of data into coherent, visually immersive, and interactive insights. Electronic reporting (ER) lets users easily configure data sources and arrange the transfer of data from the application to Power BI. The data is transferred as files in the OpenXML worksheet (Microsoft Excel workbook file) format. The transferred files are stored on a Microsoft SharePoint Server that has been configured for that purpose. The stored files are used in Power BI to make reports that include visualizations (tables, charts, maps, and so on). Power BI reports are shared with Power BI users, and they are accessed in Power BI dashboards and on the application pages. This topic explains the following tasks:

- Configure Microsoft Dynamics 365 Finance.
- Prepare your ER format configuration to get data from the Finance application.
- Configure the ER environment to transfer data to Power BI.
- Use transferred data to create a Power BI report.
- Make the Power BI report accessible in Finance.

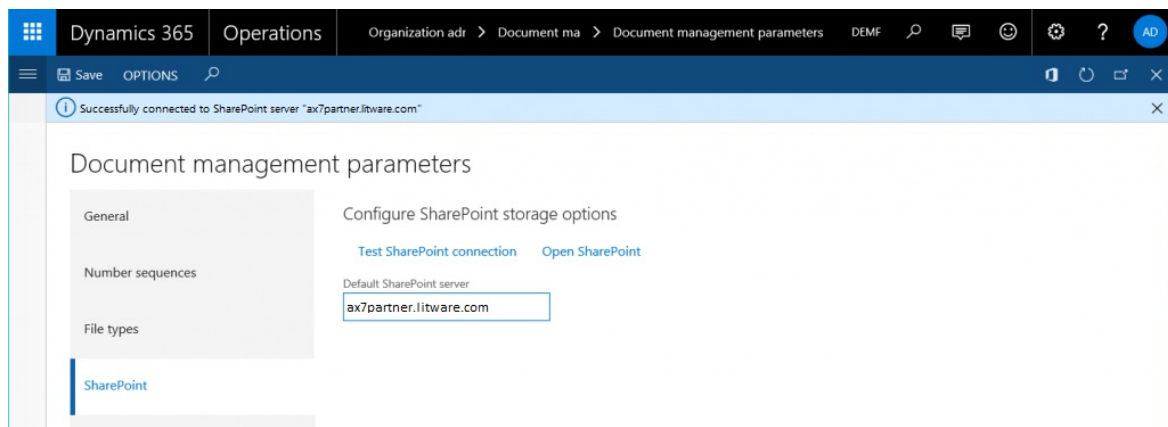

Prerequisites

To complete the example in this topic, you must have the following access:

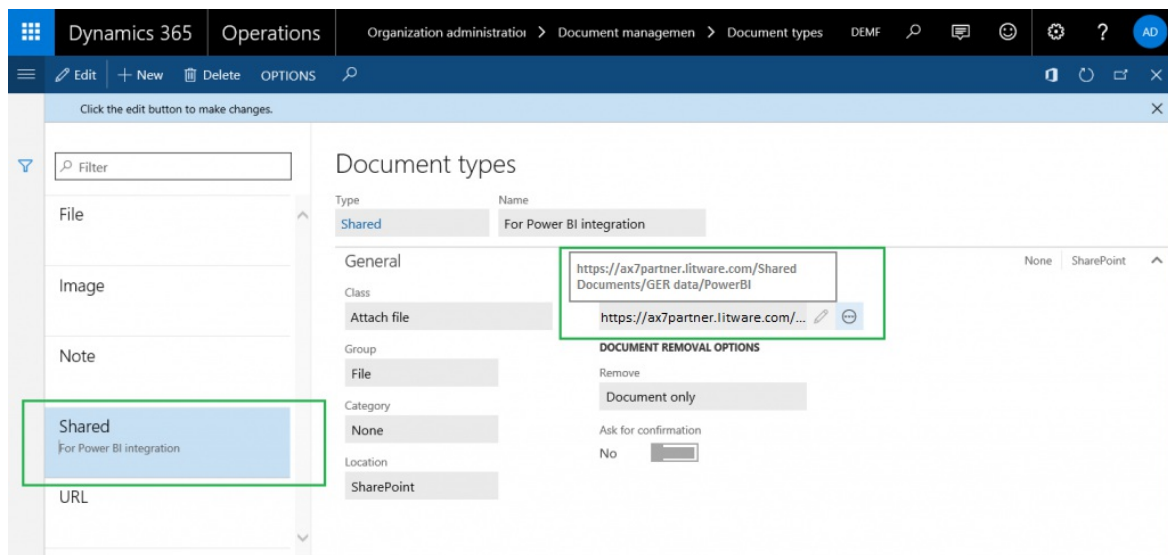

- Access for one of the following roles:
 - Electronic reporting developer
 - Electronic reporting functional consultant
 - System administrator
- Access to the SharePoint Server that is configured for use with the application
- Access to the Power BI framework

Configure document management parameters

1. On the **Document management parameters** page, configure access to the SharePoint Server that will be used in the company that you're signed in to (the DEMF company in this example).
2. Test the connection to the SharePoint Server to make sure that you've been granted access.

3. Open the configured SharePoint site. Create a new folder where ER will store Excel files that have the business data that the Power BI reports require as a source of Power BI datasets.
4. On the **Document types** page, create a new document type that will be used to access the SharePoint folder that you just created. Enter **File** in the **Group** field and **SharePoint** in the **Location** field, and then enter the address of the SharePoint folder.

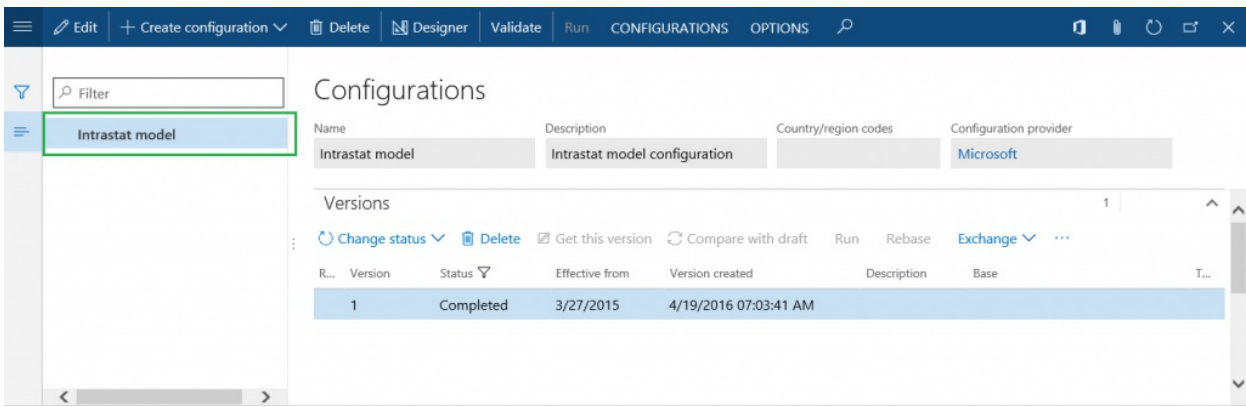

Configure ER parameters

1. In the **Electronic reporting** workspace, click the **Electronic reporting parameters** link.
2. On the **Attachments** tab, select the **File** document type for all the fields.
3. In the **Electronic reporting** workspace, make the required provider active by clicking **Set active**. For more information, play the **ER Select service provider** task guide.

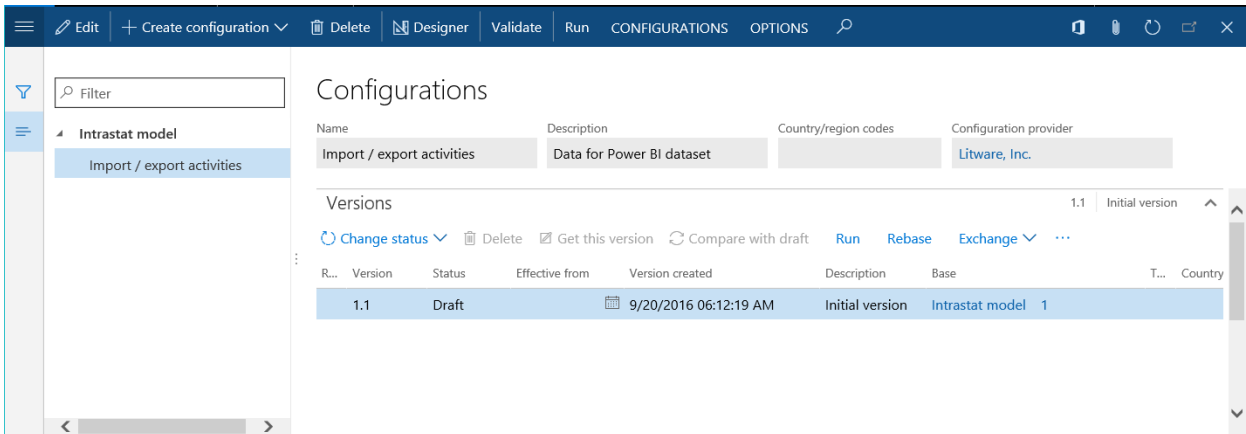

Use an ER data model as the source of data

You must have an ER data model as the source of business data that will be used on Power BI reports. This data model is uploaded from the ER configurations repository. For more information, see [Download Electronic reporting configurations from Lifecycle Services](#), or play the **ER Import a configuration from Lifecycle Services** task guide. Select **Intrastat** as the data model that will be uploaded from the selected ER configurations repository. (In this example, version 1 of the model is used.) You can then access the **Intrastat ER** model configuration on the **Configurations** page.

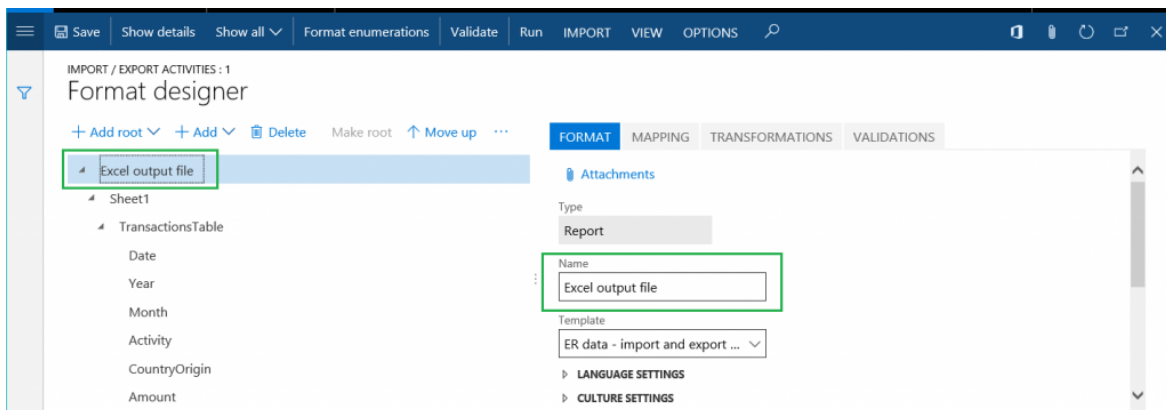

Design an ER format configuration

You must create a new ER format configuration that uses the **Intrastat** data model as the source of business data. This format configuration must generate output results as electronic documents in OpenXML (Excel file) format. For more information, play the **ER Create a configuration for reports in OPENXML format** task guide. Name the new configuration **Import / export activities**, as shown in the following illustration. Use the [ER data - import and export details](#) Excel file as a template when you design the ER format. (For information about how to import a format template, play the task guide.)

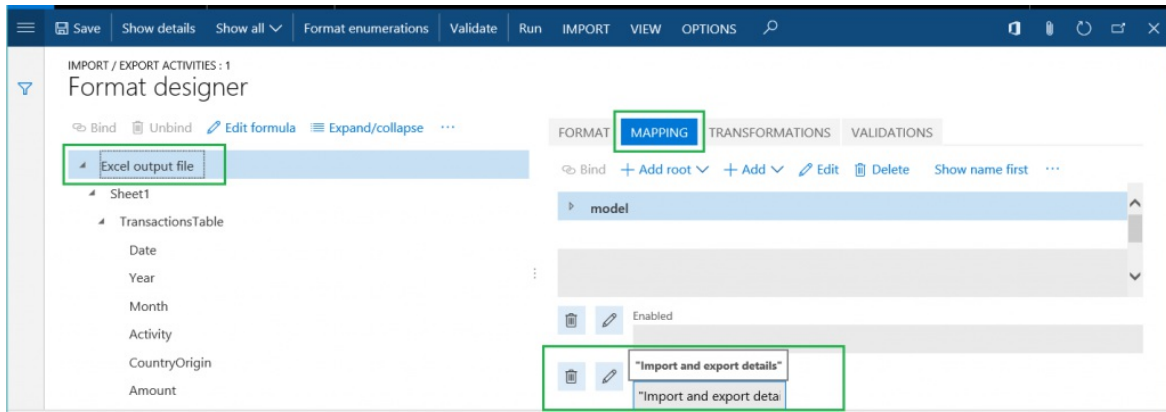

To modify the **Import / export activities** format configuration, follow these steps.

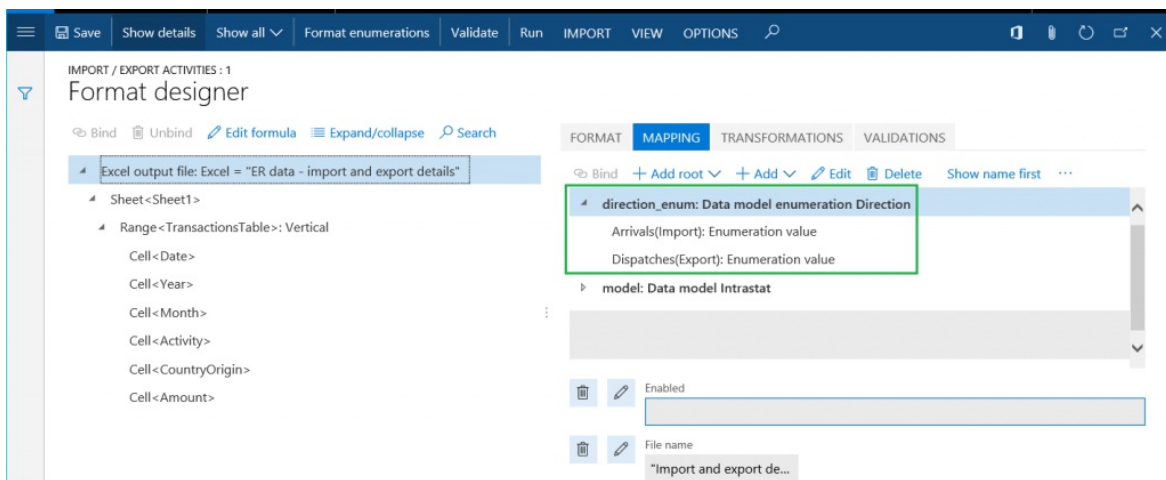

1. Click **Designer**.
2. On the **Format** tab, name the file element for this format **Excel output file**.

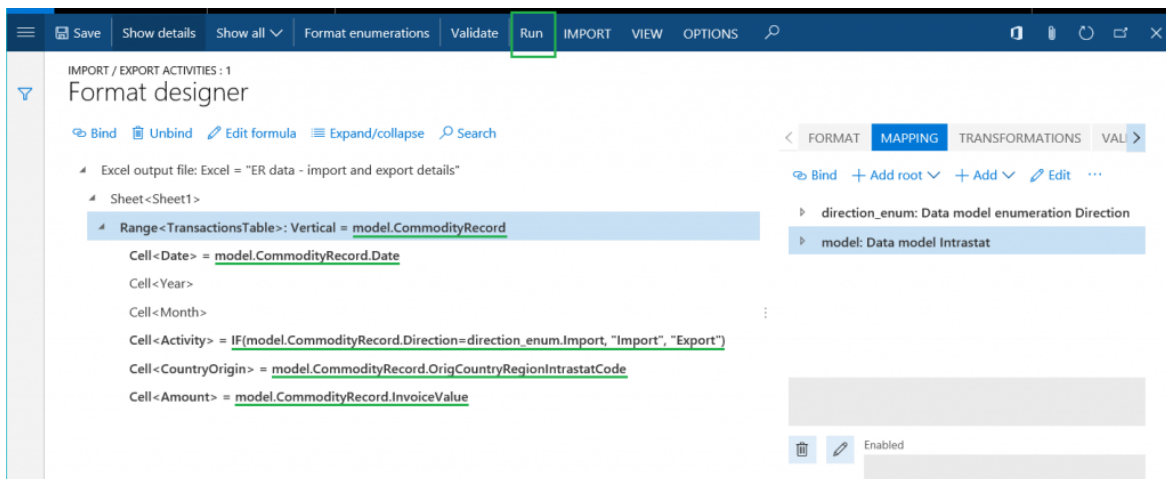

3. On the **Mapping** tab, specify the name of the Excel file that will be generated whenever this format is run. Configure the related expression to return the value **Import and export details** (the .xlsx file name extension will be added automatically).

4. Add a new data source item for this format. (This enumeration will be required for further data binding.)
 - a. Name the data source **direction_enum**.
 - b. Select **Data model enumeration** as the data source type.
 - c. Refer to the **Direction** data model enumeration.

5. Complete the binding of elements of the **Intrastat** data model and elements of the designed format, as shown in the following illustration.

After it's run, the ER format generates the output result in Excel format. It sends the details of the Intrastat transactions to the output result, and separates them as transactions that describe either import activities or export activities. Click Run to test the new ER format for the list of Intrastat transactions on the **Intrastat** page (Tax > Declarations > Foreign trade > Intrastat).

The screenshot shows the 'Intrastat' application with a table of data. The table has columns for Date, Direction, Correction, Item number, Category, Commodity, Weight, Invoice amount, Statistical amount, and Country/region of origin. Two rows are visible:

Date	Direction	Correction	Item number	Category	Commodity	Weight	Invoice amount	Statistical amount	Country/region of origin
1/31/2016	Arrivals		D0003		920 20 34	4.00	1,000.00	1,000.00	AUT
1/31/2016	Arrivals		T0006		900 22 33	5.00	700.00	700.00	CHE

The following output result is generated. The file is named **Import and export details.xlsx**, as you specified in the format settings.

The screenshot shows an Excel spreadsheet titled 'Import and export details.xlsx'. The data is organized into columns: Date, Year, Month, Activity, CountryOrigin, and Amount. The first two rows of data are:

Date	Year	Month	Activity	CountryOrigin	Amount
31.01.2016	2016	1	Import	AT	1 000,00
31.01.2016	2016	1	Import	CH	700,00

Configure the ER destination

You must configure the ER framework to send the output result of the new ER format configuration in a special way.

- The output result must be sent to the folder of the selected SharePoint Server.
- Each execution of the format configuration must create a new version of same Excel file.

On the **Electronic reporting** page (**Organization administration** > **Electronic reporting**), click the **Electronic reporting destination** item, and add a new destination. In the **Reference** field, select the **Import / export activities** format configuration that you created earlier. Follow these steps to add a new file destination record for the reference.

1. In the **Name** field, enter the title of the file destination.
2. In the **File name** field, select the name **Excel output file** for the Excel file format component.

Click the **Settings** button for the new destination record. Then, in the **Destination settings** dialog box, follow these steps.

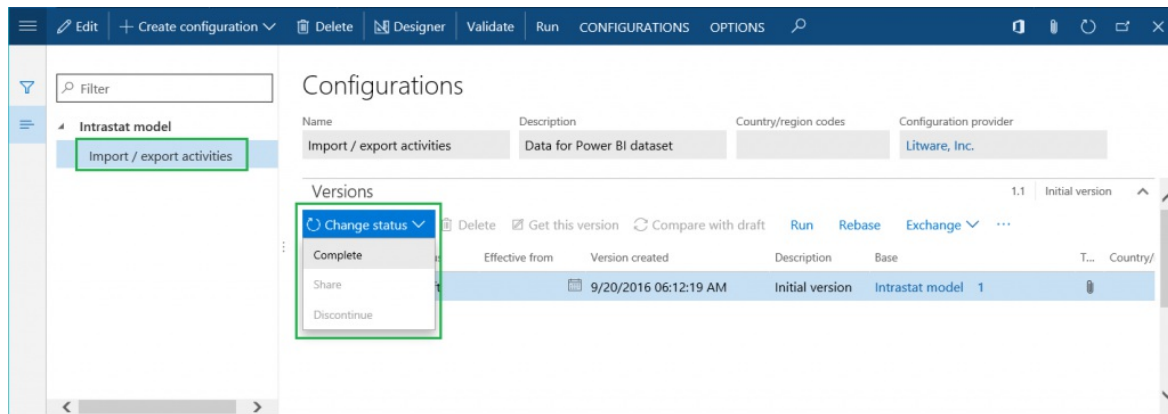

1. On the **Power BI** tab, set the **Enabled** option to **Yes**.
2. In the **SharePoint** field, select the **Shared** document type that you created earlier.

Schedule execution of the configured ER format

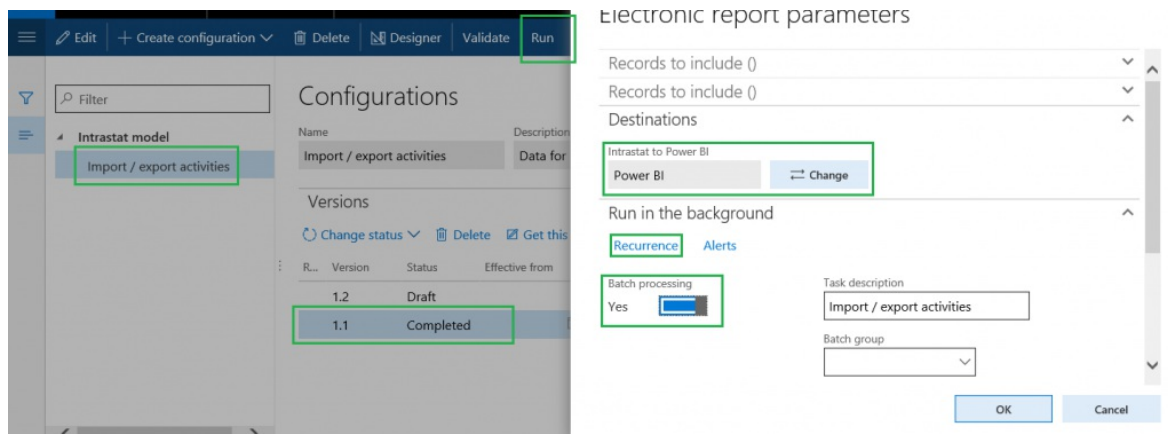

1. On the **Configurations** page (**Organization administration** > **Electronic reporting** >

Configurations), in the configurations tree, select the **Import / export activities** configuration that you created earlier.

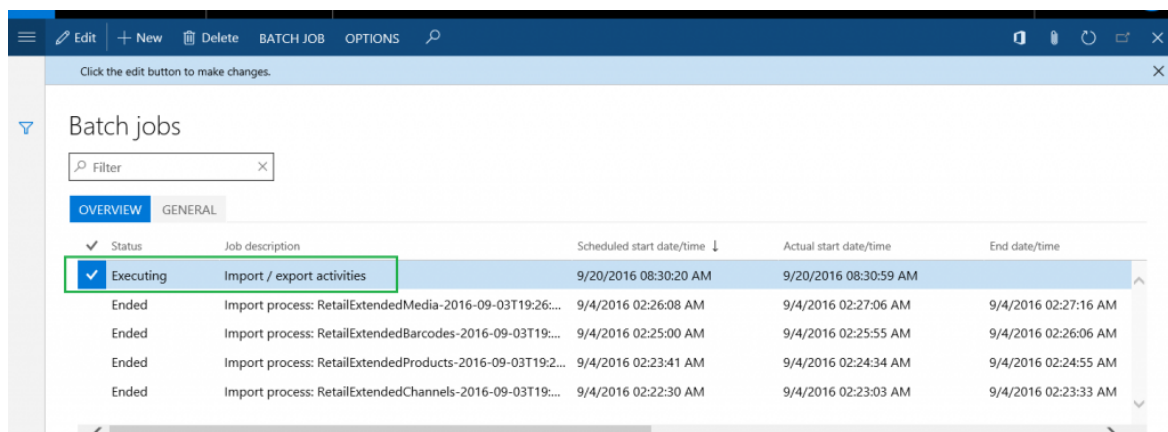

- Change the status of version 1.1 from **Draft** to **Complete** to make this format available for use.

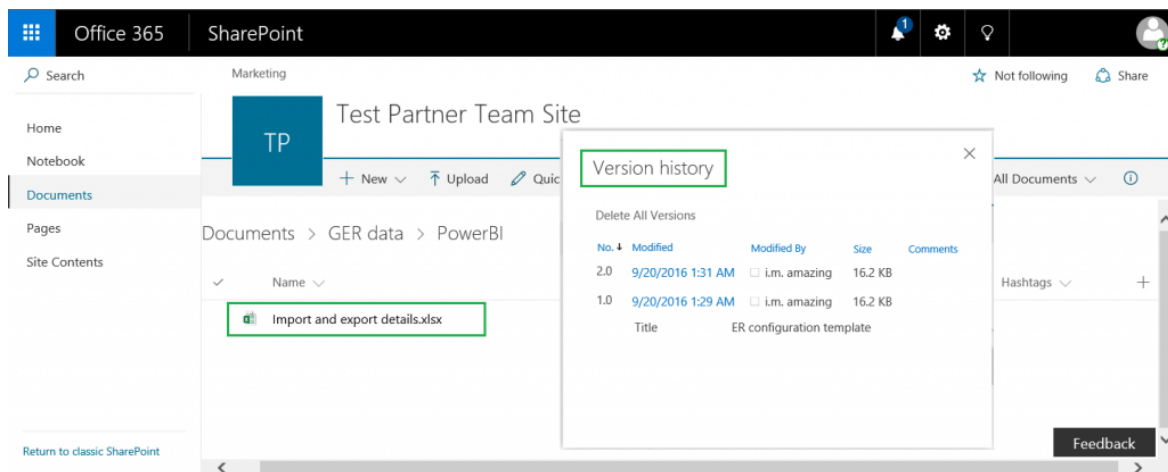

- Select the completed version of the **Import / export activities** configuration, and then click **Run**. Note that the configured destination is applied to the output result that is generated in Excel format.
- Set the **Batch processing** option to **Yes** to run this report in unattended mode.
- Click **Recurrence** to schedule the required recurrence of this batch execution. The recurrence defines how often the updated data will be transferred to Power BI.

- After it's configured, you can find the ER report execution job on the **Batch jobs** page (**System administration > Inquiries > Batch jobs**).

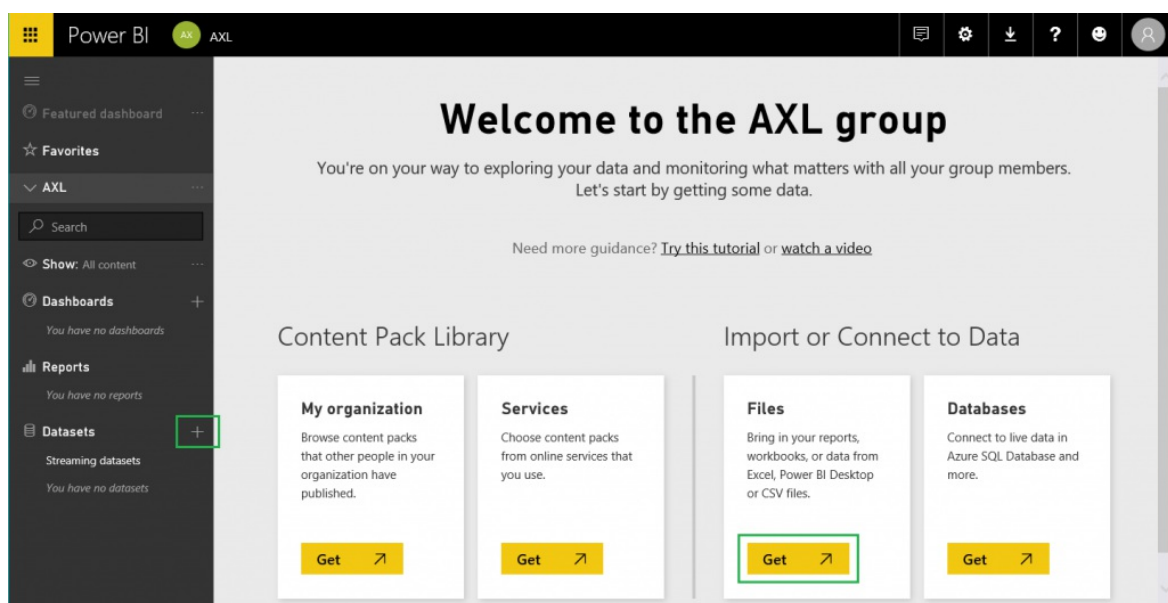

- When this job is run for the first time, the destination creates a new Excel file that has the configured name in the selected SharePoint folder. Every subsequent time that the job is run, the destination creates a new version of this Excel file.

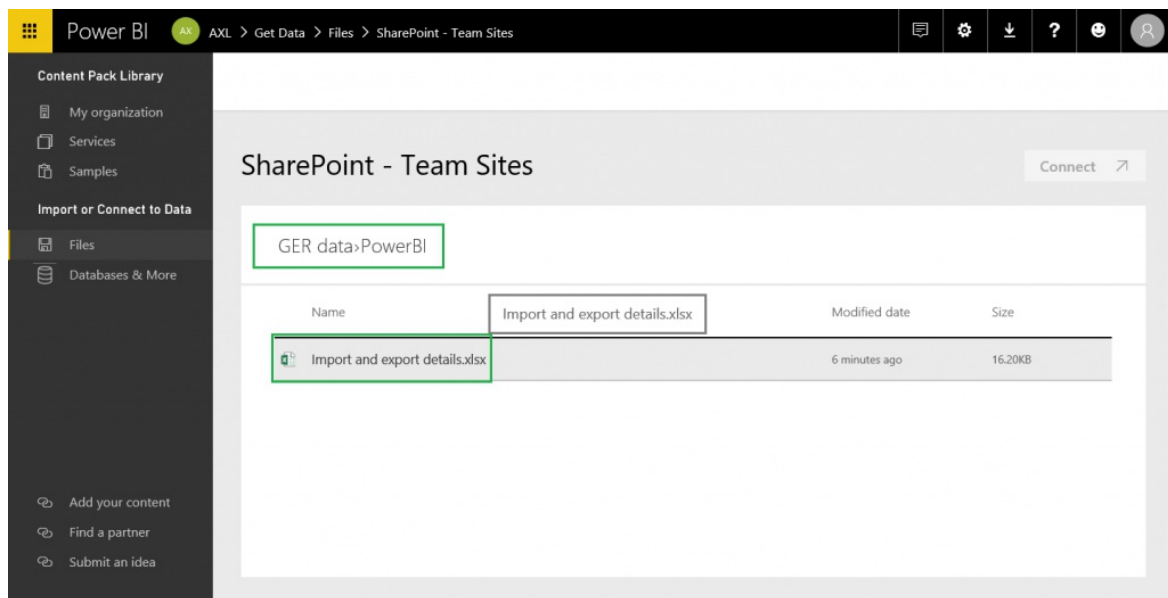

Create a Power BI dataset by using the output result of the ER format

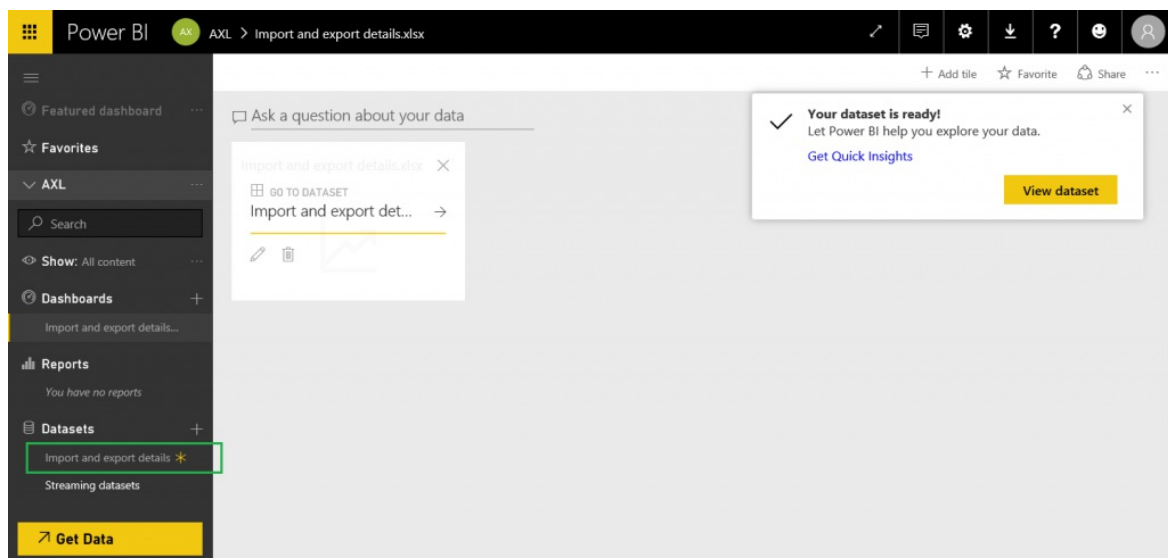

1. Sign in to Power BI, and either open an existing Power BI group (workspace) or create a new group. Either click **Add** under **Files** in the **Import or Connect to Data** section, or click the plus sign (+) next to **Datasets** in the left pane.

2. Select the **SharePoint – Team sites** option, and then enter the path of SharePoint Server that you're using (`https://ax7partner.litware.com` in our example).
3. Browse to the `/Shared Documents/GER data/PowerBI` folder, and select the Excel file that you created as the source of data for the new Power BI dataset.

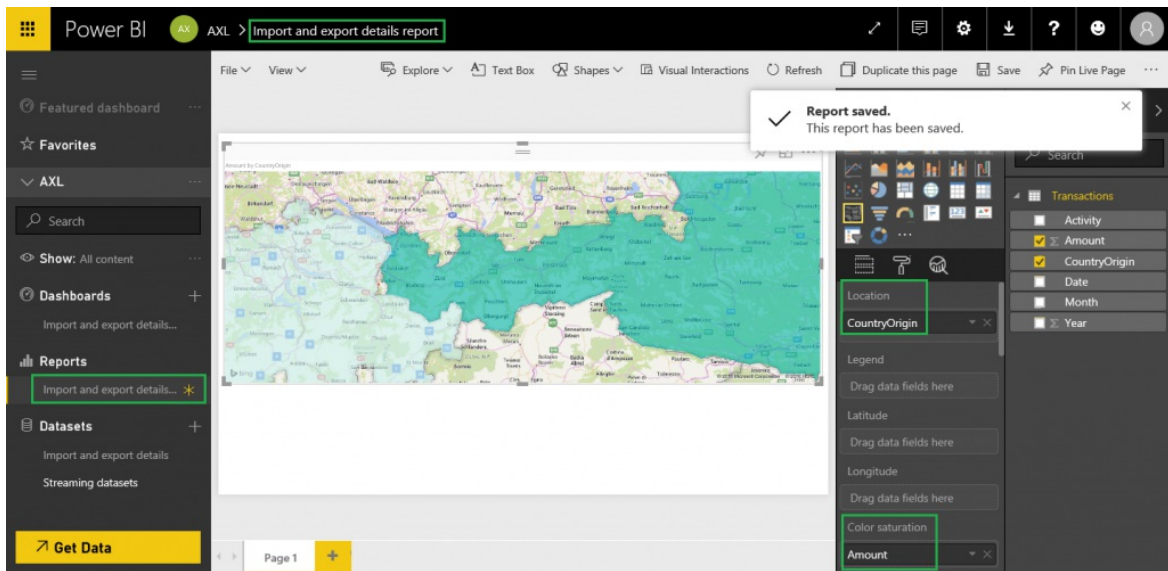

4. Click **Connect**, and then click **Import**. A new dataset is created that is based on the selected Excel file. The dataset can also be added automatically to the newly created dashboard.

5. Configure the refresh schedule for this dataset to force a periodic update. Periodic updates enable the consumption of new business data that comes via periodic execution of the ER report through new versions of the Excel file that are created on the SharePoint Server.

Create a Power BI report by using the new dataset

1. Click the **Import and export details** Power BI dataset that you created.
2. Configure the visualization. For example, select the **Filled map** visualization, and configure it as follows:
 - Assign the **CountryOrigin** dataset field to the **Location** field of the map visualization.
 - Assign the **Amount** dataset field to the **Color saturation** field of the map visualization.
 - Add the **Activity** and **Year** dataset fields to the **Filters** fields collection of the map visualization.
3. Save the Power BI report as **Import and export details report**.

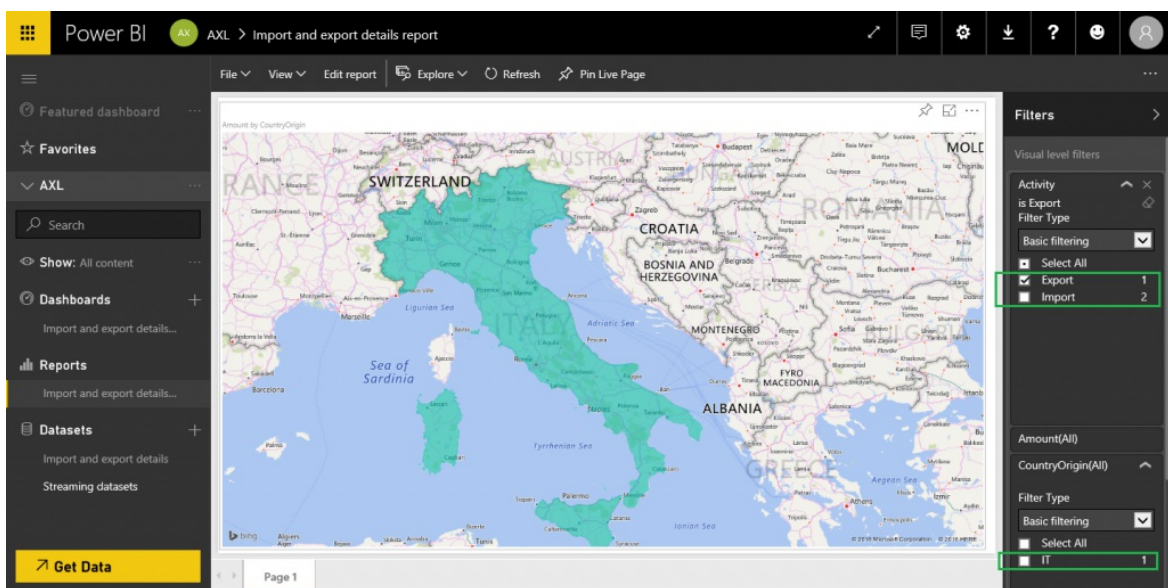

Note that the map shows the countries/regions that are mentioned in the Excel file (Austria and Switzerland in this example). These countries/regions are colored to show the proportion of invoiced amounts for each.

- Update the list of Intrastat transactions. The export transaction that originated from Italy is added.

Date	Direction	Correction	Item number	Category	Commodity	Weight	Invoice amount	Statistical amount	Is...	Country/region of origin
1/31/2016	Arrivals	<input type="checkbox"/>	D0003		920 20 34	4.00	1,000.00	1,000.00	✓	AUT
1/31/2016	Arrivals	<input type="checkbox"/>	T0006		900 22 33	5.00	700.00	700.00	✓	CHE
1/31/2016	Dispatches	<input type="checkbox"/>	D0006		900 30 10	1.00	1,500.00	500.00	✓	ITA

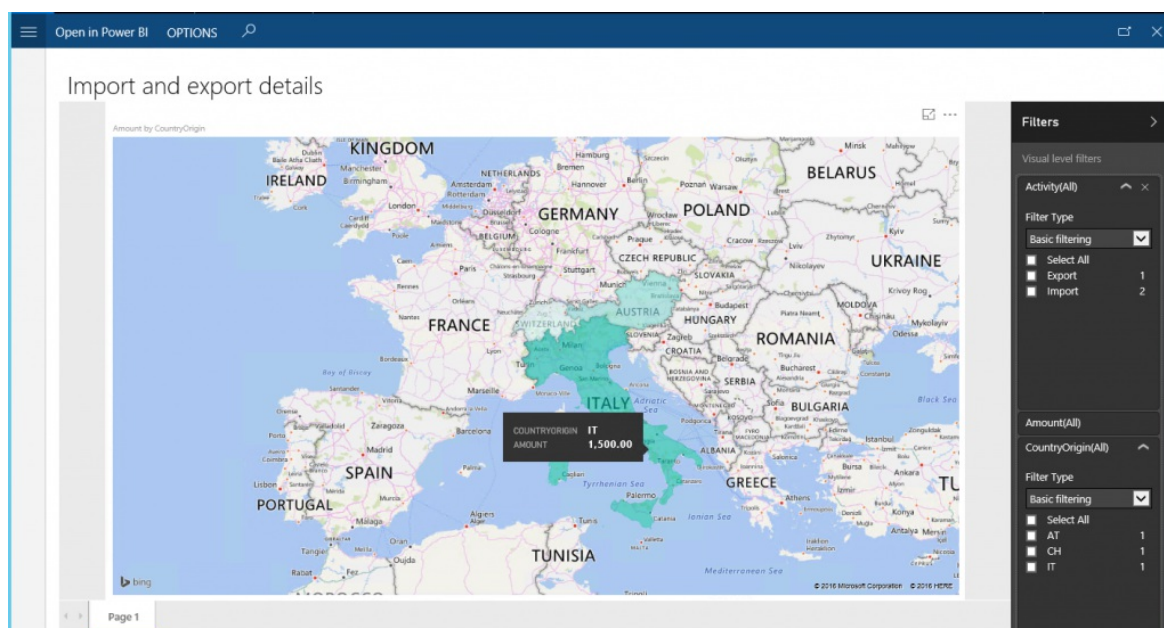

- Wait for the next scheduled execution of the ER report and the next scheduled update of the Power BI dataset. Then review the Power BI report (select to show import transactions only). The updated map now shows Italy.

Access Power BI report in Finance

Set up the integration with Power BI. For more information, see [Configure Power BI integration for workspaces](#).

1. On the **Electronic reporting** workspace page that supports Power BI integration (**Organization administration > Workspaces > Electronic reporting workspace**), click **Options > Open report catalog**.
2. Select the **Import and export details** Power BI report that you created, to show that report as an action item on the selected page.
3. Click the action item to open the page that shows the report that you designed in Power BI.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Generate printable FTI forms

2/18/2021 • 10 minutes to read • [Edit Online](#)

The Electronic reporting (ER) framework lets you generate printable free text invoice (FTI) forms as Microsoft Office documents. This topic provides information about how to build your own configurations as well as details of available configuration templates.

Overview

In addition to the existing capability of generating printable FTI forms by using Microsoft SQL Server Reporting Services (SSRS), you can now use the ER framework. You can manage printable FTI forms in Microsoft Office Excel and Word. You can also modify the layout, data flow, and formatting to meet specific requirements without making code changes.

NOTE

If you want to start with an overview of existing ER configurations for this sample of the printable FTI forms solution, you can go directly to section **Download sample ER configurations to generate printable FTI forms** later in this topic.

Create customized configurations for FTI printable forms

As part of your customized solution for printable FTI forms, you must create a set of ER configurations.

Configure the ER data model

Your application must include the ER data model configuration that contains a data model that describes the customer invoicing business domain. As a requirement, the name of the data model must be **CustomersInvoicing**. For information about how to design ER data models, see [ER Design domain specific data model](#).

Configure the ER model mapping

Your application must include the ER model mapping for the CustomersInvoicing data model. The model mapping can be in either the ER data model configuration or the ER model mapping configuration. However, the name of the root descriptor of the model mapping must be **FreeTextInvoice**.

The mapping must contain the following data sources:

- Data source type: **Table records**
 - This data source must be named **CustInvoiceJour**.
 - It must refer to the CustInvoiceJour application table.
 - It's used at runtime to pass from the application to the ER model mapping the list of invoices that have been selected for printing.
- Data source type: **Object**
 - This data source must be named **PrintMgmtPrintSettingDetail**.
 - It must refer to the **PrintMgmtPrintSettingDetail** application class.
 - It's used at runtime to pass from the application to the ER model mapping details of the print management settings for the ER format that is running.

The details of the application integration with the ER framework can be found in the

ERPrintMgmtReportFormatSubscriber class (ER Application Suite integration model) in the source code of the application.

For more information about the design of ER model mappings, see [Define ER model mappings and select data sources for them](#).

Configure the ER format

In your application instance, you must have the ER format configuration that will be used to generate FTI forms.

NOTE

This format configuration must be created for the CustomersInvoicing data model, and it must use the model mapping that has the **FreeTextInvoice** root descriptor.

For information about how to configure ER formats, see [ER Create a format configuration \(November 2016\)](#). For information about how to design ER formats to generate reports in OpenXML format, see [ER Design a configuration for generating reports in OPENXML format \(November 2016\)](#).

Configure print management

To generate FTI forms by using the ER framework, you can assign ER formats in the same way that you assign SSRS reports. To associate the ER format with all Accounts receivable FTIs, go to **Accounts receivable > Setup > Forms > Form setup > General > Print management > Free text invoice > Original**. To associate the ER format with a specific customer or invoice, follow these steps.

1. Go to **Accounts receivable > Invoices > All free text invoices**.
2. Select the FTI to associate the ER format with, and open the **Print management setup** page.
3. Select the document level to specify the scope of invoices for processing.
4. Select the ER format for the specified document level.

The screenshot shows the Dynamics 365 interface for configuring print management. The breadcrumb trail is "Accounts receivable > Invoices > All free text invoices". The page title is "Print management setup" for "US-001". The left navigation pane shows a tree view with "Free text invoice" selected, and "Copy <Default>" highlighted. The main content area is titled "ORIGINAL OR COPY IDENTIFICATION" and contains several fields: "Original / copy" (Copy), "Name" (Copy), "Sus" (All countries/regions), "No" (Report format), "Default country/region", a checked checkbox for "Customer FTI report (GER)", "FreeTextInvoice.Report", a dropdown menu showing "FreeTextInvoice.Report", "Number of copies" (1), and "Footer text".

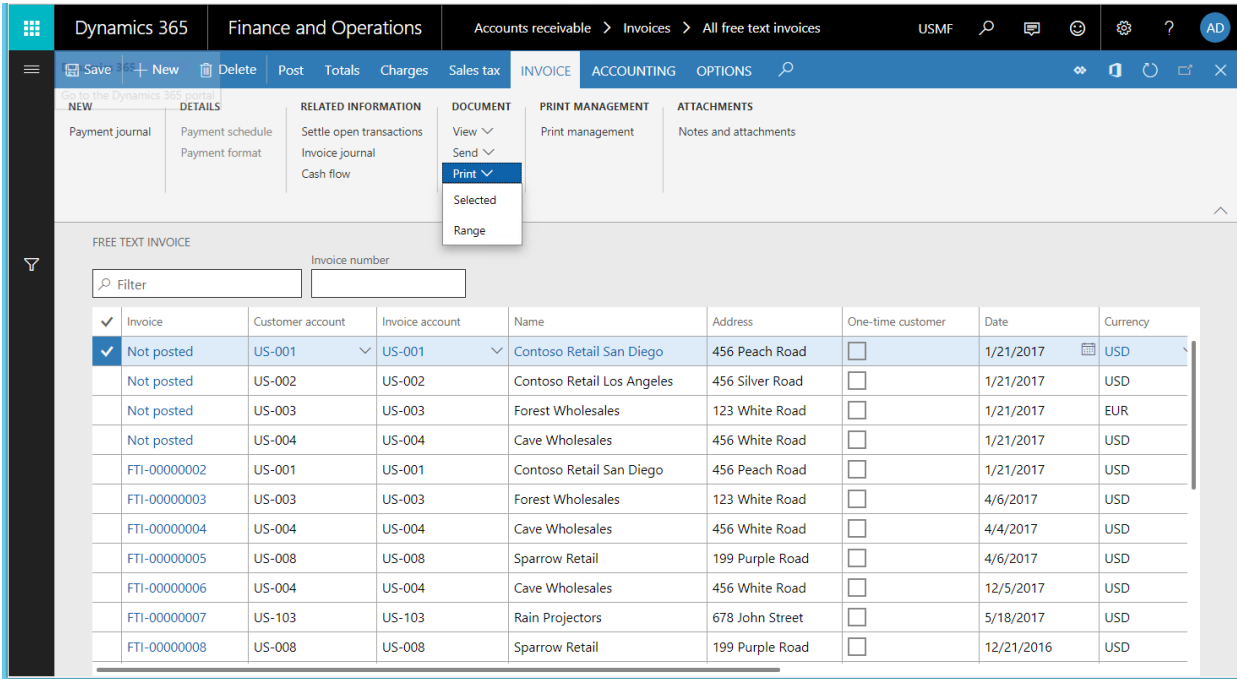

NOTE

Only ER formats that use the **FreeTextInvoice** root descriptor of the CustomersInvoicing data model appear in the **Report format lookup** field for the selected format.

Generate FTI forms

FTI forms are generated in the ER framework in the same way that SSRS reports are generated.

To generate FTI forms, you can select invoices either by range or by selection.

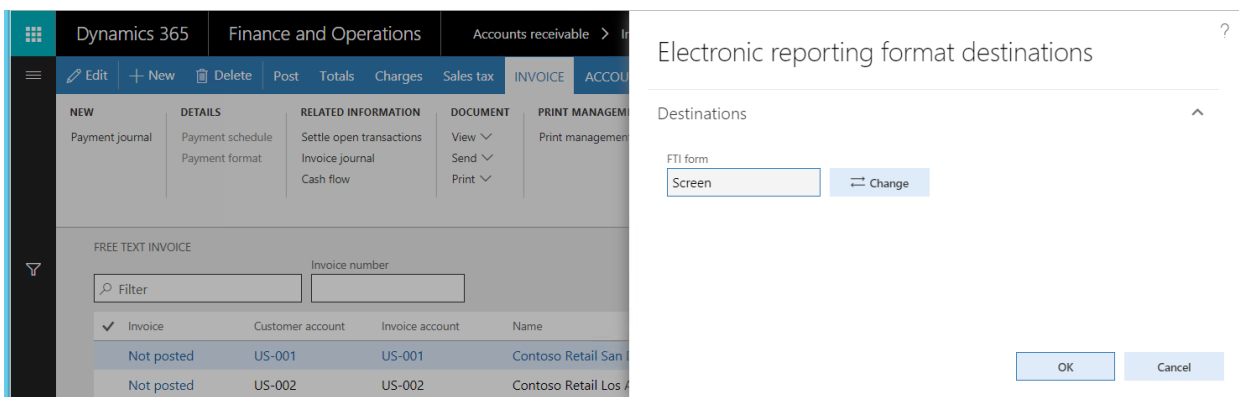

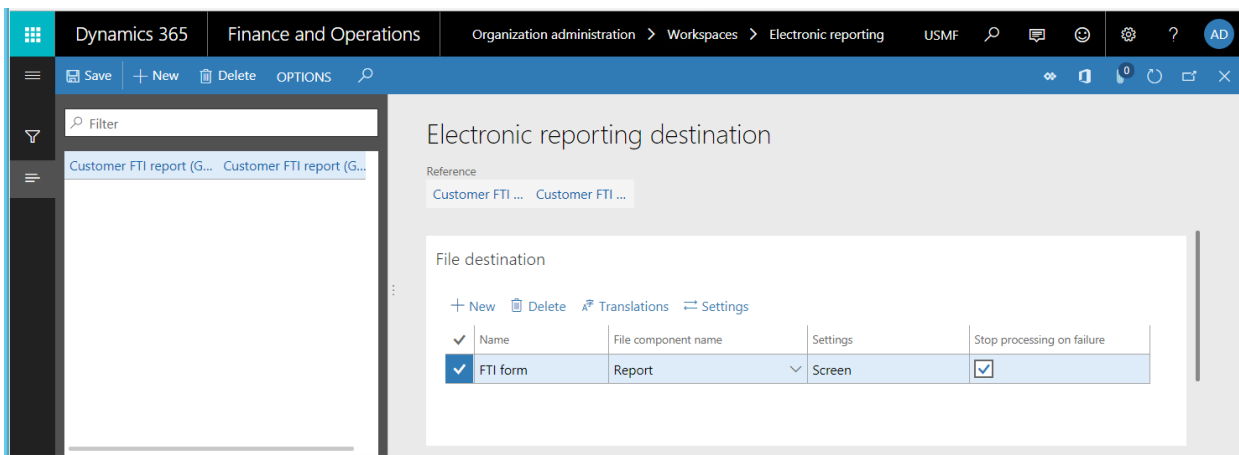

When you use ER formats to print FTI forms in this way, the default ER file destinations are used. You can't change the destination. For more information about how to configure the ER destinations for ER formats, see [Electronic reporting \(ER\) destinations](#).

You can also generate FTI forms when you post an FTI, by turning **Print invoice** on and turning **Use print management destinations** off.

NOTE

When you use ER formats to print FTI forms in this way, the default ER file destinations are used. You can change the default destination at runtime if the destination has already been configured. To change the destination, you must have the following security privilege:

- **Name:** ERFormatDestinationRuntimeMaintain
- **Label:** Maintain electronic reporting format destination during runtime

The ER framework currently supports the following destinations for generated documents:

- **Downloaded file** – Generated forms are offered as downloads that you can save by using the browser.
- **Screen** – Microsoft 365 Excel is used to preview generated FTI forms in Excel format.
- **SharePoint folder** – Generated forms are stored based on the settings of the Document management framework.
- **Application archive** – Generated forms are stored as attachments of execution log records in the Microsoft Azure Storage.
- **Email** – Generated forms are sent as email attachments.

NOTE

You can't send the FTI forms that are generated directly to the printer, because direct printing that uses the Dynamics Printer Routing Agent isn't currently supported.

Download sample ER configurations to generate printable FTI forms

You can download sample ER configurations to use as a template for your FTI solution. The configurations are stored in the Shared asset library in Microsoft Dynamics Lifecycle Services (LCS). The configurations include:

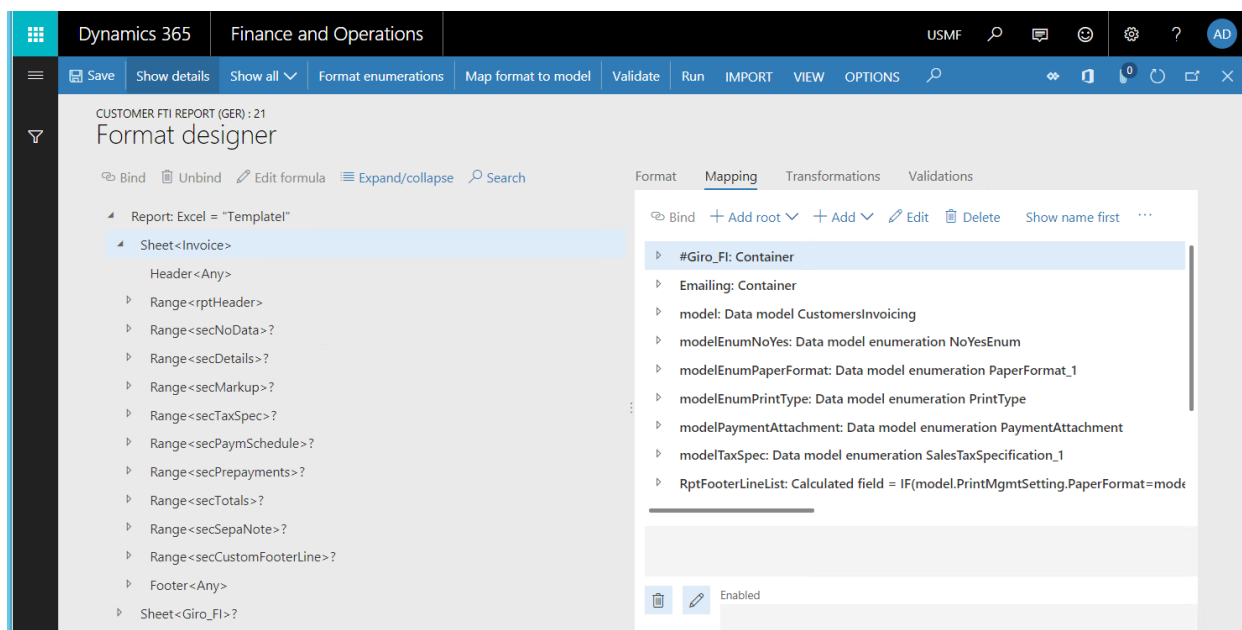

- The **Customer invoicing model** configuration contains the required data model and model mapping.
- The **Customer FTI report (GER)** configuration contains the sample format.

NOTE

These configurations have been created as samples to help clarify possible scenarios. The future of these configurations depends on the results of this evaluation and any feedback that is received.

Features that are implemented in the sample ER format

In the sample ER format configuration, an Excel file is used as a template to generate FTI forms.

Currently, this sample ER format supports the following features to generate FTI forms:

- FTI forms are generated for both original invoices that have been posted and original invoices that haven't yet been posted. Corrected invoices and credit notes aren't supported.
- FTI forms are generated in the invoice language. The format of values and dates in the generated forms is based on the settings of the user's client locale.
- Generated invoices show data unavailability notifications if there are no lines in the invoices that are processed.
- Generated invoice headers are based on the paper format that has been selected for the FTI form on the **Accounts receivable parameters** page. Company details appear in the header of the generated invoice form only if the paper format is blank.
- Generated invoice forms show company and customer tax exempt numbers when the appropriate option has been selected for the FTI form on the **Accounts receivable parameters** page.
- The generated invoice lines and invoice totals sections show the default invoice's monetary details in the invoice registration currency.
- The generated invoice totals section can show monetary details in the euro currency and the invoice registration currency when the **Print amount in currency representing the euro** option is enabled on the **Accounts receivable parameters** page.
- Generated invoice forms show any process invoice notes that are available, based on settings on the **Accounts receivable parameters** page. Notes are included for both the whole invoice and each invoice

line.

- Generated invoice forms include notes for the customer FTI form and the processing invoice language when they have been configured in the AR form notes list.
- Depending on the Print management settings, generated invoices include custom footer text when it has been configured for the invoice language, the ER format, and the FTI document scope.
- The totals section of generated invoice forms includes any cash discount information that is available.
- The payment schedule section of generated invoice forms includes any payment schedule details that are available.
- The markup section of generated invoice forms includes any charges transactions that are available.
- Generated invoice forms include sales tax details, based on the **Sales tax specification** setting on the **Accounts receivable parameters** page. This section can show tax details either in the invoice registration currency only, or in the invoice registration currency and the company accounting currency at the same time.
- Generated invoice forms show direct debit notification details. For example, they show when the method of payment that has the mandatory direct debit mandate ID was selected for the invoice, when the processing invoice was registered in the euro currency, and when the direct debit mandate ID was defined for the invoice.
- Generated invoices show any prepayment details that are available for posted invoices.
- Generated invoice forms can be sent to an invoice customer as an email attachment. The appropriate ER file destination should be configured for the ER format that is being used.

Country/region-specific features

The following country/region-specific features are included in the sample ER format to show how specific requirements can be handled in ER configurations.

Norway

The Enterprise register term is put on the header of the generated invoice form when the invoice is processed for a legal entity that is configured in the following manner:

- The country/region context for Norway is used.
- The **Print Foretaksregisteret** parameter is active on sales documents.

Spain

The **Special regime for cash accounting method** term is put on the header of the generated invoice form when the invoice is processed for a legal entity that is configured in the following manner:

- The country/region context for Spain is used.
- The special regime for the cash accounting method is enabled on the invoice processing date.

When cash discount details, such as the cash discount amount and invoice line net amount, are available, they are presented in the invoice totals section of the generated invoice form when it has been processed for a legal entity that is configured in the following manner:

- The country/region context for Spain is used.
- **Cash discount is applied in the invoice** is turned on in the invoice option (**General ledger parameters > Sales tax section**).

Italy

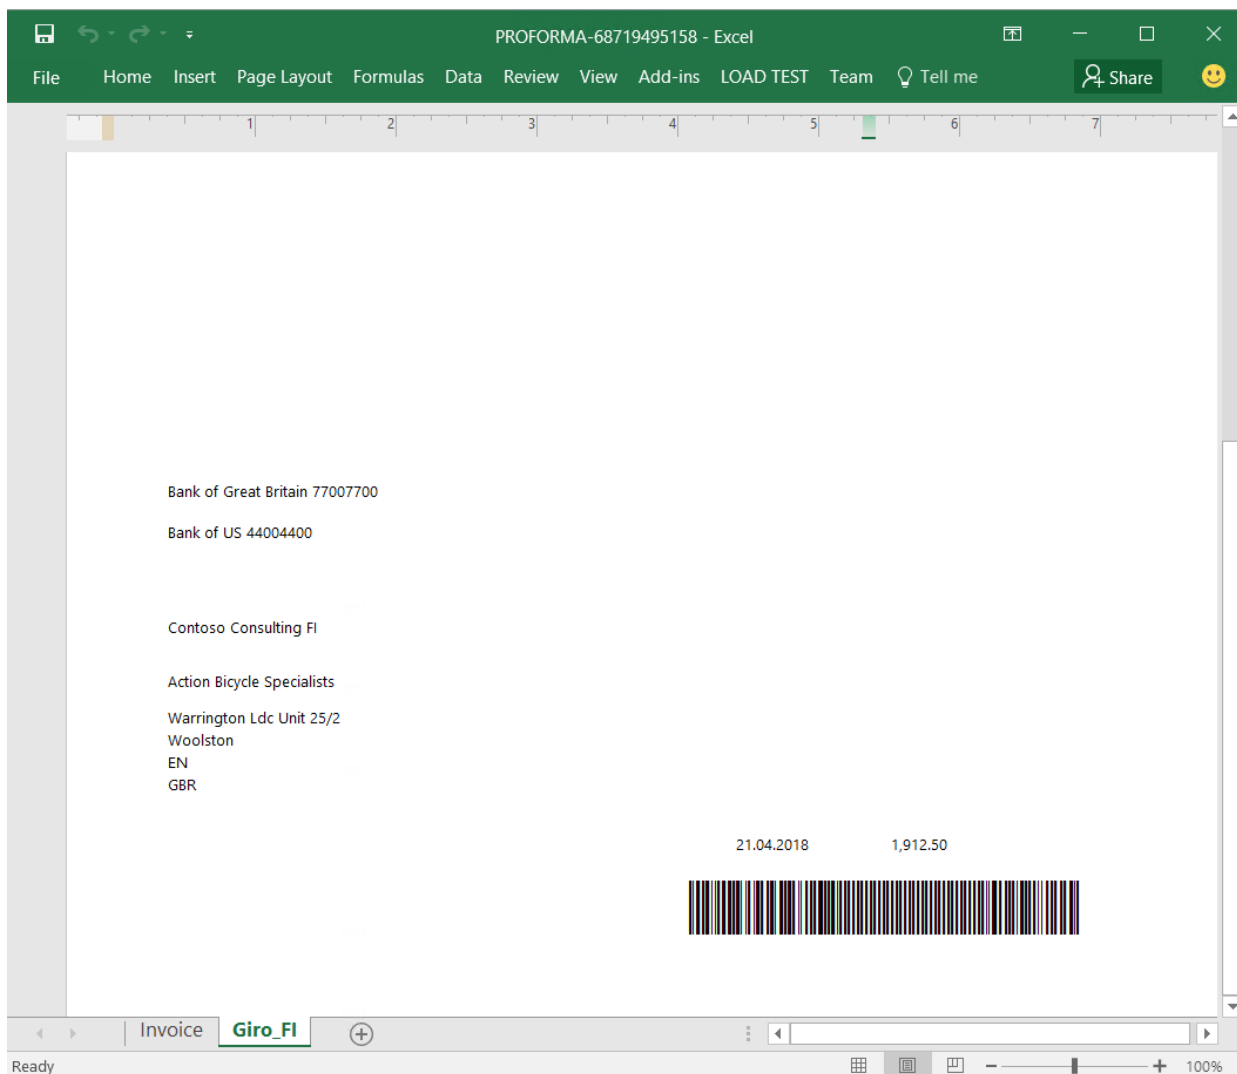

The goods discount mark is included on the invoice lines of the generated invoice when it's being processed for a legal entity that is configured using the country/region context for Italy.

Finland

In addition to the generated invoice form, Giro money transfer slips can be generated as follows:

- For the legal entity that uses the country/region context for Finland, and that has at least one bank account that is marked as **Giro account** and **Bank bar code**.

- For an invoice that is marked as required for the **Finnish** associated payment attachment.

NOTE

The sample ER format has been configured to optionally generate the Giro money transfer slips in the separate worksheet.

NOTE

You must first install the font that is used to generate the bar code on the local machine where the generated invoice form in Excel format will be previewed.

Use the sample ER format to configure email destinations

Use the following elements of the sample ER format to configure email destinations:

- The email address of a customer contact can be accessed through the following ER expression: **model.InvoiceBase.Contact.ElectronicMail**.
- The email subject text can be accessed through the following ER expression: **Emailing.TxtToUse.Subject**.
- The email body text can be accessed through the following ER expression: **Emailing.TxtToUse.Body**.

The default text of the email's subject and body is defined in the sample ER format. The language depends on the format's labels. This default text will be used for emails if a custom organization email template that has the predefined **ERFTITMP** ID hasn't been added.

NOTE

The **ERFTITMP** email template ID has been defined in the sample ER format. It can be changed as required in a new ER format that is created from this sample format.

If the organization email template that has the predefined **ERFTITMP** ID has been added for the legal entity that you're processing the invoice for, the template for the email subject and body text will be used to generate the email.

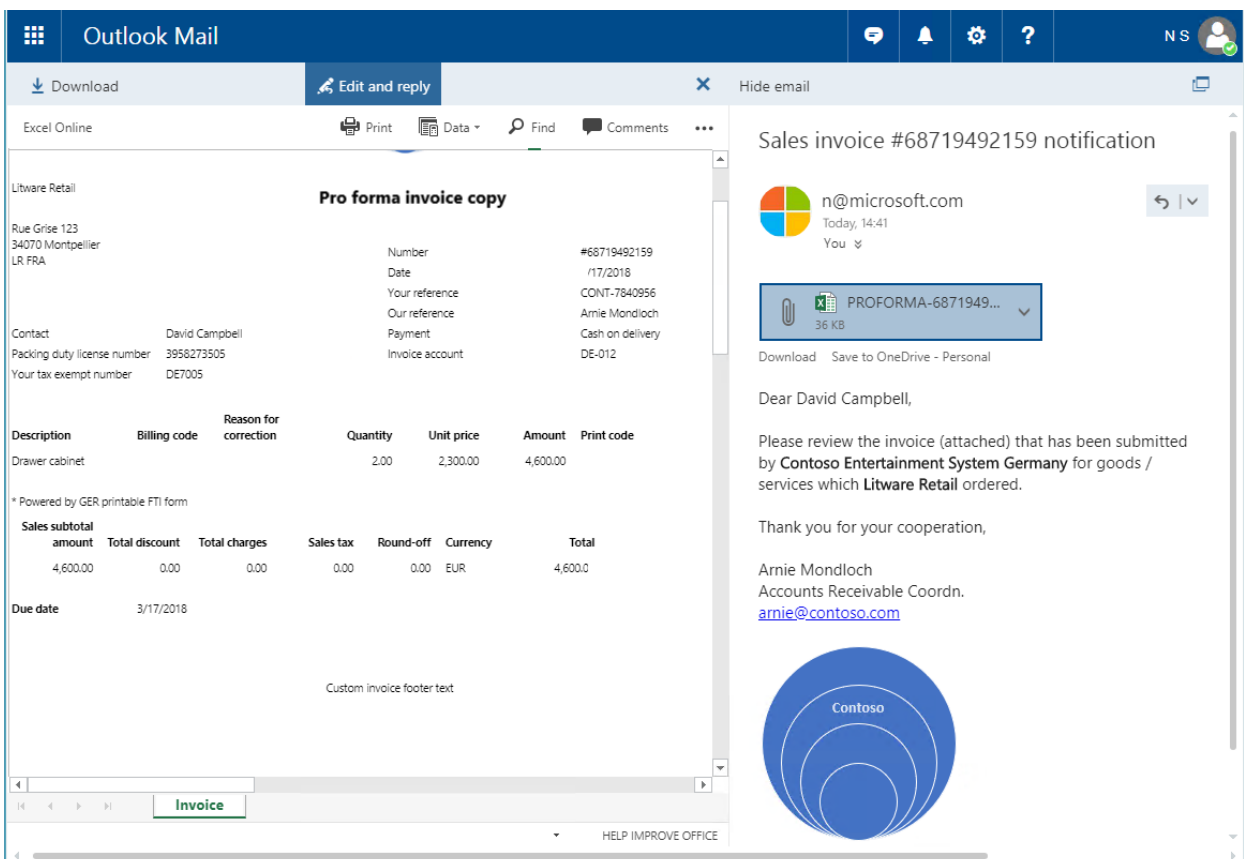

The `Emailing.TxtToUse.Subject` ER expression of the sample ER format is configured to replace any occurrences of the placeholder `%1` by the processing invoice ID.

The `Emailing.TxtToUse.Body` expression of the sample format is configured for the following substitutions for placeholders:

- `"%1"` is replaced with the name of the customer's contact person.
- `"%2"` is replaced with the company name.
- `"%3"` is replaced with the customer name.
- `"%4"` is replaced with the name of the company's contact person.
- `"%5"` is replaced with the job title of the company's contact person.
- `"%6"` is replaced with the email address of the company's contact person.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Trace the execution of ER formats to troubleshoot performance issues

2/18/2021 • 15 minutes to read • [Edit Online](#)

As part of the process of designing Electronic reporting (ER) configurations to generate electronic documents, you define the method that is used to get data out of the application and enter it in the output that is generated. The ER performance trace feature helps significantly reduce the time and cost that are involved in collecting the details of ER format execution and using them to troubleshoot performance issues. This tutorial provides guidelines about how to take performance traces for executed ER formats, and how to use the information from these traces to help improve performance.

Prerequisites

To complete the examples in this tutorial, you must have the following access:

- Access to one of the following roles:
 - Electronic reporting developer
 - Electronic reporting functional consultant
 - System administrator
- Access to the instance of Regulatory Configuration Services (RCS) that has been provisioned for the same tenant as the application, for one of the following roles:
 - Electronic reporting developer
 - Electronic reporting functional consultant
 - System administrator

You must also download and locally store the following files.

FILE	CONTENT
Performance trace model.version.1	Sample ER data model configuration
Performance trace metadata.version.1	Sample ER metadata configuration
Performance trace mapping.version.1.1	Sample ER model mapping configuration
Performance trace format.version.1.1	Sample ER format configuration

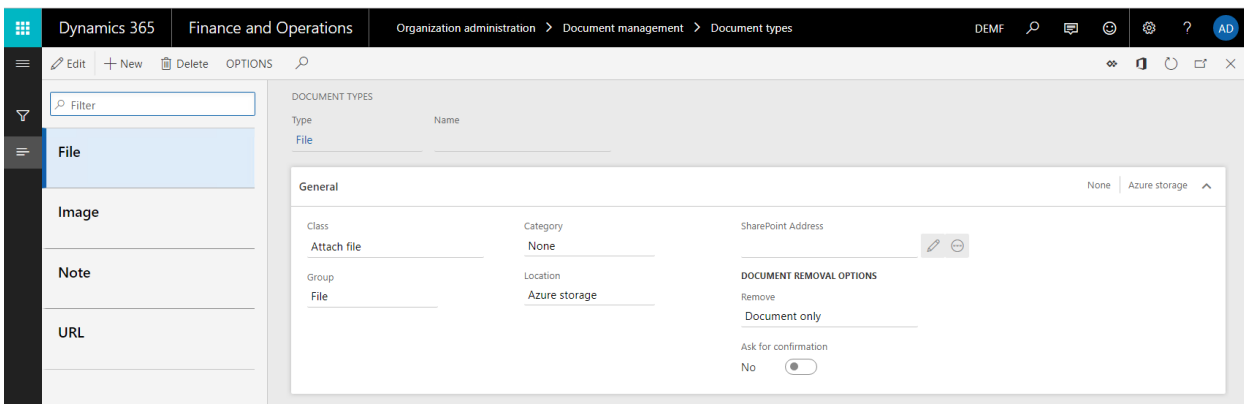

Configure ER parameters

Each ER performance trace that is generated in the application is stored as an attachment of the execution log record. The Document management (DM) framework is used to manage these attachments. You must configure ER parameters in advance, to specify the DM document type that should be used to attach performance traces. In the **Electronic reporting** workspace, select **Electronic reporting parameters**. Then, on the **Electronic reporting parameters** page, on the **Attachments** tab, in the **Others** field, select the DM document type to use for performance traces.

To be available in the **Others** lookup field, a DM document type must be configured in the following manner on the **Document types** page (**Organization administration > Document management > Document types**):

- **Class:** Attach file
- **Group:** File

NOTE

The selected document type must be available in every company of the current instance, because DM attachments are company-specific.

Configure RCS parameters

ER performance traces that are generated will be imported into RCS for analysis by using the ER format designer and the ER mapping designer. Because ER performance traces are stored as attachments of the execution log record that is related to the ER format, you must configure RCS parameters in advance, to specify the DM document type that should be used to attach performance traces. In the instance of RCS that has been provisioned for your company, in the **Electronic reporting** workspace, select **Electronic reporting parameters**. Then, on the **Electronic reporting parameters** page, on the **Attachments** tab, in the **Others** field, select the DM document type to use for performance traces.

To be available in the **Others** lookup field, a DM document type must be configured in the following manner on

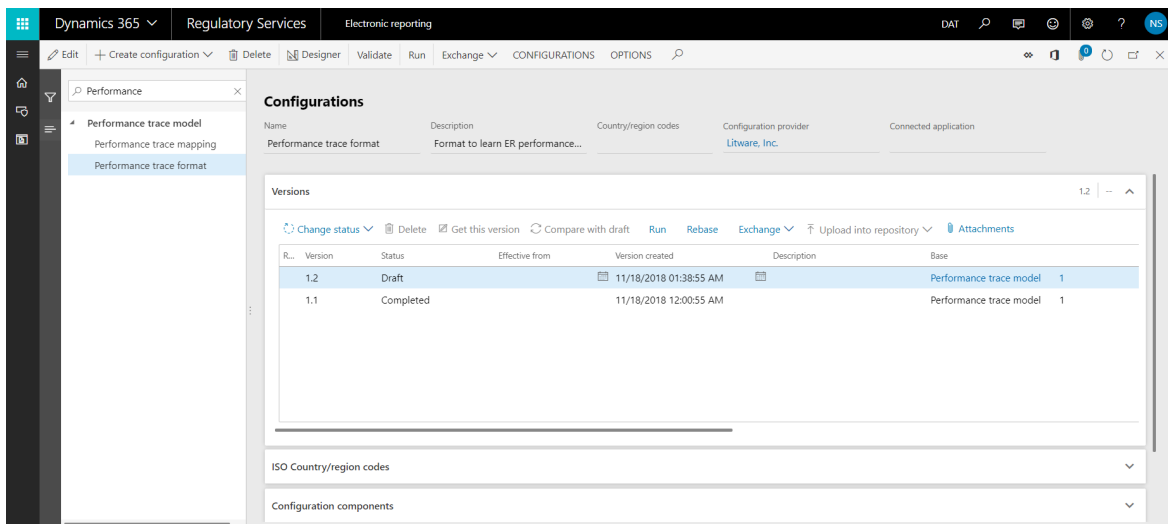

the Document types page (Organization administration > Document management > Document types):

- Class: Attach file
- Group: File

Design an ER solution

Assume that you've started to design a new ER solution to generate a new report that presents vendor transactions. Currently, you can find the transactions for a selected vendor on the **Vendor transactions** page (go to **Account payable > Vendors > All vendors**, select a vendor, and then, on the Action Pane, on the **Vendor** tab, in the **Transactions** group, select **Transactions**). However, you want to have all vendor transaction at the same time in one electronic document in XML format. This solution will consist of several ER configurations that contain the required data model, metadata, model mapping, and format components.

1. Sign in to the instance of RCS that has been provisioned for your company.
2. In this tutorial, you will create and modify configurations for the **Litware, Inc.** sample company. Therefore, make sure that this configuration provider has been added to RCS and selected as active. For instructions, see the [Create configuration providers and mark them as active](#) procedure.
3. In the **Electronic reporting** workspace, select the **Reporting configurations** tile.
4. On the **Configurations** page, import the ER configurations that you downloaded as a prerequisite into RCS, in the following order: data model, metadata, model mapping, format. For each configuration, follow these steps:
 - a. On the Action Pane, select **Exchange > Load from XML file**.
 - b. Select **Browse** to select the appropriate file for the required ER configuration in XML format.
 - c. Select **OK**.

Run the ER solution to trace execution

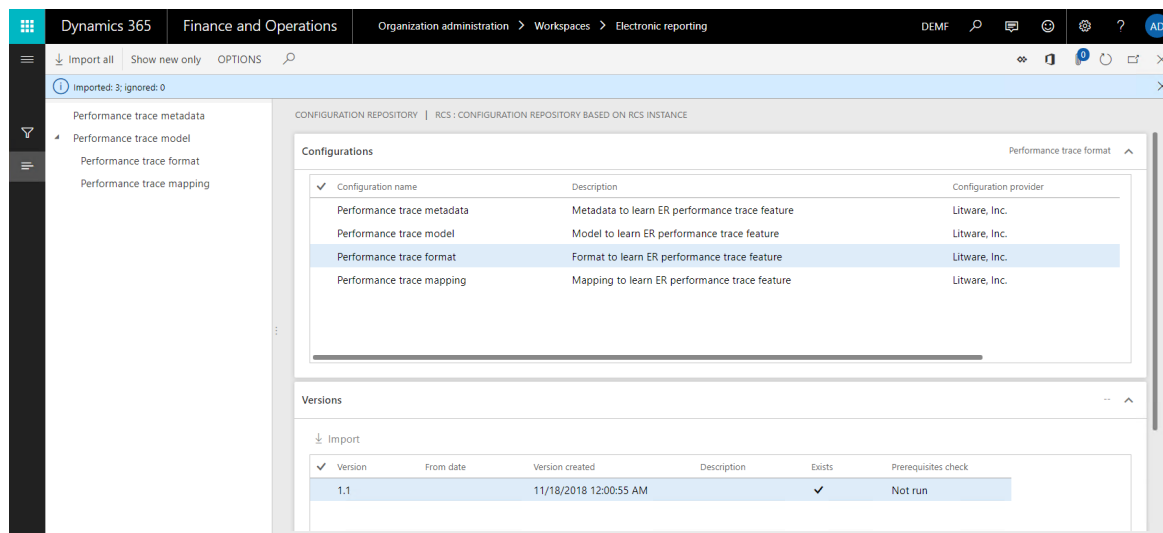

Assume that you've finished designing the first version of the ER solution. You now want to test it in your instance and analyze execution performance.

Import an ER configuration from RCS into Finance and Operations

1. Sign in to your application instance.
2. For this tutorial, you will import configurations from your RCS instance (where you design your ER components) into your instance (where you test and finally use them). Therefore, you must make sure that all the required artifacts have been prepared. For instructions, see the [Import Electronic reporting](#)

(ER) configurations from Regulatory Configuration Services (RCS) procedure.

3. Follow these steps to import the configurations from RCS into the application:
 - a. In the **Electronic reporting** workspace, on the tile for the **Litware, Inc.** configuration provider, select **Repositories**.
 - b. On the **Configuration repository** page, select the repository of the **RCS** type, and then select **Open**.
 - c. On the **Configurations** FastTab, select the **Performance trace format** configuration.
 - d. On the **Versions** FastTab, select version **1.1** of the selected configuration, and then select **Import**.

The corresponding versions of the data model and model mapping configurations are automatically imported as prerequisites for the imported ER format configuration.

Turn on the ER performance trace

1. Go to **Organization administration > Electronic reporting > Configurations**.
2. On the **Configurations** page, on the Action Pane, on the **Configurations** tab, in the **Advanced settings** group, select **User parameters**.
3. In the **User parameters** dialog box, in the **Execution tracing** section, follow these steps:
 - a. In the **Execution trace format** field, select **Debug trace format** to start to collect the details of ER format execution. When this value is selected, the performance trace will collect information about the time that is spent on the following actions:
 - Running each data source in the model mapping that is called to get data
 - Processing each format item to enter data in the output that is generatedYou use the **Execution trace format** field to specify the format of the generated performance trace that the execution details are stored in for ER format and mapping elements. By selecting **Debug trace format** as the value, you will be able to analyze the content of the trace in ER Operation designer, and see the ER format or mapping elements that are mentioned in the trace.
 - b. Set the following options to **Yes** to collect specific details of the execution of the ER model mapping and ER format components:
 - **Collect query statistics** – When this option is turned on, the performance trace will collect the following information:
 - The number of database calls that were made by data sources
 - The number of duplicate calls to the database
 - Details of the SQL statements that were used to make database calls

- **Trace access of caching** – When this option is turned on, the performance trace will collect information about the ER model mapping's cache usage.
- **Trace data access** – When this option is turned on, the performance trace will collect information about the number of calls to the database for executed data sources of the record list type.
- **Trace list enumeration** – When this option is turned on, the performance trace will collect information about the number of records that are requested from data sources of the record list type.

NOTE

The parameters in the **User parameters** dialog box are specific to the user and the current company.

Run the ER format

1. Select the DEMF company.
2. Go to **Organization administration > Electronic reporting > Configurations**.
3. On the **Configurations** page, in the configuration tree, select the **Performance trace format** item.
4. On the Action Pane, select **Run**.

Notice that the file that is generated presents information about 265 transactions for six vendors.

Review the execution trace

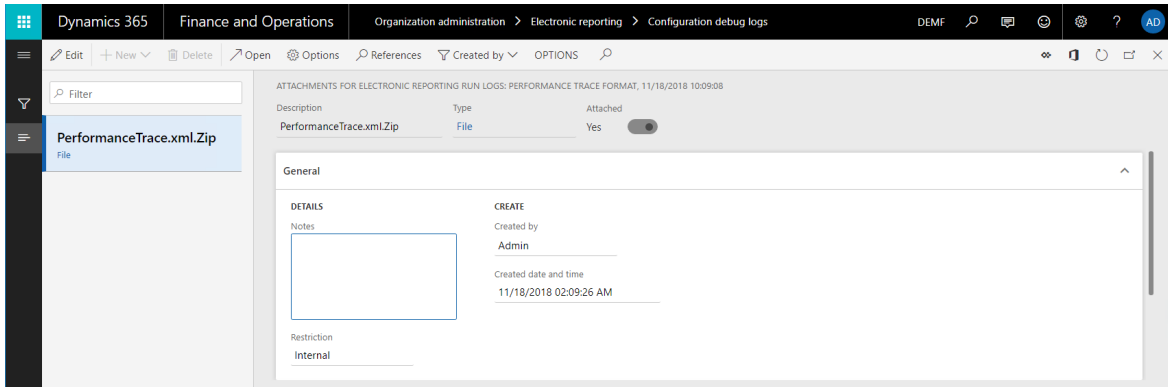

Export the generated trace from the application

Performance traces are decoupled from the source ER format and can be serialized to an external zip file.

1. Go to **Organization administration > Electronic reporting > Configuration debug logs**.
2. On the **Electronic reporting run logs** page, in the left pane, in the **Configuration name** field, select **Performance trace format** to find the log records that have been generated by the execution of the **Performance trace format** configuration.
3. Select the **Attachments** button (the paper clip symbol) in the upper-right corner of the page, or press **Ctrl+Shift+A**.

4. On the **Attachments for Electronic reporting run logs** page, on the Action Pane, select **Open** to get the performance trace as a zip file and store it locally.

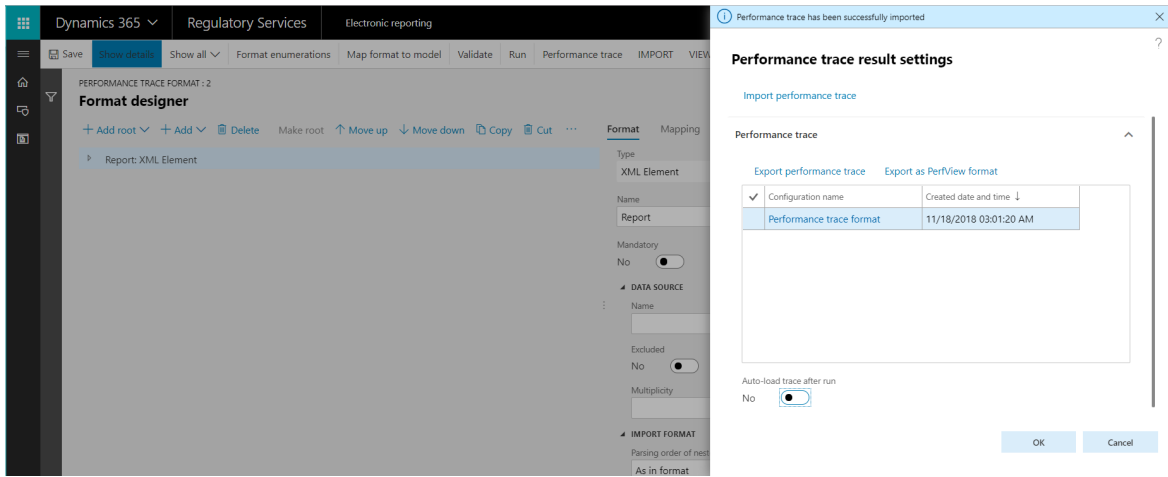

NOTE

The trace that is generated has a reference to the source ER report via a unique report identifier in **GUID** format only. The version numbering of the format isn't considered.

Notice that the association between the performance trace that has been generated for the executed ER format and the ER model mapping is based on the root descriptor that was used and the common data model. The version numbering of the format and model mapping isn't considered. The setting of the **Default for model mapping** flag for the model mapping also isn't considered.

Import the generated trace into RCS

1. In RCS, in the **Electronic reporting** workspace, select the **Reporting configurations** tile.
2. On the **Configurations** page, in the configuration tree, expand the **Performance trace model** item, and select the **Performance trace format** item.
3. On the Action Pane, select **Designer**.
4. On the **Format designer** page, on the Action Pane, select **Performance trace**.
5. In the **Performance trace result settings** dialog box, select **Import performance trace**.
6. Select **Browse** to select the zip file that you exported earlier.
7. Select **OK**.

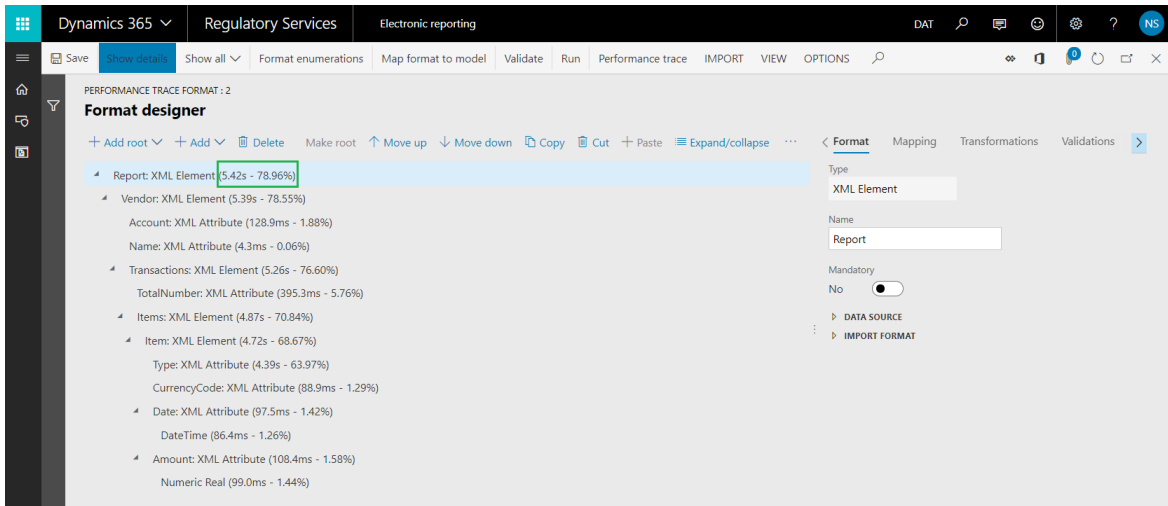

Use the performance trace for analysis in RCS – Format execution

1. In RCS, on the **Format designer** page, select **Expand/collapse** to expand the content of all format items.

Notice that additional information is shown for some items of the current format:

- The actual time that was spent entering data in the generated output by using the format item
- The same time expressed as a percentage of the total time that was spent generating the whole output

2. Close **Format designer** page.

Use the performance trace for analysis in RCS – Model mapping

1. In RCS, on the **Configurations** page, in the configuration tree, select the **Performance trace mapping** item.
2. On the Action Pane, select **Designer**.
3. Select **Designer**.
4. On the **Model mapping designer** page, on the Action Pane, select **Performance trace**.
5. Select the trace that you imported earlier.
6. Select **OK**.

Notice that new information becomes available for some data source items of the current model mapping:

- The actual time that was spent getting data by using the data source
- The same time expressed as a percentage of the total time that was spent running the whole model mapping

Notice that ER informs you that the current model mapping duplicates database requests while the `VendTable/<Relations/VendTrans.VendTable_AccountNum` data source is run. This duplication occurs because the list of vendor transactions is called two times for each iterated vendor record:

- One call is made to enter details of each transaction in the data model, based on configured bindings.
- One call is made to enter the calculated number of transactions per vendor in the data model.

The screenshot shows the 'Model mapping designer' interface. A yellow warning banner at the top states: 'Detected number of duplicate queries to database - 6. Consider caching them.' The interface is divided into several sections:

- DATA SOURCE TYPES:** A tree view on the left showing 'Data model' selected.
- DATA SOURCES:** A tree view in the center showing 'VendTable (3.04s - 76.16%)[12][Q:6]' selected. Underneath it, '<Relations (2.67s - 66.89%)' is expanded to show 'VendTrans.VendTable_AccountNum (2.67s - 66.89%)[530][Q:530]'.
- DETAILS:** A section at the bottom left containing a 'Performance statistics' table and a 'Find in tree' search box.
- DATA MODEL:** A section on the right showing the data model structure with 'Vendor = VendTable' and 'Transactions'.
- SQL Query:** A text area on the right showing a complex SQL SELECT query.

Path	Queries	Duplicated queries	Description
VendTable/<Relations/VendTrans.VendTable_AccountNum	12	6	
VendTable	1	0	

The value [Q:530] indicates that the VendTrans table was called 530 times to return a record from that table to the VendTable/<Relations/VendTrans.VendTable_AccountNum data source. The value [530] indicates that the VendTable/<Relations/VendTrans.VendTable_AccountNum data source was called 530 times to return a record from that data source and enter the details from it in the data model.

We recommend that you use caching for the VendTable/<Relations/VendTrans.VendTable_AccountNum data source, to reduce the number of calls that are made to get the details for 265 transactions and help improve the performance of the model mapping.

It can also be useful to reduce the number of calls that are made to the LedgerTransTypeList data source. This data source is used to associate each value of the LedgerTransType enumeration with its label. By using this data source, you can find an appropriate label and enter it in the data model for each vendor transaction. The current number of calls to this data source (9,027) is quite high for 265 transactions.

The screenshot shows the 'Model mapping designer' interface. A yellow warning banner at the top states: 'Detected number of duplicate queries to database - 6. Consider caching them.' The interface is divided into several sections:

- DATA SOURCE TYPES:** A tree view on the left showing 'Data model' selected.
- DATA SOURCES:** A tree view in the center showing 'LedgerTransTypeList (28.4ms - 0.71%)[9027]' selected.
- DATA MODEL:** A section on the right showing the data model structure with 'Vendor = VendTable' and 'Transactions'.
- SQL Query:** A text area on the right showing a complex SQL query.

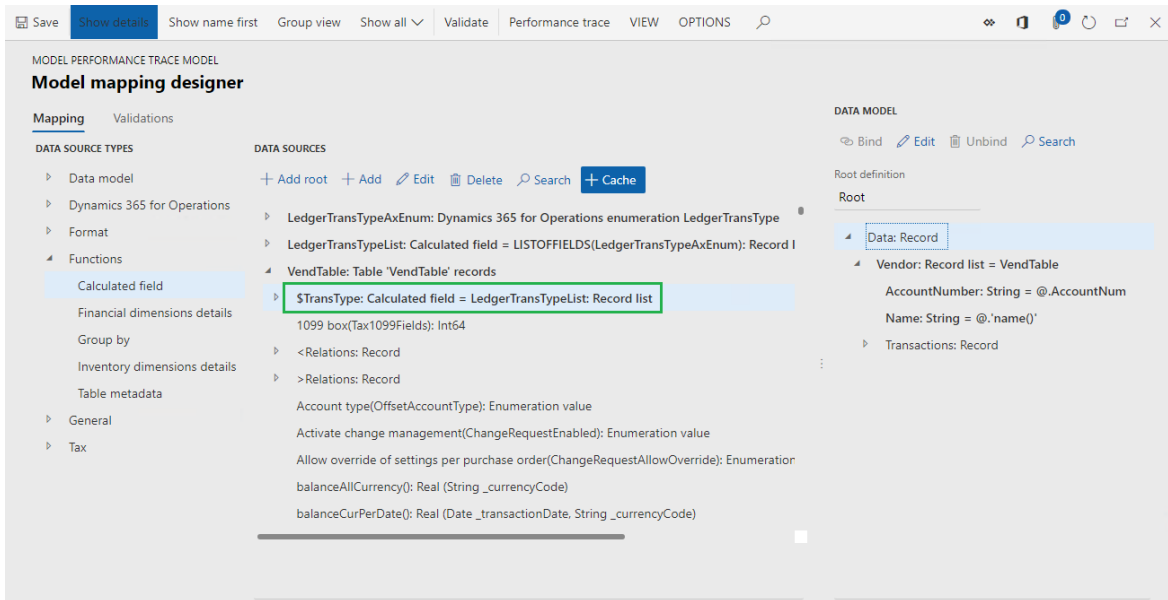

Improve the model mapping based on information from the execution trace

Modify the logic of the model mapping

1. Follow these steps to use caching, to help prevent duplicate calls to the database:
 - a. In RCS, on the **Model mapping designer** page, in the **Data sources** pane, select the **VendTable** item.
 - b. Select **Cache**.
 - c. Expand the **VendTable** item, expand the list of one-to-many relations for the VendTable data source (the **<Relations** item), and select the **VendTrans.VendTable_AccountNum** item.
 - d. Select **Cache**.

2. Follow these steps to bring the LedgerTransTypeList data source into the scope of the VendTable data source:
 - a. In the **Data source types** pane, expand the **Functions** item, and select the **Calculated field** item.
 - b. In the **Data sources** pane, select the **VendTable** item.
 - c. Select **Add**.
 - d. In the **Name** field, enter **\$TransType**.
 - e. Select **Edit formula**.
 - f. In the **Formula** field, enter **LedgerTransTypeList**.
 - g. Select **Save**.
 - h. Close the **Formula editor** page.
 - i. Click **OK**.
3. Follow these steps to do caching of the **\$TransType** field:
 - a. Select the **LedgerTransTypeList** item.
 - b. Select **Cache**.
 - c. Select the **VendTable.\$TransType** item.
 - d. Select **Cache**.

4. Follow these steps to change the **\$TransTypeRecord** field so that it starts to use the cached **\$TransType** field:

a. In the **Data sources** pane, expand the **VendTable** item, expand the **<Relations** item, expand the **VendTrans.VendTable_AccountNum** item, and select the **VendTable.VendTrans.VendTable_AccountNum.\$TransTypeRecord** item.

b. Select **Edit**.

c. Select **Edit formula**.

d. In the **Formula** field, find the following expression:

```
FIRSTORNUL (WHERE (LedgerTransTypeList, LedgerTransTypeList.Enum = @.TransType))
```

e. In the **Formula** field, enter the following expression:

```
FIRSTORNUL (WHERE (VendTable.'$TransType', VendTable.'$TransType'.Enum = @.TransType)).
```

f. Select **Save**.

g. Close the **Formula editor** page.

h. Select **OK**.

5. Select **Save**.

6. Close the **Model mapping designer** page.

7. Close the **Model mappings** page.

Complete the modified version of the ER model mapping

1. In RCS, on the **Configurations** page, on the **Versions** FastTab, select version 1.2 of the **Performance trace mapping** configuration.

2. Select **Change status**.

3. Select **Complete**.

Import the modified ER model mapping configuration from RCS into the application

Repeat the steps in the [Import an ER configuration from RCS into Finance and Operations](#) section earlier in this topic to import version 1.2 of the **Performance trace mapping** configuration.

Run the modified ER solution to trace execution

Run the ER format

Repeat the steps in the [Run the ER format](#) section earlier in this topic to generate a new performance trace.

Work with the execution trace

Export the generated trace from the application

Repeat the steps in the [Export the generated trace from the application](#) section earlier in this topic to save a new performance trace locally.

Import the generated trace into RCS

Repeat the steps in the [Import the generated trace into RCS](#) section earlier in this topic to import the new performance trace into RCS.

Use the performance trace for analysis in RCS – Model mapping

Repeat the steps in the [Use the performance trace for analysis in RCS – Model mapping](#) section earlier in this topic to analyze the latest performance trace.

Notice that the adjustments that you made to the model mapping have eliminated duplicate queries to database. The number of calls to database tables and data sources for this model mapping has been also reduced. Therefore, the performance of the whole ER solution has improved.

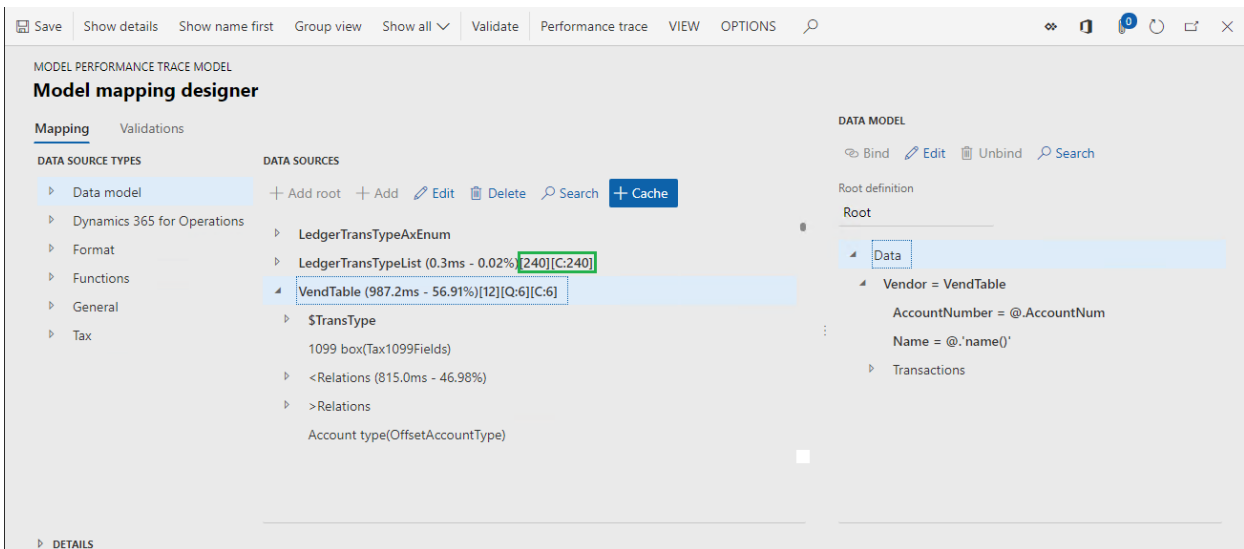

The screenshot shows the 'Model mapping designer' interface. The 'Performance statistics' table is highlighted with a green border. The table has the following data:

Path	Queries	Duplicated queries	Description
VendTable/<Relations/VendTrans.VendTable_AccountNum	6	0	
VendTable	1	0	

Below the table, a query snippet is visible, showing a complex SQL query with various table names and conditions, including 'VENDTABLE T1'.

In the trace information, the value [12] for the VendTable data source indicates that this data source was called 12 times. The value [Q:6] indicates that six calls were translated to database calls to the VendTable table. The value [C:6] indicates that the records that were fetched from the database were cached, and six other calls were processed by using the cache.

Notice that the number of calls to the LedgerTransTypeList data source has been reduced from 9,027 to 240.

Review the execution trace in the application

In addition to RCS, some versions might offer capabilities for an ER framework designer experience. These versions have an **Enable design mode** option that can be turned on. You can find this option on the **General** tab of the **Electronic reporting parameters** page, which you can open from the **Electronic reporting** workspace.

If you use one of these versions, you can analyze the details of generated performance traces directly in the application. You don't have to export them from the application and import them into RCS.

Review the execution trace by using external tools

Configure user parameters

1. Go to **Organization administration > Electronic reporting > Configurations**.
2. On the **Configurations** page, on the Action Pane, on the **Configurations** tab, in the **Advanced settings** group, select **User parameters**.
3. In the **User parameters** dialog box, in the **Execution tracing** section, in the **Execution trace format** field, select **PerfView XML**.

Run the ER format

Repeat the steps in the [Run the ER format](#) section earlier in this topic to generate a new performance trace.

Notice that the web browser offers a zip file for download. This file contains the performance trace in PerfView format. You can then use the PerfView performance analysis tool to analyze the details of ER format execution.

Ready Log Cancel

Use external tools to review an execution trace that includes database queries

Because of improvements that have been made to the ER framework, the performance trace that is generated in PerfView format now offers more details about ER format execution. In Microsoft Dynamics 365 for Finance and Operations version 10.0.4 (July 2019), this trace can also include details of executed SQL queries to the application database.

Configure user parameters

1. Go to **Organization administration > Electronic reporting > Configurations**.
2. On the **Configurations** page, on the Action Pane, on the **Configurations** tab, in the **Advanced settings** group, select **User parameters**.
3. In the **User parameters** dialog box, in the **Execution tracing** section, set the following parameters:
 - In the **Execution trace format** field, select **PerfView XML**.
 - Set the **Collect query statistics** option to **Yes**.
 - Set the **Trace query** option to **Yes**.

Run the ER format

Repeat the steps in the [Run the ER format](#) section earlier in this topic to generate a new performance trace.

Notice that the web browser offers a zip file for download. This file contains the performance trace in PerfView format. You can then use the PerfView performance analysis tool to analyze the details of ER format execution. This trace now includes the details of SQL database access during the execution of the ER format.

Business document management overview

2/18/2021 • 25 minutes to read • [Edit Online](#)

Business users use the [Electronic reporting \(ER\)](#) framework to configure formats for outbound documents in accordance with the legal requirements of various countries/regions. Users can also define the dataflow to specify what application data is placed in generated documents. The ER framework generates outbound documents in Microsoft Office formats (Excel workbooks or Word documents) by using predefined templates. The templates are populated with required data in accordance to configured dataflow while required documents are generated. Each configured format can be published as part of an ER solution to generate specific outbound documents. This is represented by an ER format configuration that can contain templates you can use to generate different outbound documents. Business users can use this framework to manage required business documents.

Business document management is built on top of the ER framework and enables business users to edit business document templates by using Microsoft 365 service or appropriate Microsoft Office desktop application. Edits to the documents might include changing business document designs and adding placeholders for additional data without source code changes and new deployments. No knowledge of the ER framework is required to update templates of business documents.

NOTE

Be aware that Business document management allows you to modify templates that are used to produce business documents such as orders, invoices, etc. While a template has been modified and a new version of it has been published, this version is used to generate required business documents. Business document management cannot be used to modify already generated business documents.

Supported deployments

Currently, the Business document management feature is implemented only for cloud deployments. If this feature is critical to your on-premises deployment, let us know by providing feedback on the [Ideas](#) site.

Supported Microsoft Office applications

To use Business document management for editing templates in Excel or Word formats by using Microsoft Office desktop applications, you must have Microsoft Office 2010 or later installed. This is supported in cloud and on-premises deployments.

To use Business document management for editing templates in Excel or Word formats by using Microsoft 365 applications, you must have Microsoft 365 Office for the web subscription. This is supported in cloud deployment.

Business document availability

For a complete list of all the reports planned for the October 2019 release, see [Configurable business documents reporting in Word and Excel](#).

For a complete list of all the reports planned for the October 2020 release, see [Configurable business documents – Word templates](#).

More reports will become available in future releases. Special notifications about additional reports will be sent

separately. To learn how to review the list of currently available reports, see the section [List of ER configurations that have been released in Finance to support configurable business documents](#) below.

To learn more about this feature, complete the example in this topic.

Configure ER parameters

Because Business document management is built on top of the ER framework, you must configure the ER parameters to start working with Business document management. To do this, you need to set up the ER parameters as described in [Configure the Electronic reporting \(ER\) framework](#). You also need to add a new configuration provider as described in [Create configuration providers and mark them as active](#).

Import ER solutions

Sample ER configurations are used in the example of this procedure. You must import, into your current instance of Dynamics 365 Finance, the ER configurations that contain the business document templates that can be edited by using Business document management. Download, and then locally store the following files to complete this procedure.

Sample ER customer invoicing solution

FILE	CONTENT
Customer invoicing model.version.2.xml	ER data model configuration
Customer FTI report (GER).version.2.3.xml	Free text invoice ER format configuration

Sample ER payment checks solution

FILE	CONTENT
Model for cheques.version.10.xml	ER data model configuration
Cheques printing format.version.10.9.xml	Payment cheque ER format configuration

Sample ER foreign trade solution

FILE	CONTENT
Intrastat model.version.1.xml	ER data model configuration
Intrastat report.version.1.9.xml	Intrastat control report ER format configuration

Use the following procedure to import each file. Import the ER *data model* configuration of each ER solution in the tables above before you import the corresponding ER *format* configuration.

1. Open the **Organization administration > Electronic reporting > Configurations** page.
2. On the top of the page, select **Exchange**.
3. Select **Load from XML file**.
4. Select **Browse** to load the required XML file.
5. Select **OK** to confirm configuration's import.

The screenshot shows the 'Customer invoicing model' configuration page in Dynamics 365 Finance and Operations. The left sidebar shows a tree view with 'Customer invoicing model' selected. The main area displays configuration details for 'Customer invoicing model', including a description and a 'Microsoft' configuration provider. Below this is a 'Versions' table with one entry: Version 2, Status Completed, Effective from (blank), Version created 1/15/2019 07:54:01 AM, and Description (blank). The top navigation bar includes 'Exchange' and 'Configurations' tabs.

Alternatively, you can import the officially published ER format configurations from Microsoft Dynamics Lifecycle Service (LCS). For example, to complete this procedure you can import the latest version of the **Free text invoice (Excel)** ER format configuration. The corresponding ER data model and ER model mapping configurations will be imported automatically.

The screenshot shows the 'Shared asset library' in Dynamics 365 Lifecycle Services. The left sidebar shows 'GER Configuration (1705)' selected. The main area displays a table of 'GER Configuration files'. The 'Free text invoice (Excel),version.155.77' configuration is selected. The right sidebar shows 'Additional details' for this configuration, including its description, asset ID, validation status, and creation/modification information.

Name	Valid	Version	Scope	Status	Modified date	Size
Cust account statement, Ext (Excel),version.24.10		1	Global	Published	11/1/2019	234 KB
Cust account statement, Ext (CN) (Excel),version.24.10.4		1	Global	Published	11/1/2019	237 KB
Reconciliation model mapping.version.24.8		1	Global	Published	11/1/2019	65 KB
Reconciliation model.version.24		1	Global	Published	11/1/2019	722 KB
Load tender model mapping.version.32.2		1	Global	Published	10/31/2019	32 KB
Free text invoice (Excel),version.155.77		1	Global	Published	10/31/2019	869 KB
Container contents model mapping.version.11.2		1	Global	Published	10/31/2019	32 KB
Container contents (Excel),version.11.2		1	Global	Published	10/31/2019	190 KB
Production pick list (Excel),version.11.5.2		1	Global	Published	10/31/2019	192 KB
Shipping pick list for load (Excel),version.11.5.3		1	Global	Published	10/31/2019	182 KB
Shipping pick list for shipment (Excel),version.11.5.3		1	Global	Published	10/31/2019	182 KB
Shipping pick list model mapping.version.11.2		1	Global	Published	10/31/2019	32 KB

For more information about importing ER configurations, see [Manage the ER configuration lifecycle](#).

Enable Business document management

To start Business document management, you need to open the **Feature management** workspace and enable the **Business document management** feature.

Use the following procedure to enable Business document management functionality for all legal entities.

1. Open the **Feature management** workspace.
2. On the **New** tab, select the **Business document management** feature in the list.
3. Select **Enable now** to turn on the selected feature.
4. Refresh the page to access the new feature.

NOTE

For more information about using the new document user interface in Business document management, see [New document user interface in Business document management](#).

The screenshot displays the 'Feature management' workspace. At the top, there are statistics: New (19), Not enabled (33), and Scheduled (0). Below these are buttons for 'Enable all' and 'Check for updates'. The main area shows a list of features with the following data:

Feature name	Enable date	Feature added	Module
Attachment recovery	8/1/2019	8/1/2019	System administration
Feature management enablement enhancements	8/1/2019	8/1/2019	System administration
Enable master plan setup wizard features.	8/1/2019	8/1/2019	Master planning
Keep GST tax document for confirmation journal	8/1/2019	8/1/2019	Tax
Business document management	8/2/2019	6/3/2019	Organization administration
Enable fixed exchange rate for reporting currency on sales ...	8/1/2019	5/9/2019	Shared AP and AR

The right-hand pane for 'Business document management' shows it was added on 6/3/2019 and enabled on 8/2/2019. The description states: 'This feature provides a new Business document management workspace, a new form for visibility of pre-loaded business document templates, and redesigned business document templates.' There is a 'Disable' button at the bottom of the pane.

For more information about activating new features, see [Feature management overview](#).

Configure parameters

Use the information in the following sections to set up the basic parameters for Business document management.

Prerequisites for parameter setup

Before you can set up Business document management, you must set up the required document type in the Document management framework. This document type is used to specify a temporary storage of documents in Office formats (Excel and Word) that are used as templates for ER reports. The temporary storage template can be edited by using the Office desktop applications.

For this document type, the following attribute values must be selected.

ATTRIBUTE NAME	ATTRIBUTE VALUE
Class	Attach file

ATTRIBUTE NAME	ATTRIBUTE VALUE
Group	File
Location	SharePoint

For information about how to set up the required document management parameters and document types, see [Configure document management](#).

Set up parameters

Basic Business document management parameters can be set up on the **Business document parameters** page. Only specific users can access the page. This includes:

- Users who are assigned to the **System administrator** role.
- Users who are assigned to any role that is configured to perform the duty, **Maintain Business document management parameters** (AOT name **ERBDMaintainParameters**).

Use the following procedure to set up the basic parameters for all legal entities.

1. Sign in as a user with access to the **Business document parameters** page.
2. Go to **Organization administration > Electronic reporting > Business document management > Business document parameters**.
3. On the **Business document parameters** page, on the **Attachments** tab, in the **SharePoint document type** field, define the document type that should be used to temporarily store templates in Office formats while they are edited using the Office desktop applications.

NOTE

Only document types that are configured using a SharePoint location are available for this parameter.

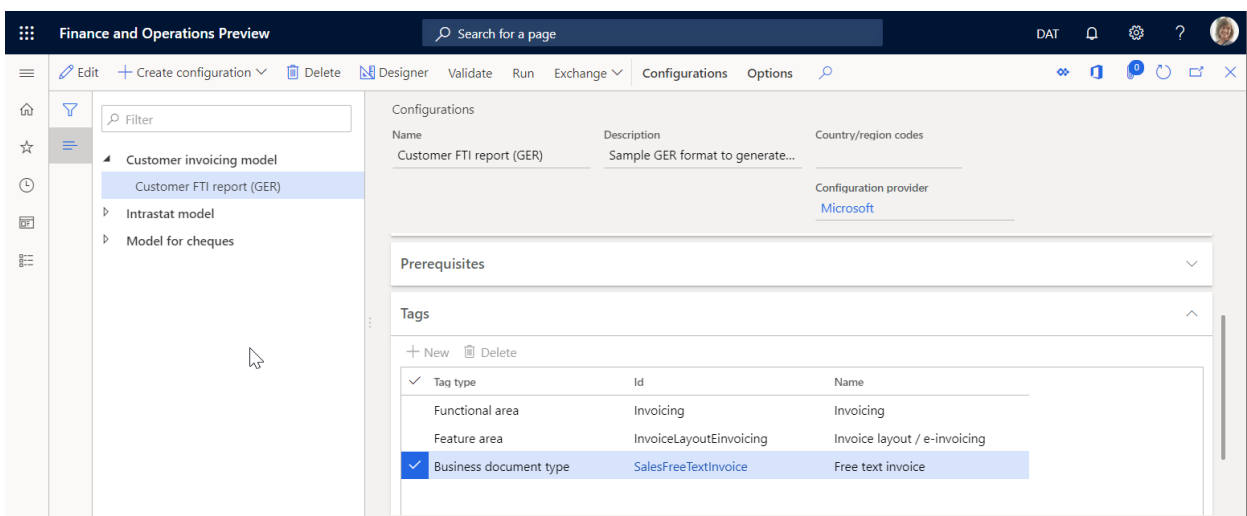

The selected document type is company-specific and will be used when the user is working with Business document management in the company for which the selected document type is configured. When the user is working with Business document management in another company, the same selected document type will be used if one has not been configured for this company. When a document type has been configured, it will be used instead of the one selected in the **SharePoint document type** field.

NOTE

The **SharePoint document type** parameter defines a SharePoint folder as temporary storage for templates that are editable using either Microsoft Excel or Word. You need to set up this parameter if you plan to use these Office desktop applications for editing templates. For more information, see [Edit a template in the Office desktop application](#). You can keep this parameter blank if you plan to modify the template by only using the functionality in Microsoft 365. For more information, see [Edit a template in Microsoft 365](#).

Configure access permissions

By default, when access to Business document management permissions is not enabled, every user with access to the Business document management workspace will see all of the ER solution templates that are available. The Business document management workspace will show only those templates that reside in ER format configurations and that are marked by a **Business document type** tag.

The list of templates available in the Business document management workspace can be restricted by configuring access permissions. This may be important when different templates are used to produce business documents for different business domains (functional areas), and you want to allow specific users access to different templates for editing in the Business document management workspace.

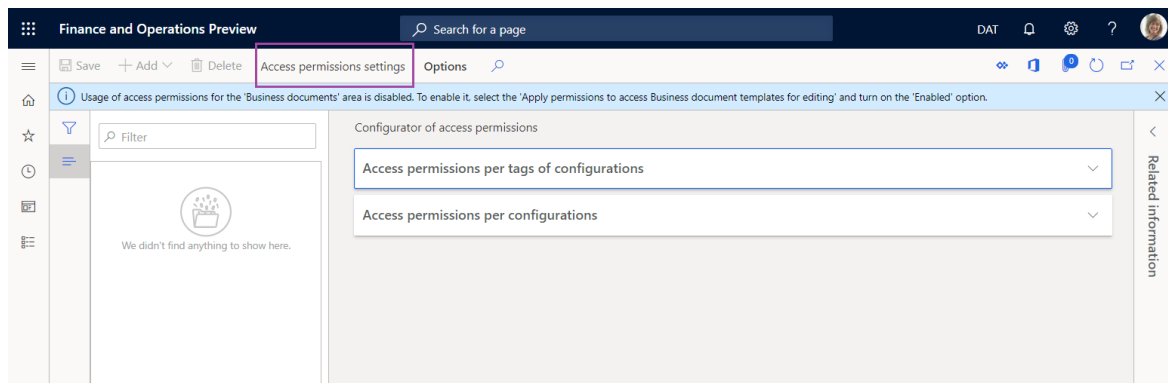

Business document management access permissions can be set on the **Configurator of access permissions**. Only the following users can access the page:

- Users assigned to the **System administrator** role.
- Users assigned to any other role that is configured to perform the duty, **Configure permissions to access Business document templates for editing** (AOT name ERBDTemplatesSecurity).

Use the following procedure to set up the access Business document management permissions for all legal entities.

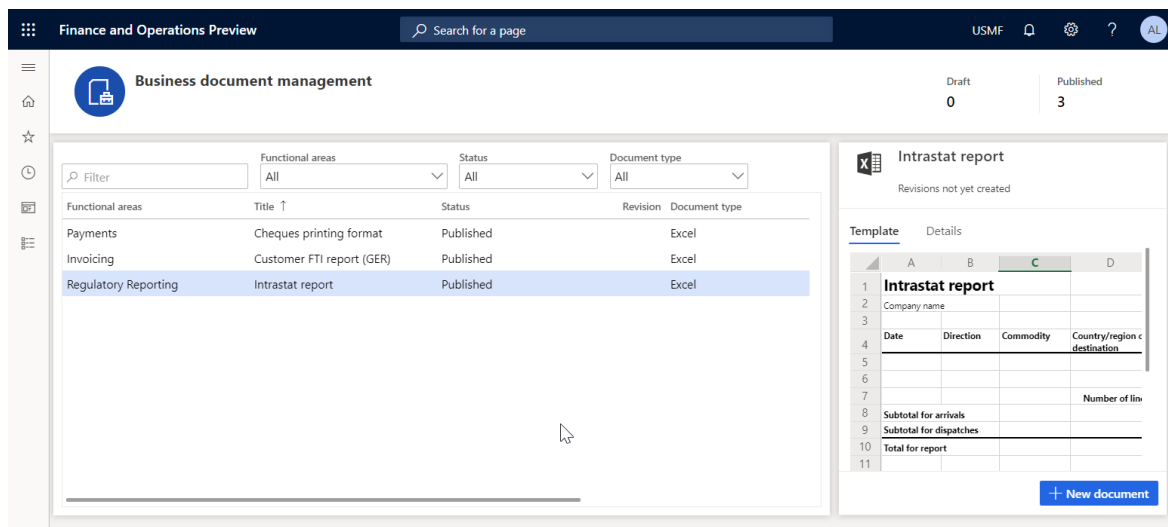

1. Sign in as a user with access to the **Configurator of access permissions** page.
2. Go to **Organization administration > Electronic reporting > Business document management > Manage access permissions**.

Pay attention to the notification informing you that the usage of access permissions for Business document management is currently not enabled.

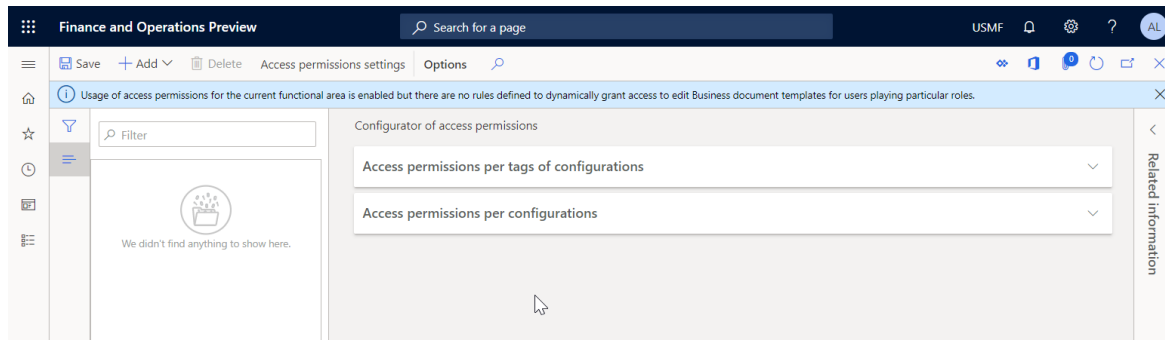

With this setting, every user assigned to any security role that is configured to perform the **Manage Business document templates** (AOT name ERBDManageTemplates) duty is able to open the Business document management workspace and can edit any template that is available.

The following graphic shows what is available in the Business document management workspace for users assigned to the **Accounts receivable clerk** role. With the current access permissions setting, the user can edit business document templates from different functional areas including invoicing, regulatory reporting, and payments.

3. On the **Configurator of access permissions** page, select **Access permissions setting**.
4. In the **Settings of access permissions to edit templates** dialog box, enable the **Apply configured access permissions** option.

5. Select **OK** to confirm that Business document management access permissions have been enabled.

6. Select **Add** to enter a new business role for which permissions to access Business document management templates must be configured.

7. In the **Security roles** dialog box, select the **Accounts receivable clerk** role and then select **OK** to confirm the role selection.

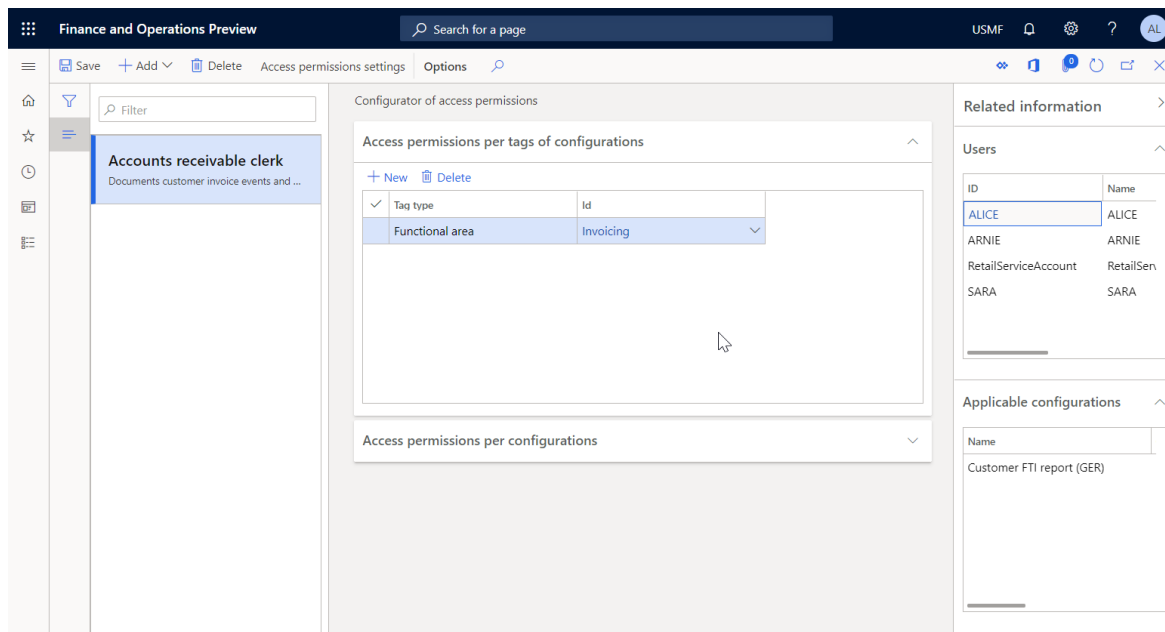

8. On the **Access permissions per tags of configurations** tab, select **New**.

9. In the **Tag type** field, select **Functional area**, and in the **ID** field, select **Invoicing**.

10. Select **Save** to store configured access permissions for the selected role.

The current setting means that for any user who is assigned to the **Accounts receivable clerk** role and performing the duty, **Manage Business document templates** (AOT name **ERBDManageTemplates**), ER format configuration templates that have the **Invoicing** value for the **Functional area** tag will be available to edit in the Business document management workspace.

11. Switch the **Related information** pane from the right side of the current page. The **Related information** pane shows how the configured access permissions will be applied, including what ER configuration templates will be available for users that are assigned to the **Accounts receivable clerk** role.

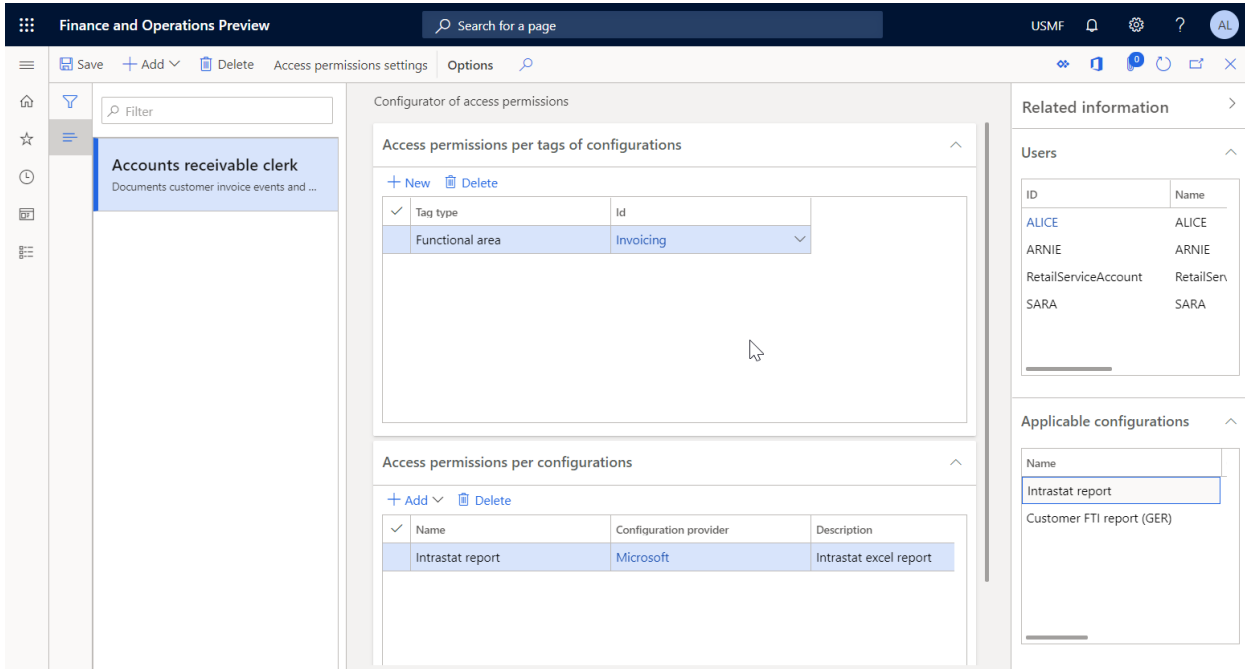

12. On the **Access permissions per configurations** tab, select the **Add** option.

13. In the **Select configuration** dialog box, mark the **Intrastat report** ER format configuration.

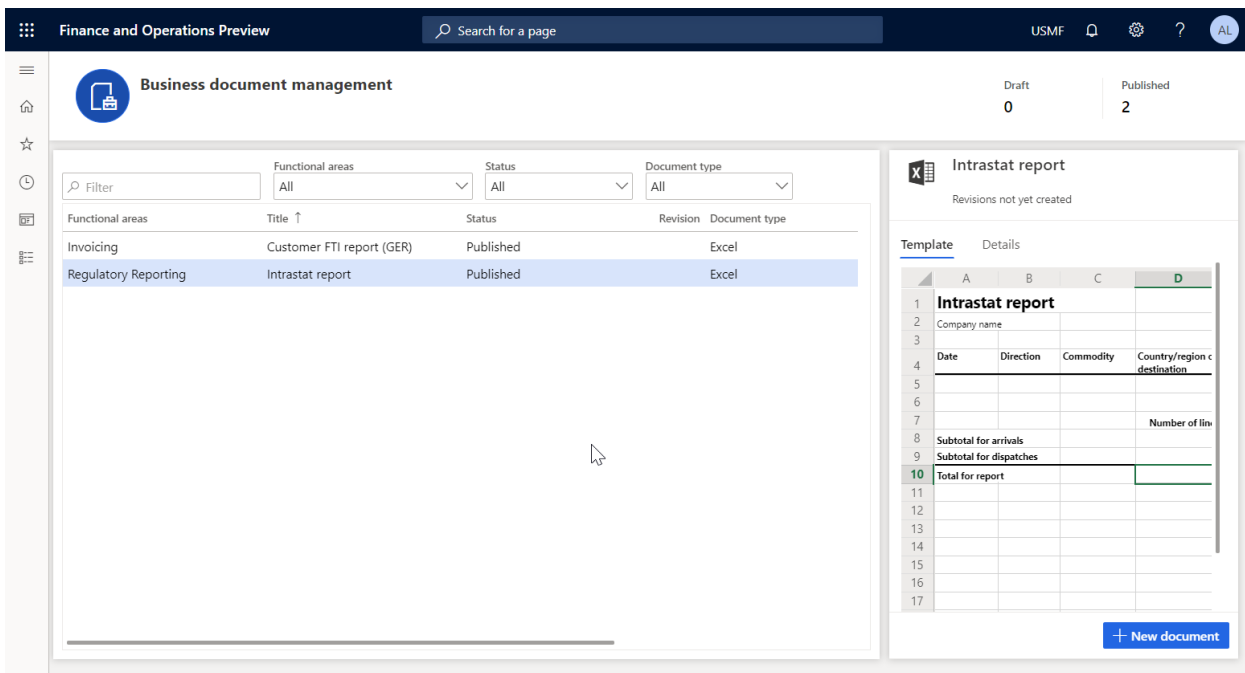

14. Select **OK** to confirm the entry of the selected configurations and then select **Save** to store the configured access permissions for the selected role.

The current setting means that for any user assigned to the **Accounts receivable clerk** role and performing the duty, **Manage Business document templates** (AOT name ERBDManageTemplates), the following templates will be available to edit in the Business document management workspace:

- Templates that have the value, **Invoicing** for the **Functional area** tag.
- Templates from ER format configurations that are listed on the **Access permissions per configurations** tab (templates from the **Intrastat report** format configuration of the **Statutory reporting** domain in this example).

The following graphic shows what the Business document management workspace provides to a user assigned to the **Accounts receivable clerk** role. With the current Business document management access permissions setting, the user can edit business document templates from the **Invoicing** domain and the **Intrastat report** ER format configuration. Templates from the **Payments** domain are not accessible for the **Accounts receivable clerk** role.

NOTE

The **Access permissions per configurations** rules are stored by using the unique identification ID of an ER format configuration. This means that these rules will not be deleted when an ER configuration that refers to them are deleted. When you import deleted configurations back to this instance, these rules will refer to them again. There is no need to set up the rules again after the deleted configurations are imported again.

Use Business document management to edit templates

Business users can access business document templates for editing in the Business document management workspace. Only the following users can access the Business document management workspace:

- Users assigned to the role, **System administrator**.
- Users assigned to any role that is configured to perform the duty, **Manage Business document templates** (AOT name **ERBDManageTemplates**).

Use the following procedure to edit free text invoice templates in the Business document management workspace. Before you complete this procedure, you must have completed all of the preceding procedures in this topic.

1. Sign in as a user with access to the Business document management workspace.
2. Open the Business document management workspace.

When the **Office-like UI experience for Business document management** feature is turned off in the **Feature management** workspace, the main grid in the **Business document management** workspace shows the following templates:

- Templates that are owned by your ER configuration provider (that is, the provider that is currently marked as active in the **Electronic reporting** workspace). After you select one of these templates, you can select **Edit template** to start or continue to edit it.
- Templates that are owned by other ER configuration providers. After you select one of these templates, you can select **New document** to create a copy of it that is owned by your ER configuration provider, and then start to edit the copy.

The screenshot displays the 'Business document management' workspace. At the top, there is a search bar and navigation icons. Below the search bar, there are filters for 'Functional areas', 'Status', and 'Document type', all set to 'All'. A table lists the following templates:

Functional areas	Title	Status	Revision	Document type	Modified date and time	Modified by
Payments	Cheques printing format	Published		Excel	8/2/2019 07:50:56 AM	Admin
Invoicing	Customer FTI report (GER)	Published		Excel	8/2/2019 06:21:34 AM	Admin
Regulatory Reporting	Intrastat report	Published		Excel	8/2/2019 07:47:23 AM	Admin

On the right side, the 'Intrastat report' template is previewed. It shows a grid with columns A, B, C, and D, and rows 1 through 12. The grid contains the following text:

Date	Direction	Commodity	Country/region c destination
Subtotal for arrivals			
Subtotal for dispatches			
Total for report			

At the bottom right of the preview, there is a '+ New document' button.

The **Template** tab presents the content of the selected template. Select the **Details** tab to review details of the selected template as well as details of an ER format configuration this template resides in. Notice that all of the templates have a status of **Published**, and contain no details in the **Revision** column. This means that these templates are not currently being edited.

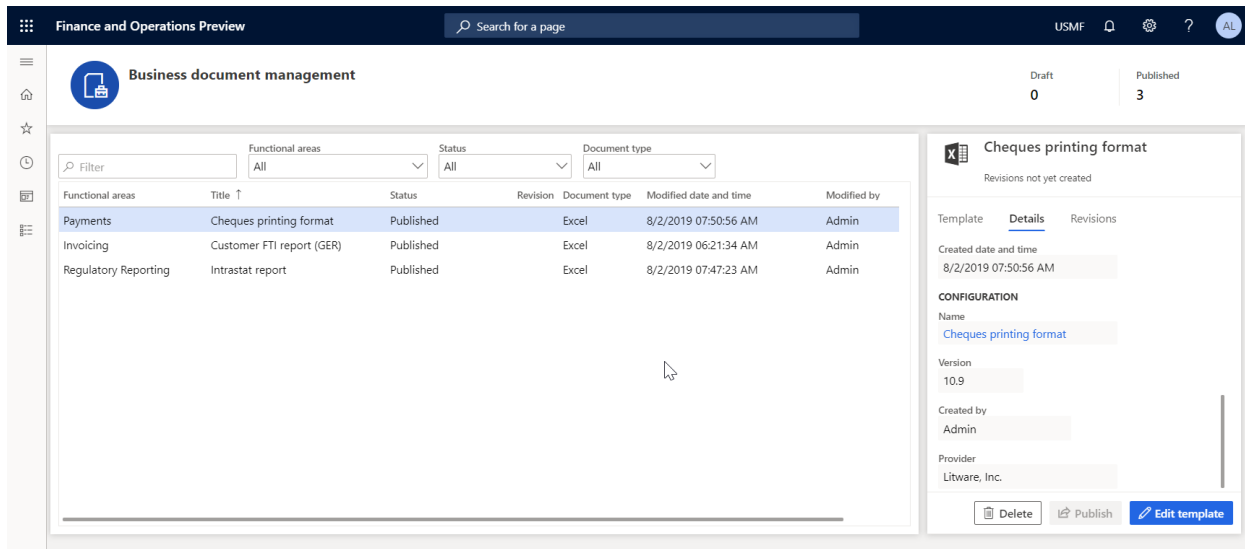

When the **Office-like UI experience for Business document management** feature is turned on in the

Feature management workspace, the main grid in the **Business document management** workspace shows templates that are owned by your ER configuration provider (that is, the provider that is currently marked as active in the **Electronic reporting** workspace). After you select one of these templates, you can select **Edit template** to start or continue to edit it.

To work with templates that are owned by other ER configuration providers, select **New document** to create a copy of the template that is owned by your ER provider. You can then start to edit the copy. For more information, see [New document user interface in Business document management](#).

Initiate editing templates owned by your configuration provider

1. In the Business document management workspace, select the **Cheques printing format** template in the list.
2. Select the **Details** tab.

The **Edit template** option is available for the selected template. This option is always available for a template in an ER format configuration that is owned by the active ER configuration provider (**Litware, Inc.** in this example). When **Edit template** is selected, the existing template from the draft version of the underlying ER format configuration will be available to edit.

Initiate editing templates owned by other providers

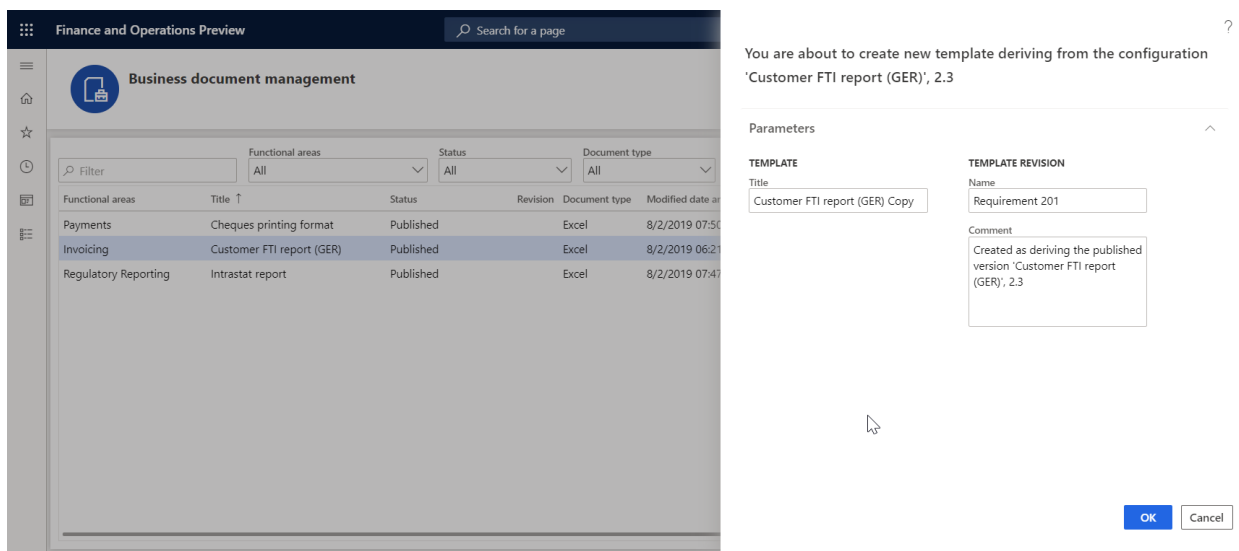

1. In the Business document management workspace, select the document that you want to use as a template.

2. Select **New document**, and in the **Title** field, change the title of the editable template if needed. The text will be used to name the ER format configuration that is automatically created. Note that the draft version of this configuration (**Customer FTI report (GER) Copy**) that will contain the edited template will

automatically be marked to run this ER format for the current user. At the same time, the non-modified original template from the base ER format configuration will be used to run this ER format for any other user.

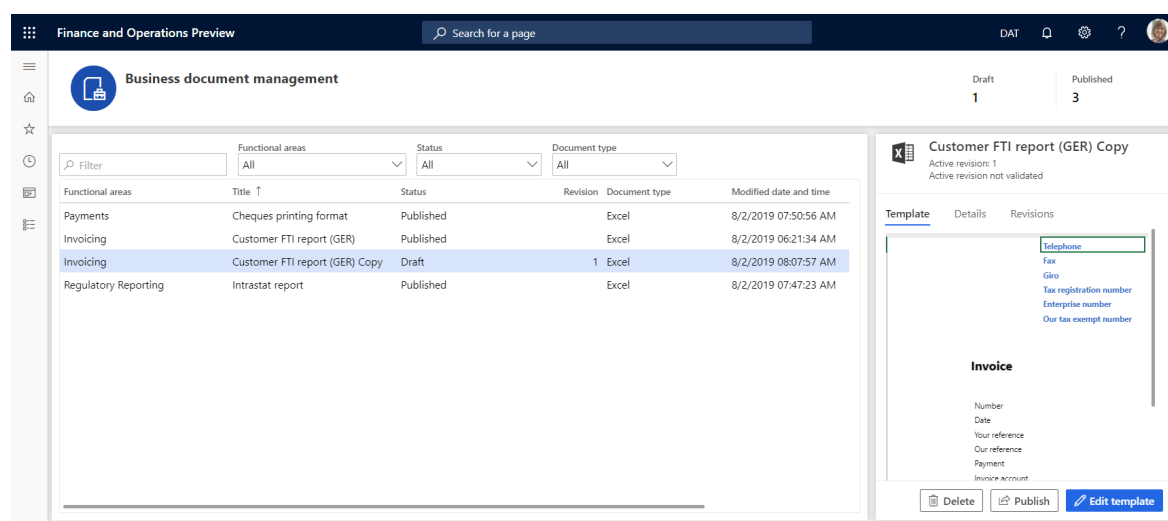

3. In the **Name** field, change the name of the first revision of the editable template that will be created automatically.
4. In the **Comment** field, change the comment for the automatically created revision of the editable template.
5. Select **OK** to confirm the start of the editing process.

The **New document** option is always available for a template in an ER format configuration provided by current and another provider (Microsoft in this example) that doesn't have any revision. The edited template will then be stored in a new ER format configuration that is automatically generated.

Start editing a template

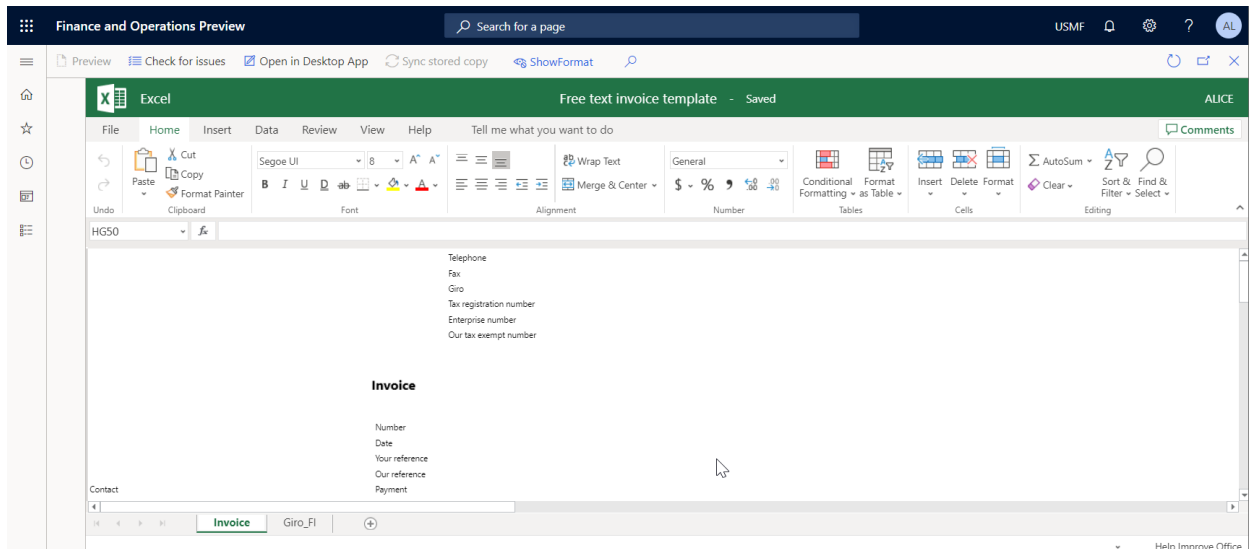

1. From the selected template, select **Edit document**.
2. In the **Name** field, change the name of the first revision of the editable template that will be created automatically.
3. In the **Comment** field, change the remark for the automatically created revision of the editable template.

4. Select **OK** to confirm the start of the editing process.

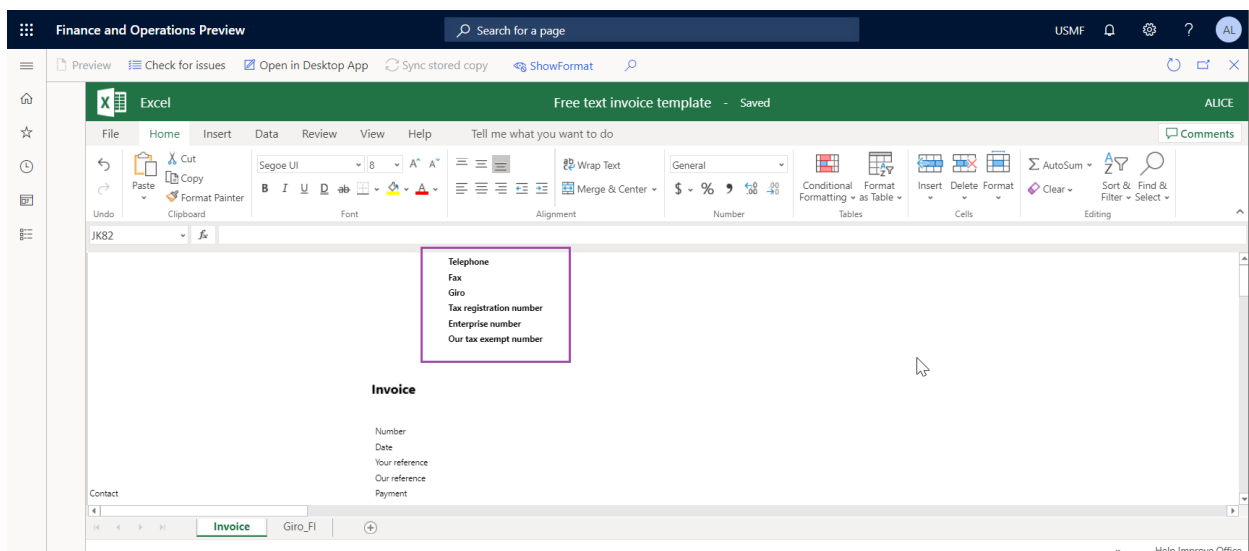

The **BDM template editor** page will open. The selected template will be available for online editing by using

Microsoft 365.

Edit a template in Microsoft 365

You can modify the template using Microsoft 365. For example, in Office online, change the font of the field prompts in the template header from **Regular** to **Bold**. These changes are automatically stored in the editable template that is stored in the primary template's storage (by default, the Azure blob storage). This is configured for the ER framework.

Edit a template in the Office desktop application

NOTE

This function is only available when the **SharePoint document type** parameter is properly configured. For more information, see [Configure parameters](#).

1. Select the **Open in Desktop App** option to modify the template by using the functionality of the Office desktop application (Excel in this example). The editable template is copied from the permanent storage to the temporary storage configured in the Business document management parameters as a SharePoint folder.
2. Confirm that you want to open the template from the temporary file storage in the Office desktop Excel application.

3. Modify the template. For example, change the font of the fields prompts in the template header by updating color from Black to Blue.

4. Select Save in the Excel desktop application to store the template changes in the temporary storage.

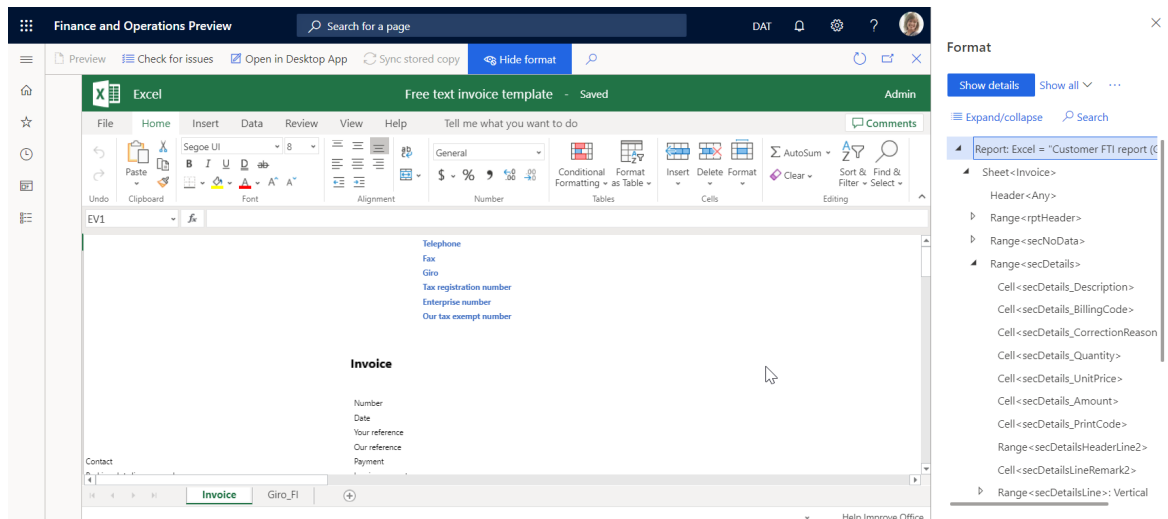

- Close the Excel desktop application.
- Select **Sync stored copy** to synchronize the temporary template storage to the permanent template storage.

NOTE

The copy of the editable template in the temporary file storage is kept for only the current session of template editing. When you finish this session by closing the **BDM template editor** page, this copy will be deleted. If you adjusted the template in the temporary file storage and did not select **Sync stored copy**, when you try to close the **BDM template editor** page, a message will ask whether you want to store introduced changes. Select **Yes** if you want to save your changes to the template in the permanent file location.

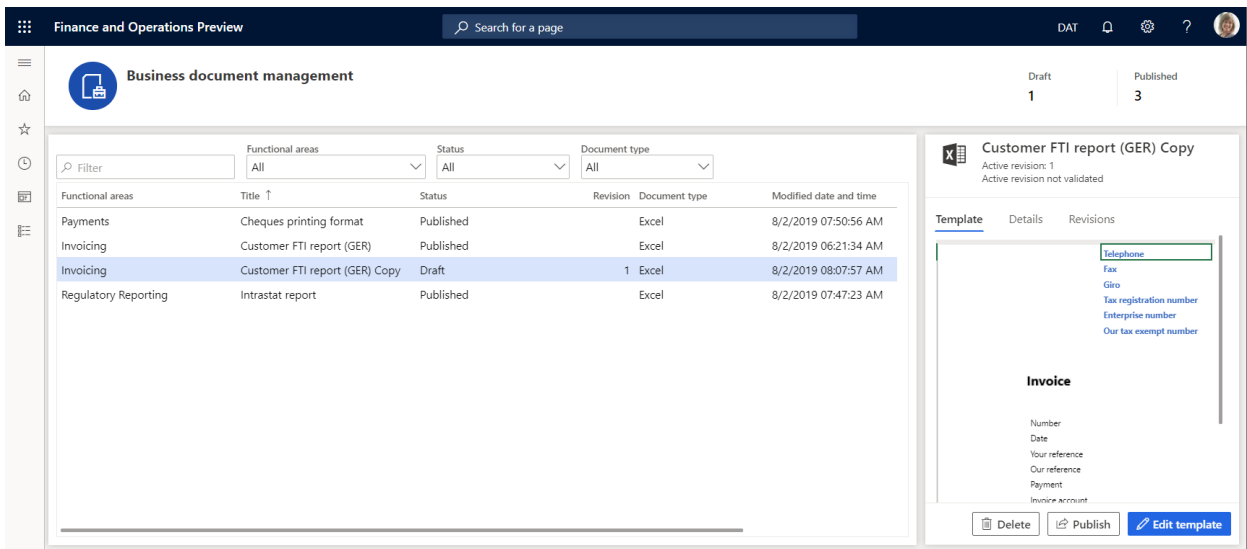

Validate a template

- On the **BDM template editor** page, select **Check for issues** to validate the modified template against the underlying ER format configuration. Follow the recommendations (if any) to align the template with the structure of the format from the base ER format configuration.
- Select **Show format** to view the current structure of the format from the base ER format configuration that must be aligned with the editable template.
- Select **Hide format** to close the pane.

- Close the **BDM template editor** page.

The updated template is shown on the **Template** tab. Notice that the status of the edited template is now **Draft** and the current revision is no longer empty. This means that the process of this template's editing has been started.

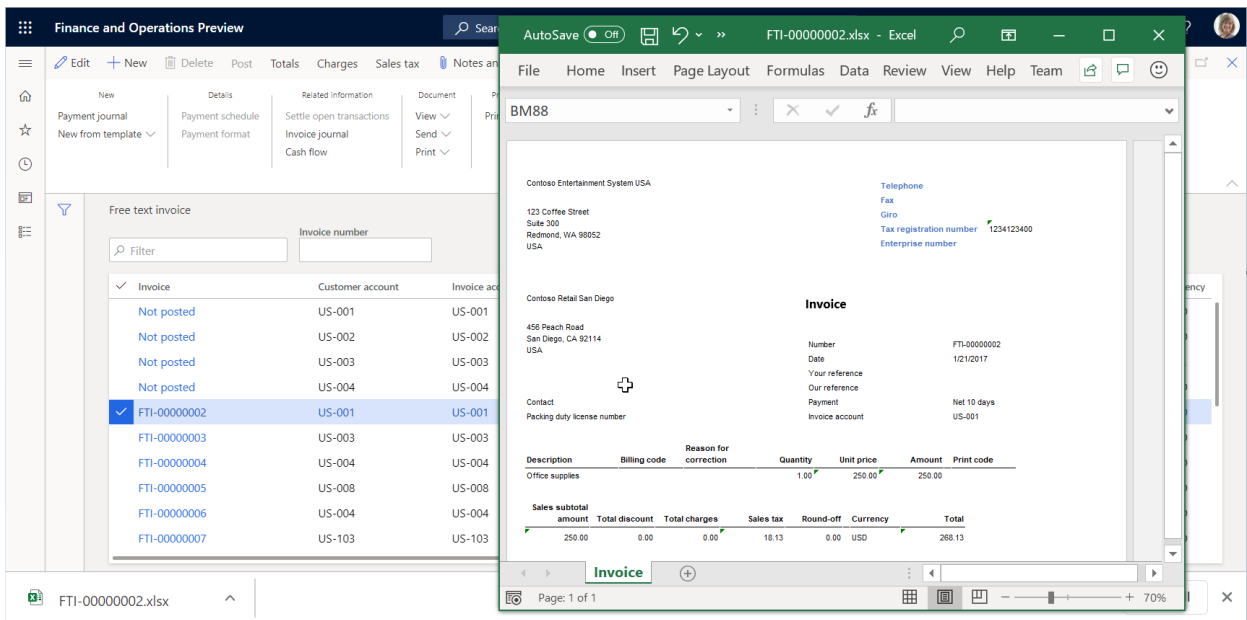

Test the modified template

1. In the application, change to the company, USMF.
2. Go to **Accounts receivable > Invoices > All free text invoices**.
3. Select the FTI-00000002 invoice, and then select **Print management**.
4. Select the **Module - accounts receivable > Documents > Free text invoice > Original document** level to specify the scope of invoices for processing.
5. In the **Report format** field, select the **Customer FTI report (GER) Copy** ER format for the specified document level.

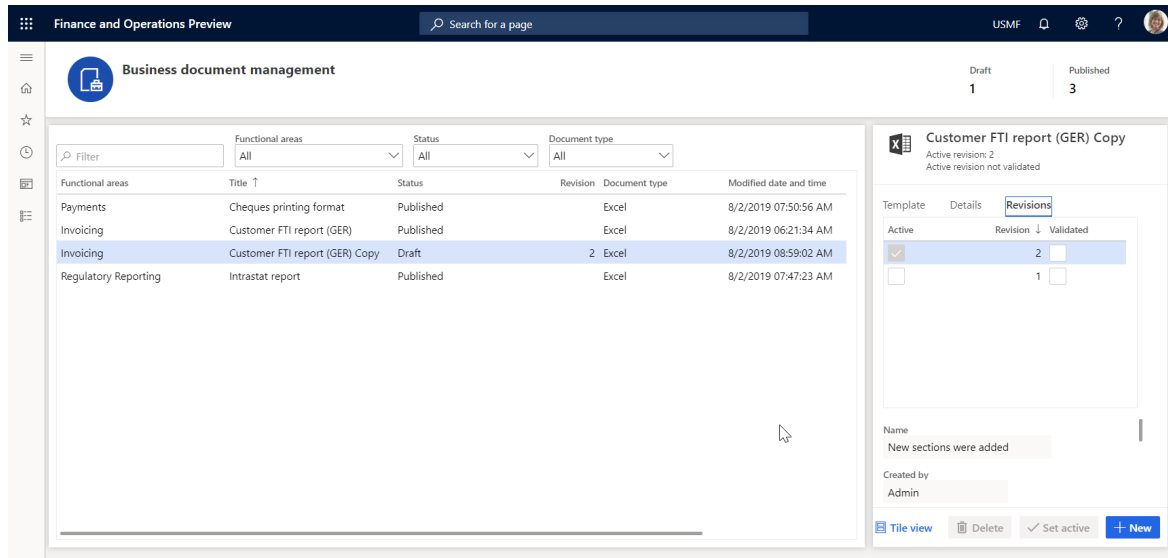

6. Press **Escape** to close the current page.
7. Select **Print**, and then select **Selected**.
8. Download the document and open it using the Excel desktop application.

The modified template is used to generate the free text invoice report for the selected item. To analyze how this report is affected by the changes that you introduced to the template, you can run this report in one application session right after you modified the template in another application session.

Create an alternative template revision

1. Open the **BDM template editor** page and select the **Customer FTI report (GER) Copy** template.
2. On the **Revisions** tab, select **New**.
3. If needed, in the **Name** field, change the name of the second revision and base it on the currently active first revision.
4. If needed, in the **Comment** field, change the remark for the automatically created revision of the editable template.

You created a new revision of your template that has been stored in the permanent template's storage. Now you can continue editing the template of the second revision that is currently selected as active.

5. Select the first revision and then select **Set active**. You can select another revision as active if at any time you want to return to that revision of the template.
6. Select the second revision, and then select **Delete**.
7. Select **OK** to confirm that you want to delete the selected revision. You can delete any of the non-active

revisions when they are no longer needed.

Delete a modified template

1. On the **BDM template editor** page, select the **Template** tab.
2. Select **Delete**.
3. If you select **OK** to confirm deletion, the **Customer FTI report (GER) Copy ER** format with the modified template will be deleted. Select **Cancel** to explore other options.

Revoke changes of template

When you edit the template from an ER format that is owned by the current active provider, you will be offered the option to revoke changes introduced for the template.

The screenshot shows the 'Business document management' interface. On the left, there is a navigation pane with icons for home, star, clock, and list. The main area displays a table of templates with filters for Functional areas, Status, and Document type. The table lists several templates, including 'Cheques printing format' which is currently in Draft status. On the right, a preview of the 'Cheques printing format' template is shown, displaying a grid with columns A, B, C, and D, and rows 1 through 18. The preview includes 'Undo', 'Publish', and 'Edit template' buttons.

Functional areas	Title	Status	Revision	Document type	Modified date and time
Payments	Cheques printing format	Draft	1	Excel	8/2/2019 09:02:04 AM
Invoicing	Customer FTI report (GER)	Published		Excel	8/2/2019 06:21:34 AM
Invoicing	Customer FTI report (GER) Copy	Draft	1	Excel	8/2/2019 09:02:28 AM
Regulatory Reporting	Intrastat report	Published		Excel	8/2/2019 07:47:23 AM

1. On the **BDM template editor** page, select the **Template** tab.
2. Select **Undo**.
3. If you select **OK** to revoke the changes introduced for the template, the modified template will be replaced by the original template and all changes will be removed. When you revoke changes to the template, you will be able to delete the template. Select **Cancel** to explore other options.

Publish a modified template

1. On the **BDM template editor** page, on the **Template** tab, select **Publish**.
2. If you select **OK** to confirm publishing, the draft version of the derived **Customer FTI report (GER) Copy ER** format that contains the modified template will be marked as completed. The modified template becomes available for other users. The completed versions of this ER format will keep only the last active revision of your template. Other revisions will be deleted. Select **Cancel** to explore other options.

Frequently asked questions

I selected **Edit document**, but instead of going to the **BDM template editor** page in **Finance**, I was sent to the **Microsoft 365** webpage.

This issue is a known issue that involves Microsoft 365 redirection. It occurs when you sign to Microsoft 365 for the first time. To work around this issue, select **Back** in your browser to return to the previous page.

I understand how to edit a template by using **Microsoft 365** in the first application session, and how to use the template in the second application session and adjust the template to see how my changes affect the generated business document. Can I use the **Office desktop** application in the same way?

Yes, you can. In the first application session, select **Open in Desktop App**. Your template will be stored in the temporary file storage and opened in the Office desktop application. Next, complete the following steps to preview your template changes in the generated business document:

1. Make changes in the template by using the Office desktop application.
2. Select **Save** in the Office desktop application.
3. On the **BDM template editor** page of the first application session, select **Sync stored copy**.
4. Execute this template ER format in the second application session.

When I select Open in Desktop App, I receive the following error message: "Value cannot be null. Parameter name: externalId." How do I work around this issue?

Most likely you signed in to the current instance of the app of the Azure AD domain which differs from the Azure AD domain that was used to deploy this instance. Because the SharePoint service, which is used to store templates for making them available for editing by using the Office desktop applications, belongs to the same domain, we have no permissions to access the SharePoint service. To resolve this issue, sign in to the current instance using the credentials of a user with the correct Azure AD domain.

List of ER configurations that have been released in Finance to support configurable business documents

The [list](#) of ER configurations for Finance is constantly updated. Open the [Global repository](#) to review the list of ER configurations that are currently supported. You can [filter](#) the Global repository to review the list of ER configurations that are used to support configurable business documents.

The screenshot shows the 'Configuration repository' interface in Finance and Operations. The left sidebar lists various configuration categories, with 'Picking list (Excel)' selected. The main area displays a table of configurations and a table of versions.

Configuration name	Description	Configuration provider	Location
Container contents model mapping		Microsoft	Global Repository
Load list (Excel)		Microsoft	Global Repository
Load list (Word)	Initial version	Microsoft	Global Repository

New document user interface in Business document management

2/18/2021 • 2 minutes to read • [Edit Online](#)

Business document management lets business users edit business document templates by using a Microsoft 365 service or the appropriate Microsoft Office desktop application. Edits might include design changes or new deployments, or users might add placeholders to include additional data without having to change the source code. For more information about how to work with Business document management, see [Business document management overview](#).

The new document user interface (UI) is clearer and more comfortable to use. The **Business document** area shows only the templates that are available for the current provider.

The **New document** button lets users create and edit a template in an Electronic reporting (ER) format configuration that is provided by another provider. In the example in this topic, the provider is Microsoft.

Make the new document UI in Business document management available

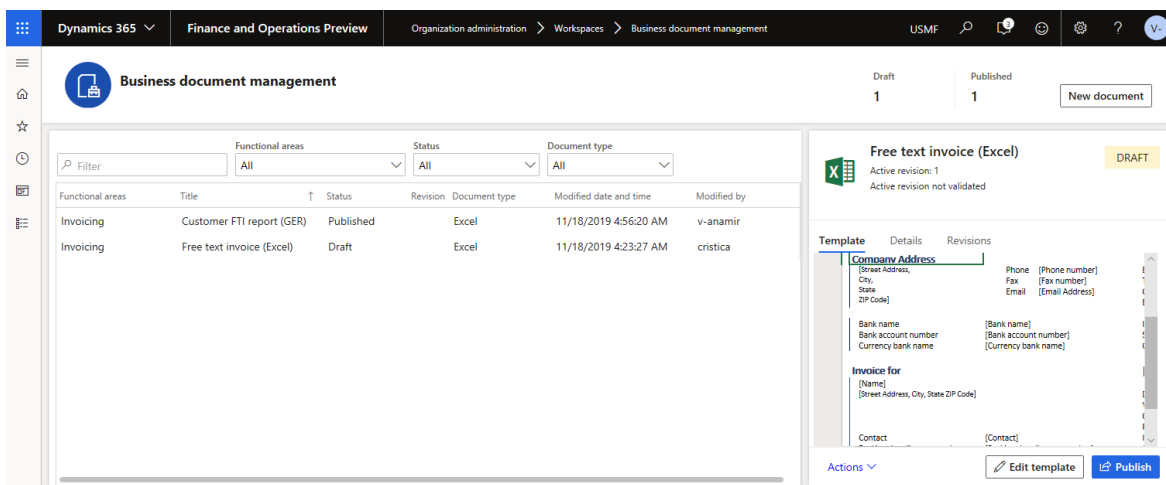

To start to use the new document UI in Business document management, you must turn on the **Office-like UI experience for Business document management** feature in the **Feature management** workspace.

Follow these steps to turn on this feature for all legal entities.

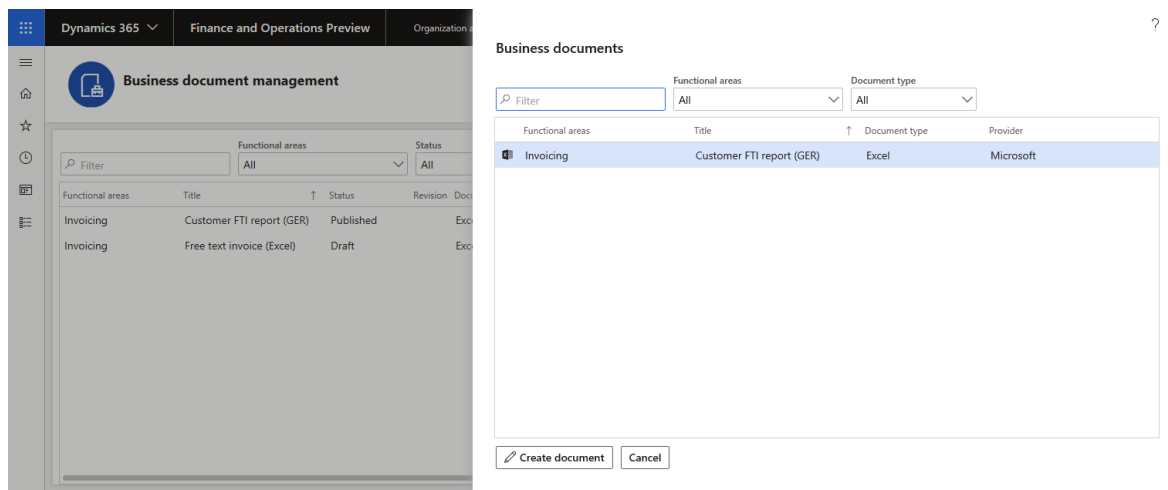

1. In the **Feature management** workspace, on the **New** tab, select the **Office-like UI experience for Business document management** feature in the list.
2. Select **Enable now** to turn on the selected feature.
3. Refresh the page to access the new feature.

Edit templates that are owned by other providers

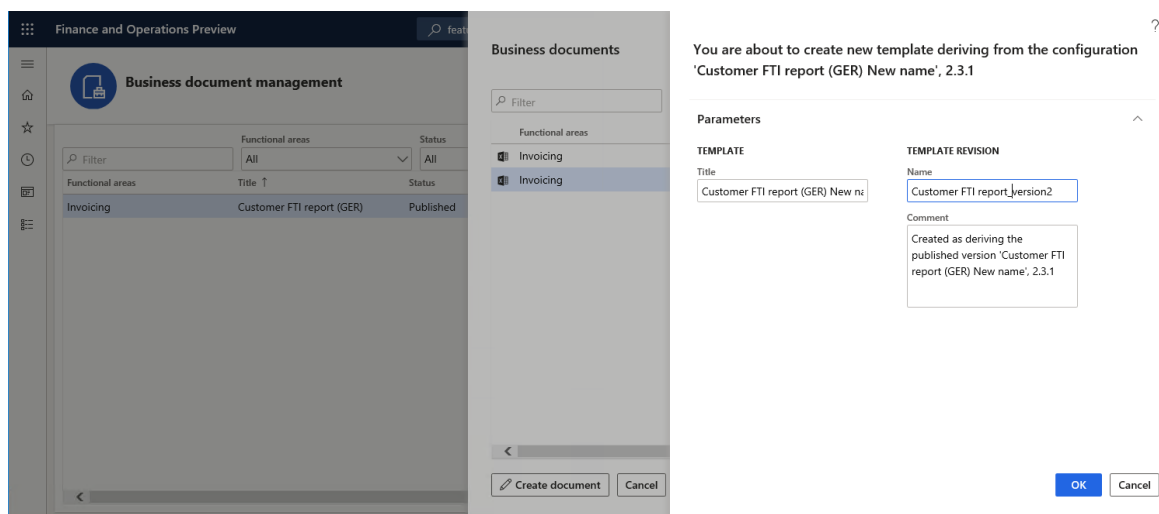

1. In the **Business document management** workspace, select **New document**.

2. In the dialog box, select the document to use as a template, and then select **Create document**.

3. In the new dialog box, in the **Title** field, change the title as you require. The title text is used to name the new ER format configuration that is automatically created. The draft version of this configuration (**Customer FTI report (GER) Copy**) will contain the edited template and will be used to run this ER format for the current user. The original template from the base ER format configuration will be used to run this ER format for every other user.
4. In the **Name** field, change the name of the first revision of the editable template that will be automatically created.
5. In the **Comment** field, update the remarks for the revision of the editable template that will be automatically created.
6. Select **OK** to confirm the start of the editing process.

The **New document** button is used to create and edit a template in an ER format configuration that is provided by another provider. In this example, the provider is Microsoft. When you select **New document**, you can view all the templates that are owned by current and other providers. After you select the template, it's opened for editing. The edited template will then be stored in a new ER format configuration that is automatically generated.

For more information, see [Business document management overview](#).

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Add new fields to a business document template in Microsoft Excel

2/18/2021 • 5 minutes to read • [Edit Online](#)

You can add new fields to a template that is used to generate business documents in Microsoft Excel format. These fields can be added as placeholders that are used to fill generated documents with required information from the application. For every field that you add, you can also specify a binding to the data sources, to specify what application data will be entered in the field when the template is used to generate business documents.

To learn more about this feature, complete the example in this topic. This example shows how to update a template to fill in the fields in free text invoice forms that are generated.

Configure Business document management to edit templates

Because Business document management (BDM) is built on top of the [Electronic reporting \(ER\) overview](#) framework, you must configure the required ER and BDM parameters before you can start to work with BDM.

1. Sign in to the instance of Microsoft Dynamics 365 Finance as the system administrator.
2. Complete the following steps of the example in the [Business document management overview](#) topic:
 - a. Configure ER parameters.
 - b. Turn on BDM.

You can now start to use BDM to edit business document templates.

Import ER solutions that contain a template

The example in this procedure uses the officially published ER solution. You must import the ER configurations of this solution into your current instance of Finance.

The **Free text invoice (Excel)** ER format configuration of this solution contains the business document template in Excel format that can be edited by using BDM. Import the latest version of this ER format configuration from Microsoft Dynamics Lifecycle Service (LCS). The corresponding ER data model and ER model mapping configurations will be imported automatically.

For more information about how to import ER configurations, see [Manage the ER configuration lifecycle](#).

 Bank account number [Bank account number] S
 Currency bank name [Currency bank name] C

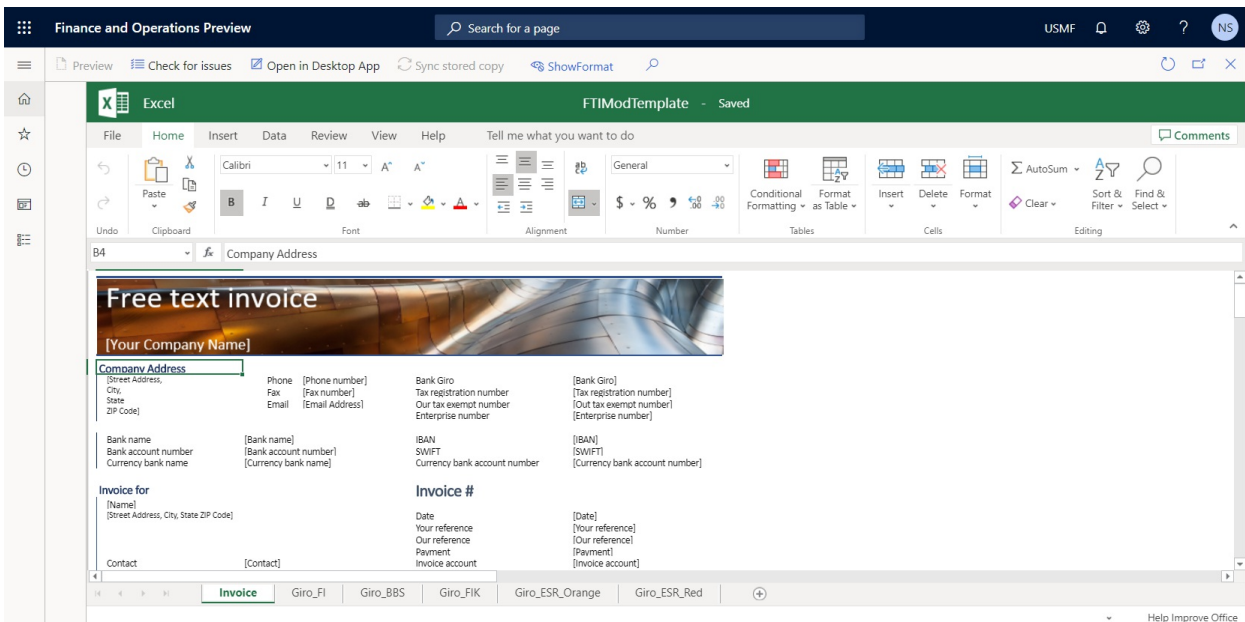

Invoice for

[Name] C
 Street Address, City, State ZIP Code V

+ New template

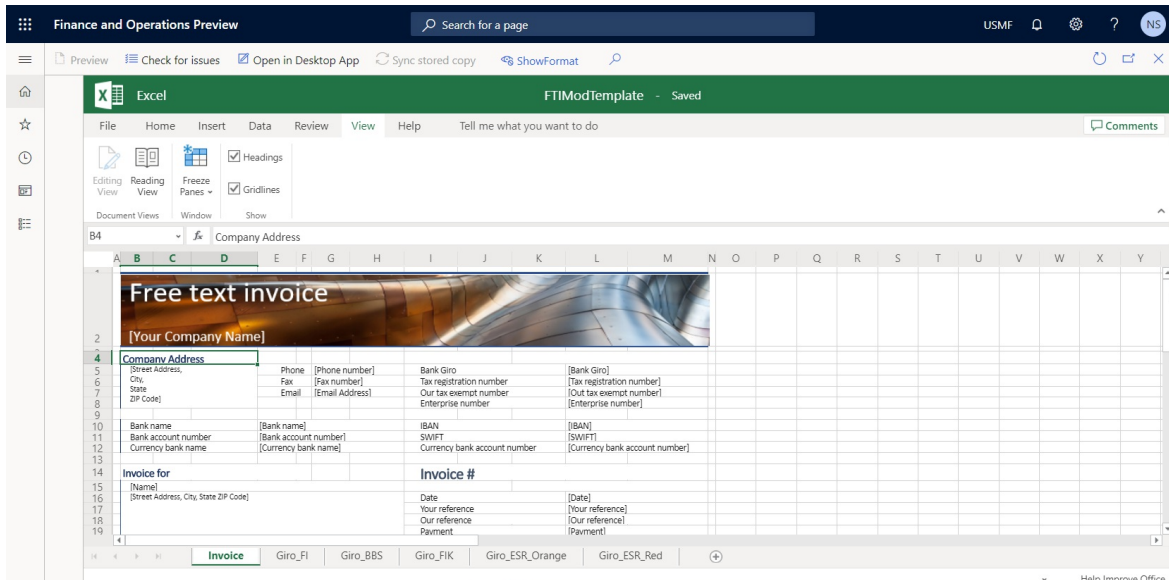

3. In the grid, select the **Free text invoice (Excel)** template.
4. In the right pane, select **New template** to create a new template that is based on the selected template.
5. In the Title field, enter **Free text invoice (Excel) Contoso** as the title of the new template.
6. Select **OK** to confirm the start of the editing process.

The BDM template editor page appears. You can use Microsoft 365 to edit the selected template online in the embedded control.

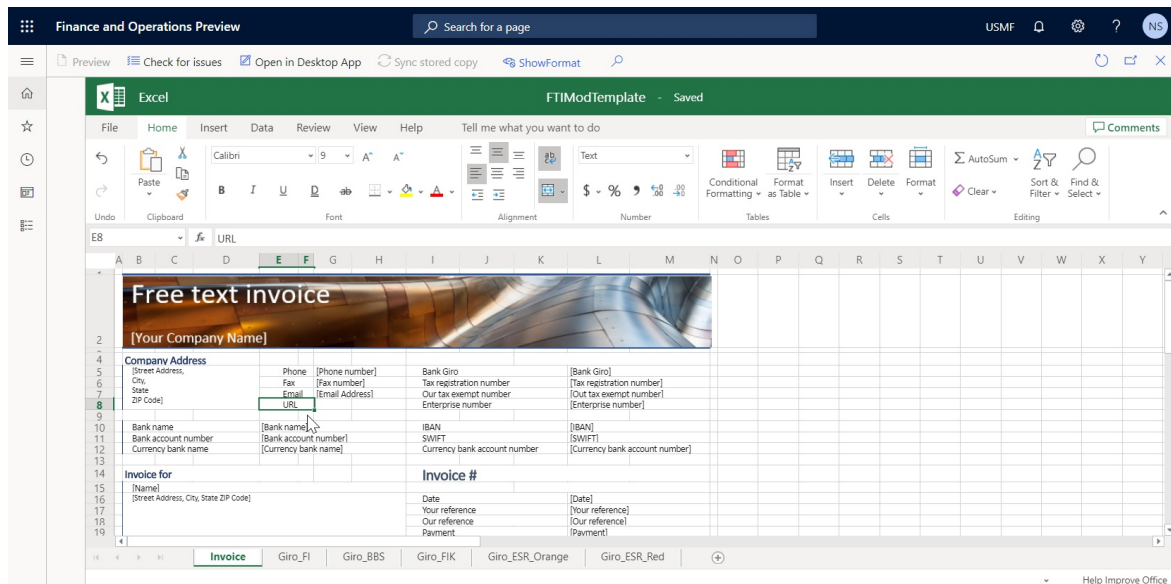

Add the label for a new field to the template

1. On the BDM template editor page, on the Excel ribbon, on the View tab, select the Headings and Gridlines check boxes for the editable Excel template.

2. Select cells E8:F8.
3. On the Excel ribbon, on the Home tab, select Merge & Center to merge the selected cells into a new merged E8:F8 cell.
4. In the merged cell E8:F8, enter URL.
5. Select merged cell E7:F7, select Format painter, and then select merged cell E8:F8 to format it in the same way as merged cell E7:F7.

Format the template to reserve space for a new field

1. On the BDM template editor page, select merged cell G8:H8.
2. On the Excel ribbon, on the Home tab, select Merge & Center to merge the selected cells into a new merged G8:H8 cell.
3. Select merged cell G7:H7, select Format painter, and then select merged cell G8:H8 to format it in the same way as merged cell G7:H7.

4. In the Name box field, select CompanyInfo.

The **CompanyInfo** range of the current Excel template holds all the fields that are used to fill the header of a generated report with the details of the current company as a seller party.

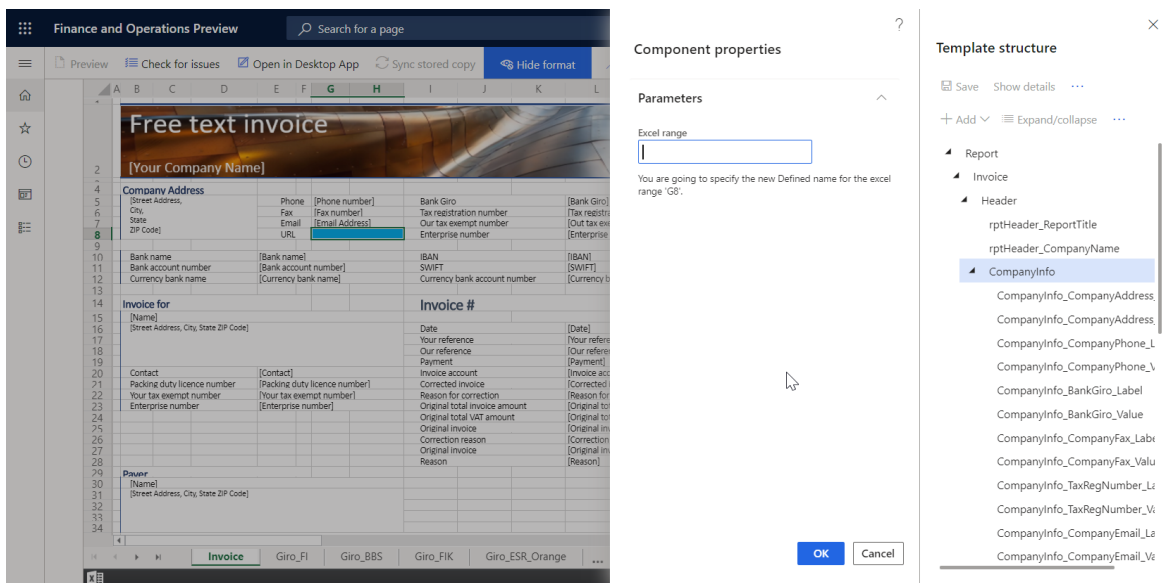

Add a new field to the template

1. On the BDM template editor page, on the Action Pane, select **Show format**.
2. In the **Template structure** pane, select **Add**.

NOTE

You must adjust the section of the template that you want to use as a new field. You already made this adjustment by formatting merged cell G8:H8.

3. Select **Excel\Cell** to add a new field as a cell in the template.

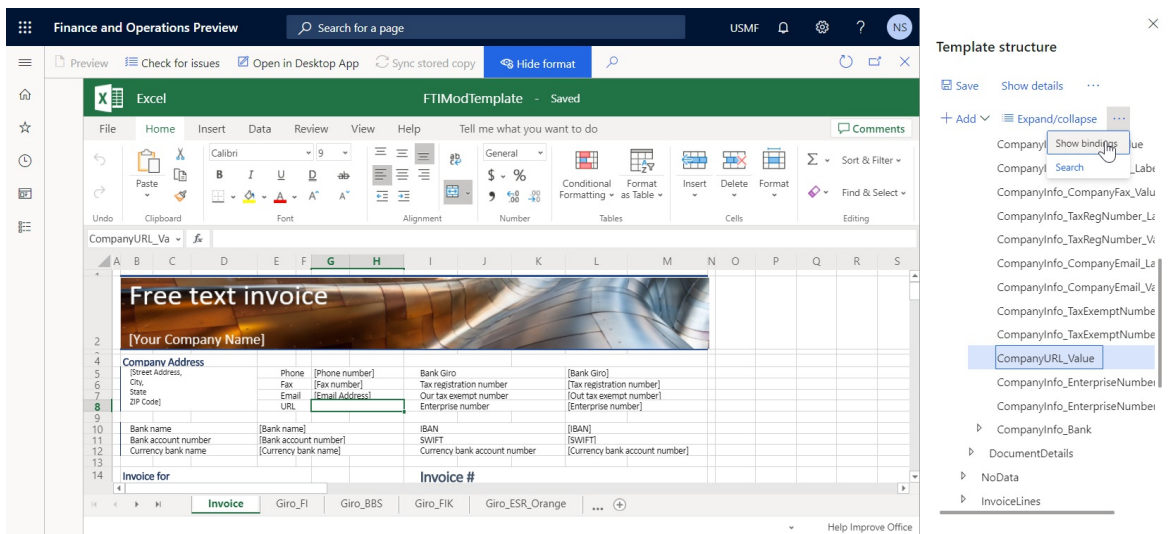

You can select **Excel\Range** if you want to add a new range to the template. The range that is entered can contain multiple cells. You can add these cells later.

Notice that the **CompanyInfo** template component, is automatically selected in the **Template structure** pane, because it's the most suitable parent component in the current template structure for the field that you're adding.

4. In the **Excel range** field, enter **CompanyURL_Value**.
5. Select **OK**.

6. In the Template structure pane, select the ellipsis button (...), and then select Show bindings.

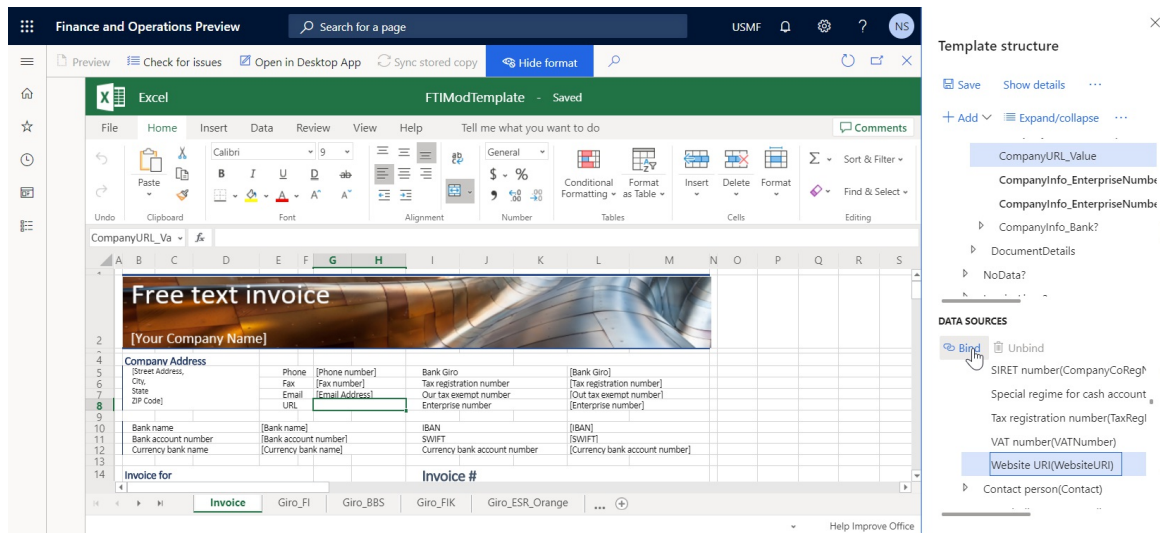

The Template structure pane now shows the data sources that are available in the underlying ER format.

7. Select CompanyInfo_Value as the field that you plan to bind to a data source of the underlying ER format.

8. In the Data sources section of the Template structure pane, expand Model > InvoiceBase > CompanyInfo.

9. Under CompanyInfo, select the WebsiteURI item.

10. Select **Bind**.

11. In the **Template structure** pane, select **Save**, and then close the BDM template editor page.

In the **Business document management** workspace, the **Template** tab in the right pane shows the updated template. In the grid, notice that the **Status** field for the edited template has been changed to **Draft**, and the **Revision** field is no longer blank. These changes indicate that the process of editing this template has been started.

Review company settings

1. Go to **Organization administration > Organizations > Legal entities**.
2. On the **Contact information** FastTab, verify that the company URL is entered.

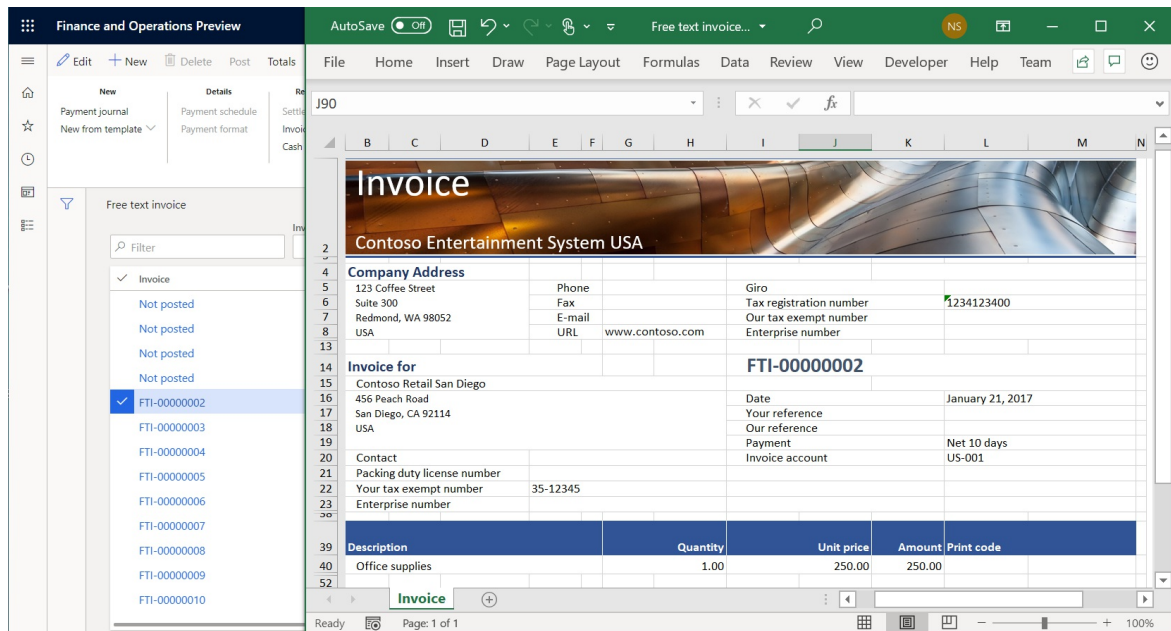

Generate business documents to test the updated template

1. In the application, change the company to USMF, and go to **Accounts receivable > Invoices > All free text invoices**.
2. Select invoice FTI-00000002, and then select **Print management**.
3. In the left pane, expand **Module - accounts receivable > Documents > Free text invoice**.
4. Under **Free text invoice**, select the **Original document** level to specify the scope of invoices for processing.
5. In the right pane, in the **Report format** field, select the **Free text invoice (Excel) Contoso** template for the specified document level.

6. Press **Esc** to close the current page.
7. Select **Print > Selected**.
8. Download the generated document, and open it in Excel.

The modified template is used to generate the free text invoice report for the selected item. To analyze how this report is affected by changes that you make to the template, run the report in one application session immediately after you change the template in another application session.

Extend the list of Electronic reporting (ER) functions

2/18/2021 • 2 minutes to read • [Edit Online](#)

Various types of functions are supported in Electronic reporting expressions for data transformation – text, date and time, mathematical logical, information, data type conversion, and other (business domain-specific functions). In addition to built-in functions, Electronic reporting lets you extend the list of available functions. This article includes an overview of key tasks that you must complete to introduce a new function.

All Electronic reporting functions in application code are represented as classes that extend the **ERExpression** class. Two types of functions are recognized:

- **Fixed number of arguments** – These functions are represented by classes that include methods that have the prefix **parm** (see **parmInput**, **parmStartNum** in the sample code the follows). The order of arguments is set by the **SysOperationDisplayOrderAttribute** attribute.
- **Variable number of arguments** – These functions (see the **ERExpressionGenericCase** class) are represented by classes that implement the **ERObjectContainer** interface. An additional **Add** method is used to declare the types that a function accepts.

Here are the recommended steps for introducing a new function for Electronic reporting expressions:

- Select a base class for your function, based on the return value type (see **ERExpressionString** in the sample code that follows).
 - Create a new class that extends the selected class (see **ERExpressionStringMid** in the sample code the follows).
 - Provide required attributes:
 - **SysOperationLabelAttribute** – This attribute defines the function’s name.
 - **SysOperationHelpTextAttribute** – This attribute defines the function’s Help text.
 - **ERComponentGroupAttribute** – This attribute defines the group that the function belongs to. (For more information, see [Formula designer in Electronic reporting \(ER\)](#).)
 - Provide arguments:
 - For a fixed number of arguments function, provide methods that have the prefix **parm**, and use the **SysOperationDisplayOrderAttribute** attribute to set the order of the arguments.
 - For a variable number of argument function, implement the **ERObjectContainer** interface.
 - Provide an evaluation method.

Here is an example.

```

/// <summary>
/// Returns the characters from the middle of a text string, given a starting position and length.
/// </summary>
[
    SysOperationLabelAttribute ('MID'),
    SysOperationHelpTextAttribute ("@ElectronicReporting:ExpressionStringMidHelpText"),
    ERComponentGroupAttribute ("@ElectronicReporting:String")
]
class ERExpressionStringMid extends ERExpressionString
{
    ERExpressionString input;
    ERExpressionInt startNum;
    ERExpressionInt numChars;
    public str evaluateString(ERIDataContext _dataContext)
    {
        return subStr(
            this.parmInput().evaluateString(_dataContext),
            this.parmStartNum().evaluateInt(_dataContext),
            this.parmNumChars().evaluateInt(_dataContext));
    }
    [DataMemberAttribute, SysOperationLabelAttribute ("@ElectronicReporting:Input"),
    SysOperationDisplayOrderAttribute ("1")]
    public ERExpressionString parmInput(ERExpressionString _input = input)
    {
        input = _input;
        return input;
    }
    [DataMemberAttribute, SysOperationLabelAttribute ("@ElectronicReporting:NumChars"),
    SysOperationDisplayOrderAttribute ("3")]
    public ERExpressionInt parmNumChars(ERExpressionInt _numChars = numChars)
    {
        numChars = _numChars;
        return numChars;
    }
    [DataMemberAttribute, SysOperationLabelAttribute ("@ElectronicReporting:StartNum"),
    SysOperationDisplayOrderAttribute ("2")]
    public ERExpressionInt parmStartNum(ERExpressionInt _startNum = startNum)
    {
        startNum = _startNum;
        return startNum;
    }
    public str toString()
    {
        return ERExpressionStringPresenter::namedFunctionToStr(this);
    }
}

```

Suggested guidance

The following guidance is intended to help you design your custom Electronic reporting functions:

- Reuse the names of Microsoft Excel functions whenever you can, so that Electronic reporting formulas remain Excel-like. In this way, you will keep Electronic reporting formulas intelligible for end users.
- Electronic reporting doesn't support list types for primitive data types. Therefore, we have decided to use a data container list that has a single **Value** item in it.
- Release a new function's list extension as a new application hotfix. Electronic reporting designers will refer to the hotfix number in Electronic reporting configurations that use that new custom function. Whenever a configuration of this type is imported into a new instance, Electronic reporting will evaluate whether the required hotfix has been installed, to maintain compliance between the Electronic reporting configuration and the version that configuration is imported into.

ER framework API changes for Application update 7.3

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic describes how the API of the Electronic reporting (ER) framework has been changed in the Dynamics 365 for Finance and Operations, Enterprise edition Application update 7.3.

There are two types of changes to the ER APIs:

- Several X++ classes were moved from X++ to an external assembly.
- The rest of X++ classes were marked as internal.

How to access classes that were moved from X++ to an external assembly

To access external classes, you need to add the **using** directive to the beginning of your file.

```
using Microsoft.Dynamics365.LocalizationFramework;
```

You can then access an external class without any additional changes, for example.

```
var destination = new ERFileDestinationMemory();
```

You can also create an alias for your namespace.

```
using LF = Microsoft.Dynamics365.LocalizationFramework;
```

You can then refer to an external class by using the namespace alias that you created.

```
var destination = new LF.ERFileDestinationMemory();
```

How to access internal X++ objects by using ERObjectsFactory

In Application update 7.3 and later updates, the calling code must access the ER objects by using the methods of the **ERObjectsFactory** class. Several examples of these changes are shown.

Code to display a format mapping lookup

Before Application update 7.3

```
// pattern
ERFormatMappingTableLookup::lookupFormatMapping(<form control>, <model name>[, <data container name>]);
// sample code
ERFormatMappingTableLookup::lookupFormatMapping(_referenceGroupControl, bankLCMiscChargeReportERModelName);
```

Application update 7.3 and later

```
// pattern
ERObjectsFactory::createFormatMappingTableLookupForControlAndModel(<form control>, <model name>[, <data
container name>]).performFormLookup();
// sample code
ERObjectsFactory::createFormatMappingTableLookupForControlAndModel(_referenceGroupControl,
bankLCMiscChargeReportERModelName).performFormLookup();
```

Code to run a format mapping for data export

Before Application update 7.3

```
// pattern
ERFormatMappingRun::constructByFormatMappingId(<format mapping id>, <file name>, <show prompt
dialog>).run();
// sample code
ERFormatMappingRun::constructByFormatMappingId(erBinding, '', true).run();
```

Application update 7.3 and later

```
// pattern
ERObjectsFactory::createFormatMappingRunByFormatMappingId(<format mapping id>, <file name>, <show prompt
dialog>).run();
// sample code
ERObjectsFactory::createFormatMappingRunByFormatMappingId(erBinding, '', true).run();
```

Code to run a format mapping for data import

Before Application update 7.3

```
// pattern
ERModelMappingDestinationRun::constructByImportFormatMappingId(<mapping id>, <integration point>).run();
// sample code
ERModelMappingDestinationRun::constructByImportFormatMappingId(custPaymModeTable.ERModelMappingTable,
CustVendOutPaymConstants::IntegrationPoint).run();
```

Application update 7.3 and later

```
// pattern
ERObjectsFactory::createMappingDestinationRunByImportFormatMappingId(<mapping id>, <integration
point>).run();
// sample code
ERObjectsFactory::createMappingDestinationRunByImportFormatMappingId(custPaymModeTable.ERModelMappingTable,
CustVendOutPaymConstants::IntegrationPoint).run();
```

Code to create a browser file destination

Before Application update 7.3

```
// sample code
new ERFileDestinationBrowser();
```

Application update 7.3 and later

```
// sample code
ERObjectsFactory::createFileDestinationBrowser();
```

Code to create an attachment file destination

Before Application update 7.3

```
// pattern
ERFileDestinationAttachment::construct(<record>, ERDocuManagement::instance().otherDocuType());
// sample code
ERFileDestinationAttachment::construct(_cashRegisterFiscalTrans_W,
ERDocuManagement::instance().otherDocuType());
```

Application update 7.3 and later

```
// pattern
ERObjectsFactory::createFileDestinationAttachmentWithOtherDocuType(<record>);
// sample code
ERObjectsFactory::createFileDestinationAttachmentWithOtherDocuType(_cashRegisterFiscalTrans_W);
```

Specify a custom storage location for generated documents

2/18/2021 • 4 minutes to read • [Edit Online](#)

The application programming interface (API) of the Electronic reporting (ER) framework lets you extend the list of storage locations for documents that ER formats generate. This topic includes an overview of the main tasks that you must complete to add a custom storage location.

Prerequisites

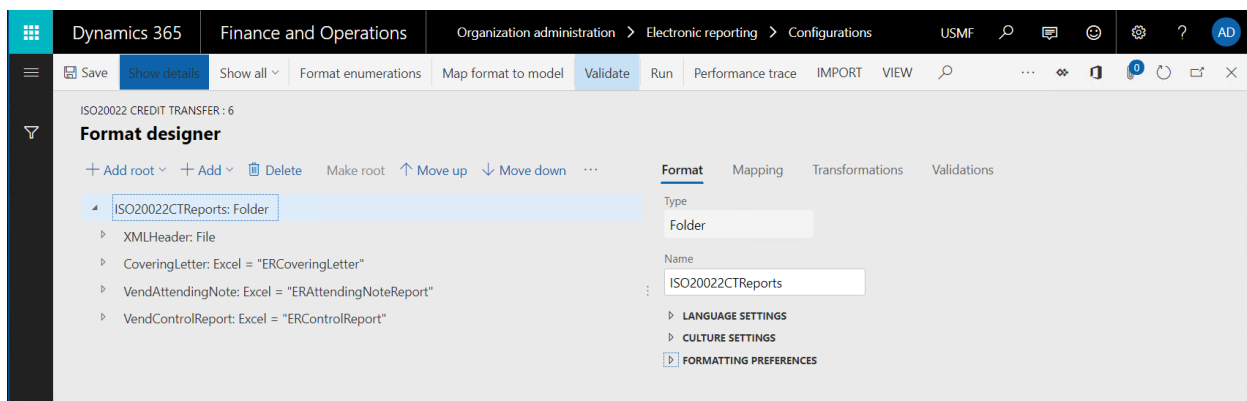

You must deploy a topology that supports continuous build. (For more information, see [Deploy topologies that support continuous build and test automation](#).) You must have access to this topology for one of the following roles:

- Electronic reporting developer
- Electronic reporting functional consultant
- System administrator

You must also have access to the development environment for this topology.

Create or import an ER format configuration

In the current topology, [create a new ER format](#) to generate documents that you plan to add a custom storage location for. Alternatively, [import an existing ER format into this topology](#).

IMPORTANT

The ER format that you create or import must contain at least one of the following format elements:

- File
- Folder
- Merger
- Attachment

Create a new document type

To specify how documents that an ER format generates are routed, you must configure [Electronic reporting \(ER\) destinations](#). In each ER destination that is configured to store generated documents as files, you must specify a

document type of the Document management framework. Different document types can be used to route documents that different ER formats generate.

1. Add a new **document type** for the ER format that you created or imported earlier. In the illustration that follows, the document type is **FileX**.
2. To differentiate this document type from other document types, include a specific keyword in its name. For example, in the illustration that follows, the name is **(LOCAL) folder**.
3. In the **Class** field, specify **Attach file**.
4. In the **Group** field, specify **File**.

NOTE

Document types are company-specific. To use an ER format with a configured destination in multiple companies, you must configure a separate document type in each company.

Review source code

Review the code of the `insertFile()` method of the `ERDocuManagement` class. Notice that the `AttachingFile()` event is raised while the generated file is attached to a record.

```

/// <summary>
/// Inserts file as attachment in Document Management.
/// </summary>
/// <param name = "_owner">A record as the attachment owner.</param>
/// <param name = "_stream">The file stream.</param>
/// <param name = "_filePath">The file path with name.</param>
/// <param name = "_attachmentName">The name of file attachment.</param>
/// <returns>The reference to inserted file.</returns>
[Hookable(false)]
public DocuRef insertFile(
    Common _owner,
    System.IO.Stream _stream,
    str _filePath,
    str _attachmentName,
    DocuTypeId _docuTypeId)
{
    DocuRef docuRef;
    if (_stream)
    {
        DocuType::createDefaults();
        if (!this.isDocuTypeValid(_docuTypeId))
        {
            throw error(strFmt("@ElectronicReporting:DocuTypeIsValid", _docuTypeId));
        }
        var args = ERDocuManagementAttachingFileEventArgs::construct(_owner, _stream, _filePath,
            _attachmentName, _docuTypeId);
        ERDocuManagementEvents::onAttachingFile(args);
        if (args.isHandled())
        {
            docuRef = args.getDocuRef();
        }
        else
        {
            docuRef = this.attachFile(_owner, _stream, _filePath, _attachmentName, _docuTypeId);
        }
    }
    return docuRef;
}

```

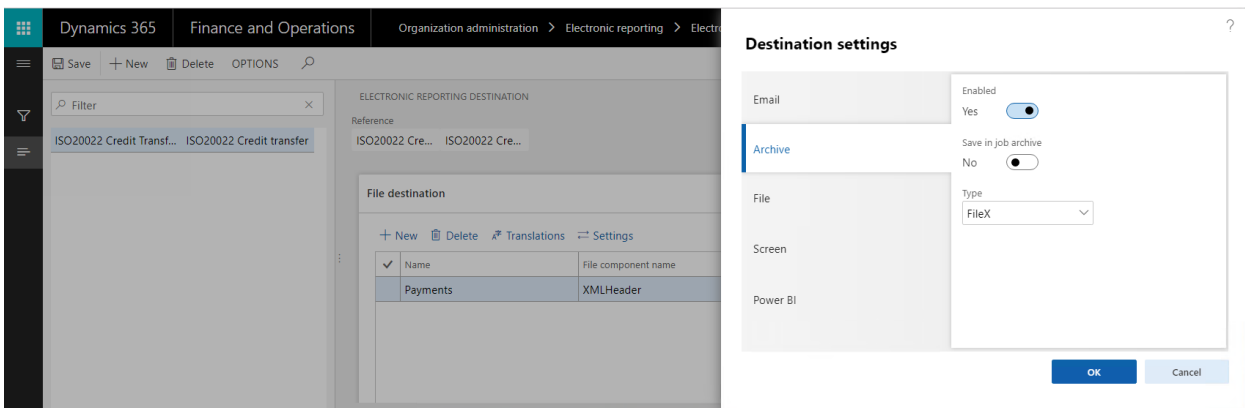

The **AttachingFile()** event is raised when the following ER destinations are processed:

- **Archive** – When this destination is used, a new record for the ER format that is run is created in the ERFormatMappingRunJobTable table. The **Archived** field in this record is set to **False**. If the ER format is successfully run, the generated document is attached to this record, and the **AttachingFile()** event is raised. The document type that is selected in this ER destination determines the storage location for the attached file (Microsoft Azure Storage or a Microsoft SharePoint folder).
- **Job archive** – When this destination is used, a new record for the ER form that is run is created in the ERFormatMappingRunJobTable table. The **Archived** field in this record is set to **True**. If the ER format is successfully run, the generated document is attached to this record, and the **AttachingFile()** event is raised. The document type that is configured in the ER parameters determines the storage location for the attached file (Azure Storage or a SharePoint folder).

Configure an ER destination

1. Configure the archived destination for one of the previously mentioned elements (file, folder, merger, or attachment) of the ER format that you created or imported. For guidance, see [ER Configure destinations](#).
2. Use the document type that you added earlier for the configured destination. (For the example in this topic, the document type is FileX.)

Modify source code

1. Add a new class to your Microsoft Visual Studio project, and write code to subscribe to the **AttachingFile()** event that was mentioned earlier. (For more information about the extensibility pattern that is used, see [Respond by using EventHandlerResult](#).) For example, in the new class, write code that performs the following actions:
 - a. Store generated files in a folder of the local file system of the server that runs the Application Object Server (AOS) service.
 - b. Store these generated files only when the new document type (for example, the **FileX** type that has the "(LOCAL)" keyword in its name) is used while a file is attached to the record in the ER execution job log.

```

class ERDocuSubscriptionSample
{
    void new()
    {
    }
    [SubscribesTo(classStr(ERDocuManagementEvents),
    staticDelegateStr(ERDocuManagementEvents,
    attachingFile))]
    public static void ERDocuManagementEvents_attachingFile(ERDocuManagementAttachingFileEventArgs
    _args)
    {
        if (!_args.isHandled())
        {
            DocuType docuType = DocuType::find(_args.getDocuTypeId());
            if (strContains(docuType.Name, '(LOCAL)'))
            {
                _args.markAsHandled();
                var stream = _args.getStream();
                if (stream.CanSeek)
                {
                    stream.Seek(0, System.IO.SeekOrigin::Begin);
                }
                using (var localStream = System.IO.File::OpenWrite(@"c:\0\" +
                _args.getAttachmentName()))
                {
                    stream.CopyTo(localStream);
                }
            }
        }
    }
}

```

2. Rebuild your project.

Run the ER format that you created or imported

1. Execute the ER format that you created or imported.
2. Go to **Organization administration > Electronic reporting > Electronic reporting jobs**. Find the record that was created for this execution job, and that has the generated file attached to it.
3. Explore the local C:\0 folder to find same generated file.

Arrival overview

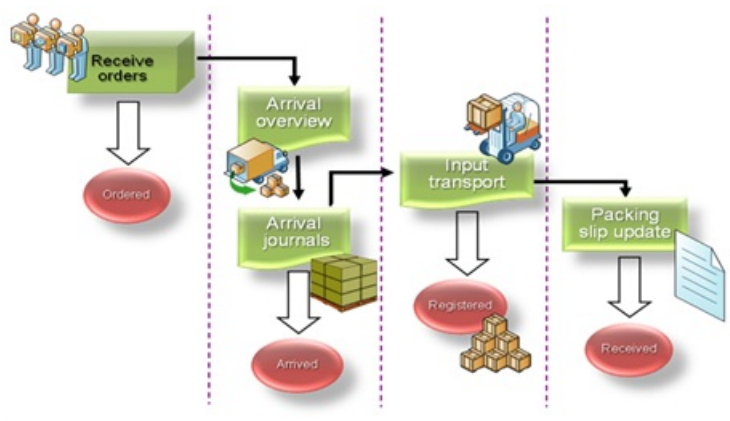

2/18/2021 • 7 minutes to read • [Edit Online](#)

This topic provides information about the Arrival overview feature. The Arrival overview page is part of this feature and provides an overview of all items that are expected to arrive as incoming items.

The **Arrival overview** page provides an overview of all expected incoming items. It also shows arrivals that can be initialized based on the overview. This topic focuses on the receiving process.

Business scenario

Consider the following scenario in the inbound processes.

Sammy, a receiving clerk, wants to know what is expected to be received on the current day. On the **Arrival overview** page, Sammy can get an overview of the current tasks, and a rough estimate of quantities, volume, weight, different order types, and so on. Later, a delivery arrives at one of the inbound docks, and Sammy receives a list of the delivery. On the **Arrival overview** page, Sammy can perform the following tasks:

- Identify the matching receipt order, and register the receipt as **In progress**. The lines that are required for a registration are automatically generated, and the receipt can be monitored, even though the transactions haven't yet been posted as **Registered**.
- Access the appropriate arrival journal reference (that is, the **Item arrival** journal or the **Production input** journal), and identify journals that are ready for a product receipt update.

Arrival overview page

To open the **Arrival overview** page, click **Inventory management > Inbound orders > Arrival overview**. You can view a list of orders that are expected to be received. The overview is divided into a header and lines. The header information is grouped by the order type, expected receipt date, and delivery destination. When a header line is selected for arrival, all the detail lines that are related to the receipt reference are selected for arrival in the line details part of the page. When all related journal lines have been posted, this information isn't shown.

Arrival overview profiles

The **Arrival overview** page provides an overview of items that are expected to arrive and the date when they are expected to arrive. As part of the arrival process, multiple sets of personal settings can be used. Individual users can define their personal settings on the **Arrival overview profiles** page.

Set up item arrival

In our example, Sammy wants to set up a new computer at a location that will be used to receive finished goods that come from production at Site 1. On the **Arrival overview profiles** page, Sammy creates a new setup that is named **Site 1 production** and specifies the following settings.

1. On the **Arrival options** FastTab, in the **Range** field group, enter information about a day interval and the warehouses to include in the overview.
2. On the **Arrival options** FastTab, in the **Journal** field group, enter a receiving warehouse, a location, and a journal name (item arrival/production input).
3. On the **Arrival query details** FastTab, in the **Site** field group, in the **Restrict to site** field, enter a site to limit the view in the overview area.
4. On the **Arrival query details** FastTab, in the **Transaction types shown** field group, set the **Production orders** option to **Yes**.
5. On the **Arrival query details** FastTab, in the **Miscellaneous** group, set the **Update on startup** option to **Yes** if the view should be automatically updated at startup. Set the **Update on range change** option to **Yes** if the view should be automatically updated when range values are changed.

For this example, the **Arrival overview profile name** field on the **Arrival options** FastTab of the **Arrival overview** page is set to **Site 1 production**.

Prerequisites for arrival journals

To automatically create arrival journals from the **Arrival overview** page, you must define appropriate information in the **Journal** field group on the **Arrival options** FastTab.

- You must specify a journal name to create a journal.

JOURNAL

Name

WArr

Warehouse

22

Location

In_01

- If you specify values in the **Warehouse** and **Location** fields, those values are applied on the journal lines. If you don't specify values, the system uses the values from the dimension that is specified on the inventory transactions.

Items that are received from one expected receipt order

On the **Receipts** FastTab, Sammy selects a line and then clicks **Start arrival**. All related lines that are in the specified range and that have a quantity to register are automatically selected. An item arrival journal is generated that has a match between the expected receipt order and the journal. The quantity is automatically initialized on all lines that are created.

Items that are received from more than one expected receipt order

On the **Receipts** FastTab, Sammy selects multiple lines and then clicks **Start arrival**. An item arrival journal is generated that has a match between all the expected receipt orders and the journal. All lines are created on one item arrival journal header, and the quantity is automatically initialized.

Receive items from one or more expected receipt orders

View information

To get an overview of expected receipts in a date interval, Sammy enters the following information in the fields on the **Arrival options** FastTab on the **Arrival overview** page and then clicks **Update** to update the view:

- Arrival overview profile name: **Inquiry**
- Show lines: **All**

- Days back: (Blank)
- Days forward: 0
- Warehouses: **GW, MW**

Sammy can view the following information:

- All related receipt orders for the system date and an infinite number of days back from it (the **InventTrans.StatusDate** interval), and receipts to warehouses GW and MW, regardless of status.
- Detailed line information for more than one order. Sammy can select multiple header lines in the overview and then click **Show all selected** to view all the corresponding line detail information for all selected orders.
- Information about a specific purchase order. To show only information that is related to a specific reference number in the overview, Sammy can enter an account number in the **Account number** field and an order number in the **Reference number** field.
- An overview of the registration tasks that are due for all the order lines that an item arrival journal has been created for but hasn't yet been posted. To view this information, Sammy can select **In progress** in the **Show lines** field.

Update journals

To register one or more order lines that are due to be processed, Sammy can select the lines in the overview grid or in the line grid, and then click **Journals > Show arrivals from receipts**. The item arrival headers that match the lines are shown. To update the purchase order product receipt for the registered items, Sammy can access the item arrival journal headers that are ready for update. To access these item arrival journal headers, he clicks **Journals > Product receipt ready journals**. All the header lines that are ready for product receipt update in the specified warehouse range are shown. (The header lines that are shown aren't related to the day interval).

Start an arrival registration

By selecting multiple lines on the **Arrival overview** page, Sammy can start an arrival of more than one receipt reference. When he selects a line from the receipts overview, the corresponding line details are selected. If a quantity for registration exists, the **Start arrival** button is available. Sammy can use two methods to start the arrival registration:

- To filter the page so that it shows only records that meet specific criteria, in the **Vendor reference** field, scan a reference number from a vendor, such as the bar code for a delivery note.
- In the overview part or the details part of the **Arrival overview** page, manually select or cancel the selection of records for arrival registration. Then, when Sammy clicks **Start arrival**, the selected records are automatically created in an item arrival journal. The records include line information, and all unique field information is assigned.

Update arrival information and process a product receipt

When all goods have been registered, the warehouse manager or purchasing manager can update the received items with a product receipt to add the physical cost. To update arrival information and post a product receipt, follow these steps.

1. Click **Inventory management > Inbound orders > Arrival overview**.
2. On the **Arrival overview** page, click **Journals > Product receipt ready journals** to show a list of the journals that are ready for product receipt update.
3. Select the journals that must be updated, and then click **Functions > Product receipt**.
4. On the **Posting** page, enter the product receipt number, if it isn't already available on the journal, and then click **OK** to process the product receipt.

Summary

The **Arrival overview** page can help the warehouse manager and warehouse workers achieve an overview of expected work that must be done as part of an inbound process. The page can also be used to start the item arrival process, to help guarantee that items are tracked at the first entry into the warehouse.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Set up an item arrival overview profile

2/18/2021 • 2 minutes to read • [Edit Online](#)

1

This topic focuses on the setup of an arrival overview profile. The arrival overview profile is a collection of rules that will be applied when the Arrival overview page is opened by a user. You can use this procedure in demo data company USMF. This procedure would typically be carried out by a receiving clerk.

1. In the navigation pane, go to **Modules > Inventory management > Setup > Distribution > Arrival overview profiles**.
2. Select **New**. Because you will almost always work in the same warehouse offloading full truck loads, you should create an arrival overview profile to simplify the process of registering received items.
3. In the **Arrival overview profile name** field, type a value.
4. In the **Show lines** field, select an option. Select which lines to show for the receipts:
 - **All** – Show all lines, regardless of status.
 - **In progress** – Show lines for receipts in which the progress is Complete or Partly. This means that for each line, either the full quantity or part of the quantity has been registered in an arrival journal.
 - **Not complete** – Show lines for receipts in which the progress is None or Partly. This means that for each line, nothing or only part of the quantity has been registered in an arrival journal.
5. Expand or collapse the **Arrival options** section.
6. In the **Days forward** field, type a value. This sets a filter to show the receipt lines expected to be received within the next few days (depending on the number you set).
7. In the **Days back** field, type a value. This sets a filter to show the receipt lines expected to be received a number of days before today.
8. In the **Warehouses** field, type a value. Filter on one or more warehouses.
9. In the **Mode of delivery** field, select a value. This sets a filter to show only the receipt lines with this Mode of delivery.
10. In the **Name** field, select WHS.
11. In the **Warehouse** field, select warehouse 24. This is the default warehouse that will be used for registered receipt lines that use this profile.
12. In the **Location** field, select **Baydoor**. This is the default location that will be used for registered receipt lines that use this profile.
13. Expand or collapse the **Arrival query details** section.
14. In the **Restrict to site** field, select site 2. This sets a filter to show only the receipt lines with this site.
15. Set the **Purchase orders** option to **Yes**. Select receipt lines from purchase orders.
16. Set the **Transfer orders** option to **Yes**. Select receipt lines from transfer orders.
17. Select **Save**.
18. Close the page.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Quality management overview

2/18/2021 • 15 minutes to read • [Edit Online](#)

This topic describes how you can use quality management in Dynamics 365 Supply Chain Management to help improve product quality within your supply chain.

Quality management can help you manage turnaround times when you handle nonconforming products, regardless of their point of origin. Because diagnostic types are linked to correction reporting, Supply Chain Management can schedule tasks to correct problems and prevent them from recurring.

In addition to functionality for managing nonconformance, quality management includes functionality for tracking issues by problem type (even internal problems), and for identifying solutions as short-term or long-term. Statistics about key performance indicators (KPIs) provide insight into the history of previous nonconformance issues and the solutions that were used to correct them. You can use historical data to review the effectiveness of previous quality measures and determine appropriate measures to use in the future.

When you set up a quality association, Supply Chain Management can generate quality orders for various business processes, events, and conditions. The quality association can cover a specific item, a specific group of items, or all items.

Examples of the use of quality management

Quality management is flexible and can be implemented in various ways to meet the requirements of specific levels of supply chain operations. The following examples illustrate possible uses of these features:

- Automatically start a quality control process, based on predefined criteria (upon warehouse registration of a purchase order from a specific vendor).
- Block inventory during inspection to prevent non-approved inventory from being used (full blocking of purchase order quantities).
- Use item sampling as part of a quality association to define the amount of current physical inventory that must be inspected. Sampling can be based on fixed quantities, a percentage, or full license plate.

NOTE

The *Quality management for warehouse processes* feature extends the capabilities of quality management. If you are using this feature, then see [Quality management for warehouse processes](#) for examples of how quality management works when it's enabled.

- Create quality orders for partial receipts. To create a quality order that is based on the quantity that is physically received with an order, you must select the **Per updated quantity** check box on the **Item sampling** form.
- Create test types that include minimum, maximum, and target test values, and perform qualitative-versus-quantitative testing that has predefined validation results.
- Specify an acceptable quality level (AQL) to control quality measure tolerances.
- Specify the resources that an inspection operation requires, such as a test area and test instruments.

Working with quality associations

The business process that uses a quality association can be related to various source documents, such as purchase orders, sales orders, or production orders.

Each quality association record defines the set of tests, the AQL, and the sampling plan that applies to the quality orders that are generated. You must define a quality association record for each variation in a business process. For example, you can set up a quality association that generates a quality order when a purchase order product receipt is updated. Depending on the setup of the execution plan, the triggering process itself can be blocked while there is an open quality order, or the next processes, such as purchase order invoicing, can be blocked.

Note: While there are open quality orders, inventory quantities are automatically blocked from being issued. Depending on the **Full blocking** setting on the **Item samplings** page, the quantity is either the quantity on the quality order or the quantity on the source document line.

For a given business process, the quality association record identifies the event and the conditions that a quality order is generated for. The conditions can be specific to either a site or a legal entity. A quality order that involves destructive tests can be generated only when on-hand inventory exists for the event.

The following examples illustrate how a quality association record is defined for the variations in each business process. For each example, the following table summarizes the events and conditions that are defined by a quality association record.

REFERENCE TYPE	EVENT TYPE	EXECUTION	EVENT BLOCKING	DOCUMENT REFERENCE	
Inventory	Not applicable	Not applicable	None	All	
Sales	Picking process is scheduled	Before	None	Specific ID, Group, or All only	
			Picking process		
			Packing slip		
	Invoice				
	Packing slip	Before	None		
			Packing slip		
Invoice					
Purchase	Receipt list	Before	None		
			Receipt list		
			Product receipt		
			Invoice		
	Registration	Not applicable	None		None
					Product receipt
					Invoice
					Product receipt

			Invoice	
	Product receipt	Before	None	
			Product receipt	
		After	None	
			Invoice	
Production	Registration	Not applicable	None	All
			Report as finished	
			End	
	Report as finished	Before	None	
			Report as finished	
			End	
After	None			
	End			
Quarantine	Report as finished	Before	Report as finished	
			End	
		After	End	
	End	Before	End	
Route operation	Report as finished	Before	None	Specific ID, Group, or All, and Resource specific, Group, or All
			Report as finished	
		After	None	
Co-product production	Registration	Not applicable	None	All
	Report as finished	Before		
		After		

The following table provides more information about how quality orders can be generated for specific types of processes.

TYPE OF PROCESS	WHEN QUALITY ORDERS CAN BE AUTOMATICALLY GENERATED	WHEN QUALITY ORDERS CAN BE GENERATED IF DESTRUCTIVE TESTING IS REQUIRED	CONDITION INFORMATION	MANUAL GENERATION INFORMATION
Purchase order	Before or after a receipts list or product receipt for the material that is received is posted	After the product receipt for the material that is received is posted, because the material must be available for destructive testing	The requirement for a quality order can reflect a particular site, item, or vendor, or a combination of these conditions.	A manually generated quality order that refers to a purchase order can use information in a quality association record, such as the test sampling plan.
Quarantine order	Before or after the quarantine order is reported as finished or ended	Quality orders that require destructive tests can't be generated. It's assumed that the quarantine order functionality handles the disposition of the material that is destroyed.	The requirement for a quality order can reflect a particular site, item, or vendor, or a combination of these conditions.	A manually generated quality order that refers to a quarantine order can use information in a quality association record, such as the test sampling plan.
Sales order	Before a scheduled picking process or packing slip update for the items that are being shipped	At any step	The requirement for a quality order can reflect a particular site, item, or customer, or a combination of these conditions.	A manually generated quality order that refers to a sales order can use information in a quality association record, such as the test sampling plan.
Production order	Before or after the finished quantity for the production order is reported	After the finished quantity for the production order is reported	The requirement for a quality order can reflect a particular site or item, or a combination of these conditions.	A manually generated quality order that refers to a production order can use information in a quality association record, such as the test sampling plan.
Production order that has a route operation	Before or after the report is finished for an operation	After the reporting production is finished for the last operation	The requirement for a quality order can reflect a particular, site, item, or operations resource, or a combination of these conditions.	A manually generated quality order that refers to a route operation can use information in a quality association record, such as the test sampling plan.
Inventory	A quality order cannot be automatically generated for a transaction in an inventory journal or for transfer order transactions.			A quality order must be created manually for an item's inventory quantity. Physical on-hand inventory is required.

Quality order auto-generation examples

Purchasing

In purchasing, if you set the **Event type** field to **Product receipt** and the **Execution** field to **After** on the **Quality associations** page, you get the following results:

- If the **Per updated quantity** option is set to **Yes**, a quality order is generated for every receipt against the purchase order, based on the received quantity and settings in the item sampling. Every time that a quantity is received against the purchase order, new quality orders are generated based on the newly received quantity.
- If the **Per updated quantity** option is set to **No**, a quality order is generated for the first receipt against the purchase order, based on the received quantity. Additionally, one or more quality orders are created based on the remaining quantity, depending on the tracking dimensions. Quality orders aren't generated for subsequent receipts against the purchase order.

Production

In production, if you set the **Event type** field to **Report as finished** and the **Execution** field to **After** on the **Quality associations** page, you get the following results:

- If the **Per updated quantity** option is set to **Yes**, a quality order is generated based on every finished quantity and settings in the item sampling. Every time that a quantity is reported as finished against the production order, new quality orders are generated based on newly finished quantity. This generation logic is consistent with purchasing.
- If the **Per updated quantity** option is set to **No**, a quality order is generated the first time that a quantity is reported as finished, based on the finished quantity. Additionally, one or more quality orders are created based on the remaining quantity, depending on the tracking dimensions of the item sampling. Quality orders aren't generated for subsequent finished quantities.

QUALITY SPECIFICATION	PER UPDATED QUANTITY	PER TRACKING DIMENSION	RESULT
Percentage: 10%	Yes	Batch number: No Serial number: No	Order quantity: 100 1. Report as finished for 30 <ul style="list-style-type: none">• Quality order #1 for 3 (10% of 30) 2. Report as finished for 70 <ul style="list-style-type: none">• Quality order #2 for 7 (10% of the remaining order quantity, which equals 70 in this case)

<p>Fixed quantity: 1</p>	<p>No</p>	<p>Batch number: No Serial number: No</p>	<p>Order quantity: 100</p> <ol style="list-style-type: none">1. Report as finished for 30<ul style="list-style-type: none">• Quality order #1 for 1 (for the first reported-as-finished quantity, which has a fixed value of 1)• Quality order #2 for 1 (for the remaining quantity, which still has a fixed value of 1)2. Report as finished for 10<ul style="list-style-type: none">• No quality orders are created.3. Report as finished for 60<ul style="list-style-type: none">• No quality orders are created.

Fixed quantity: 1	Yes	Batch number: Yes Serial number: Yes	Order quantity: 10 1. Report as finished for 3: 1 for #b1, #s1; 1 for #b2, #s2; and 1 for #b3, #s3 <ul style="list-style-type: none">• Quality order #1 for 1 of batch #b1, serial #s1• Quality order #2 for 1 of batch #b2, serial #s2• Quality order #3 for 1 of batch #b3, serial #s3 2. Report as finished for 2: 1 for #b4, #s4; and 1 for #b5, #s5 <ul style="list-style-type: none">• Quality order #4 for 1 of batch #b4, serial #s4• Quality order #5 for 1 of batch #b5, serial #s5 Note: The batch can be reused.
-------------------	-----	---	--

Fixed quantity: 2	No	Batch number: Yes Serial number: Yes	Order quantity: 10 1. Report as finished for 4: 1 for #b1, #s1; 1 for #b2, #s2; 1 for #b3, #s3; and 1 for #b4, #s4 <ul style="list-style-type: none"> • Quality order #1 for 1 of batch #b1, serial #s1 • Quality order #2 for 1 of batch #b2, serial #s2 • Quality order #3 for 1 of batch #b3, serial #s3 • Quality order #4 for 1 of batch #b4, serial #s4 • Quality order #5 for 2, without a reference to a batch and a serial number 2. Report as finished for 6: 1 for #b5, #s5; 1 for #b6, #s6; 1 for #b7, #s7; 1 for #b8, #s8; 1 for #b9, #s9; and 1 for #b10, #s10 <ul style="list-style-type: none"> • No quality orders are created.
-------------------	----	---	---

NOTE

The *Quality management for warehouse processes* feature adds capabilities for quality order processing for production with **Event type** set to *Report as finished* and **Execution** set to *After*, and for purchases with **Event type** set to *Registration*. For details, see [Quality management for warehouse processes](#).

Quality management pages

PAGE	DESCRIPTION	EXAMPLE
------	-------------	---------

PAGE	DESCRIPTION	EXAMPLE
Quality associations	See the previous sections of this article.	<p>A quality association defines all the following information for a quality order that is generated:</p> <ul style="list-style-type: none"> • The transaction event • The set of tests that must be performed on the items • The AQL • The sampling plan <p>You must define a quality association for each variation in a business process that requires automatic generation of quality orders. For example, a quality order can be generated in the business processes for purchase orders, quarantine orders, sales orders, and production orders.</p>
Tests	<p>Use this page to define and view the individual tests that determine whether your products meet quality specifications. You can assign one or more individual tests to a test group. In this case, you also specify test-specific information, such as the acceptable measurement values. Measurement values are used for quantitative tests, and test variables are used for qualitative tests.</p> <ul style="list-style-type: none"> • A quantitative test has a test type of Integer or Fraction, and also has a designated unit of measure. Quality specifications and test results are expressed as numbers. • A qualitative test has a test type of Option. Qualitative tests require additional information about the test variable that is being measured and its enumerated options. Quality specifications and test results are expressed according to an outcome. 	<p>A manufacturing company performs two tests on purchased material: a quantitative test about material quality and a qualitative test about packaging damage. The company defines additional information about the qualitative test to identify the test variable (damaged packaging) and its outcomes. The company uses the Test groups page to assign the two tests to a test group and to specify the test-specific information. The test group is assigned to a quality order, so that the company can report test results for the two tests.</p>

PAGE	DESCRIPTION	EXAMPLE
Test groups	<p>Use this page to set up, edit, and view test groups and the individual tests that are assigned to a test group. The upper pane displays test groups, and the lower pane displays the tests that are assigned to a selected test group. You assign several policies to a test group, such as a sampling plan, an AQL, and the requirement for destructive testing. When you assign an individual test to a test group, you define additional information, such as the sequence, documents, and validity dates. For a quantitative test, the information that you define also includes the acceptable measurement values. For a qualitative test, the information includes the test variable and default outcome. The test group that is assigned to a quality order defines the default set of tests that must be performed on the specified item. However, you can add, delete, or change tests on the quality order. Test results are reported for each test on a quality order.</p>	<p>A manufacturing company defines a test group for each variation of its quality guidelines. The various test groups reflect differences in the sampling plans, the sets of tests that must be performed together, the AQL, and other factors. For quantitative tests, there are also differences in the acceptable measurement values. To enforce its quality guidelines, the company assigns a test group to each rule for automatically generating quality orders on the Quality associations page, and also assigns a test group to quality orders that are manually created.</p>
Item quality groups	<p>Use this page to set up, edit, and view the items that are assigned to a quality group or the quality groups that are assigned to an item. A quality group represents common testing requirements for items. After you define the test requirements on the Test groups page, you can define the rules for automatically generating quality orders. To simplify the process, you don't define rules for individual items. Instead, you define rules for a quality group, by using the Quality associations page. You can also use the Item quality groups page for a selected quality group to assign relevant items to that group. You can also use the Item quality groups page for a selected item to assign relevant quality groups to that item.</p>	<p>A manufacturing company purchases various raw materials that have the same testing requirements for incoming inspection. The company defines a quality group and then assigns the item numbers that are associated with the raw materials to that group. Later, the company purchases a new type of raw material that has the same testing requirements. Instead of setting up new testing requirements for the new material, the company adds the item number for the new material to the existing quality group. The same manufacturing company also produces items that have the same production testing requirements and ships items that have the same requirement for pre-shipment testing. The company defines two additional quality groups and then assigns the relevant item numbers to each group.</p>

PAGE	DESCRIPTION	EXAMPLE
Test variables	Use this page to define and view the variables that are associated with a qualitative test. For each variable, you define enumerated outcomes that represent the possible options. You define tests on the Tests page. For qualitative tests, you must set the test type to Option . Use the Test groups page to assign a test variable to an individual test.	A manufacturing company that produces cookies uses an inspection test for the finished product. This inspection test has several variables. One variable is taste, and the possible outcomes for this variable are good and bad. A second variable is color, and the possible outcomes are too dark, too light, and correct.
Test variable outcomes	Use this page to set up, edit, and to view the possible test results for a test variable that is associated with a qualitative test. For each outcome, you assign a pass or fail status. You must define a variable and its outcomes for each qualitative test that is defined on the Tests page. (For qualitative tests, the test type is set to Option on the Tests page.) Use the Test groups page to assign a test variable and the default outcome to an individual qualitative test.	A manufacturing company that produces cookies uses an inspection test for the finished product. This inspection test has of several variables. One variable is taste, and the possible outcomes for this variable are good and bad. A second variable is color, and the possible outcomes are too dark, too light, and correct. A status of pass or fail is assigned to each outcome. During the inspection test for each variable, the inspector reports the test result by selecting one of the outcomes.

Quality management processes

2/18/2021 • 7 minutes to read • [Edit Online](#)

This article provides information about the quality management process for nonconforming products. It describes how you can use quality control functionality, how to define and maintain nonconformances, and how to handle corrections.

Quality assurance involves product testing and the management of nonconforming material. Quality management processes help guarantee a high level of product quality in your supply chain. These processes also help optimize supply chain processes and increase customer satisfaction. Quality management can help you manage turnaround times when you're dealing with nonconforming products, regardless of point of origin of those products. You can link diagnostic results to correction tasks. The system can schedule tasks to correct problems and therefore help prevent recurrences of those problems in the future. Quality management also lets you track issues (including internal problems) by problem type, and lets you identify solutions as either short-term or long-term. Statistics about key performance indicators (KPIs) provide insight into nonconformance problems that have previously occurred and the solutions that were applied to correct them. You can use historical data to help review the effectiveness of quality measures that have previously been taken and to determine appropriate measures in the future.

Controlling the quality management process

Here are some of the ways that you can control the quality management process:

- Create quality orders that are based on trigger points such as "at product receipt" for inbound operations or "at product pick-up" for outbound operations.
- Document test results, and determine whether the results meet the established test criteria and acceptable quality levels.
- Use document management for detailed product specifications and user-specific notes as part of reporting during the inspection process.
- Maintain nonconforming products, and correlate these products with additional nonconformance information to track down the original cause of a problem.
- Document the cost of managing a nonconformance. This cost can include the items (such as spare parts), miscellaneous charges, and the timesheet hours that are required in order to correct the nonconformance.
- Schedule error correction processes by using correction handling that is linked to quality orders.

Product testing and quality orders

Product testing is typically referred to as quality control and uses quality orders. By using the quality control functionality, you can do the following:

- Define the tests that must be performed for material. These tests include the quality specifications, the applicable test instrument, documents that describe the test, a sampling plan, and the acceptable quality levels (AQL).
- Create a quality order that identifies the tests that must be performed for a specific order, such as a purchase or production order, or for a specific inventory quantity. You can create a quality order manually or generate a quality order automatically, based on quality guidelines.
- Define the quality guidelines that are related to purchase, quarantine, production, or sales orders in each business process, so that a quality order can be automatically generated that identifies the testing requirements for incoming or outgoing material.
- Record the test results in a quality order, validate the test results against the AQL, and print a certificate of analysis that displays the test results.

Nonconformance

A nonconformance describes an item that has a quality problem. The nonconformance process lets you create a nonconformance order that describes a quantity of nonconforming material, the problem source, the problem type, and explanatory notes. You can define a classification of problem types to make analysis of nonconforming material easier. You can also print a nonconformance tag and a nonconformance report to guide the disposition of nonconforming material. For example, the tag and report might indicate a condition of **Unusable** or **Restricted usage**.

The following table lists the six default nonconformance types and describes the information that must be recorded for each type.

NONCONFORMANCE TYPE	SOURCE INFORMATION
Customer	The customer account number, the sales order number, or a lot number of a sales order transaction. For example, the nonconformance might be related to a specific sales order shipment or to customer feedback about product quality.
Service request	The customer account number, the sales order number, or a lot number of a sales order transaction. For example, the nonconformance might be related to a specific sales order shipment or to a customer's complaint about item quality.
Vendor	The vendor account number, the purchase order number, or a lot number of a purchase order transaction. For example, the nonconformance might be related to a purchase order receipt or to a vendor's concern about a part that it supplies.
Production	The production order number or a lot number of a production order transaction. For example, the nonconformance might be related to a specific batch that was produced.
Internal	The quality order number or a lot number of a quality order transaction. For example, the nonconformance might be related to the tests that are performed as part of a quality order or to an employee's concern about product quality.
Co-product production	A co-product production order nonconformance that is related to batch production orders.

Nonconformances are associated with a problem type. Problem types are defined on the **Problem types** page, where you specify which problem types can be associated with each nonconformance type. For example, the problem types for nonconformances of the **Service request** type might reflect a classification of customer complaints, whereas the problem types for nonconformances of the **Internal** type might represent a classification of defect codes.

When you create a new nonconformance, you select the nonconformance type and the problem type. The initial approval status is **New**, which represents a request for action. The next step is to change the approval status to **Approved** or **Refused**, to indicate that you will or won't take action on the nonconformance. You can also close a nonconformance (by selecting a separate check box) to indicate that you're finished with it, or you can reopen a nonconformance to indicate that additional consideration is required.

You can enter comments for a nonconformance by attaching a document. It's a good idea to define a unique document type for nonconformances by using the **Document type** page. You can then use the **Report setup** page to define whether comments for this document type should be printed on the nonconformance report and nonconformance tag. The conformance report and nonconformance tag can help with material disposition. You can selectively generate reports and tags, based on selection criteria that are associated with a nonconformance. These criteria include the nonconformance number, item, customer, vendor, and status.

The nonconformance report displays the nonconformance number, item, and problem type. Depending on your report setup policy, the report might also display related notes about the nonconformance. The nonconformance tag displays similar information, and also includes the quarantine zone and type (such as **Restricted usage** or **Unusable**) that you assigned to the nonconformance to help guide disposition of the defective material.

Approved nonconformance

You can optionally define one or more related operations for an approved nonconformance. A related operation describes the work that should be performed, and contains a list of the quality operations that you've defined and descriptive text about the reason for the work. After you define an operation, you can optionally define the miscellaneous charges, items, and timesheet labor hours that are required in order to perform the work. The calculated costs are shown for the related operation, and the total calculated costs are shown for the nonconformance. The calculated costs and the underlying details (about items, labor hours, and miscellaneous charges) represent reference information, and they are used only in the quality management function.

You can optionally create a quality order from a nonconformance by first performing an inquiry for quality orders and then creating the new quality order. For example, a quality order might identify the need to test (or retest) the defective material. The newly created quality order displays the link to the originating nonconformance.

You can optionally link one nonconformance to another and create a new nonconformance from an existing one. For example, the link can reflect the interconnection between quality problems.

Correction handling

The **Corrections** page lets you create a list of nonconformances that must be corrected. Each correction item is associated with the diagnostic type that caused the problem to be discovered. The **Corrections** page also contains information about who must perform a corrective action, and when. You can describe the details of the problem and the corrective action that is required by attaching a document to the correction. After the nonconformance has been addressed or corrected, you "close" the correction item by selecting the **Completed** option. You can also indicate that the solution was a short-term solution.

It's a good idea to define a unique document type for corrections by using the **Document type** page. You can then use the **Report setup** page to define whether comments for this document type are printed on the correction report. A printed correction report displays information about the nonconformance and the related nonconformance notes. The report also includes correction information, such as the diagnostic type, and the related correction notes.

Quality management for warehouse processes

2/18/2021 • 39 minutes to read • [Edit Online](#)

The *Quality management for warehouse processes* feature lets you integrate item sampling controls into the warehouse receiving process by using advanced warehouse management. Warehouse work can be automatically generated to move inventory to the quality control location, based on a percentage or a fixed quantity, or based on every n th license plate. After a quality order has been completed, work can be automatically generated to move inventory to the next location in the process, depending on the quality results.

The *Quality management for warehouse processes* feature extends the capabilities of the basic quality management feature. It provides the option to create quality orders for the inventory that is sent to the quality control location, although quality orders aren't always required. Therefore, it allows for a lightweight quality control process that is based on warehouse work.

Turn on the Quality management for warehouse processes feature

Before you can use this feature, it must be turned on in your system. Admins can use the [feature management](#) settings to check the status of the feature and turn it on. In the **Feature management** workspace, the feature is listed in the following way:

- **Module:** *Warehouse management*
- **Feature name:** *Quality management for warehouse processes*

Key benefits

The *Quality management for warehouse processes* feature automatically generates work as part of the receiving process, to move the inventory quantity that is required for quality control to a quality control location. If the quantity that is received exceeds the quantity that is required for quality control (according to the item sampling setup), the excess quantity is moved to an inbound location that is defined in the location directive setup. After the quality order is validated, work is automatically generated to move the quantity for the quality order to a new inbound or return location, based on the validation result and the location directive setup. The automatic generation of work that has only the quantity that must be moved to and from quality control provides an integrated process experience.

NOTE

When the *Quality management for warehouse processes* feature is turned on, you can still take advantage of the manual process. In the manual process, inventory movement and movement by template are used to have a warehouse worker trigger the creation of warehouse work to move inventory from a quality control location to a new location. You can also still set up an inbound location directive that moves inventory in its entirety from a receiving location to a quality control location without considering the item sampling setup.

Quality management and the Quality management for warehouse processes feature

When the *Quality management for warehouse processes* feature is turned on, it changes the setup of key warehouse management and quality management entities. The following illustration provides an overview of the entities that enable quality orders for warehouse processes. Text in parentheses indicates suggested actions when quality management was applied before the *Quality management for warehouse management processes*

feature was turned on.

Quality Association (New & Adjust)	
Item Sampling (New & Adjust)	
Enable for each Warehouse	
Mobile device menu item & Menu device menu (New & Adjust)	
Work Template (New & Adjust)	Location Directive (New & Adjust)
Work Classes (New)	

Enablers: The Quality item sampling and Quality order work order types

The *Quality management for warehouse processes* feature introduces two work order types that enable the work creation process:

- **Quality item sampling** – This work order type is used to create work that moves registered inventory to quality control.
- **Quality order** – This work order type is used to create work that moves inventory from quality control to a new location, based on the location directive setup.

Work classes, location directives, and work templates

The *Quality item sampling* and *Quality order* work order types are consumed by location directives, work classes, and work templates.

Before warehouse work can be automatically generated to move inventory to quality control, you must follow these steps to set up your system.

1. Create separate work classes for the *Quality item sampling* and *Quality order* work order types. In this way, you ensure that appropriate work can be automatically generated based on the two work order types, and that this work can then be run by using the warehouse app.
2. Set up a work template for each work order type:
 - Set up a work template that uses the *Quality item sampling* work order type to automatically move registered inventory to a quality control location.
 - Set up a work template that uses the *quality order* work order type to move inventory from a quality control location after quality control is completed.
3. For each work order type, set up location directives that apply the correct quality control locations that the inventory should be moved to. After quality control is completed, the location directive for the *Quality order* work order type ensures that a new destination location will be selected so that the inventory can be moved out of the quality control location.
4. Set up the relevant mobile device menu items to support the movement of received inventory to the quality control location, and the movement of inventory that passes or fails quality control from the quality control location to a new location.

For a step-by-step example that shows how to complete this setup, see the [example scenario](#) at the end of this topic.

Enable a warehouse for quality management

Before the *Quality management for warehouse processes* feature can be applied for a specific warehouse, you must follow these steps to make the feature available for that warehouse.

1. Go to **Warehouse management > Setup > Warehouse > Warehouses**.
2. Select the warehouse to enable for quality management.
3. On the **Warehouse** FastTab, set the **Enable quality order for warehouse processes** option to *Yes*. (Note that this option can be set to *Yes* only for warehouses that use warehouse management processes.)

When the **Enable quality order for warehouse processes** option is set to *Yes*, the quality association setup controls whether the *Quality management for warehouse processes* feature is actually applied for the selected warehouse. You can change the setting of the option to *No* at any time. In that case, the feature will no longer apply for the warehouse, regardless of the quality association setup.

Quality control

The *Quality management for warehouse processes* feature controls several key settings for quality associations and item sampling.

Quality associations

Each [quality association record](#) defines the set of tests, the acceptable quality level (AQL), and the sampling plan that apply to the quality orders that are generated. To set up a quality association record, follow these steps.

1. Go to **Inventory management > Setup > Quality control > Quality associations**.
2. Create or select the quality association entry for the item or group that you're working with, or for all items.
3. On the **Conditions** FastTab, set the **Applicable warehouse type** field to one of the following values:
 - **Quality management for warehouse processes only** – Activate the *Quality management for warehouse processes* feature. You can select this value only if the reference type is either *Purchase* or *Production*.
 - **All** – Inactivate the *Quality management for warehouse processes* feature. Select this value for all reference types except *Purchase* and *Production*.

NOTE

The *Quality management for warehouse processes* feature takes effect only if the item on the source document line uses advanced warehouse management processes, and if the **Enable quality order for warehouse processes** option is set to *Yes* for the warehouse on the source document line.

As each item is registered (or reported as finished), the system determines which quality associations apply to it.

When the *Quality management for warehouse processes* feature is turned on, the applicable warehouse type is logically inserted into the fourth search group of the quality association search hierarchy. The following table provides a logical representation of the search hierarchy.

SEARCH GROUP	DESCRIPTION
Group 1	For each quality association, check the Reference type , Event type , and Execution match values against the item. If there is a match against the source document line, move on to group 2.

SEARCH GROUP	DESCRIPTION
Group 2	For each quality association, check the Item code value (<i>Table</i> , <i>Group</i> , or <i>All</i>) against the item. <i>Table</i> is more specific than <i>Group</i> , and <i>Group</i> is more specific than <i>All</i> . If there is a match for <i>Table</i> (a specific item), move on to group 3. If there is no match for <i>Table</i> , search for a match for <i>Group</i> . If there is no match for <i>Group</i> , <i>All</i> applies. If there is a match, move on to group 3.
Group 3	For each quality association, check the Account code and Resource code values against the item. The logic that is applied resembles the logic that is applied for the Item code value.
Group 4	For each quality association, check the Applicable warehouse type value (<i>Quality management for warehouse processes only</i> or <i>All</i>) against the item. If the Enable quality order for warehouse processes option is set to <i>Yes</i> for the warehouse on the source document, and the item on the source document line is set to <i>Use warehouse management processes</i> , both associations where there is a match for <i>Quality management for warehouse processes only</i> and associations where there is a match for <i>All</i> will be applicable in parallel, if both exist. If the Enable quality order for warehouse processes option is set to <i>No</i> for the warehouse on the source document, and the item on the source document line is set to <i>Use warehouse management processes</i> , only quality management will be applicable.

For example, you've defined a warehouse where the **Enable quality order for warehouse processes** option is set to *Yes*, and you have two quality associations that are defined for the *Purchase* reference type: one for all items and one for the *Registration* event type. The only difference between the two quality associations is the **Applicable warehouse type** value: it's set to *All* for one quality association and *Quality management for warehouse processes only* for the other. In this case, both quality associations are equally specific, and both will be applicable.

The value of the **Test group** field for the quality associations is also a factor. This field defines the test procedure that must be applied. If the **Test group** value is the same for both associations, only one quality order will be created, for the quality association where the **Applicable warehouse type** value is *Quality management for warehouse processes only*. If the **Test group** value isn't the same for both associations, two quality orders will be created. The first quality order will be created for the quality association where the **Applicable warehouse type** value is *Quality management for warehouse processes only*. The second quality order will be created for the quality association where the **Applicable warehouse type** value is *All*.

NOTE

The *Quality management for warehouse processes only* value is considered more specific than *All* when the criteria for the quality associations for groups 1 and 2 are the same, and when the test group is the same. Two quality orders will be created only when the test groups differ.

Reference types

When the **Reference type** value is *Purchase*, and the **Applicable warehouse type** value is *Quality management for warehouse processes only*, the **Event type** field on the **Process** FastTab must be set to *Registration*. *Registration* is the only supported event type for the *Purchase* reference type when you are using the *Quality management for warehouse processes* feature.

Quality processing policy

The *Quality management for warehouse processes* feature enables work to be created based only on item sampling. Therefore, it allows for a lightweight process. The inventory that work is created depends on the item sampling that is associated with the quality association. When the lightweight process is used, after a worker puts the quantity in the quality control location, the quality department can manually create a quality order, if a quality order is required.

The **Quality processing policy** field on the **Quality order process** FastTab controls whether a quality order is also created when work is created to move an item to the quality control location. This field can be set to *Create quality order* or *Create work only*. The default value is *Create quality order*.

NOTE

Regardless of whether you create quality orders manually or automatically, the system automatically generates work to move items out of the quality control location when the quality order is marked as validated.

The creation of quality order work is unrelated to the quality association setup. If a work template exists that has a **Work order type** value of *Quality order*, and if the query criteria are met for that work template, validation of a quality order will trigger the creation of quality order work.

Referenced item sampling

Each quality association must reference an item sampling. An item sampling defines the quantity that will be sent for quality control. It can be set up so that it applies only to quality associations where the **Applicable warehouse type** value is *Quality management for warehouse processes only*. If the **Sampling scope** value for an item sampling is *Load* or *Shipment*, or the **Quantity specification** value is *Full license plate*, the item sampling can be referenced only by quality associations where the **Applicable warehouse type** value is *Quality management for warehouse processes only*.

If you define an item sampling that uses the *Quality management for warehouse processes only* applicable warehouse type, you will receive an error if you try to reference it from a quality association that doesn't use the *Quality management for warehouse processes* feature.

NOTE

Item sampling that uses full blocking isn't supported for quality associations where the **Applicable warehouse type** field is set to *Quality management for warehouse processes only*.

Item sampling

Item sampling controls how often items are sent for quality control. The *Quality management for warehouse processes* feature introduces the concept of *item sampling scope*. The system uses the item sampling scope when it evaluates whether and how quality orders and/or quality item sampling work and quality order work should be created.

To set up item sampling, go to **Inventory management > Setup > Quality control > Item sampling**, and set the **Sampling scope** field to one of the following values:

- **Order** – The source document line will be the basis for evaluating whether and how quality orders and/or quality item sampling work and quality order work are created. This value is the default value, and when it's selected, the system works the same way that it works when the *Quality management for warehouse processes* feature isn't turned on.
- **Load** – Loads will be used as the basis for evaluating whether and how a quality order and/or work is created. This value is available only when the *Quality management for warehouse processes* feature is turned on.
- **Shipment** – Shipments will be used as the basis for evaluating whether and how a quality order and/or

work is created. This value is available only when the *Quality management for warehouse processes* feature is turned on.

NOTE

When the **Sampling scope** field is set to *Load or Shipment*, the load entity and shipment entities will be used, if they are available. If they aren't available, the order entity will be used.

The *Quality management for warehouse processes* feature also introduces the *Full license plate* value for the **Quantity specification** field. This value supports the creation of quality order work and quality item sampling work, based on license plates. When you select this value, the following changes occur:

- The **Break count by item** option and the **Per nth license plate** field on the **Process** FastTab become available.
- The **Value** field on the **Sampling quantity** FastTab becomes unavailable.
- The **Per updated quantity**, **Location**, and **License plate** options are all set to *Yes*, and the settings can't be changed.

The **Break count by item** option controls whether the license plate count is evaluated per item or across all items in the sampling scope. Product variants are treated as the same item. This option also controls whether the license plate count is reset for each item.

The value of the **Per nth license plate** field controls how often quality orders are created in relation to the number of items that are registered. For example, a value of *3* will send every third item to quality control, starting with the first item. The value must be more than 0 (zero).

While workers receive items by using the warehouse app, the system validates whether a quality association is set up for each incoming item. If a quality association is set up, the system uses the item sampling record that is configured for that quality association to determine how it will create quality orders, quality item sampling work, and purchase order work.

NOTE

When receipt registration is done in the web client (by using the small registration page or the item arrival journal for purchase order lines), no quality item sampling work or purchase order work will be created, regardless of the setup. Instead, for items that match a quality association, the referenced item sampling will be used to control the creation of quality orders only.

Examples of automatic generation of quality orders

The following examples show how the setup of a quality association and an associated item sampling affects the generation of quality orders when the **Applicable warehouse type** field is set to *Quality management for warehouse processes only*.

When the **Quantity specification** value is *Full license plate*, the **Per nth license plate** field controls which license plates quality item sampling work is created for. The first license plate always goes to quality control, and then the value of this field specifies that every *n*th license plate after that license plate should also go.

The **Reference type** value for the following examples is *Purchase*, and the **Event type** value is *Registration*.

SAMPLING SCOPE	QUANTITY SPECIFICATION	PER UPDATED QUANTITY	PER STORAGE DIMENSION	BREAK COUNT BY ITEM	PER NTH LICENSE PLATE	RESULT
Order	Full license plate	Yes <i>(locked/not</i>	Location:	No	3	Order

SAMPLING SCOPE	QUANTITY SPECIFICATION	PERCENTAGE (locked/not editable) PER UPDATED QUANTITY	PER STORAGE DIMENSION Plate: Yes (locked/not editable)	BREAK COUNT BY ITEM	PER NTH LICENSE PLATE	line quantity RESULT

When a worker validates one of the quality orders that are shown in the previous table, the system automatically generates quality order work to move inventory from the quality control location to the location that is defined in the location directive for the *Quality order* work order type. You can set up any location for this purpose, such as a return or storage location, depending on the test result for the quality order. For an example of this setup, see the [example scenario](#) at the end of this topic.

You can reopen a quality order that has already been validated, provided that the quality order work that is related to moving the inventory from the quality control location doesn't have a **Work status** value of *Closed* or *In progress*.

Process insights when multiple quality associations coexist

More than one quality associations can be defined for and applied to the same source document line, and the **Applicable warehouse type** field can be set to *Quality management for warehouse processes only* for some of those quality associations and *All* for others.

In the following example, the **Reference type** value is *Purchase*.

1. The first quality association is set up in the following way:

- **Applicable warehouse type:** *Quality management for warehouse processes only*
- **Item code:** *A0001*
- **Account code:** *All*
- **Test group:** *Enclosure*
- **Item sampling:** *5 pcs*

2. The second quality association is set up in the following way:

- **Applicable warehouse type:** *All*
- **Item code:** *All*
- **Account code:** *All*
- **Test group:** *Enclosure*
- **Item sampling:** *1 pcs*

3. The third quality association is set up in the following way:

- **Applicable warehouse type:** *Quality management for warehouse processes only*
- **Item code:** *All*
- **Account code:** *104*
- **Test group:** *Impedance*
- **Item sampling:** *Every second license plate* (This setting means that the first, third, fifth, and so on, license plates that are received will create a quality order.)

4. The fourth quality association is set up in the following way:

- **Applicable warehouse type:** *All*
- **Item code:** *All*
- **Account code:** *All*
- **Test group:** *Impedance*
- **Item sampling:** *5 pcs*

5. The fifth quality association is set up in the following way:

- **Applicable warehouse type:** *All*
- **Item code:** *All*
- **Account code:** *All*
- **Test group:** *Cone*
- **Item sampling:** *10%*

A purchase order for a quantity of 10 of item A0001 is now created for vendor 104. Then a purchase order line that has a quantity of 10 is registered as received on one license plate by using the warehouse app. Here is the result:

- There is one quality order from the first quality association for the *Enclosure* test group. The quantity is 5. There is no quality order from the second quality association, because the criteria for the first quality association are more specific relative to the *Enclosure* test group.
- There is one quality order for the third quality association for the *Impedance* test group. The quantity is 10. There is no quality order from the fourth quality association, because the criteria for the first quality association are more specific relative to the *Impedance* test group.
- There is one quality order for the fifth quality association for the *Cone* test group. The quantity is 1.

In connection with the creation of one quality order for each of the three quality associations, quality item

sampling work is also created. The registered quantity is only 10. However, because of the item sampling setup, the sum of the quality order quantities that are created for the *Quality management for warehouse processes* *only* applicable warehouse type is 16, which exceeds the physical registered quantity of 10. Therefore, work won't be created for the full quality order quantities (16), because only 10 are physically available for movement to the quality control location. The priority that is used to create quality item sampling work follows the order of quality order creation:

- **First quality order (quantity = 5):** Quality item sampling work is created for 5. A quantity of 5 (10 – 5) now remains for subsequent creation of quality item sampling work.
- **Second quality order (quantity = 10):** Quality item sampling work is created for 5. A quantity of 0 (zero) now remains for subsequent creation of quality item sampling work.
- **Third quality order (quantity = 1):** No quality item sampling work is created.

As part of the process of creating the quality orders, an inventory blocking of a quantity of 10 is created. This inventory blocking is referenced against each of the three quality orders. The sum of the quality order quantities is 16.

When the quality orders are validated, the system tries to create quality order work for each quality order that is validated. Because the sum of the quality order quantities exceeds the quantity that is actually blocked and therefore available for work creation, quality order work can't be created for the full quality order quantities, as shown here. (This example continues the previous example.)

1. Validate the second quality order that is created (quantity = 10). Quality order work is created for a quantity of 4.

The creation of quality order work is triggered by a change in the inventory blocking quantity. Because the sum of quality order quantities was 16, validation of a quantity of 10 will cause the remaining quality order quantities to be validated as equal to 6. The inventory blocking quantity is reduced from 10 to 6. The reduced quantity of 4 is allotted to quality order work creation.

2. Validate the first quality order that is created (quantity = 5). Quality order work is created for a quantity of 5.

The creation of quality order work is triggered by a change in the inventory blocking quantity. Because the sum of quality order quantities was 6, validation of a quantity of 5 will cause the remaining quality order quantities to be validated as equal to 1. The inventory blocking quantity is reduced from 6 to 1. The reduced quantity of 5 is allotted to quality order work creation.

3. Validate the third quality order that is created (quantity = 1). Quality order work is created for a quantity of 1.

The creation of quality order work is triggered by a change in the inventory blocking quantity. Because the sum of quality order quantities was 1, validation of a quantity of 1 will cause the remaining quality order quantities to be validated as equal to 0 (zero). The inventory blocking is removed (that is, the inventory blocking quantity is reduced from 1 to 0). The reduced quantity of 1 is allotted to quality order work creation.

NOTE

The creation of quality order work depends on the inventory blocking quantity that is referenced against one or more quality orders. If the sum of the quality order quantities exceeds the referenced inventory blocking quantity, the order that the quality orders are validated in determines the creation of quality order work.

Canceling quality item sampling work

You can cancel the work that is created for quality item sampling. To control what occurs when this work is canceled, follow these steps.

1. Go to **Warehouse management > Setup > Warehouse management parameters**.
2. On the **General** tab, on the **Work** FastTab, set the **Unregister receipt when cancelling work** option to one of the following values:
 - **Yes** – When quality item sampling work is canceled, the associated quality order is deleted, and the inventory is unregistered.
 - **No** – When quality item sampling work is canceled, the associated quality order isn't deleted, and the inventory isn't unregistered.

Cross-docking

You can have a quality association setup that creates item sampling work. However, when cross-docking exists in parallel with a quality association that creates quality item sampling work, if there is only enough quantity to satisfy cross-docking, only item sampling work is created. In cases where the **Enable quality order for warehouse processes** option set to *Yes* for the receiving warehouse, and the **Applicable warehouse type** field is set to *Quality management for warehouse processes only* for a quality association, the creation of quality item sampling work takes precedence over the creation of cross-docking work. If the quantity exceeds the requirement for cross-docking, the system still creates only item sampling work.

Destructive testing

You can define a test group that performs destructive testing. In the case of a destructive test, the assumption is that, regardless of the test result, the quantity of the item that is tested will be destroyed as part of the test. The way that the *Quality Management for warehouse processes* feature supports destructive testing resembles the way that quality management supports it when the feature isn't turned on. Before the quality order can be validated, the quality controller must specify the pick location for the quantity that has been destroyed. You can register picking from the quality order page by selecting **Inventory > Pick** on the Action Pane. After the pick for the quality order quantity is registered, validation can be completed.

Example scenario

Prepare the scenario

To work through this scenario, you must prepare your system in the following way:

- Make sure that demo data is installed on the system, and select the **USMF** legal entity.
- Turn on the *Quality management for warehouse processes* feature in [feature management](#).
- Configure warehouse 51 to use the *Quality management for warehouse processes* feature by following these steps:
 1. Go to **Warehouse management > Setup > Warehouse > Warehouses**.
 2. Select warehouse 51.
 3. On the **Warehouse** FastTab, set the **Enable quality order for warehouse processes** option to *Yes*.

Quality-in setup – Move to the quality control location

You must now prepare a basic setup that will enable your system to support the *Quality Management for warehouse processes* feature for warehouse 51. (The demo data defines a quality management location that is named *QMS*. That location is referenced several times in this scenario.) You will prepare the following elements, as described in the subsections of this section:

- Work class

- Work template
- Location directive
- Item sampling
- Quality association
- Mobile device menu items

Work class for quality-in

1. Go to **Warehouse management > Setup > Work > Work classes**.
2. Create a work class, and set the following values:
 - **Work class ID:** *QualityIn*
 - **Description:** *Quality item sampling*
 - **Work order type:** *Quality item sampling*

Work template

1. Go to **Warehouse management > Setup > Work > Work templates**.
2. Set the **Work order type** field to *Quality item sampling*.
3. Create a work template, and set the following values:
 - **Work template:** *51 Quality*
 - **Work template description:** *51 Quality*
4. Add a line to the work template, and set the following values:
 - **Work type:** *Pick*
 - **Work class ID:** *QualityIn*
5. Add a second line to the work template, and set the following values:
 - **Work type:** *Put*
 - **Work class ID:** *QualityIn*

Location directive

1. Go to **Warehouse management > Setup > Location directives**.
2. Set the **Work order type** field to *Quality item sampling*.
3. Create a location directive, and set the following values:
 - **Name:** *51 to quality*
 - **Work type:** *Put*
 - **Site:** 5
 - **Warehouse:** *51*
4. Add a line for the location directive, and set the following values:
 - **From quantity:** *1*
 - **To quantity:** *1000000*
5. Create a location directive action, and set the following value:
 - **Name:** *Quality*
6. For the new location directive action, select **Edit query**, and specify a **Range** record that has the following values:
 - **Table:** *Locations*
 - **Field:** *Location profile ID*

- **Criteria:** *QMS*

7. Select **OK** to save the query, and save the new location directive.

Next, you must change the sequence of the existing purchase order location directives for warehouse 51. The demo data includes two location directives that have a **Work order type** value of *Purchase*: one is named *51 QMS*, and the other is named *51 PO Direct*. To ensure that the *Quality management for warehouse processes* feature is applied for warehouse 51, you must make sure that the *51 QMS* location directive isn't applied. However, instead of deleting that location directive (because you might want to use it in the future), you can just change the sequence.

1. Go to **Warehouse management > Setup > Location directives**.
2. Set the **Work order type** field to *Purchase order*.
3. In the sequence list, select sequence number 5, for the *51 PO Direct* location directive.
4. Move the selected sequence up to sequence number 4.
5. Verify that sequence number of the *51 QMS* location directive is now at least 5.

Item sampling

The *Quality management for warehouse processes* feature adds some new item sampling capabilities. The **Sampling scope** value can now be *Order*, *Shipment*, or *Load*, and the **Sampling quantity** value can now be *Full license plate*.

1. Go to **Inventory management > Setup > Quality control > Item sampling**.
2. Create an item sampling record, and set the following values:
 - **Item sampling:** *3rd LP*
 - **Description:** *Every third license plate*
 - **Sampling Scope:** *Order*
3. On the **Sampling quantity** FastTab, set the **Quantity specification** field to *Full license plate*.
4. On the **Process** FastTab, set the **Per nth license plate** field to *3*.
5. In the **Per storage dimension** section, enable both **Warehouse** and **Inventory status**.

Quality associations

Create a quality association that will use the new item sampling.

1. Go to **Inventory management > Setup > Quality control > Quality associations**.
2. Create a quality association record, and set the following values:
 - **Reference type:** *Purchase*
 - **Item code:** *Table*
 - **Item:** *M9201*
 - **Site:** *5*
3. On the **Process** FastTab, set the **Event type** field to *Registration*.
4. On the **Conditions** FastTab, set the **Applicable warehouse type** field to *Quality management for warehouse processes only*.
5. On the **Quality order process** FastTab, set the **Quality processing policy** field to *Create quality order*.
6. On the **Specifications** FastTab, right-click in the **Test Group** field, and then select **View details** to open the **Test groups** page.
7. On the **Test groups** page, on the **Overview** tab of the upper grid, create a test group, and set the following values:

- **Test Group:** *QMS*
 - **Description:** *QMS test*
 - **Acceptable quantity:** *100*
 - **Item Sampling:** *3rd LP (Select)*
8. On the **Overview** tab of the lower grid, add a record for one test, and set the following values:
 - **Sequence:** *1*
 - **Test:** *Enclosure measuring*
 9. On the **Test** tab of the lower grid, set the following values:
 - **Test variables:** *Pass/Fail*
 - **Default outcome:** *Pass*
 10. Save the new test group, and close the **Test groups** page.
 11. Back on the **Quality associations** page, in the **Test group** field, select **QMS**.
 12. Save the record.

Mobile device menu items for quality-in

To complete the setup to move goods to the quality control location, you must make the quality item sampling work available from a mobile device menu item.

1. Go to **Warehouse management > Setup > Mobile device > Mobile device menu items**.
2. Select the **Purchase Put-away** mobile device menu item.
3. On the **Work classes** FastTab, add the *QualityIn* work class ID.

Summary: Your setup to move goods to quality control

You've now defined a quality association that uses the *Quality management for warehouse processes* feature to trigger the creation of a quality order. You've set up the work and location data for warehouse 51 to ensure that specific work is created when purchase registration is done for item M9201. This setup ensures that every third license plate that is registered will be moved to a quality location (*QMS*), and that a quality order will be created for the license plate quantity. Everything else will be moved to put-away instead of the quality control location.

Process quality management work

1. Go to **Procurement and sourcing > Purchase orders > All purchase orders**.
2. Create a purchase order, and set the following values:
 - **Specify Vendor account:** *104*
 - **Warehouse:** *51*
3. Add a purchase order line, and set the following values:
 - **Item:** *M9201*
 - **Quantity:** *20*
 - **UoM:** *ea*
 - **Warehouse:** *51*
4. Write down the purchase order number, so that you can use it later.
5. Go to a mobile device or emulator that is running the warehouse app, and sign in to warehouse 51 by using *51* as the user ID and *1* as the password.
6. Go to **Inbound > Purchase Receive**, and enter the following values:
 - **PONum:** The number of the purchase order that you just created
 - **Qty:** *5*
 - **Unit:** *ea*

7. Continue to receive against the line, *5 ea* at a time, until the line is fully received. (A total of four license plates will be created.)
8. Sign out of the warehouse app.
9. Back in the web client, go to **Procurement and sourcing > Purchase orders > All purchase orders**.
10. Find and open your purchase order.
11. In the **Purchase order lines** section, select the line for item number *M9201*, and then select **Purchase order lines > Work details**.
12. Notice that the second and third work headers that were created are regular put-away work, whereas the first and the fourth work headers are quality item sampling work. This result is consistent with the item sampling setup, which is configured to sample every third license plate.

Move to the quality control location

You will now move the license plates to their designated locations. The first and fourth license plates will go to the quality control location, whereas the second and third license plates will go directly to storage.

1. Go to a mobile device or emulator that is running the warehouse app, and sign in to warehouse 51 by using *51* as the user ID and *1* as the password.
2. Go to **Inbound > Purchase put away**, and put away each license plate from the previous procedure until you've closed all the work.

Summary: Process quality management work

You've now run the quality item sampling work for the first and fourth license plates by moving them to the quality control location. You've also put away the second and third license plates. The next step is to do the quality order testing and control.

Quality-out setup: Move from the quality control location to storage or return

When workers report quality order results, the system automatically generates work.

You will now continue with the required base setup of the work class, work template, and location directive to enable quality management for warehouse processes, so that the required work can be created to move the quality order quantity from the quality control location to a designated warehouse location.

Work class for quality-out

1. Go to **Warehouse management > Setup > Work > Work classes**.
2. Create a work class, and set the following values:
 - **Work class ID:** *QualityOut*
 - **Description:** *Quality Out*
 - **Work order type:** *Quality Order*

Work templates

1. Go to **Warehouse management > Setup > Work > Work templates**.
2. Change the **Work order type** value to *Quality order*.
3. Create a work template, and set the following values:
 - **Work template:** *51 quality out*
 - **Work template description:** *51 quality out*
4. Add a line, and set the following values:
 - **Work type:** *Pick*

- **Work class ID:** *QualityOut*

5. Add a second line, and set the following values:

- **Work type:** *Put*
- **Work class ID:** *QualityOut*

Location directives

1. Go to **Warehouse management > Setup > Location directives**.

2. Change the **Work order type** value to *Quality order*.

3. Create a location directive, and set the following values:

- **Name:** *51 Pass*
- **Work type:** *Put*
- **Site:** *5*
- **Warehouse:** *51*

4. On the Action Pane, select **Edit query** to open the query editor dialog box.

5. On the **Range** tab, set the following values:

- **Table:** *Quality orders*
- **Field:** *Status*
- **Criteria:** *Pass*

6. Select **OK** to save the query and close the dialog box.

7. On the **Lines** FastTab, add a line, and set the following values:

- **From quantity:** *1*
- **To quantity:** *1000000*

8. On the **Location directive actions** FastTab, add a row, and set the following value:

- **Name:** *Pass*

9. On the **Location directive actions** FastTab, select **Edit query** to open the query editor dialog box.

10. On the **Range** tab, set the following values:

- **Table:** *Locations*
- **Field:** *Zone ID*
- **Criteria:** *Bulk*

11. Select **OK** to save the query and close the dialog box.

12. On the Action Pane, select **Save** to save the new location directive.

13. Create a second location directive, and set the following values:

- **Name:** *51 Fail*
- **Work type:** *Put*
- **Site:** *5*
- **Warehouse:** *51*

14. On the Action Pane, select **Edit query** to open the query editor dialog box.

15. On the **Range** tab, set the following values:

- **Table:** *Quality orders*
- **Field:** *Status*
- **Criteria:** *Fail*

16. Select **OK** to save the query and close the dialog box.
17. On the **Lines** FastTab, add a line, and set the following values:
 - **From quantity:** 1
 - **To quantity:** 1000000
18. On the **Location directive actions** FastTab, add a row, and set the following value:
 - **Name:** *Fail*
19. On the **Location directive actions** FastTab, select **Edit query** to open the query editor dialog box.
20. On the **Range** tab, set the following values:
 - **Table:** *Locations*
 - **Field:** *Zone ID*
 - **Criteria:** *Return*
21. Select **OK** to save the query and close the dialog box.
22. On the Action Pane, select **Save** to save the new location directive.

Mobile device menu items for quality-out

1. Go to **Warehouse management > Setup > Mobile device > Mobile device menu items**.
2. Select the **QMS put-away** mobile device menu item.
3. On the **Work classes** FastTab, add the *QualityPut* work class ID.

Warehouse workers will now be able to pick quality order work by using the **QMS Put-away** menu item. Goods that failed quality control goods can be put in a return location, and goods that passed can be put in the bulk-001 location.

Summary: Your setup to move goods from quality control

You've set up the work and location data for warehouse 51, to ensure that work is automatically created when quality orders are completed. This setup ensures that each quality-controlled license plate is moved to either a bulk location or a return location.

Process quality management work

1. Go to **Inventory management > Periodic tasks > Quality management > Quality orders**.
2. Select the first quality order for the quantities that were registered.
3. Select **Validate**. The status of the test is updated to *Fail*.
4. Go to **Warehouse management > All work**.
5. Open the work that you just created, and notice that the **Work order type** value is *Quality order*. The work includes a line where the put location is *Return* and the status is *Fail*. (If the status of the quality order were *Pass*, the put location would be *Bulk* instead.)
6. Go back to **Inventory management > Periodic tasks > Quality management > Quality orders**.
7. Select the second quality order for the items that were registered.
8. Select **Results** above the lower grid. Update the **Result quantity** value to 5, and verify that the **Test result** value is changed to a check mark.
9. Select **Validate**, and close the page.
10. Back on the **Quality orders** page, select **Validate**, and do the validation. The status is updated to *Pass*.

NOTE

The validation event triggers the creation of the quality order work to move the quantity from the quality control location to a new location.

11. Go to **Warehouse management > All work**.
12. Select the work that was just created, and notice that a second quality order work header has been created, where the put location is *BULK-001*.
13. Go to a mobile device or emulator that is running the warehouse app, and sign in to warehouse 51 by using *51* as the user ID and *1* as the password.
14. Go to **Quality > Put Away from QMS**, and process each of the two license plates that are related to both pieces of work, so that all work is closed.

NOTE

Consider adding the quality-out entry to a mobile device menu item where the activity code is *Display open work list*. For an example, see the mobile device menu item that is named **Work list** in the demo data. First add the *Quality order* work class to a user-directed menu item, because this work class is required for work to be shown in the work list. Then add the *Quality order* work class to the **Work list** menu item. Users who have access to the work list will then be able to pick and process the work that is automatically generated by quality order validation.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Nonconformance management

2/18/2021 • 3 minutes to read • [Edit Online](#)

This article describes the basic setup that is required in order to use nonconformances. Additional setup is required if you want to use quality orders.

To enable nonconformance management, follow these steps:

1. Define the Inventory and warehouse management parameters that are related to nonconformances:
 - Set the **Use quality management** option to **Yes**.
 - In the **Hourly rate** field, enter an hourly labor rate in the local currency. The hourly rate is used to calculate costs for operations that are related to a nonconformance. The hourly rate and calculated costs provide reference information for a nonconformance. They don't interact with other functionality.
 - Use the **Quality management** tab on the **Report setup** page to define the type of document to print. You can print a nonconformance report, a nonconformance tag, or a correction report. You can define more than one record to print different document types on a report, or to print internal and external notes. You might find it helpful to use the **Document type** page to define a unique document type for nonconformances and a unique document type for corrections. For example, want to enter notes about a nonconformance by using the unique document type for nonconformances. In this case, identify the unique document type in the report options.
 - Enable number sequences for nonconformance and correction references.
2. Enable user approval of nonconformances. Use the **Name** field on the **Users** page to assign an employee to each user who must approve a nonconformance. The system uses the employees who change the status of a nonconformance to track the nonconformance history. Users can't approve a nonconformance unless they have been assigned an employee identifier.
3. Define the problem types that will be assigned to nonconformances. Use the **Problem types** page to define a classification of quality problems that are encountered for the various nonconformance types. You can set up the following nonconformance types: **Internal**, **Customer**, **Vendor**, **Service request**, **Production**, and **Co-product production**. Use the **Non conformance types** page to authorize a problem type to be used in one or more nonconformance types. For example, a problem type that is related to a defect code might apply to all nonconformance types, whereas a problem type that is related to customer complaints might apply only to the **Customer** and **Service request** nonconformance types.
4. Define quarantine zones to provide guidance about defective material should be handled. Use the **Quarantine zones** page to define zones that can be assigned to a nonconformance. The printed nonconformance tag will show the assigned quarantine zone and information about usage, to provide guidance about how to handle defective material. The zones might correspond to inventory locations or operations resources.
5. Define the diagnostic types that will be assigned to corrections. Use the **Diagnostic types** page to define a classification of diagnostic actions. A correction specifies what type of diagnostic action should be taken for an approved nonconformance, and who should take that action. It also specifies the requested completion date and the planned completion date.
6. Define the related operations that will be assigned to nonconformances. Use the **Operations** page to define a classification of the work that can be performed for an approved nonconformance. When you assign a related operation to a nonconformance, you can provide detailed information, such as

information about the associated material, labor hours, and miscellaneous charges that are required in order to perform the operation. This information is used to calculate an estimated cost for the operation. The detailed information and estimated costs are for reference. The related operations for quality differ from the operations that can be defined for a production route.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Set up prerequisites for nonconformance management

2/18/2021 • 3 minutes to read • [Edit Online](#)

Use this topic to enable nonconformance management processes. A nonconformance describes a procedure or item that has a quality problem, where the descriptive information includes the source and type of problem. This procedure uses the USMF demo data company. This procedure is typically performed by a quality manager.

Enable quality management processes within the company

1. In the navigation pane, go to **Modules > Inventory management > Setup > Inventory and warehouse management parameters**.
2. Select the **Quality management** tab.
3. Select **Yes** in the **Use quality management** field to enable quality management processes for the company.
4. In the **Hourly rate** field, enter a number in the local currency. The hourly rate is used for calculating costs for operations that are related to a nonconformance. The hourly rate and calculated costs provide reference information for a nonconformance, and they do not interact with other functionality.
5. Select **Report setup** to define the quality report note types that will be used on different kinds of quality management reports.

Enable user for nonconformance processing

1. In the navigation pane, go to **Modules > System administration > Users > Users**.
2. Use the Quick Filter to find the user who will be approving or rejecting the nonconformance records. For example, filter on the **Name** field with a value of . To process the approval of a nonconformance, the user who approves or rejects nonconformances must have a "Name" value assigned on the **Users** page. To use the document notes, the user must also have Document handling activated in the user options.
3. Mark the row of the desired record.
4. Select **User options**.
5. Select the **Preferences** tab.
6. Select **Yes** in the **Enable document handling** field.

Define diagnostic types for nonconformance processing

1. In the navigation pane, go to **Modules > Inventory management > Setup > Quality management > Diagnostic types**. Use the **Diagnostic types** page to define a classification of diagnostic actions. A correction identifies what type of diagnostic action should be taken on an approved nonconformance, who should perform it, and the requested and planned completion date.
2. Select **New**.
3. In the **Diagnostic** field, type a value.
4. In the **Description** field, type a value.

Define quality charges for nonconformance processing

1. In the navigation pane, go to **Modules > Inventory management > Setup > Quality management > Quality charges**. Use the **Quality charges** page to define a classification of charges that will be used in operations related to nonconformances.

2. Select **New**.
3. In the **Charges code** field, type a value.
4. In the **Description** field, type a value.

Define the operations for nonconformance processing

1. In the navigation pane, go to **Modules > Inventory management > Setup > Quality management > Operations**. Use the **Operations** page to define a classification of the work that may be performed for an approved nonconformance. When you relate an operation to a nonconformance, you can define information about the associated material, labor hours, and miscellaneous charges that are required to perform the operation. This information provides the basis for calculating an estimated cost for performing the operation.
2. Select **New**.
3. In the **Operation** field, type a value.
4. In the **Description** field, type a value.

Define problem types for nonconformance processing

1. In the navigation pane, go to **Modules > Inventory management > Setup > Quality management > Problem types**. Use the **Problem types** page to define a classification of quality problems that are encountered in the various nonconformance types. The nonconformance types include **Internal**, **Customer**, **Vendor**, **Service request**, **Production**, and **Co-product production**. A single problem type can be associated with multiple nonconformance types.
2. Select **New**.
3. In the **Problem type** field, type a value.
4. In the **Description** field, type a value.
5. Select **Non conformance types**. Use the **Non conformance types** page to authorize the use of a problem type for one or more of the nonconformance types. For example, a problem type regarding a defect code could apply to all nonconformance types, whereas a problem type about customer complaints may only apply to the customer and service request nonconformance types.
6. Select **New**.
7. In the **Non conformance type** field of the new row, select an option.

Define quarantine zones for nonconformance processing

1. In the navigation pane, go to **Modules > Inventory management > Setup > Quality management > Quarantine zones**.
2. Select **New**.
3. In the **Quarantine zone** field, type a value.
4. In the **Description** field, type a value.
5. Close the page.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Create and process a conformance

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic explains how to perform nonconformance management, based on an existing quality order. You can run this recording in the USMF demo company and can use the suggested values. Typically, this procedure is performed by a quality clerk. As a prerequisite, complete the instructions in [Inspect the quality of goods](#). To process the approval of a nonconformance, the user who runs the task recording must have a "Name" value assigned on the Users page. To use the document notes, the user must also have Document handling activated in the user options.

Select a quality order

1. In the navigation pane, go to **Modules > Inventory management > Periodic tasks > Quality management > Quality orders**.
2. In the list, select the quality order that was created in [Inspect the quality of goods](#).

Create a nonconformance

1. On the Action Pane, select **Inquiries**.
2. Select **Non conformances**.
3. Select **New**.
4. In the drop-down menu of the **Problem type** field, select the problem that was found during the inspection process.
5. Select **OK**.

Approve/reject a nonconformance

1. Select **Functions**.
2. Select **Approve non conformance**. For this example, approve the nonconformance. Approved nonconformances can be associated with related operations to record work that is done as part of the nonconformance handling and, as in this topic, the processing of correction handling.
3. Select **Yes**.

Create a correction action

1. Select **Corrections**.
2. Select **New**.
3. In the **Personnel number** field of the new row, select the desired record from the drop down menu.
4. Click **Select**.
5. Select **Attach**. Create a note about the correction. For this example, the action is to contact the vendor to discuss the nonconformance case.
6. Select **New**.
7. Select **Note**. Depending on the report setup, different document types can be printed on the reports that are related to nonconformance management.
8. In the **Description** field, type a value.
9. Close the page.

Maintain a correction

1. Select **Mark complete**.
2. Select **OK**.
3. Close the page.

Close a nonconformance

1. Select **Functions**.
2. Select **Close non conformance**.
3. Select **Yes**.
4. Close the pages.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Quarantine orders

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic describes how quarantine orders are used to block inventory.

Quarantine orders can be used to block inventory. For example, you might want to quarantine items for quality control reasons. Inventory that has been quarantined is transferred to a quarantine warehouse. **Note:** If you're using advanced warehouse management processes (in Warehouse management), quarantine order processing is used only for return sales orders.

Quarantine on-hand inventory items

When you quarantine items, you can either create the quarantine orders manually or set up the system to create the quarantine orders automatically during inbound processing. To create quarantine orders automatically, select the **Quarantine management** option on the **Inventory policies** tab on the **Item model groups** page. You must also specify a default quarantine warehouse in the **Quarantine warehouse** field for the receiving warehouses. When the physically on-hand inventory is recorded in a purchase order or production order, quarantined items are automatically moved to a quarantine warehouse in Supply Chain Management. This movement occurs because the status of the quarantine order is changed to **Started**. When you create quarantine orders manually, the item doesn't have to be set up for quarantine management in the associated item model group. For this process, you must specify the on-hand inventory that should be quarantined and the quarantine warehouse that should be used. You can use the quarantine order statuses to help plan the process.

Quarantine order statuses

Quarantine orders can have the following statuses:

- Created
- Started
- Reported as finished
- Ended

Created

When a quarantine order has been created manually, but the item isn't yet in the quarantine warehouse, the quarantine order has a status of **Created**. Two inventory transactions are generated. One transaction is an issue transaction that can have a status of **On order**, **Reserved physical**, or **Picked**. The other transaction is a receipt transaction that can have a status of **Ordered** or **Registered** at the quarantine warehouse. You can reserve, pick, and register updates to the inventory by using the usual processes.

Started

When a quarantine order has a status of **Started**, the inventory is transferred from the regular warehouse to the quarantine warehouse, and two inventory transactions are generated. One transaction has a status of **Deducted**, and the other transaction has a status of **Received**. At the same time, two inventory transactions are created to handle the return transfer. These transactions aren't dated. One transaction has a status of **Reserved physical**, and the other transaction has a status of **Ordered**.

Reported as finished

By clicking **Report as finished**, you can report a started quarantine order as finished. The item is released from quarantine but isn't yet moved back to the regular warehouse. The movement back to the regular warehouse can be processed via an Item arrival journal that can be initialized during the Report as finished process.

Ended

When a quarantine order is ended, the item is moved from the quarantine warehouse back to the regular warehouse. The status of the item transaction is set to **Sold** at the quarantine warehouse and **Purchased** at the regular warehouse.

Quarantine order scrap

As part of the quarantine order process, you can scrap inventory. When you process scrap, the status of the inventory will be set to **Sold** by an issue transaction from the quarantine warehouse.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Set up quality orders

2/18/2021 • 5 minutes to read • [Edit Online](#)

This procedure shows you how to enable a quality management process where incoming inventory must be inspected immediately after arrival registration. The procedure will typically be carried out by a quality manager. The process includes the creation of a quality group, to define the items that are going to be sampled, and a test group to group the tests that are to be performed on items in the quality group. You can run this guide in the USMF demo data company.

Enable quality management

1. Go to **Navigation pane > Modules > Inventory management > Setup > Inventory and warehouse management parameters**.
2. Click the **Quality management** tab.
3. Set the **Use quality management option** to 'Yes'.
4. Click **Report setup**. In USMF, the report setup for quality management is already defined. If this wasn't done, you'd add new lines here for the different report types, and select the type of document to be used for each report.
5. Close the page.
6. Close the page.

Create a test

1. Go to **Inventory management > Setup > Quality control > Tests**.
2. Click **New**.
3. In the **Test** field, type a value.
4. In the **Description** field, type a value.
5. In the **Type** field, select 'Option'. In this example, we'll select "Option" which will make it possible to assign the test results based on pre-defined values.
6. Click **Save**.
7. Close the page.

Create Test variables to define the way test results are recorded

1. Go to **Inventory management > Setup > Quality control > Test variables**.
2. Click **New**.
3. In the **Variable** field, type a value.
4. In the **Description** field, type a value.
5. Click **Save**.
6. Click **Outcomes**.
7. Click **New**.
8. In the **Outcome** field, type a value.
9. In the **Description** field, type a value.
10. In the **Outcome status** field, select 'Pass'.
11. Click **Save**.
12. Click **New**.

13. In the **Outcome** field, type a value.
14. In the **Description** field, type a value.
15. Click **Save**.
16. Close the page.
17. Close the page.

Set up item sampling

1. Go to **Inventory management > Setup > Quality control > Item sampling**.
2. Click **New**.
3. In the **Item sampling** field, type a value.
4. In the **Description** field, type a value.
5. In the **Value** field, enter a number. This value relates to the Quantity specification that's selected in the adjacent field.
6. Expand or collapse the **Process** section.
7. Select or clear the **Full blocking** check box. If you select this option, the whole lot or order line quantity is blocked if a test is failed. If you don't select it, only the items in the quality order are blocked.
8. Click **Save**.
9. Close the page.

NOTE

The *Quality management for warehouse processes* feature provides additional item sampling capabilities. It adds a concept of *item sampling scope* and the ability to define a full license plate as the quantity specification. If you have enabled this feature, then see [Quality management for warehouse processes](#) for details.

Create a quality group

1. Go to **Inventory management > Setup > Quality control > Quality groups**.
2. Click **New**.
3. In the **Quality group** field, type a value. Use a descriptive name to help you identify which kind of items the group will contain (your sampling criteria).
4. In the **Description** field, type a value.
5. Click **Save**.
6. Click **Add items**.
7. Select the **Item number** row. In this example the filtering will be run based on the item number.
8. In the **Criteria** field, type a value. For example, type T* to filter on the item numbers that start with T.
9. Click **OK**.
10. Click **OK**.
11. Click **Item quality groups**.
12. Close the page.
13. Close the page.

Create a test group

1. Go to **Inventory management > Setup > Quality control > Test groups**.
2. Click **New**.
3. In the **Test group** field, type a value. Give the **Test group** a name that will help you remember what kind of tests are being run, and which quality group it should be associated with. For example, it's to be used with a

quality group that selects items starting with "T", you could call it "T-item tests".

4. In the **Description** field, type a value.
5. In the **Item sampling** field, select the item sampling line that you created before.
6. In the list, find and select the desired record.
7. Click **Add**.
8. In the **Sequence number** field, enter a number.
9. In the **Test** field, select the test that you created earlier.
10. In the list, find and select the desired record.
11. Click the **Test** tab.
12. In the **Variable** field, select the test variable that you created before
13. In the list, find and select the desired record.
14. In the **Default outcome** field, click the drop-down button to open the lookup.
15. In the list, click the link in the selected row.
16. Click **Save**.
17. Close the page.

Define when quality orders will be created

1. Go to **Inventory management > Setup > Quality control > Quality associations**.
2. Click **New**.
3. In the **Reference type** field, select an option.
4. In the **Item code** field, select 'Group'. In this example, we'll select "Group" and use the quality group we created before. You could also set this to "Table" to specify the items manually, or select "All" to add all items to the quality order.
5. In the **Item** field, select the quality group that you created before. The options available in the Item field depend on what you set in the Item code field.
6. In the list, find and select the desired record.
7. Expand or collapse the **Process** section.
8. In the **Event type** field, select an option. This is the event that triggers the test. The options available here depend on which process you selected in the Reference type field.
9. In the **Execution** field, select an option.
10. Expand or collapse the **Quality order process** section.
11. In the **Event blocking** field, click the drop-down button to open the lookup. This field shows the list of processes that it's possible to block if the quality order is still open. The options depend on what you selected in the Event type field.
12. In the list, click the link in the selected row. This will be depending on the previous selected values. Select if the following processes must be blocked while having open quality orders linked to a source document line.
13. Expand or collapse the **Specifications** section.
14. In the **Test group** field, select the test group that you created before.
15. In the list, find and select the desired record.
16. Click **Save**.
17. Close the page.

NOTE

The *Quality management for warehouse processes* feature provides additional options for setting up quality associations. It adds a new condition (**Applicable warehouse type**) and a new setting (**Quality processing policy**). If you have enabled this feature, then see [Quality management for warehouse processes](#) for details.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Inspect the quality of goods

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic explains how to process a quality order. You can run this guide in demo data company USMF. Before you start this example procedure, you need to confirm purchase order "000016" and post a product receipt. This will automatically create a quality order. Quality inspections are typically carried out by a quality clerk.

Select a quality order

1. In the navigation pane, go to **Modules > Inventory management > Periodic tasks > Quality management > Quality orders**.
2. Select the quality order that was created before you started this procedure.

Record test results

1. Select **Results**.
2. Select **Edit**.
3. In the **Result quantity** field, enter a number.
4. In the **Outcome** field, select the desired record in the drop-down menu.
 - In this example the result is based on a pre-defined outcome. Normally you would record a more specific test result, for example a size or other dimension.
5. Select **Save**.
6. Close the page.

Validate the quality order

1. Select **Validate**.
2. In the **Validated by** field, select the user performing the inspection from the drop-down menu.
3. Click **Select**.
4. Select **OK**.
5. Close the page.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Inventory blocking

2/18/2021 • 3 minutes to read • [Edit Online](#)

This topic provides an overview of inventory blocking, which is part of the quality inspection process in Supply Chain Management. You can use inventory blocking to prevent items from being processed or consumed.

You can block inventory items in the following ways:

- Manually
- By creating a quality order
- By using a process that generates a quality order
- By using inventory status blocking

Blocking items manually

You can block a quantity of an item by creating a transaction on the **Inventory blocking** page. Only items that are available as on-hand inventory can be blocked manually. For manually blocked quantities, you must decide whether planning activities include expected receipts as an expected on-hand quantity. Expected receipts are blocked items that you expect to be available as on-hand inventory after inspection is completed. You can maintain the expected date. By default, the **Expected receipts** option is selected for items that are blocked through a quality order. You can cancel a manual block on a quantity by deleting the transaction on the **Inventory blocking** page.

Blocking items by creating a quality order

You can specify items that must be inspected by creating a quality order on the **Quality orders** page. When you create a quality order, the quantity that you specify for an item is blocked. The sampling plan that is associated with a quality order controls only the quantity of items that must be inspected, not the quantity that is blocked. The quantity that is entered on the quality order is the quantity that is blocked, regardless of the quantity that the sampling plan specifies should be sent for inspection.

NOTE

Using both the batch expiry date and blocking inventory status features is not supported by master planning. This could result in double exclusion of on-hand inventory, which can occur during master planning. We recommend that you rely on batch disposition codes, instead of inventory status, for blocking expired batches.

Blocking items by using a process that generates a quality order

If a quality process specifies that an item must be inspected, a quantity of the item is blocked automatically. Therefore, when a quality order is generated automatically, the item sampling plan that is associated with the quality order controls the both quantity of items that is blocked and the quantity that must be inspected. If the **Full blocking** option on the **Item sampling** page is selected, the full quantity of, for example, a purchase order line is blocked during inspection, regardless of the item sampling quantity.

Example

In the following example, a quality order is generated when a purchase order packing slip is posted. On the **Quality associations** page, you specified that posting of a purchase order packing slip is the process that activates a quality order.

SETUP	USER ACTION	RESULT
<p>A quality association specifies that a quality order must be generated when a purchase order packing slip is posted. The item sampling setup of the quality order specifies that 10 percent of the quantity on the purchase order line must be inspected. Furthermore, because the Full blocking option selected in the item sampling setup, the full quantity of the purchase order line must be blocked during inspection, regardless of the quantity that is sent for inspection.</p>	<p>The packing slip is posted.</p>	<p>A quality order is generated. Ten percent of the purchase order quantity for the item is sent to inspection. The full quantity of the purchase order line is blocked.</p>

Blocking items by using inventory status blocking

You can specify which inventory statuses are blocking statuses by using the **Inventory blocking** parameter on the **Inventory statuses** page. You can't use inventory statuses as blocking statuses for production orders, sales orders, transfer orders, outbound transactions, or project integrations. For outbound work, use items that have an available inventory status. If items have a status of **Broken**, and master planning is run on those items, the items are considered missing, and inventory is automatically replenished.

Create and maintain an inventory blocking

2/18/2021 • 2 minutes to read • [Edit Online](#)

This procedure shows how to prevent physical on-hand inventory from being reserved by other outbound source documents by using the inventory blocking. You can run the procedure in demo data company USMF using the example values that are shown. You need to have an item with physical on-hand inventory available before you start this procedure.

Create an inventory blocking

1. In the **Navigation pane**, go to **Modules > Inventory management > Periodic tasks > Inventory blocking**.
2. Click **New**.
3. In the **Item number** field, click the drop-down button to open the lookup.
4. In the list, select the item you want to choose. Select an item number with physical on-hand inventory that you want to block. If you're using USMF you can select item M9201.
5. In the **Quantity** field, enter a number. If you're using item M9201, you need to select less than 200.
6. Expand the **Inventory dimensions** fastTab.
7. In the **Warehouse** field, click the drop-down button to open the lookup.
8. In the list, find and select the desired record. If you're using item M9201, you can select warehouse 51.
9. Click **Save**.

Update the conditions of the inventory blocking

1. In the **General** fastTab, in the **Quantity** field, enter a number. Update the inventory quantity field to reflect the quantity to block.
2. In the **Expected date** field, enter a date. You might want to indicate when the blocked inventory is expected to become available for reservation by assigning an expected date. If the Expected receipts option is selected for the inventory blocking, as it is by default when you manually create a blocking, this date will appear on the expected transaction.
3. Click **Save**.

Remove the inventory blocking

1. On the **Action Pane**, click **Delete**.
2. Click **Yes**.
3. Close the page.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Inventory journals

2/18/2021 • 5 minutes to read • [Edit Online](#)

This topic describes how you can use inventory journals to post various types of physical inventory transactions.

The inventory journals in Supply Chain Management are used to post physical inventory transactions of various types, such as the posting of issues and receipts, inventory movements, the creation of bills of materials (BOMs), and the reconciliation of physical inventory. All these inventory journals are used in a similar way, but they are divided into different types.

Types of inventory journals

The following types of inventory journals are available:

- Movement
- Inventory adjustment
- Transfer
- BOM
- Item arrival
- Production input
- Counting
- Tag counting

Movement

When you use an inventory movement journal, you can add cost to an item when you add inventory, but you must manually allocate the additional cost to a particular general ledger account by specifying a general ledger offset account when you create the journal. This inventory journal type is useful if you want to overwrite the default posting accounts.

Inventory adjustment

When you use an inventory adjustment journal, you can add cost to an item when you add inventory. The additional cost is automatically posted to a specific general ledger account, based on the setup of the item group posting profile. Use this inventory journal type to update gains and losses to inventory quantities when the item should keep its default general ledger offset account. When you post an inventory adjustment journal, an inventory receipt or issue is posted, the inventory values are changed, and ledger transactions are created.

Transfer

You can use transfer journals to transfer items between stocking locations, batches, or product variants without associating any cost implications. For example, you can transfer items from one warehouse to another warehouse within the same company. When you use a transfer journal, you must specify both the "from" and "to" inventory dimensions (for example, for Site and Warehouse). The on-hand inventory for the defined inventory dimensions is changed accordingly. Inventory transfers reflect the immediate movement of material. In-transit inventory isn't tracked. If in-transit inventory must be tracked, you should use a transfer order instead. When you post a transfer journal, two inventory transactions are created for each journal line:

- An inventory issue at the "from" location.
- An inventory receipt at the "to" location.

BOM

When you report a BOM as finished, you can create a BOM journal. By using a BOM journal, you can post the

BOM directly. This posting generates an inventory receipt of the product, together with an associated BOM and an inventory issue of the products that are included in the BOM. This inventory journal type is useful in simple or high-volume production scenarios where routes aren't required.

Item arrival

You can use the item arrival journal to register the receipt of items (for example, from purchase orders). An item arrival journal can be created as part of arrival management from the **Arrival overview** page, or you can manually create a journal entry from the **Item arrival** page. If you enable the item arrival journal name to check for picking locations, Supply Chain Management looks for a location for received items and, if there is room, generates location destinations for the incoming items.

Production input

Production input journals work like the item arrival journals but are used for production orders.

Counting

Counting journals let you correct the current on-hand inventory that is registered for items or groups of items, and then post the actual physical count, so that you can make the adjustments that are required to reconcile the differences. You can associate counting policies with counting groups to help group items that have various characteristics, so that those items can be included in a counting journal. For example, you can set up counting groups to count items that have a specific frequency, or to count items when stock falls to a particular level. For information about how to define counting groups, see [Define inventory counting processes](#).

Tag counting

Tag counting journals are used to assign a numbered tag to a count lot. The tag should contain a tag number, item number, and item quantity. To ensure that a tag is used only one time, and that all tags are used, every item number should have a unique set of tags that has its own number sequence. Three status values can be set for each tag:

- **Used** – The item number is counted for this tag.
- **Voided** – The item number is voided for this tag.
- **Missing** – The item number is missing for this tag.

When you post a tag counting journal, a new counting journal is created, based on the tag counting journal lines. For more information about tag counting, see [Inventory tag counting](#).

Working with journals

A journal can be accessed by only one user at a time. If several users must access journals at the same time to create journal lines, those users must select journals that aren't currently being used, to prevent information from being overwritten. In situations where multiple departments use the same journal type, it's helpful to create multiple journal names (for example, one per department). It can also be helpful to divide journals so that each posting routine is entered in its own unique inventory journal. For posting routines that are associated with inventory transactions, create one journal for periodic inventory adjustments and another for inventory counting.

Posting journal lines

You can post the journal lines that you create at any time until you've locked an item from additional transactions. The data that you enter in a journal remains in that journal, even if you close the journal without posting the lines.

Data entity support for inventory journals

Data entities support the following types of integration scenarios:

- Synchronous service (OData)
- Asynchronous integration

For more information, see [Data entities](#).

NOTE

Not all inventory journals are OData-enabled, therefore you cannot use the Excel data connector to get data published, updated, and imported back to Supply Chain Management.

Another difference between the journal data entities is the ability to use composite entities that include both the header and line data. Currently, you can use the composite entities for:

- Inventory adjustment journal
- Inventory movement journal

These two inventory journals only support the *Initialize stock* scenario as part of a data management import project:

- When a journal header number is not specified, but a number sequence is specified for the journal type, the import job will automatically create journal headers per 1000 lines. For example, importing 2020 lines will result in the following three journal headers:
 - Header 1: will contain 1000 lines
 - Header 2: will contain 1000 lines
 - Header 3: will contain 20 lines
- It is assumed that unique line information exists per inventory dimension, which can be a product, storage, and tracking dimension. Therefore, it's not possible to import journal lines where only the date field differs on the lines within the same import project.

Additional resources

[Data entities](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Inventory journal approval workflows

2/18/2021 • 5 minutes to read • [Edit Online](#)

This topic describes how to set up and use inventory journal approval workflows for various types of physical inventory transactions, such as issues and receipts, inventory movements, bills of materials (BOMs), and the reconciliation of physical inventory. Inventory journal workflows help ensure that only approved inventory journals can be posted to transactions.

NOTE

Inventory journal approval workflows apply only to transactions recorded using the Inventory Management module. They don't work with inventory journals triggered from the Warehouse Management module.

Turn on the inventory journal approval workflows feature

Before you can use this feature, it must be turned on in your system. Admins can use the [feature management](#) settings to check the status of the feature and turn it on. In the **Feature management** workspace, the feature is listed in the following way:

- **Module:** *Inventory and warehouse management*
- **Feature name:** *Inventory journal approve workflow*

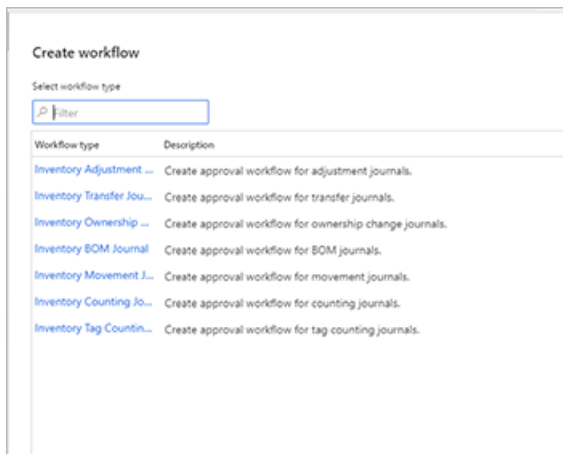

Create your inventory journal approval workflows

To set up this feature, you must create a workflow for each of the inventory journal types you want to control. Because different inventory journal types can have different approval hierarchies and workflow steps, you can configure individual workflows for each inventory journal type.

Workflows support version control, and each has a workflow ID and an active version. You can choose to activate each new workflow version immediately upon creation or keep it inactive. If you need different workflows for the same journal type, then create multiple workflows for that journal type, and then assign each of these to a different journal name that uses that type.

To create your inventory journal approval workflows:

1. Go to **Inventory Management > Setup > Inventory management workflows**.
2. Select **New** on the Action Pane.
3. Choose the inventory journal type for which you want to set up a workflow:
 - **Inventory tag counting journal**
 - **Inventory ownership change journal**
 - **Inventory movement journal**
 - **Inventory transfer journal**
 - **Inventory counting journal**
 - **Inventory BOM journal**
 - **Inventory adjustment journal**

- The workflow editor app launches on your machine. (You may be asked to approve this action.) Use it to design your workflow as needed. For details about how to use the workflow editor, see [Workflow system overview](#).
- After saving and closing the workflow editor app, you must choose whether to activate this workflow version or keep it as inactive.

NOTE

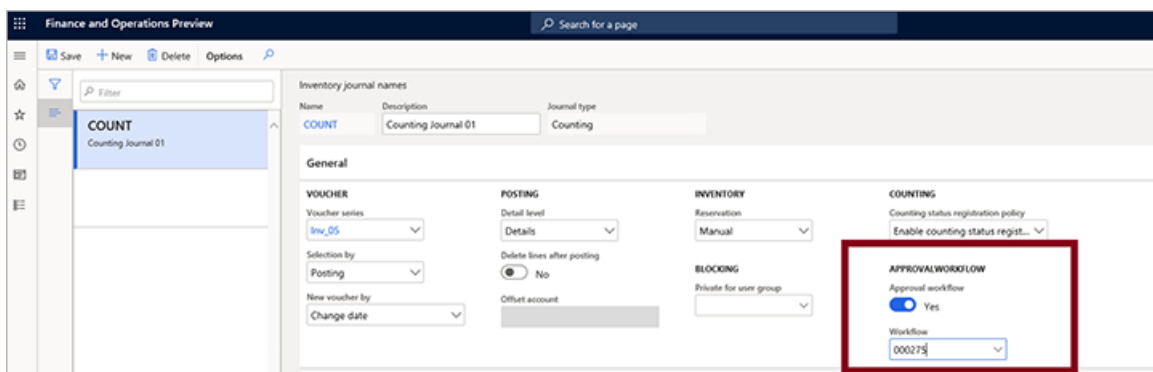

Workflows provide version control, which means that you can view a list of versions you have created and choose which one is active. To view the list of available versions and choose which to activate, select a workflow listed on the **Inventory management workflows** page. On the Action Pane, open the **Workflow** tab, and select **Versions**. Only one version can be active at a time for each workflow ID.

Assign approval workflows to inventory journal names

The next step is to assign an inventory journal workflow to each inventory journal name. For each inventory journal type, you can set up multiple inventory journal names.

To associate an inventory journal workflow with an inventory journal name:

- Go to **Inventory management > Setup > Journal names > Inventory**.
- Select a journal name from the list column to open its settings page.
- On the **General** FastTab, set **Approval workflow** to **Yes**. If you are prompted to approve the action, select **Yes**.

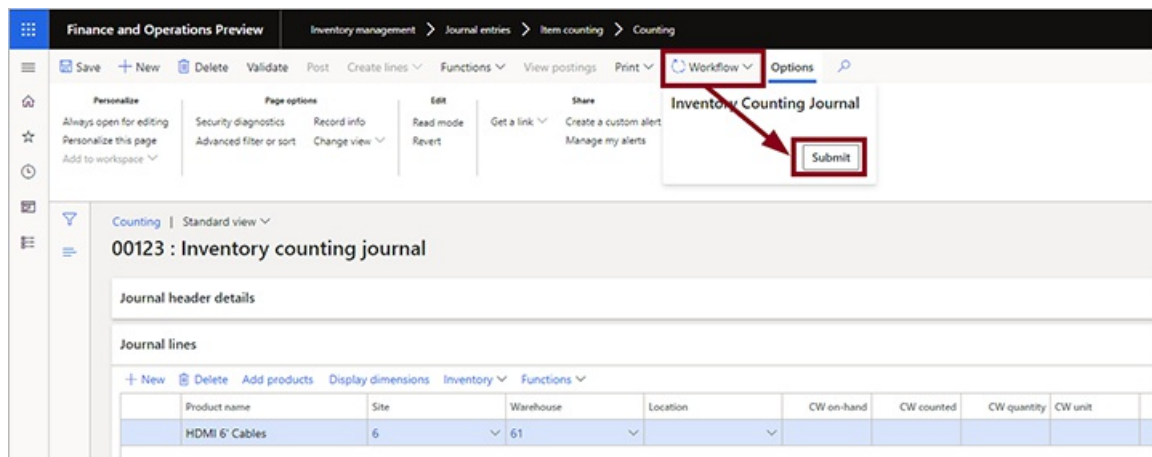

- Open the **Workflow** drop-down list and select the appropriate workflow. The list shows each active workflow that you have created using the workflow editor app.

Create an inventory journal and send it for approval

After you associate an inventory journal name with its matching inventory journal approval workflow, you'll be able to create new inventory journals that use that name and then send these journals for approval using that workflow. You won't be able post the inventory journal until it has been approved by the approvers configured in the workflow.

1. On the navigation pane, expand **Inventory management > Journal entries > Items** and then select an inventory journal type.
2. Select **New** to create a new journal of your selected type.
3. The **Create inventory journal** dialog box opens. Fill out the form as needed and then select **OK** to save the journal.
4. Complete the journal as required.
5. When you create or open an inventory journal with an approval workflow associated with it, the **Workflow** button will be active in the Action Pane. When you are ready to submit the journal for approval, select the **Workflow** button to open a drop-down dialog box and then select **Submit**. The approval request will then route to the relevant approver, who will be alerted using the notification method configured for the workflow.

To recall an approval request, open the relevant journal, select the **Workflow** button and then select **Recall**. This will reset the workflow.

When your journal has been approved, you'll be able to post it. To post the journal, select **Post** from the Action Pane. If the **Post** button isn't active the journal hasn't been approved yet.

Respond to an inventory journal approval request

If you are an approver, you should receive a message each time your approval is needed (as configured in the relevant workflow). Then you can approve or reject a journal approval request by doing the following:

1. On the navigation pane, expand **Inventory management > Journal entries > Items** and then select an inventory journal type.
2. Open the relevant journal and review it.
3. Select the **Workflow** button on the Action Pane to open a drop-down dialog box. Select one of the following:
 - **Approve** - To approve the request.
 - **Reject** - To reject the reject the request.
 - **More > Request change** - To send a message to the requester asking them to change something specific and then resubmit.
 - **More > Delegate** - To delegate the approval to another user.
 - **More > Recall** - To recall the approval request (resets the workflow).
 - **More > Workflow history** - To view the history of this approval workflow so far.

Review the approval history

As with other types of workflows, you can use the **Workflow history** page to view the approval workflow history for any journal.

To review the workflow history for a journal:

1. On the navigation pane, expand **Inventory management > Journal entries > Items** and then select an inventory journal type.
2. Open the relevant journal.
3. Select the **Workflow** button on the Action Pane to open a drop-down dialog box. Select **Workflow history**. For more information, see [View workflow history](#).

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Inventory locations

2/18/2021 • 2 minutes to read • [Edit Online](#)

Inventory locations are used with basic warehousing (WMS I) to determine where items are stored and where items are picked from in a WMS I warehouse.

This topic applies to features in the Inventory management module. It does not apply to features in the Warehouse management module.

The term location refers to the place that items are stored and drawn from.

For each location, the place where the item is inserted can also be specified. By default, they are the same. Items are usually inserted and drawn from the same side of a location, but not always. For example, items that are stored in live storage racks are inserted from one aisle and drawn from another. The main input is given by a location name, which is usually determined by its coordinates: warehouse, aisle, rack, shelf, and bin. This name or ID can be entered manually or generated from the location coordinates—for example, 01-02-03-4 for aisle 1, rack 2, shelf 3, bin 4 in the Inventory locations page. Location properties

A location has the following characteristics:

- Size (height, width, depth, and thereby volume)
- Warehouse, aisle, rack, shelf, and bin position
- Location type (bulk location, picking location, inbound dock, outbound dock, production input location, inspection location, or kanban supermarket)

Check text can be used in online systems to verify that the operator has selected the correct location for a specific item. This check text can be created manually or by default.

Sort codes

Use sort codes to optimize the handling of picking lines, which describe the information that is required for picking items from inventory, including the picking order. Sort codes can be specified by the aisle and other coordinates, or assigned manually for the location.

Blocked locations

Occasionally, you might want to indicate that a location is blocked for a period of time, for example, to allow for repairs. At other times, you may want to indicate blocking of only the input or only output.

Tree structure

In the Inventory locations page, you can view the warehouse layout in a tree structure based on the coordinates of inventory locations, in a defined display format.

Maintain inventory locations via the warehouse form

It is possible to copy locations from one warehouse to another and to create locations via a wizard. Before you run the wizard you should make sure that you have defined the default location names on the Warehouse page.

[Create a new warehouse layout](#)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Inventory statuses

2/18/2021 • 4 minutes to read • [Edit Online](#)

This article describes how you can use inventory statuses to categorize and keep track of inventory.

Set up and use inventory statuses

You can use inventory statuses to categorize inventory. You can then initiate appropriate actions, such as replenishment or put-away work.

Here are some examples of ways that you can use inventory statuses:

- Create inventory statuses for on-hand inventory, inbound transactions, and outbound transactions.
- Specify a default inventory status for warehouse transactions.
- Change an inventory status for items before arrival, during arrival, or when the items are put away during inventory movement.
- Use an inventory status to price items that are returned and to plan item coverage during master planning.

An inventory status is one of the dimensions in the storage dimension group. Inventory statuses can be categorized as available or unavailable, and you can use the **Inventory blocking** parameter to block items that have an unavailable inventory status. Items that have a blocked status are considered physical inventory, and they can't be used on a production order, sales order, transfer order, or outbound transaction.

You can use warehouse items that have either available or unavailable inventory statuses for inbound work. For example, you create an available status that is named *Ready*, an unavailable status that is named *Damaged*, and a blocked status that is named *Blocked*. When you create a purchase order for received or returned items, if any items are damaged or broken, you can change the inventory status of those items to *Damaged* on the purchase order line. After these items are received, the status is automatically set to *Blocked*. If you scan the damaged items by using a mobile device, Supply Chain Management can use location directives and work templates to show information about an appropriate location or range of locations where you can put away those items. For returned items, an issue type of *Reservation* is created on the **Inventory transactions** page.

NOTE

You can't change the status of inventory at locations where open work exists. For example, if you did a purchase receive for an item, but didn't do the putaway step, then open work would exist for the receiving location and you would get an error if you tried to change the status of inventory at that location. Completing or cancelling the related work would allow you to change the status.

For outbound work, use items that have an available inventory status. If you have items that have a status of *Broken*, and master planning is run on these items, the items are considered missing, and inventory is automatically replenished.

After you set up inventory statuses, you can set the default inventory status for a site, item, and warehouse. You can also set a default status for sales, transfer, and purchase orders. The default status for sales orders and outbound transfer order can't have the **Inventory blocking** option set to *Yes*. The inventory status that is inherited from the default settings on a site, warehouse, item, purchase order, transfer order or sales order can be changed by using the mobile device, or on the purchase order, sales order, or transfer order line.

To plan coverage for items that have an available inventory status, select the **Coverage plan by dimension** option for a storage dimension on the **Storage dimension groups** page. When you open the **Item Coverage**

wizard, items that have an available status appear on the **Status** page. To create coverage settings for these items, select the inventory status ID for the available inventory statuses. Based on the coverage settings, you can calculate the item requirements and forecast the supply and demand of available items during master planning. You can't create an item coverage setup that has a blocked inventory status. Alternatively, use the **Item coverage** page to create or modify the item coverage parameters.

Change inventory statuses

You can change inventory statuses either by using the **On-hand by location** page or by using the *Inventory status change* periodic task.

- When using the *Inventory status change* periodic task, you can select which records to include and set the task to run in the batch at the desired interval.
- To change inventory status as an ad-hoc process, go to **On-hand by location** page, select the relevant records, and then select the **Inventory status change** button.

NOTE

The *Change the inventory status of items controlled by tracking dimensions* feature allows you to change the inventory status of items controlled by tracking dimensions, including the ability to update only selected records. Use [feature management](#) to enable the feature as needed. When the feature is enabled, you'll be able to do the following:

- On the **On-hand by location** page, you can group lines based on shown dimensions using the **Display dimensions** button and change the status for the selected lines.
- On the **On-hand by location** page, you can select multiple records and then use the **Inventory status change** button to change all of them at once.
- On the **Inventory status change** periodic task you will be able to filter by tracking dimensions.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Create a new warehouse layout

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic describes how to set up information about the locations in a warehouse. This applies only to warehouses created using "basic warehousing" in the Inventory management module, not to warehouses created in the Warehouse management module. You can use this procedure in demo data company USMF, or on your own data.

Set the default location capacity

1. In the navigation pane, go to **Modules > Inventory management > Setup > Inventory and warehouse management parameters**.
2. Select the **Locations** tab.
3. In the **Standard width** field, enter a number.
4. In the **Standard depth** field, enter a number.
5. In the **Standard height** field, enter a number.
6. Select **Save**.
7. Close the page.

Define the location name format

1. In the navigation pane, go to **Modules > Inventory management > Setup > Inventory breakdown > Warehouses**.
2. Select **New**.
3. In the **Warehouse** field, type a value.
4. In the **Name** field, type a value.
5. In the **Site** field, select the desired record in the lookup.
6. Toggle the expansion of the **Location names** section. The options in this section define the default format for location names. In our example, we'll include the aisle number, rack number and shelf number.
7. Set the **Include aisle** option to **Yes**.
8. Set the **Include rack** option to **Yes**.
9. In the **Format** field, for the rack, type a value.
10. Set the **Include shelf** option to **Yes**.
11. In the **Format** field, for the shelf, type a value.

Define warehouse locations

1. On the Action Pane, select **Warehouse**.
2. Select **Location Wizard**.
3. Select **Next**.
4. De-select the **Outbound docks** option
5. De-select the **Bulk locations** option
6. Select **Next** until you come to the option to select **Finish**.
7. Close the page.
8. Refresh the page.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Maintain barcode types

2/18/2021 • 2 minutes to read • [Edit Online](#)

This procedure shows you how to set up a new barcode definition which can then be used as part of the picking list report. You can walk through this procedure in demo data company USMF, or using your own data. If you are using USMF you can use the example values that are shown. These tasks would typically be carried out by a warehouse manager.

1. Go to Bar codes.
2. Click New.
3. In the Barcode setup field, type a value.
4. In the Description field, type a value.
5. In the Bar code type field, select an option.
 - If you're using USMF, you can select 'Code 39'.
6. In the Size field, enter a number.
7. In the Maximum length field, enter a number.
8. Click Save.
9. Close the page.
10. Go to Inventory and warehouse management parameters.
11. In the Barcode setup field, enter or select a value.
 - Select the barcode setup that you created before, but be aware that the bar code format must match the format of the unique identifier for the record type used in the process. For example, for picking routes, the bar code format should match the format of the picking route reference, which is typically a number sequence.
12. Click Save.
13. Close the page.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Check the availability of stock

2/18/2021 • 2 minutes to read • [Edit Online](#)

This procedure shows you how to check on-hand and physical on-hand inventory for a specific item number. It also shows you how to get supply information related to an item. Physical on-hand inventory is the on-hand inventory that's available – that is, it's purchased, received and registered. On-hand inventory includes the available on-hand inventory, but also the inventory that's been ordered and is expected, but not yet received or registered. You can walk through this procedure in demo data company USMF, or using your own data. If you are using USMF you can use the example values that are shown. These tasks would typically be carried out by a warehouse worker.

Check on-hand inventory for an item

1. Go to **Navigation pane > Modules > Inventory management > Inquiries and reports > On-hand inventory**.
2. Select the **Item number** row. To query the on-hand inventory by item number, select the row where the Table is set to **On-hand inventory** and Field is set to **Item number**.
3. In the **Criteria** field, select the item you want to query. If you're using the USMF demo data company, you can select 'M9201'.
4. Click **OK**.
5. On the **Action Pane**, click **Dimensions**. The **Dimensions** tab allows you select how much detail you want to see about your on-hand inventory. If you need data related to reservation, you must display all inventory dimensions for the items that use advanced warehouse (WMS) processes.
6. Click **OK**.
7. On the **Action Pane**, click **Related information**. If you don't see this option, you may need to click on the Ellipsis button (...) to see additional Action Pane options.
8. Click **Supply overview**. The **Supply overview** tab provides supply information for a specific item, such as the quantity on-hand, the lead time, and vendor information.
9. Expand the **On-hand** section.
10. Expand the **Vendors** section.
11. Close the page.
12. Close the page.

Check physical on-hand inventory

1. Go to **Navigation pane > Modules > Warehouse management > Inquiries and reports > Physical on-hand inventory**.
2. In the **Item number** field, type a value. You can use the Site and Warehouse fields to filter the list of items.
3. Refresh the page.
4. On the **Action Pane**, click **Display Dimensions**. The **Dimensions Display** tab allows you select how much detail you want to see about your on-hand inventory.
5. Click **OK**.
6. Close the page.

Check on-hand inventory by location

1. Go to **Navigation pane > Modules > Warehouse management > Inquiries and reports > On hand**

by location.

2. In the **Warehouse** field, type a value. If you're using the USMF demo data company, you can use '51'.
3. Refresh the page.
4. Click **Display Dimensions**.
5. Click **OK**.
6. Close the page.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Inventory on-hand list

2/18/2021 • 7 minutes to read • [Edit Online](#)

This topic describes how to use the **On-hand list** page to inspect on-hand inventory details. It shows a few of the ways that the various filtering and sorting options work together, and how those options can sometimes produce unexpected results when they are combined.

Query your on-hand inventory

To check the availability of inventory, go to **Inventory management > Inquiries and reports > On-hand list**.

The **On-hand list** page is automatically updated when transactions are made in inventory. Those transactions might be forecasted, physical, or financial transactions.

Use the following tools to find the set of products that you're looking for:

- On the Action Pane, select **Dimensions** to open a dialog box where you can add or remove columns that are shown in the **On-hand** grid.
- In the **Filters pane**, enter values for specific fields to show only records that match those values. Note that filters that you define here apply to source tables that might be aggregated later, according to the dimensions that you've selected to show. For information about how this behavior can affect your results, see the [examples](#) later in this topic.
- In the **Filters pane**, select **Apply** to generate the list of matching on-hand inventory in the **On-hand** grid.
- In the **On-hand** grid, select any column heading to sort or filter by values in that column. A QuickFilter at the top of the grid provides additional filtering options. These filters apply to the results, not to the source tables. For information about how this behavior can affect your results, see the [examples](#) later in this topic.

For each matching item, the **On-hand** grid provides the following columns of inventory information.

COLUMN	DESCRIPTION
Physical inventory	The physical quantity that is available in inventory.
Physical reserved	The total quantity that was physically reserved.
Available physical	The available (not reserved) quantity that is available in physical inventory. Available physical is a calculated field. The value equals the Physical inventory value minus the Physical reserved value.
Available physical on extra dimensions	The available physical quantity for all the dimensions that are shown in the grid.
Ordered in total	The total quantity that is included on inbound orders or that has a positive quantity in various inventory journals.
On order	The total quantity that is included on outbound orders or that has a negative quantity in various inventory journals.

COLUMN	DESCRIPTION
Ordered reserved	The total quantity that is reserved on ordered receipts. The value in this field represents the total quantity of items in outbound transactions that have a status of <i>Ordered reserved</i> . Items that are reserved as ordered aren't physically available in inventory. Therefore, they can't be directly picked and delivered.
Available for reservation	The total quantity of on-hand inventory that can be reserved. Note: If the Reserve ordered items check box is selected on the Inventory and warehouse management parameters page, the value in this field includes expected receipts. If the check box is cleared, the value excludes expected receipts.
Total available	The total available quantity. Total available is a calculated field. The value equals the Available physical value plus the Ordered in total value minus the On order value.

Apply filters to find the records that you're looking for

Use the **Filters** pane to filter the on-hand inventory list so that it includes only records where the field values match the filtering criteria. To define a filter, follow these steps.

1. In the **Filters** pane, find the field that you want to filter on.
2. In the field below the name of the target field, select a logical operator (for example, *starts with*, *equal to*, or *greater than*).
3. Enter or select the value to look for.

IMPORTANT

The **On-hand list** page is assembled from a detailed on-hand inventory table that includes all available dimensions. However, the list on this page is a summary. Therefore, it might combine rows from the source table by aggregating values according to the dimensions that are shown.

The filters that you define in the **Filters** pane apply to the source table, not to the aggregated list. This behavior can sometimes produce unexpected results. For information about how this behavior can affect your results, see the [examples](#) later in this topic.

However, the [filters that are provided in the grid](#) do apply to the aggregated list. These filters include both the QuickFilter at the top of the grid and the filter for each column heading.

You can modify the set of filters that is available in the **Filters** pane by following these steps.

- To remove a filter from the pane, select its **Close** button (X).
- To add a filter, select **Add** at the top of the **Filters** pane. The **Add filter fields** dialog box that appears shows a list of the available fields. It also shows information about the data type and table for each field. Use the column headings to filter and sort the list as you require, and then select the check box for each field that you want to add to the **Filter** pane. When you've finished, select **Insert** to apply your changes.

Select which dimensions to show

Dimensions tell you more about each item in the on-hand inventory list, and give you more ways to sort and filter the list. The dimensions that you select to show also affect how rows are aggregated on the **On-hand list** page. This aggregation, in turn, can affect how rows from the source tables are combined in the results that you see. For information about how this behavior can affect your results, see the [examples](#) later in this topic.

To customize the selection of inventory dimensions that is shown, follow these steps.

1. On the Action Pane, select **Dimensions**.

The **Dimension display** dialog box that appears shows every dimension.

2. Select the check box for each dimension that you want to include in the grid.
3. If you want your selection to be used by default the next time that you open the **On-hand list** page, set the **Save setup** option to **Yes**. If you set this option to **No**, your selection will be used only during the current session. Therefore, the next time that you open the page, the current default selection will be used.
4. Select **OK** to close the dialog box and apply your changes.

Filter on the output of the inventory on-hand list

You can select any column heading in the **On-hand** grid to sort or filter by values in that column. A QuickFilter at the top of the grid provides additional filtering options. These filters apply to the results, not to the source tables. For information about how this behavior can affect your results, see the [examples](#) later in this topic.

NOTE

You can't filter and sort by all columns. Most of the quantity columns don't include sorting and filtering controls, because they are calculated fields. The **On order** column is an exception.

Examples

Your system includes a detailed (non-aggregated) inventory table that shows the following on-hand inventory.

ITEM NUMBER	SITE	WAREHOUSE	PHYSICAL INVENTORY	AVAILABLE PHYSICAL
IA0001	1	1	1	1
IA0001	1	2	2	2
IA0001	1	3	1	1

Scenario 1

The **On-hand list** page is set up to show the following final dimensions:

- Item number
- Site
- Warehouse

In the **Filters** pane, the following filtering criteria are set up:

- **Item Number** | is exactly | *IA0001*
- **Available Physical** | less than or equal | *1*

Here is the resulting output.

ITEM NUMBER	SITE	WAREHOUSE	PHYSICAL INVENTORY	AVAILABLE PHYSICAL
IA0001	1	1	1	1
IA0001	1	3	1	1

Scenario 2

The **On-hand list** page is set up to show the following final dimensions:

- Item number
- Site

In the **Filters** pane, the following filtering criteria are set up:

- **Item Number** | is exactly | *IA0001*
- **Available Physical** | less than or equal | *1*

Here is the resulting output.

ITEM NUMBER	SITE	PHYSICAL INVENTORY	AVAILABLE PHYSICAL
IA0001	1	2	2

Note that the settings in the **Filters** pane apply to the detailed (non-aggregated) inventory table that is shown at the beginning of this section. Therefore, the criterion **Available Physical** | less than or equal | *1* finds two rows from that table (the first and third rows, each of which shows an **Available Physical** value of *1*). However, in this scenario, the **On-hand list** page isn't set up to show the **Warehouse** dimension. Therefore, it aggregates the two original rows into a single resulting row, because both rows have identical values in all the dimensions that are shown. This row appears to violate the filtering criterion, because the **Available Physical** value is shown as *2*. However, the result is correct, because the settings in the **Filters** pane apply to the source table, not to the aggregated table that is shown on the **On-hand list** page.

NOTE

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Initialize stock levels in the warehouse

2/18/2021 • 2 minutes to read • [Edit Online](#)

This procedure shows you how to get the on-hand inventory updated manually using an Inventory movement journal. (It's also possible to update on-hand inventory by importing transactions in data entities.) You can run this guide in demo data company USMF where all the prerequisites like journal name, item setup, posting profiles, and accounts are available. The guide suggests specific values for the item and dimensions that are used. If you choose a different item, you may need to enter values for different dimensions.

1. Go to Inventory management > Journal entries > Items > Movement.
2. Click New.
3. In the Name field, click the drop-down button to open the lookup.
4. Select IMov.
 - It's a good practice to use different journal name templates for the different business purposes.
5. In the list, click the link in the selected row.
6. In the Offset account field, specify the values '140200'.
 - This is the offset account that will be the default account on the journal lines. It's possible to override the default to assign different offset accounts per line.
7. Click OK.
8. Click New.
9. In the Item number field, click the drop-down button to open the lookup.
10. Select item A0001.
11. In the list, click the link in the selected row.
12. Click the Inventory dimensions tab.
13. In the Site field, click the drop-down button to open the lookup.
14. Select site 1.
15. In the Warehouse field, click the drop-down button to open the lookup.
16. Select warehouse 13.
17. In the list, click the link in the selected row.
18. In the Location field, click the drop-down button to open the lookup.
19. Select location 13.
20. In the Quantity field, enter a number.
21. Click Save.
22. Click Post.
23. Check or uncheck the Transfer all posting errors to a new journal check box.
 - If you enable this option, any lines that fail to post will be copied to a new journal. You can use the information in the log to correct the issues and then re-post the lines.
24. Click OK.
25. Close the page.
26. Close the page.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Transfer physical inventory within the warehouse

2/18/2021 • 2 minutes to read • [Edit Online](#)

This procedure walks you through the process of creating and posting an inventory transfer journal in order to register movement of an item from one location in a warehouse to another. You need to have an inventory journal name set up for inventory transfers before you start this. You can walk through this procedure in demo data company USMF using the example values that are shown, or using you can use your own data if you have products and locations set up. These tasks would normally be carried out by a warehouse employee.

Create an inventory transfer journal

1. In the **Navigation pane**, go to **Inventory management > Journal entries > Items > Transfer**.
2. Click **New**.
3. In the **Name** field, enter or select a value.
4. Click **OK**. There is the option to specify 'From' and 'To' dimensions for each journal line. These are essential for this journal type. You can transfer items to locations using different rules. In this example we'll transfer an item within the same warehouse, from a license plate controlled location to a location that is not license plate controlled.

Create journal lines

1. In the **Journal lines fastTab**, click **New**.
2. In the **Item number** field, enter or select a value. If you are using USMF, you can select 'A0001'.
3. In the **From site** field, enter or select a value. If you are using USMF, you can select '2'.
4. In the **To site** field, enter or select a value. If you are using USMF, you can select '2'.
5. In the **From warehouse** field, enter or select a value. If you are using USMF, you can select '24'.
6. In the **To warehouse** field, enter or select a value. If you are using USMF, you can select '24'.
7. In the **From location** field, enter or select a value. If you are using USMF, you can select 'FL-001'.
8. In the **To location** field, enter or select a value. If you are using USMF, you can select 'BULK-001'.
9. In the **Quantity** field, enter a number.
10. In the **Line details fastTab**, click the **Inventory dimensions** tab.
11. In **From inventory dimensions**, in the **License plate** field, enter or select a value. If you are using USMF, you can select '24'.
12. Click **Save**.

Post the inventory transfer journal

1. On the **Action Pane**, click **Post**.
2. Click **OK**.

View inventory transactions

1. Click **Inventory**.
2. Click **Transactions**. Here you can see the transactions that were created when you posted your journal.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Adjust stock levels in the warehouse (basic warehousing)

2/18/2021 • 2 minutes to read • [Edit Online](#)

This procedure walks you through the process of creating and posting an inventory adjustment journal in order to adjust stock levels of products in the warehouse. You need to have an inventory journal name set up for inventory adjustments before you start this. You can walk through this procedure in demo data company USMF, or using your own data. These tasks would normally be carried out by a warehouse employee.

Create an inventory adjustment journal

1. Go to Inventory management > Journal entries > Items > Inventory adjustment.
2. Click New.
3. In the Name field, click the drop-down button to open the lookup.
4. In the list, click on the inventory adjustment journal name you want to use.
 - Some other fields will be populated based on the setup of the inventory adjustment journal name you select.
5. Click OK.

Create journal lines

1. Click New.
2. In the list, mark the item number field.
3. In the Item number field, Select an item. If you are using demo data company USMF, type 'D0001'.
4. In the Site field, click the drop-down button to open the lookup.
5. In the list, select a site.
6. In the Warehouse field, click the drop-down button to open the lookup.
7. In the list, select a warehouse.
 - If you have selected an item with Location as a mandatory dimension, you would have to specify the location here.
8. In the Quantity field, enter a number.
 - The cost price field specifies the cost per unit for inventory receipts. If the cost is not specified for the item number or if you wanted to change it manually, you would do this here.

Validate and post the inventory adjustment journal

1. Click Validate.
2. Click OK.
3. Click Post.
 - When you post this kind of journal, an inventory receipt or issue is posted, the inventory level and value are changed, and ledger transactions are generated.
4. Click OK.
5. Close the form.
6. Close the page.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Inventory tag counting

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic provides information about tag counting, which you use to compare the actual contents of a warehouse with the on-hand inventory.

By creating lines on the **Tag counting** page, you place a tag number on each inventory item, such as a number from 1 to 500. During the count, you enter the item number and the quantity on a corresponding tag. This tag can then be used as the basis for input in the tag counting journal. After you post the tag counting journal, a new counting journal is created on the **Counting** page. The new journal is based on the tag counting journal lines that you created. To tag-count items by a specific inventory dimension, select the dimension on the **Display dimension** page that is displayed when you create the tag counting journal. For example, to count items in a specific warehouse, select the **Warehouse** check box. If the **Lock items during count** slider on the **Inventory and warehouse management parameters** page is selected, items can't be physically updated during counting. However, items in tag counting journals aren't locked during counting. Inventory transactions aren't created until the tag counting lines are posted and transferred to a counting journal. If tags are entered randomly, and you want to identify missing tags, click the **Tag** column header to sort the lines by tag.

Count inventory in a warehouse

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic describes the process of creating and posting an inventory counting journal in order to count a specific item at a location in the warehouse. The procedure applies to "basic warehousing" functionality, available in the Inventory management module, not to the warehousing functionality that's available in the Warehouse management module. You can walk through this procedure in demo data company USMF, or using your own data. If you're using your own data, make sure that you have products and locations set up, and that you've created an inventory journal name for counting journals. Inventory counting is normally carried out by a warehouse employee.

Create an inventory counting journal

1. Go to **Navigation pane > Modules > Inventory management > Journal entries > Item counting > Counting**.
2. Select **New**.
3. In the **Name** field, select the inventory counting journal name you want to use from the drop-down list. Some other fields will be populated based on the setup of the inventory counting journal name that you select.
4. In the **Worker** field, select the drop-down button to open the lookup.
5. In the list, **Select** the worker you want to use.
6. Select **OK**.

Create journal lines

1. Select **New**.
2. In the **Item number** field, select the desired record from the drop-down list. If you are using demo data company USMF, select **A0001**.
3. In the **Site** field, select the desired record from the drop-down list. If you are using demo data company USMF, select site **2**.
4. In the **Warehouse** field, select the desired record from the drop-down list. If you are using demo data company USMF, select warehouse **24**.
5. In the **Location** field, select the desired record from the drop-down list. If you are using demo data company USMF, select location **BULK-001**.
6. In the **Counted** field, enter a number. If you enter a counted number that's different to the number shown in the **On-hand** field, the **Quantity** field is updated to show the discrepancy.
7. Select **Save**.

Post the inventory counting journal

1. Select **Post**. When you post an inventory counting journal, if the counted amount differs from amount that's reported in the **On-hand** field an inventory receipt or issue is posted, the inventory level and value are changed, and ledger transactions are generated.
2. Select **OK**.

View inventory transactions

1. Select **Inventory**.

2. Select **Transactions**. Here you can see any related transactions that will be created when you post your inventory counting journal.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Define inventory counting processes

2/18/2021 • 4 minutes to read • [Edit Online](#)

This topic describes the configuration of basic inventory counting processes by creating a counting group and a counting journal. It also shows you how to enable counting policies on a warehouse and item level. These tasks would typically be carried out by a warehouse supervisor. It is a prerequisite to have some existing released products and warehouses. If you're using a demo data company, you can run this procedure in the USMF company with any stocked item.

Create a counting group

1. In the navigation pane, go to **Modules > Inventory management > Setup > Inventory > Counting groups**.
2. Select **New**.
3. In the **Counting group** field of the new row, type a value.
4. In the **Name** field, type a value.
5. In the **Counting code** field, select an option.
 - **Manual** – Includes lines every time you run the job. In other words, you decide the counting interval for the counting group.
 - **Period** – Includes lines for the period in the counting journal when the period interval has expired.
 - **Zero in stock** – If on-hand inventory reaches zero (0), lines are generated in the counting journal when the job is run. If the on-hand inventory reaches 0 after a count, lines are generated the next time that you start the count.
 - **Minimum** – Inserts lines in the counting journal if the on-hand inventory is equal to or less than the minimum that is specified.
 - Optional: If you have specified **Period** in the **Counting code** field, you must type the interval for the period in the **Counting period** field. The unit for intervals is days.
 - When you run the job for creating new lines in the counting journal, new lines are created at the interval specified in this field, regardless of how often you run the same job. For example, if **Counting period** is set to 7, and journal lines were last generated for a count on January 1, if another job is started on January 5, seven days have not passed and so no lines are generated in the journal for that period interval. If you start the job again on January 8, lines are generated for the period in the counting journal, because 7 days have passed.
6. Select **Save**.

Create a counting journal name

1. In the navigation pane, go to **Modules > Inventory management > Setup > Journal names > Inventory**.
2. Select **New**.
3. In the **Name** field, type a value.
4. In the **Description** field, type a value.
5. In the **Journal type** field, select **Counting**. Optional: you can select a different voucher series ID if you

want a specific number sequence for the voucher IDs generated when creating counting journals. Voucher series are created in the **Number sequences** page.

6. In the **Detail level** field, select an option.

- This is the level of detail that is applied when the journal is posted.
- Optional: you can change the value in the Reservation field. This is the method used to reserve items during counting.
- **Manual** – The items are reserved manually in the Reservation form.
- **Automatic** – The order quantity is reserved from the available, on-hand inventory for the item.
- **Explosion** – The reservation is part of the master planning of the transaction.

7. Select **Save**.

Set standard counting journal name

1. In the navigation pane, go to **Modules > Inventory management > Setup > Inventory and warehouse management parameters**.
2. Select the **Journals** tab.
3. In the drop down menu of the **Counting** field, select the journal you previously created. This journal will then be the default journal name for inventory journals of the **Counting** type.
4. Select the **General** tab. Optional: Select this option to lock an item during the counting process to prevent updates for packing slips, picking lists, or picking list registrations.

Set the counting policy for an item

1. In the navigation pane, go to **Modules > Product information management > Products > Released products**.
2. In the list, select the link for the Item number of the product that you want to set counting policies on. You must select an item that is inventory tracked. A non-stocked product can't be counted. If you are using USMF demo data you can select item A0001.
3. Select **Edit**.
4. Toggle the expansion of the **Manage inventory** section.
5. In the drop-down menu of the **Counting group** field, select the counting group you previously created. This product will now be included when inventory counting journal lines are created using this counting group.
6. Select **Save**.

Set the counting policy for an item in a specific warehouse

1. On the Action Pane, select **Manage inventory**.
2. Select **Warehouse items**.
3. Select **New**.
4. In the drop-down menu of the **Warehouse** field, select the warehouse you want to set up specific counting policies for.
5. In the drop-down menu of the **Counting group** field, select a counting group. You can select a specific counting group that should apply to the item in the specific warehouse you have selected. When counting is performed in that warehouse, this counting policy will override the general counting policy for the item.
6. Select **Save**.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Set up consignment

2/18/2021 • 6 minutes to read • [Edit Online](#)

This topic explains how to use the inbound consignment inventory processes.

Consignment inventory is inventory that's owned by a vendor, but stored at your site. When you're ready to consume or use the inventory, you take over the ownership of the inventory. This topic includes information about how to physically receive vendor-owned inventory on-hand without creating general ledger transactions, how to start a production process where the vendor-owned inventory can be physically reserved, and how to change the ownership of the raw material in order to be able to process the consumption as part of the production order processing. There's also some information about how vendors can monitor consumption of their inventory using the vendor collaboration interface.

Overview of the consignment process

In this example scenario, company USMF has a consignment agreement with vendor US-104 for the raw material M9211CI.

1. A consignment replenishment order is manually created by someone in USMF, based on the expected demand. The order is created for vendor US-104 and a line is added for item MS9211CI.
2. The vendor gets informed about the expected delivery. This can happen in one of three ways:
 - Someone working at USMF sends the order information to the vendor.
 - The vendor can monitor the expected inventory on-hand using the vendor collaboration interface.
 - Someone working at USMF filters the data on the **On-hand inventory** page to show only the records for vendor US-104, where the receipt status is **Ordered**, and then sends this information to the vendor.
3. The inventory is delivered from US-104 to USMF.
4. When the material arrives at USMF, the consignment replenishment order is updated with a product receipt. Only the physical quantities of the vendor-owned inventory are recorded. There are no general ledger transactions created, because the inventory is still owned by the vendor.
5. The vendor monitors updates to the physical on-hand inventory using the **On-hand consignment inventory** page.
6. Now that the physical inventory is on-hand, the production process reserves the vendor-owned inventory and starts the production order for the finished goods that are going to consume the raw material M9211CI.
7. The owner of the reserved raw materials that are going to be consumed in today's production is changed from US-104 to USMF. This is done using an Inventory ownership change journal. This process creates purchase orders where the **Origin** field is set to **Consignment**.
8. The vendor monitors the consumption (change of ownership) on the **Products received from consignment inventory** page and issues an invoice based on the agreements between the two companies.
9. The production process consumes the raw material via a production picking list. The physical reservation is automatically updated to reflect that the on-hand inventory is owned by USMF.
10. The invoice from US-104 is processed against the purchase orders which were auto-generated when the inventory ownership change journal was processed. Payment is made to vendor US-104 for the inventory that was consumed.

USMF carries out additional periodic processes:

- The physical movement of the vendor-owned inventory between different warehouses is processed using a transfer journal.

- The physical inventory on-hand is updated using an **Item counting** journal. Counting can also be used by the vendor to update the on-hand inventory, if they have permission to do this.

The vendor, US-104, can monitor the updates using the **On-hand consignment inventory** page.

Consignment replenishment orders

A consignment replenishment order is a document that is used to request and keep track of inventory quantities of products that a vendor intends to deliver within a certain date interval by creating ordered inventory transactions. Typically, this will be based on the forecast and actual demand of the specific products. The inventory that's going to be received against the consignment replenishment order remains in the ownership of the vendor. Only the possession of the products related to the physical receipt update is recorded and therefore no general ledger transaction updates occur.

The **Owner** dimension is used to separate information about which inventory is owned by the vendor and which is owned by the receiving legal entity. Consignment replenishment order lines have an **Open order** status as long as the full quantity of the lines has not been received or cancelled. When the full quantity has been received or canceled, the status is changed to **Completed**. The physical on-hand inventory that's related to a consignment replenishment order can be recorded using a Registration process as well as a Product receipt update process. Registration can be done as part of the item arrival process or by manually updating the order lines. When the Product receipt update process is used, a record is made in the product receipt journal, which can be used to acknowledge the receipt of goods to the vendors.

The screenshot shows the 'RECEIVE' page in a software application. The page is divided into several sections:

- Top Bar:** Includes 'Save', '+ New', 'Delete', and tabs for 'RECEIVE', 'GENERAL', and 'OPTIONS'.
- GENERATE and JOURNALS:** Two columns with 'Product receipt' options.
- CONSIGNMENT REPLENISHMENT ORDERS:** A section with the order ID 'USMF-000000003'.
- Replenishment order header:** Contains fields for 'Vendor account' (US-103) and 'Vendor name' (Rain Projectors).
- GENERAL:** A section with 'Consignment replenishment order' (USMF-0000...) and a 'Contact' dropdown menu.
- Replenishment order lines:** A table with columns for 'Line number', 'Item number', 'Product name', 'Quantity', 'Unit', 'Requested delivery date', and 'Confirmed delivery date'. The first line is highlighted with a blue checkmark and contains the following data:

Line number	Item number	Product name	Quantity	Unit	Requested delivery date	Confirmed delivery date
1	M9211CI	Wiring harness	800.00	ea		

Inventory ownership change journal

The process of changing the owner of the inventory from the vendor to the receiving legal entity is done using an Inventory ownership change journal. No expected inventory transactions are created for the journal. The only inventory transactions created are those that relate to a posted journal. When the journal is posted:

- The vendor-owned inventory is issued using an **Ownership change** reference with a **Sold** status.
- On-hand inventory is received by the legal entity that's consuming it using a product receipt updated inventory transaction on the purchase order. This sets the status of the order to **Received**. Purchase orders used for consignment have the **Origin** field set to **Consignment**.

It's not possible to update the quantity on consignment purchase order lines after the order has been created.

Operation completed

+ New Delete Inventory Functions

✓	Date	Item number	From site	To site	From warehouse	To warehouse	From owner	To owner	Quantity
	9/20/2016	M9211CI	5	5	51	51	US-104	USMF	500.00
	9/20/2016	M9211CI	5	5	51	51	US-103	USMF	700.00

Vendor collaboration in consignment processes

The vendor collaboration interface has three pages related to the inbound consignment process:

- **Purchase orders consuming consignment inventory** - Shows detailed purchase order information related to the ownership change from the consignment process.
- **Products received from consignment inventory** - Shows information about the items and quantities that have product receipts updated during the ownership change process.
- **On-hand consignment inventory** - Shows information about the consignment items that they are expected to deliver, and the items that are already physically available at the customer site.

Inventory owners

In order to record physical inbound consignment inventory, you need to define a vendor owner. This is done on the **Inventory owner** page. When you select a **Vendor account** this generates default values for the **Name** and **Owner** fields. The value in the **Owner** field will be visible to the vendor, so you might want to change it if your vendor account names aren't easy for external people to recognize. It's possible to edit the **Owner** field, but only up to the point when you save the **Inventory owner** record. The **Name** field is populated with the name of the party that the vendor account is associated with, and this cannot be changed.

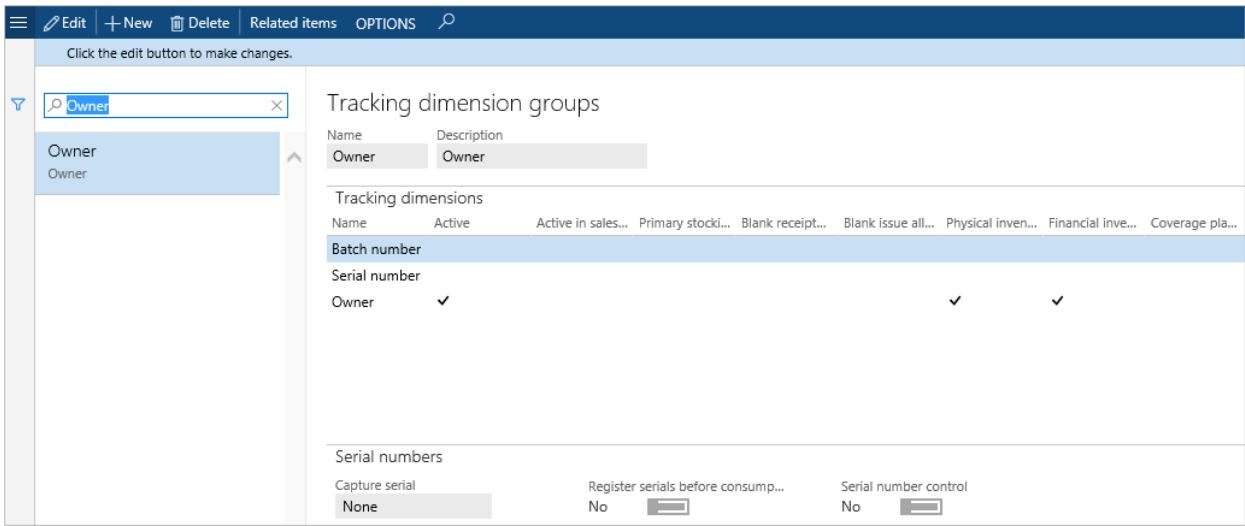

Inventory owners

Filter

Vendor account	Name	Owner ↑
US-103	Rain Projectors	US-103
1001	Acme Office Supplies	1001
US-101	Fabrikam Electronics	US-101
US-104	Fabrikam Supplier	US-104
	Contoso Entertainment System...	USMF

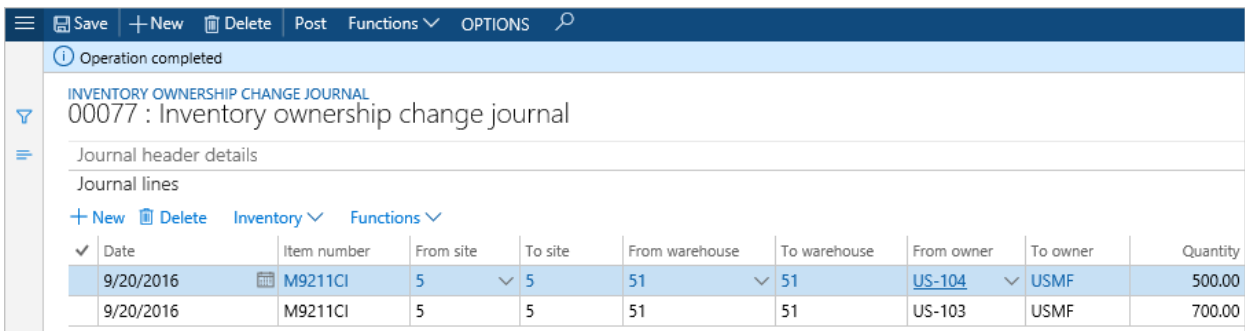

Tracking dimension group

Items that are going to be used in consignment processes must be associated with a **Tracking dimension group** where the **Owner** dimension is set to **Active**. The **Owner** dimension always has the **Physical inventory** and **Financial inventory** options selected. The **Coverage plan by dimension** is never selected.

Inventory ownership change journal

The **Inventory ownership change** journal is used to record the transfer of ownership of consignment inventory from the vendor to the legal entity that's consuming it. Like any inventory journal, it must be identified with an Inventory journal name. These names are created on the **Inventory journal names** page, and the **Journal type** must be set to **Ownership change**.

Vendor collaboration in consignment processes

If your vendors are using the vendor collaboration interface, they can use this to monitor the consumption of inventory at your site. For more information about setting up vendors to use vendor collaboration, see [Vendor portal user security](#).

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Change the ownership of consignment inventory based on production demand

2/18/2021 • 2 minutes to read • [Edit Online](#)

This procedure shows how to change the owner of consignment inventory from the vendor to your legal entity when there is demand for the inventory in production. This change of ownership is done by creating and posting an inventory ownership change journal. The ownership change journal lines can be created manually or, as shown in this recording, based on existing production demand. Typically, a shop floor supervisor performs this task. You can use this procedure in the USMF demo data company or on your own data. If you're using your own data, make sure that you have the following prerequisites: an inventory journal name that has been set up for inventory ownership change, physically recorded vendor-owned on-hand items, and one or more production order lines for the material. This procedure is for a feature that was added in Dynamics 365 for Operations, version 1611.

NOTE

Outbound consignment processes are not supported out-of-the-box and automatic ownership journal processing is not supported.

Create an inventory ownership journal

1. Go to Inventory management > Journal entries > Items > Inventory ownership change.
2. Click New.
 - The inventory ownership change journal is used to change the owner of consignment inventory from the vendor to the current legal entity. This change of ownership is done by releasing the on-hand inventory that is owned by the vendor and then receiving that inventory in the current legal entity.
3. In the Name field, enter or select a value.
 - You can select only inventory journal names that have a journal type of Ownership change.
4. Click OK.
5. Click Functions.
6. Click Create journal lines from production orders.
 - You can start the change of ownership process by querying all the production lines that have demand for consumption of raw material.
7. In the Inventory issue statuses to include field, select an option.
 - This option lets you filter by the issue status of the inventory transactions. For example, you can create journal lines for inventory that has the Picked and Reserved physical statuses.
8. Expand the Records to include section.
 - This section lets you apply additional filtering. For example, you can select a specific raw material date.
9. Click OK.

Post the inventory ownership change journal

1. Click Post.
 - When the journal is posted, the vendor-owned inventory is released by using an "Ownership change" reference. The inventory is then received as on-hand by using an inventory transaction that is updated with a purchase order product receipt. Note that only transactions that are related to the posted

journal are created. No expected inventory transactions are created.

2. Click OK.
3. Close the page.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Create a consignment replenishment order

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic explains how to create a consignment replenishment order where you can track the expected delivery from a vendor into your consignment inventory. It also shows how to record a receipt of products so that the consignment inventory is registered as on-hand inventory owned by the vendor. This procedure would typically be done by a procurement professional. You can use this guide in demo data company USMF. This procedure is for a feature that was added in Dynamics 365 for Operations, version 1611.

Create a consignment replenishment order

1. In the navigation pane, go to **Modules > Procurement and sourcing > Consignment > Consignment replenishment orders**.
2. Select **New**.
3. In the **Vendor account** field, select vendor **US-104** (you must select a vendor that's registered as an owner in the **inventory owners** page).
4. Select **OK**.
5. Select **Add line**.
6. In the **Item number** field, type (you must select an item that is set up for consignment inventory).
7. In the **Quantity** field, enter a number.
8. In the **Requested delivery date** field, enter a date. The requested and confirmed dates are used by the MRP engine for the expected arrival of the goods.
9. In the **Confirmed delivery date** field, enter a date.
10. Expand the **Line details** section.
11. Select the **Inventory dimensions** tab.
12. To show the owner in the **Inventory dimensions owner** field, refresh the page. Vendor US-104 is now listed as the owner.

Check the inventory transaction status

1. Select **Inventory**.
2. Select **Transactions**.
3. In the desired row, notice that the **Receipt** field is set to **Ordered**.
4. Close the page.

Receive items

1. Select **Product receipt**.
2. In the **External product receipt** field, type a value.
3. In the **Quantity** field, enter a number that's lower than the number that's shown there.
4. Select **OK**.

Check the on-hand inventory

1. Select **Inventory**.
2. Select **On-hand**.
3. Select **Overview**. The items that have been received as consignment inventory owned by the vendor are

available on-hand. The remaining quantity on the consignment replenishment order is shown in the **Ordered in total** field.

4. Close the page.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Monitor consignment inventory using vendor collaboration

2/18/2021 • 2 minutes to read • [Edit Online](#)

This procedure shows how to use vendor collaboration to see information about the stock level of product that you have placed in consignment with a customer. You can also monitor the consumption of the stock when the customer takes ownership of the inventory. You can use this procedure in the USMF demo data company. This procedure is for a feature that was added in Dynamics 365 for Operations, version 1611.

View consumed inventory

1. Go to Vendor collaboration > Consignment inventory > Products received from consignment inventory.
 - The list shows the product receipt lines that were generated when ownership of the consignment inventory was changed from the vendor to the customer. You might have to scroll to the right to see quantities and other information. You can use the information in this list to generate invoices for your customer. You can also export the data to Microsoft Excel.
2. Click View purchase order.
3. Expand the Line details section.
 - The line is marked as Consignment, and the header section shows that the purchase order has a status of Received.
4. Close the page.

View on-hand inventory

1. Go to Vendor collaboration > Consignment inventory > On-hand consignment inventory.
 - The On-hand consignment inventory page shows the stock that you own at the customer's warehouse. You can show additional dimensions, such as the site and warehouse, by clicking the Display dimensions tab.

NOTE

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Item and raw material tracing in inventory, production, and sales

2/18/2021 • 10 minutes to read • [Edit Online](#)

This topic describes how you can use item tracing to identify where items or raw materials have been used, are being used, or will be used in production and sales processes.

Item tracing functionality is available on the **Item tracing** page. The following sections describe how you can use item tracing, and what the options and limitations are.

What is item tracing?

Item tracing is a business intelligence (BI) tool that provides visibility into the source and destination of items and raw materials in the supply chain. Manufacturers can trace items, raw materials, or ingredients back to the vendor, and forward through the production and sale of the finished product. Item tracing helps manufacturers comply with regulatory requirements, and also helps quality officers and production managers analyze and take action to address variances in the quality of products and materials. Here are some examples of the ways that manufacturers can use item tracing:

- Identify the amount of an item or raw material that is currently in inventory, and where it's stored.
- Determine how much of the item or raw material has been shipped, and which customers it was shipped to.
- Identify any planned shipments that include the item or raw material.
- Locate production orders that use the item or raw material, and that are planned, in progress, or reported as finished.
- Find out where the item or raw material was purchased.
- Investigate where an item or raw material was consumed in the production of another item.

What can I trace, and are there any limitations?

You can trace historical inventory transactions for items and raw materials, based on an item number and a tracking dimension, such as a serial number, batch number, or vendor batch number. You can trace an item or raw material only if a tracking dimension is assigned to it. Because tracing is based on inventory transactions, there are some limitations when you trace items. For example, there are limitations that are related to transactions for projects, fixed assets, and commerce. Additionally, co-products are shown in the trace details, but by-products aren't included. The trace includes all warehouse transactions from one location to another. Therefore, users might find the amount of information overwhelming. The trace is displayed for one legal entity at a time. There are no cross-company capabilities in an intercompany context. You must start a new trace for each company where an item is received or issued.

What criteria can I specify for an item trace?

The criteria that are required for an item trace are the item number, a tracking dimension (such as a batch number or serial number), and the direction. The following table describes the criteria that you can use in an item trace.

FIELD GROUP	DESCRIPTION
-------------	-------------

FIELD GROUP	DESCRIPTION
Item number	Enter the identifier for the item or raw material that you're tracing.
Product dimensions	Optional: Trace specific aspects of the product definition, such as a configuration, size, color, or style.
Tracking dimensions	Enter a batch number, vendor batch number, or serial number tracking dimension. When you use the batch number as a criterion, the vendor batch number is displayed if you've captured that information.
Storage dimensions	Optional: Trace items that have been stored in a specific location.
Period	Optional: Enter dates to limit the trace to a specific period. The trace details will show only documents and transactions that were created between these dates.
Forward or backward	Select the direction for the trace. You can trace forward or backward: <ul style="list-style-type: none"> • Backward – Trace downstream to identify the source, the quantity that remains on hand, and any production orders that are at least partially reported as finished. • Forward – Trace upstream to identify the destination. You can find the sales orders, and the customers that the traced item or raw material has been at least partially shipped to.

What information is included in the trace details?

The results of a trace appear in chronological order in the tree on the **Details** FastTab of the **Item tracing** page. The order varies, depending on the trace direction. The details include all transactions from the purchase of the item from the vendor to the sale of the item to the customer. Trace results also include interim products that are related to the item or the tracking dimension that was specified in the trace criteria. The top node shows the quantity of the item, in the inventory unit, that remains on hand, based on the storage dimensions that were specified in the trace criteria. **Note:** The trace details provide a snapshot of the information that was available when the trace was done. The trace details aren't updated if the information changes after the trace is done.

Why don't some nodes contain any details?

To reduce the amount of information in the trace details, only the node for the first instance of the item or raw material includes details. If a selected node doesn't contain details, you can view the node that does contain details by clicking **Go to traced line**. You can then return to the node that you left by clicking **Go back**.

Can I view only a particular type of document? For example, can I view only production orders, customers, or vendors?

Yes, from the trace details, you can open list pages that include only a particular type of document or transaction. You can access these pages from the **Tracing** menu item on the Action Pane, in the **Item**, **Sales**, **Purchase**, **Production**, and **Quality** groups. For example, to view a list of the vendors in the trace details, click **Tracing > Purchase > Vendors**. The list pages summarize the documents or transactions from the trace

details. The **Pending transactions**, **Pending orders**, and **Not shipped sales orders** list pages also show other information that isn't included in the trace details. Additionally, they always show results as of the current date, even if a date range was specified. The following table describes the additional details that these pages can include.

LISTS	DESCRIPTION
Not shipped sales orders	View sales order lines that haven't been picked, and that therefore aren't shown in the trace details.
Pending orders	View all pending production orders for the traced item, regardless of the tracking dimensions that were used in the trace criteria. You can also view pending production orders where the traced item is an ingredient, and where no registrations have been made and no transactions are reported as finished for the order.
Pending transactions	View pending inventory transactions for the traced item that includes the specified tracking dimensions or a blank tracking dimension. You can also view pending inventory transactions for items and tracking dimension combinations, or a blank value, in the trace details.

How many levels can I trace up or down in a BOM or formula?

You can trace one level up or down in a bill of materials (BOM) or formula. For example, if you run a trace on raw materials, you can see the finished product and any co-products. However, if you trace a co-product, the trace details don't include the finished product.

How can I view more details about a document or transaction in the trace details?

On the **Details** FastTab, there are two ways to view more information about a selected document or transaction in the trace details:

- When you select a node in the trace details on the **Details** FastTab, the other FastTabs on the page display information about the document or transaction in the node.
- Open the details page for the document in a selected node by clicking **View details**. For example, if you select a node that describes a production order, and you click **View details**, the **Production orders details** page appears.

Some FastTabs give you access to additional information about the selected node. For example, on the **Non conformances** FastTab, you can click **Inquiries** to investigate whether there is a history of non-conformance. On the **Batch** FastTab, you can click **On-hand list** to view the amount of physical inventory that is currently on hand and any inventory transactions that involve the batch.

Can I run more than one trace and then compare the details?

After you run the trace, you can use the following options on the **Trace from node** button to run a new trace on the transaction in the selected node:

- **Backward** or **Forward** – Start a new trace for the selected node, and overwrite the details of the current trace.
- **New backward** or **New forward** – Start a new trace in a new window, and keep the details of the current trace.

If you want to use the **New backward** or **New forward** option, you must use the **Open in a new window** functionality to have a new trace appear in a new window.

Can I save the trace details?

You can save the information on the **Details** tab as an XML file by clicking **Export** below the *Tracing* action on the Action Pane. In addition to the trace details, the XML file includes the trace criteria, parent node, and on-hand quantity. The capability to save the details of a trace is useful if, for example, you want to attach the information to a quality order or other compliance documentation. You can specify where the file is saved. To view the file immediately, select the **Show document** option. **Note:** The file is always saved, even if you only want to view it. By default, the XML file opens in a browser window. However, you can right-click the file, select **Open with**, and then select the program to use to display the contents.

Can I calculate a balance for a particular item or ingredient?

You can export the information from the summary pages to Microsoft Excel. Open the relevant page, click the **Open in Microsoft Office** icon, and then select **Export to Microsoft Excel**. This functionality is especially useful when you want to calculate a mass balance for an item or ingredient from the **Transactions summary** page. On the **Transactions summary** page, you can filter on the item or ingredient, and optionally on the batch, and then export the information to Excel. In Excel, you can isolate, for example, the on-hand quantity, the quantity that was sold, and the amount that was used in production.

Can I investigate whether there is a history of issues with items or raw materials?

The trace details include information about quality orders and nonconformances that involve the item or raw material. To view a summary of quality orders and nonconformances, click **Quality orders** or **Non conformances** on the Action Pane. **Note:** Destructive quality orders can appear more than one time in the trace details. When a destructive quality order is created for a document, such as a purchase order, it appears for each transaction for that document.

Are there any reporting capabilities that are related to item tracing?

You can generate the **Shipped to customers** report to identify the amount of the item or raw material that has been shipped and the customers that it was shipped to. For an inquiry that is related to compliance, you can generate the report for all customers. For an inquiry that is related to customer service, you can generate the report for a selected customer. If the product was a raw material that was used in the production of a finished item, the finished item is also included. **Note:** If you're using the features for deleting or archiving sales orders, the report results also include any sales orders that have been deleted or archived.

Can I trace coproducts and byproducts?

You can trace co-products, but you can't trace a by-product, because tracking dimensions aren't typically assigned to by-products. When you trace an item, the trace details include any related co-products. A node that contains a co-product includes the word "co-product" in the details. You can also view details about a co-product by selecting the node in the trace details and then clicking the **Production** FastTab.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Trace an item or raw material

2/18/2021 • 2 minutes to read • [Edit Online](#)

This procedure demonstrates how to use item tracing to identify where items or raw materials have been used or are being used. With this procedure, you can identify an item, trace it back to the source, and then trace forward through the production and sale of the finished product. The process can be used to investigate the customers impacted, the sales orders affected, and more. This procedure uses demo data company USP2.

Trace an item backwards using a known batch number

1. In the **Navigation pane**, go to **Modules > Inventory management > Inquiries and reports > Tracking dimensions > Item tracing**.
2. In the **Item number** field, select 'P9100'.
3. In the list, click the link in the selected row.
4. In the **Forward or backward** field, select 'Backward'.
5. In the **Batch number** field, select 'as-12-344-01'.
6. In the list, click the link in the selected row.
7. Click **OK**.

Identify an item, trace it forward, and make an analysis

The top node of the tree represents the on hand quantity of the selected item and batch. You need to expand the nodes of the tree to find the item that the forward trace should be executed on.

1. In the tree, expand 'the nodes described below, and then select the last node'.

Expand: 'P9100 / 1 / 10 / as-12-344-01 ● 2 keg ● 7.00 gal \P9100 ● Picked ● Sales order 000072 ● 12/22/2015 ● -1 keg ● -4.00 gal ● Site=1, Warehouse=10, Batch number=as-12-344-01 \P9100 ● Production B-000050 ● 12/9/2015 ● 7 keg ● 27.00 gal ● Site=1, Warehouse=10, Batch number=as-12-344-01 ● Co-products: P9101' and then select that node.

2. In the tree, expand 'the node described below and then select that node'.

Starting from the node that you've just selected, expand 'M9103 ● Production line B-000050 ● 12/9/2015 ● -160.00 lb ● Size=70, Color=OK, Site=1, Warehouse=10, Batch number=App01' and then select that node.

3. Click **Trace from node**.
4. Click **Forward**.
5. On the **Action Pane**, click **Tracing**.

There are several tracing options which provide information about the customers impacted by the item that you're tracing, and the sales orders related to the item which have and haven't been shipped.

6. Click **Customers**.
7. Close the page.
8. On the **Action Pane**, click **Tracing**.
9. Click **Shipped sales orders**.

10. Close the page.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Merge inventory batches

2/18/2021 • 8 minutes to read • [Edit Online](#)

This article provides information about how to consolidate two or more inventory batches into a merged batch.

When you merge batches, calculations can help optimize the characteristics and batch attributes of the merged batch. After you select the source batches, you can review and change the merged batch before you post it. You can also transfer the batch merge to an inventory journal for approval. Inventory can then be reserved or posted directly from that inventory journal. When you post a merged batch, the inventory is adjusted for the source batches and the merged batch.

Are there any prerequisites?

Yes, there are some things that you must set up before you can use the merge batch tools. The following table describes the prerequisites.

PAGE	DESCRIPTION
Journal names, inventory	You must create a journal name of the type BOM that is used by default when you post batch merges in inventory journals. Optional but recommended: You can specify that reservations should be made automatically when the batch merge is transferred to the inventory journal. Otherwise, there is a risk that the on-hand inventory might be changed after the batch merge details are set up and the journal is posted. To enable automatic reservations for the journal name, select Automatic in the Reservation field.
Inventory and warehouse management parameters	You must specify the default journal name for the inventory journal.

PAGE	DESCRIPTION
Released products	<p>Here are the recommended settings for the item:</p> <ul style="list-style-type: none"> • To automatically generate batch numbers for merged batches, you must assign the released product to a batch number group. You can also enter a batch number manually when you create a merged batch, or select an existing batch number. If you select an existing batch number, make sure that the selected batch hasn't been included in any inventory transactions. • If you're using shelf life or best-before dates for the released product, the dates for a merged batch are calculated based on the selection in the Batch merge date calculation field. The following options are available: <ul style="list-style-type: none"> ◦ Earliest – The calculation is based on the earliest date that is specified for a source batch that is selected for the batch merge. ◦ Latest – The calculation is based on the latest date that is specified for a source batch that is selected for the batch merge. ◦ Manual – No calculation is done. If a date is the same on all source batches, a date is suggested. You can change that date. If a date isn't the same on the source batches, you can manually enter the date.
Batch number group	Optional: To generate a batch number when you create a merged batch, you must assign a batch number group to the released product. Otherwise, you can enter a batch number manually.

When might I want to merge batches of inventory?

Here are some examples of scenarios where it might be useful to merge batches:

- As Sammy is walking through his warehouse, he notices that several batches of the same item have low quantities. He is expecting to receive several new shipments, and he realizes that he can free some floor space by merging the odd quantities into a new batch.
- Sammy is receiving inventory, and he wants to combine the new batch with one that he has already received, to improve the batch attribute value of the existing batch. By doing so you create a new batch.

Can I merge batches across sites and legal entities?

No, you can merge only batches that have the same site and warehouse storage dimensions in one legal entity. However, you can specify a different location and pallet ID for the merged batch.

Can I merge partial quantities?

No, you can merge only the full quantity of batches. The batch merge functionality is intended as an inventory feature, not a production feature.

What if the batches have different batch attribute values?

When you select the source batches to combine in the merged batch, Supply Chain Management verifies whether all the batches have the characteristics or attribute values. When an attribute value is the same, a value

is suggested for the merged batch. You can change that value. Attribute values that aren't the same are left blank for the merged batch, and you can enter those values manually. If the batch attribute type for the attribute value is an integer or a fraction, and the values aren't the same for all the source batches, the value is calculated by using a weighted average calculation. The calculated value is rounded up or down to the nearest increment. If the value is blank for a source batch, the batch and its quantity aren't included in the calculation. **Example** The following example shows a weighted average calculation for a merged batch. Two of the source batches have a blank value for a batch attribute type that is an integer. The following attribute is assigned to the source batches.

ATTRIBUTE	MINIMUM	INCREMENT	MAXIMUM
Grade	3	3	30

The source batches have the following attribute values for the **Grade batch** attribute.

BATCH	QUANTITY	ATTRIBUTE	ATTRIBUTE VALUE
B1	10	Grade	Blank
B2	15	Grade	15
B3	20	Grade	20
B4	25	Grade	Blank
B5	30	Grade	25

When you add these batches as source batches, the following values are assigned to the merged batch.

BATCH	QUANTITY	ATTRIBUTE	ATTRIBUTE VALUE
B6	100	Grade	21

The values and quantities for batches B1 and B4 aren't included in the weighted average calculation. Therefore, here is how the value for the merged batch is calculated.

VALUE	QUANTITY (WEIGHT)	RELATIVE WEIGHT	RELATIVE WEIGHT × VALUE
15	15	0.230769231	3.461538462
20	20	0.307692308	6.153846154
25	30	0.461538462	11.53846154
	Total: 65, which is the sum of the weights		Total: 21.5384615, which is rounded to 21 (the nearest increment)

What if the batches have different batch dates?

If the batches have different batch dates, some of the dates are calculated based on the values in the **Batch dates** group on the **Merged batch** FastTab of the **Batch merge** page. The system calculates values for the fields in the **Batch dates** group. These values include the manufacturing date, expiration date, shelf advice date, and best-before date. The dates are calculated based on settings for the item in the **Item data** field group of the

Released product details page. You can change the values or enter them manually. For all other dates, no calculation is done. The same principle is used for batch attribute values. If a date is the same for all the source batches, that date is suggested for the merged batch. If the date isn't the same for all source batches, the date is blank on the merged batch, and you can enter it manually.

What if the dimensions are different on the batches that I want to merge?

Here is how product dimensions, tracking dimensions, and storage dimensions are handled:

- **Product dimensions** – All product dimensions for the selected item must be the same. You can't merge batches across product dimensions.
- **Tracking dimensions** – A new batch number is automatically generated if a batch number group is specified for the item. If a batch number group isn't assigned to an item, you can select an existing batch or enter the number manually. Serial numbers are transferred from the source batch to the inventory journal lines for the merged batch.
- **Storage dimensions** – The site and warehouse storage dimensions must be the same for all the source batches and the merged batch. However, you can specify a new location and pallet ID for the merged batch.

How does posting work?

Posting works in two ways, depending on whether you use an approval process for journals. You can use the **Transfer to journal** and **Post the batch merge** actions to transfer the batch merge to a journal where it can be verified and posted, or you can post the batch merge directly. The main difference between the two actions is that a transfer to a journal doesn't post the batch merge. Both actions create a new batch if an existing batch isn't selected, update all batch details and attribute values, and create an inventory journal.

- **Transfer to journal** – Transfer the batch merge details to a new inventory journal. If you've set up automatic reservations, the quantities in the source batches are reserved. The details of the batch merge can't be changed. To modify the batch merge, you must delete the journal. The journal can be used as a task that another employee must perform later. The reservation of the batch quantity to the journal line is secured. This allocation lets a quality planner or a warehouse manager create tasks for his or her employees.
- **Post the batch merge** – Post the batch merge directly. This action can be performed after the physical merge has occurred.

You can approve the inventory journal for the batch merge from the **All batch merges** list page. Click **Journal > Post**. After a journal is posted, you can't change the details in the merged batch. After you transfer a batch merge to an inventory journal, you can change the details only if the journal is deleted.

After I merged a catchweight item, why can't I see the catchweight information in the inventory journal?

You can merge batches of catch-weight items just like all other items. However, the catch-weight information doesn't appear in the inventory journal. We recommend that you verify the catch-weight information before you transfer the batch merge to the inventory journal.

NOTE

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Correct inventory tracking information

2/18/2021 • 2 minutes to read • [Edit Online](#)

This procedure walks you through the process of creating and posting an inventory transfer journal in order to correct inventory tracking information. In this example, we'll update the information of a batch controlled item by changing an incorrectly registered batch to another batch. You can walk through this procedure in demo data company USPI, or using your own data. If you use your own data, you need to have an item that's batch-enabled, and it must not be location-controlled. You also need to have an inventory journal name set up for inventory transfers. These tasks would normally be carried out by a warehouse employee.

Create an inventory transfer journal

1. Go to Transfer.
2. Click New.
3. In the Name field, enter or select a value.
4. Click OK.

Create journal lines

1. Click New.
2. In the Item number field, enter or select a value.
 - If you are using USPI, select item M5003.
3. In the Quantity field, enter a number.
4. Click the Inventory dimensions tab.
5. In the Batch number field, enter or select a value.
6. In the Site field, enter or select a value.
7. In the Warehouse field, enter or select a value.
8. In the Batch number field, enter or select a value.

Post the journal

1. Click Post.
2. Click OK.

Check tracing information

1. Click Inventory.
2. Click Trace.
3. Click OK.
 - Using this tracing information you can back trace which batch you corrected inventory from. You can also use the Item tracing page to see this information.
4. Close the page.

Check inventory transactions

1. Click Inventory.
2. Click Transactions.

- Here you can see the transactions that were created when you posted your journal.

NOTE

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Working with serialized items

2/18/2021 • 6 minutes to read • [Edit Online](#)

This topic explains how you can register serial numbers on packing slips or invoices during the sales process. This functionality is useful if a company wants to capture serial numbers for service and warranty purposes, but doesn't have to maintain serial numbers in inventory from receipt to issue.

Many companies just want to capture serial numbers for service and warranty purposes, and don't have to maintain serial numbers in inventory from receipt to issue. In these scenarios, you can register the serial numbers on the packing slips or invoices when products are sold. If products are later returned, you can trace each product to an invoice to determine whether you sold the product, and whether the service or warranty obligations are valid.

You must enable serial numbers for the sales process by selecting the **Active in sales process** option on the **Tracking dimension groups** page. The following events then occur in Supply Chain Management:

- On the **Serial numbers** FastTab, the **Serial number control** option is selected. When this option is selected, you must register one serial number for each item on the packing slip or invoice.
- All selections on the tracking dimension group for serial numbers are cleared, except the **Blank issue allowed** option. You can select the **Blank issue allowed** option to override the serial number control, and allow products to be packed and invoiced without registering serial numbers.

When do I register serial numbers during the sales process?

You can register serial numbers either on the packing slip for a sales order or on the invoice. When you prepare an invoice for a serialized item that was shipped together with a packing slip, you can select which serial numbers on the packing slip to invoice. The number of registered serial numbers must not exceed the quantity of items that were shipped. If you're creating a partial invoice, you can select fewer serialized items than were registered on the packing slip. When you print a packing slip or an invoice, the serial numbers that were registered are included.

Can I enter serial numbers by scanning them, or do I have to type them?

You can either scan or type serial numbers. When you use a scanner, the scan mode determines whether the serial numbers are added to or removed from the list of serial numbers on the invoice or packing slip. If you want to scan serial numbers by using, for example, a hand-held bar code scanner, configure the scanner to send an Enter or TAB command after the serial number. This command will indicate the end of the data stream. Otherwise, you must press Enter or TAB on the keyboard after you scan each serial number.

If I enable serial numbers for the sales process, do I have to register all serial numbers for all items?

The setup of the tracking dimension group that is assigned to the product determines whether serial numbers must be registered for all items on a packing slip or invoice. When you enable serial numbers for the sales process, the **Serial number control** option is automatically selected. You must then register one serial number, or register a blank registration for an unreadable number, for each item on the packing slip or invoice. If you don't want to require a serial number for each item, select the **Blank issue allowed** option on the tracking dimension group that is assigned to the item. You can then register fewer serial numbers than the quantity of items that are being shipped. If you register more serial numbers than the quantity of items that are being

shipped, you won't be able to post the packing slip or invoice.

Can I register serial numbers for partial invoices and partial shipments?

You can create partial invoices and packing slips for sales orders, and register only the serial numbers for the items that those invoices and packing slips include. If you want to create a partial invoice, and you have more than one packing slip for the sales order, you can include serial numbers from more than one packing slip. However, there can be only one packing slip that doesn't include all serial numbers. For example, if you have three packing slips, and each packing slip includes two serialized items, you can't create a partial invoice for one item from each packing slip.

What do I do when a serial number isn't readable?

If a serial number can't be read or scanned, you can create a blank line for the item by clicking **Not readable** on the **Serial numbers** page. If the serial number becomes available later, you can update the invoice or packing slip. For more information, see the next section, "Can I correct or change the serial numbers I have registered for a sales order?"

Can I correct or change the serial numbers that I have registered for a sales order?

Yes, you can correct serial numbers if the following conditions are met:

- **Invoices** – You can change the serial numbers for items that you haven't yet invoiced. The packing slip is then also updated. However, if a sales order line was corrected by registering a negative quantity, you can't change serial numbers for the sales order line.
- **Packing slips** – You can't partially correct a packing slip line that contains serialized items. You must reverse the full quantity for the line. If a packing slip has been canceled or corrected, you don't have to register the reversed serial numbers again when you create a new packing slip for the same serialized items. The numbers that were registered will be used.

Can I view the serial numbers that were shipped together with a specific packing slip, or that were included on an invoice?

Yes, you can run an inquiry on the packing slip journal line or invoice journal line to view a list of all serial numbers that were included in the document.

Can I view the serialized items that I have on hand?

No, you can't view the serialized items that you have on hand, because serial numbers aren't registered for items until the items are sold.

Can I register serial numbers for catchweight items?

No, you can't register serial numbers for catch-weight items during the sales process. Additionally, if a product is set up as a catch-weight item, you can't assign the product to a tracking dimension group that is set up to use serial numbers only during the sales process.

Can I register serial numbers at the retail POS?

Yes, the retail point of sale (POS) will prompt the user to enter a serial number when the user sells an item that is assigned a tracking dimension group that is set up to use serial numbers only during the sales process.

What security roles are required in order to register serial numbers during the sales process?

This functionality is available to all roles that can maintain sales packing slips and sales invoices. The following duties let workers correct serial numbers, and register blank entries for serial numbers that can't be read or scanned:

- Maintain serial number corrections
- Maintain registration of non-readable serial numbers

NOTE

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Inventory on-hand mobile workspace

2/18/2021 • 3 minutes to read • [Edit Online](#)

This topic provides information about the **Inventory on-hand** mobile workspace. This workspace helps you gain insights into reserved and available inventory anytime and anywhere.

This mobile workspace is intended to be used with the Finance and Operations mobile app.

Overview

Typically, companies have multiple shipments and multiple receipts of inventory every day. These movements constantly change the on-hand inventory status. The **Inventory on-hand** mobile workspace lets you see the cross-company on-hand inventory status, so that you can gain the latest insights into inventory data on the mobile device of your choice. Regardless of whether you work in the warehouse, purchasing, sales, manufacturing, or management, or have other roles, you can access on-hand inventory data anytime and anywhere.

The mobile workspace provides an instant view of the on-hand status across facilities. It lets you view on-hand inventory across facilities, current material reservations, and unreserved on-hand inventory. You can also enter item numbers to query on-hand inventory, and can do a filtered search for on-hand products or variants.

Specifically, the mobile workspace provides these features:

- You can search by product number or product name to find products to view the on-hand inventory status for.
- For the selected products, you can view the following information:
 - On-hand inventory per site
 - On-hand inventory per warehouse
 - On-hand inventory per location
 - On-hand inventory per batch (for batch-controlled products)
 - On-hand inventory per inventory status
- Product on-hand inventory is shown in the following ways:
 - By physical inventory (This view represents the total amount.)
 - By physical reserved (This view represents the reserved amount.)
 - By available physical (This view represents available amount that has no reservations.)

Prerequisites

The prerequisites differ, based on the version of Supply Chain Management that has been deployed for your organization.

Prerequisites if you use Supply Chain Management

If Supply Chain Management has been deployed for your organization, the system administrator must publish the **Inventory on-hand** mobile workspace. For instructions, see [Publish a mobile workspace](#).

Prerequisites if you use Platform update 3 or later

If Platform update 3 or later has been deployed for your organization, the system administrator must complete the following prerequisites.

PREREQUISITE	ROLE	DESCRIPTION
Implement KB 4013633.	System administrator	KB 4013633 is an X++ update or metadata hotfix that contains the Inventory on-hand mobile workspace. To implement KB 4013633, your system administrator must follow these steps. <ol style="list-style-type: none"> 1. Download the metadata hotfix from Microsoft Dynamics Lifecycle Services (LCS). 2. Install the metadata hotfix. 3. Create a deployable package that contains the SCMMobile model, and then upload the deployable package to LCS. 4. Apply the deployable package.
Publish the Inventory on-hand mobile workspace.	System administrator	See Publish a mobile workspace .

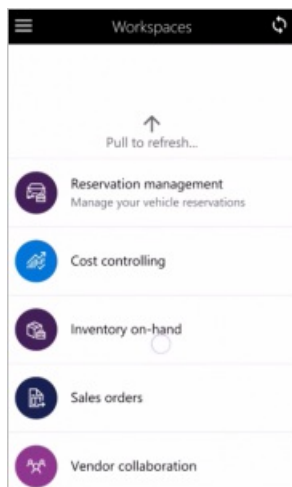

Download and install the mobile app

Download and install the Finance and Operations mobile app:

- [For Android phones](#)
- [For iPhones](#)

Sign in to the mobile app

1. Start the app on your mobile device.
2. Enter your Dynamics 365 URL.
3. The first time that you sign in, you're prompted for your user name and password. Enter your credentials.
4. After you sign in, the available workspaces for your company are shown. Note that if your system administrator publishes a new workspace later, you will have to refresh the list of mobile workspaces.

View the on-hand inventory for a product by using the Inventory on-hand mobile workspace

1. On your mobile device, select the **Inventory on-hand** workspace.
2. Select **Check on-hand for an item**. You see a list of the products that are loaded into your app for offline use. By default, 50 items are loaded, but a developer can change this number. For more information, developers should see [Mobile platform](#).
3. If your item isn't in the list, select **Search more**. Search by product number, or switch to a search by product name.
4. Select a product. If the item has an image, the image is shown.
5. Select one of the following options to view the status of on-hand inventory:
 - View on-hand per site
 - View on-hand per warehouse
 - View on-hand per location
 - View on-hand per batch (for batch-controlled products)
 - View on-hand per inventory status

Product on-hand inventory is shown in the following ways:

- By physical inventory (This view represents the total amount.)
- By physical reserved (This view represents the reserved amount.)
- By available physical (This view represents the available amount that has no reservations.)

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Troubleshoot inventory operations

2/18/2021 • 7 minutes to read • [Edit Online](#)

This topic describes how to fix issues that you might encounter while you work with inventory operations.

I can't find the "Workflow" drop-down dialog box for inventory journals.

Issue description

You can't find the **Workflow** drop-down dialog box on the journal page, or related workflow operations aren't available.

This issue can occur for three reasons, as described in the following subsections.

Issue resolution 1

If the issue applies to all users, it might be occurring because the approval workflow hasn't been assigned to the journal name. To fix the issue, follow these steps.

1. Go to **Inventory Management > Setup > Journal names > Inventory**.
2. In the list pane, select a journal name to open its settings.
3. On the **General** FastTab, set the **Approval workflow** option to *Yes*. If you're prompted to confirm the change, select **Yes**.
4. In the **Workflow** field, select the workflow that you want to use for the selected journal name.

Issue resolution 2

If your workflow uses customized code, issues might occur after you upgrade the system. For example, in the journal workflow, the **Submit** button might be grayed out so you can't select it to approve a submission.

If the **Submit** button is grayed out, your workflow might have been customized, which means the method of the workflow, `canSubmitToWorkflow()` in `FormDataUtil`, has been extended. To fix this issue, change the way that you extend the method of the `canSubmitToWorkflow()` to use the structure in the following example.

```
[ExtensionOf(formStr(InventJournalMovement))]  
public final class InventJournalMovement_extension  
{  
    public boolean canSubmitToWorkflow()  
    {  
        boolean ret = YourLogicOfCanSubmitToWorkflow();  
  
        return ret;  
    }  
}
```

Issue resolution 3

If the issue applies only to a few specific users, those users might not have the security privileges that are required to run workflow operations on inventory journals. Verify that each affected user has the *Maintain inventory journal workflow* security privilege. By default, this privilege is assigned to a duty that has same name, and that duty is applied to the *Warehouse worker* and *Warehouse manager* roles.

My inventory journal remains in system-locked status, and the

workflow batch job doesn't work.

Issue description

One of your inventory journals is locked by some operation and isn't being released. For example, if an unknown error occurs during posting (which is a system lock operation), the journal might remain in system-locked status. In this case, the workflow work item handler will throw an error while it does lock validation.

Issue resolution

Sign in to the SQL Server instance for Supply Chain Management, and check whether

`InventJournalTable.SystemBlocked` is set to `1`. If it is, make sure that the journal should not be in locked status, and then reset `InventJournalTable.SystemBlocked` to `0`.

My inventory journal workflow is never completed, and the journal can't be edited or posted.

Issue description

After you submit a journal approval workflow, workflow processing stops responding, and you can't edit or process your journals.

Issue resolution

There are several reasons why workflow processing might not be completed. Check for the following issues:

- Go to **Inventory management > Setup > Inventory management workflows**, and review the configuration of the affected workflow. For more information, see [Inventory journal approval workflows](#).
- The workflow might be encountering an exception or error. Review the work item history of the affected workflow to see whether it includes an application error that terminates the workflow.
- The inventory journal can be updated or edited only if it's approved. If recall is active, you can try to recall the journal. Execution of the workflow batch job might be suspended for multiple reasons. Some of these reasons might be caused by the workflow framework issue.

Inventory journal workflow conditions apply only at the journal level, not at the line level

Issue description

You might experience this issue if, for example, you try to set up an inventory journal workflow condition on the cost amount. You set up the condition so that step 1 is run only when the cost amount is less than 100. You then set up another condition so that step 2 is run only when the cost amount is more than or equal to 100. Then, when the workflow is run, the workflow history shows only one line, and the first condition is always evaluated as *true*, regardless of the value that is submitted.

Issue workaround

In the current release, inventory workflow conditions apply only at the journal level, not at the line level. This behavior is by design. We recommend that you set your condition criteria only on journal-level attributes.

The filter pane on the On-hand list page doesn't filter results as I expect.

Issue description

The filters in the filter pane on the **On-hand list** page don't filter results as you expect.

Issue resolution

This behavior is by design.

The **On-hand** listpage is assembled from a detailed on-hand inventory table that includes all available dimensions. However, the list on this page is a summary. Therefore, it might combine rows from the source table by aggregating values according to the dimensions that are shown.

Filters that are set up in the filterpane apply to the source table, not to the aggregated list. This behavior can sometimes produce unexpected results, as shown in [these examples](#).

However, the [filters that are provided in the grid](#) do apply to the aggregated list. These filters include both the QuickFilter at the top of the grid and the filter for each column heading.

The unit and unit quantity aren't working correctly in the inventory journal.

Issue description

You might encounter one or both of the following issues when you work with units and quantities in an inventory journal:

- You don't see units or unit quantities in the inventory journal while a unit of conversion is set up for the released product, and you can't change the unit in the inventory journal.
- You see the **Quantity** and **Unit** fields in the inventory journal, but you don't see the **Unit quantity** field. If you change the unit, enter a quantity, and post the journal, the journal still shows the original unit of measurement for that quantity.

Issue resolution

To fix this issue, follow these steps.

1. In the **Feature management** workspace, make sure that the *Using unit of measure and unit quantity in inventory journals* feature is turned on. This feature adds the **Unit** and **Unit quantity** fields to the journal.
2. After the feature is turned on, use the **Quantity**, **Unit quantity**, and **Unit** fields in the following way:
 - **Quantity** – Specify the quantity by using the default unit that is defined for the released product. However, the default unit itself isn't shown here. If a conversion is set up between the default unit and the unit that is selected in the **Unit** field, the **Quantity** field is automatically updated, based on the selections in the **Unit quantity** and **Unit** fields.
 - **Unit quantity** – Specify the quantity by using the unit that is selected in the **Unit** field.
 - **Unit** – Select the unit to apply to the value in the **Unit quantity** field.

I receive the following error message: "Maximum number of decimals for the stock keeping unit is 0."

Issue description

When you try to post an inventory transaction or an inventory reservation, you receive the following error message: "Maximum number of decimals for the stock keeping unit is 0."

This issue occurs when the inventory transaction quantity is specified as a decimal value that is below the level of precision that the field supports. For example, a quantity of *0.5* has been specified for an inventory transaction, but only integer quantities are supported. Therefore, the value should be *1* instead of *0.5*.

Issue resolution

1. Run the following script on your SQL Server instance to round quantities in the inventory transactions. This script will correct values in the **inventTrans** table.

```
update it set it.QTY = round(it.qty, decimalPrecisionValue) from inventtrans it where
it.DATAAREAID='XXXX' and it.PARTITION=XXXXXX and it.qty <> round(it.qty, decimalPrecisionValue) and
exists (select 'x' from INVENTTABLEMODULE a, unitofmeasure b where a.unitid =b.SYMBOL and
a.partition=it.partition and a.PARTITION=b.PARTITION and MODULETYPE =0 and
b.DECIMALPRECISION=decimalPrecisionValue and a.DATAAREAID='XXXX' and a.ITEMID =it.ITEMID and
it.DATAAREAID=a.DATAAREAID)
```

2. Run an on-hand consistency check where the **fix error** option is turned on. This check will correct values in the **inventSum** table.

IMPORTANT

We strongly recommend that you carefully edit the script as required for your environment, test it in a test environment, and then check the resulting data before you run the script in a production environment.

Outbound process overview

2/18/2021 • 2 minutes to read • [Edit Online](#)

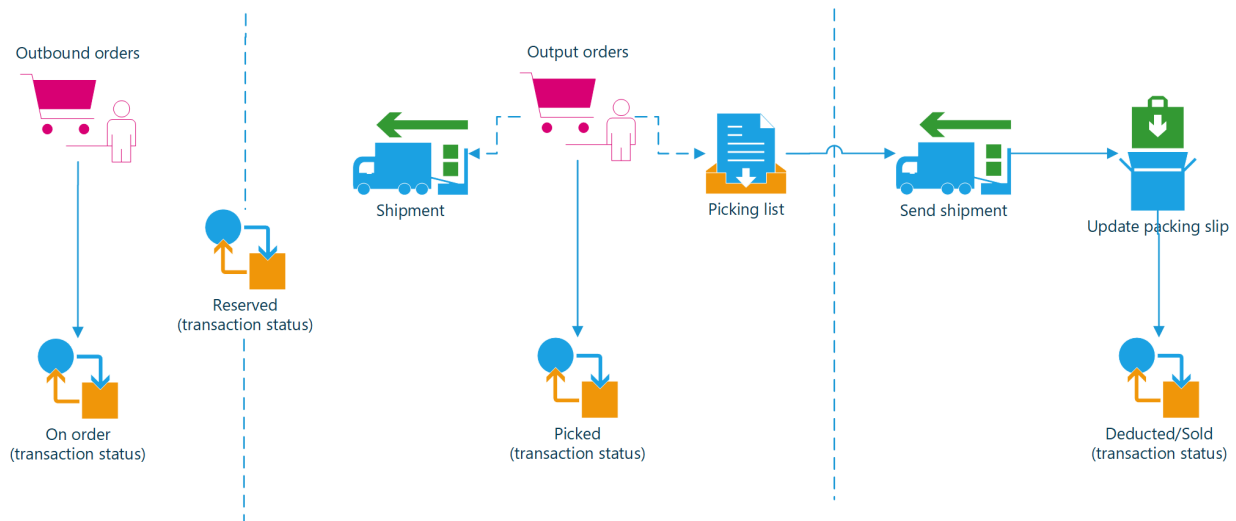

This topic provides an overview of the outbound process in Inventory management.

Output orders

Output orders are used to link sales order lines and transfer order lines with the outbound picking processes that use picking lists.

When picking lists are generated from either sales orders or transfer orders, output orders and shipments are automatically created. A picking list has a one-to-one relationship with a shipment. The transfer order shipment or the sales order packing slip can be processed from the shipment.

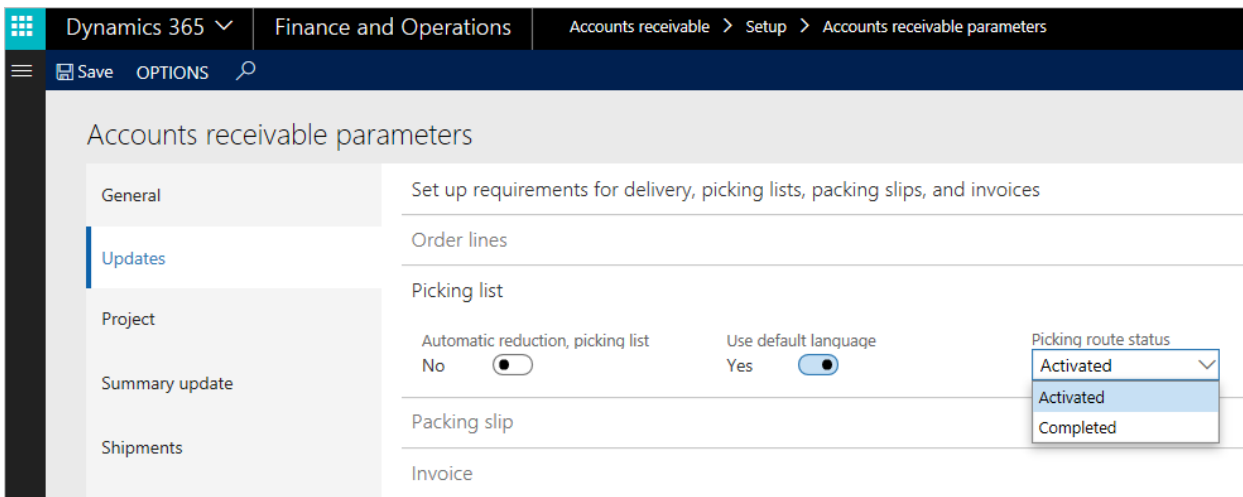

The following diagram shows an overview of the process for outbound orders.

You can set up outbound rules to define how the program should handle the outbound process. You can use these rules to control the shipment process. In particular, you can use the rules to control which stage in the process a shipment can be sent during. The following settings define how the outbound processes are handled.

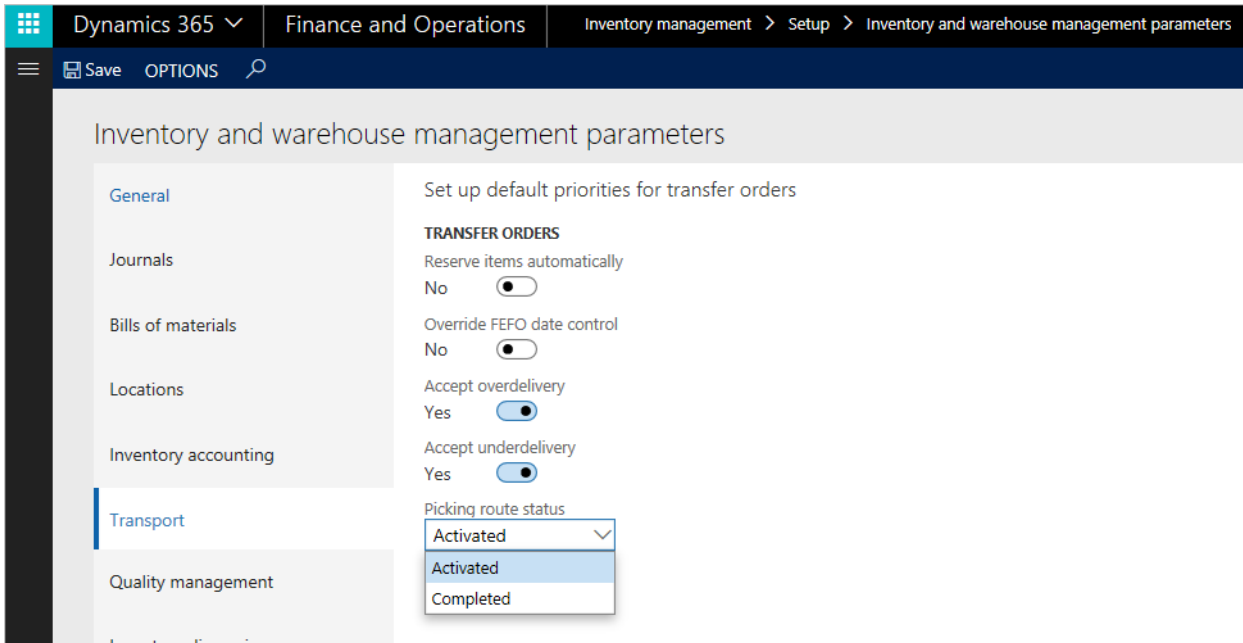

Picking route status for sales and transfer orders

Go to **Account receivable > Setup > Account receivable parameters**, and then, on the **Updates** tab, select a value in the **Picking route status** field.

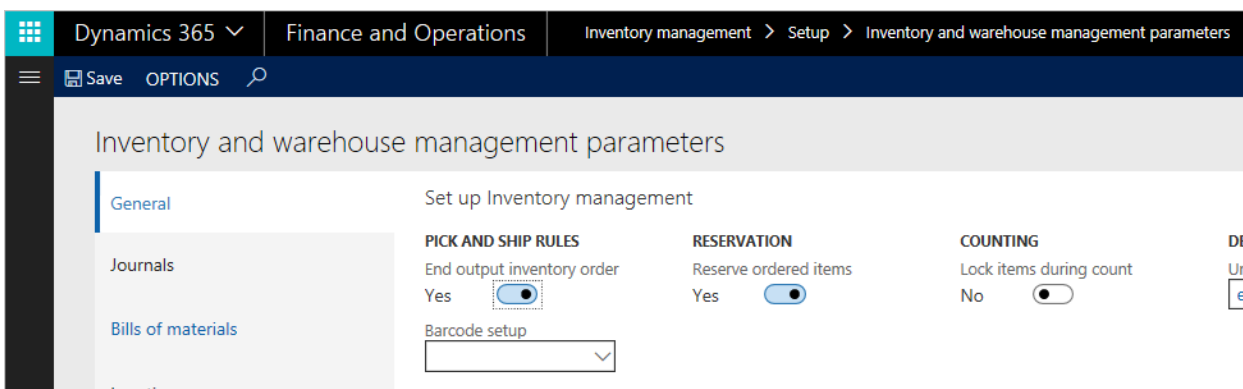

If the **Picking route status** field is set to **Completed**, the picking process occurs automatically as part of the process of generating picking lists. If the field is set to **Activated**, the picking list lines must be manually updated.

The same setup applies to transfer orders. Go to **Inventory management > Setup > Inventory and warehouse management parameters**, and then, on the **Transport** tab, select a value in the **Picking route status** field.

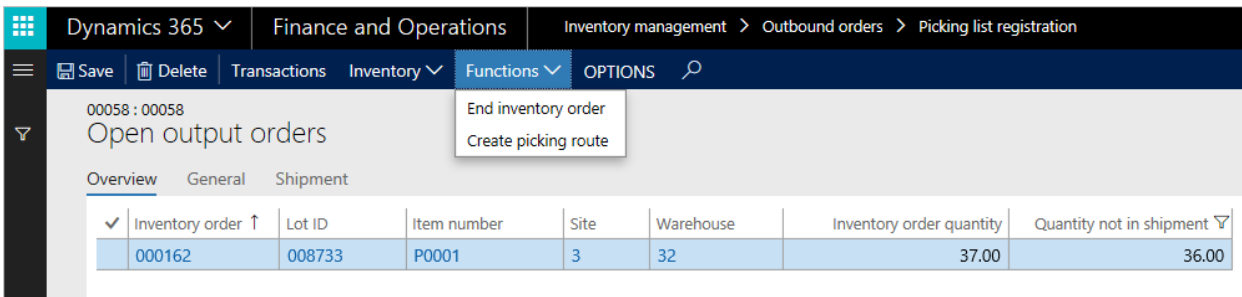

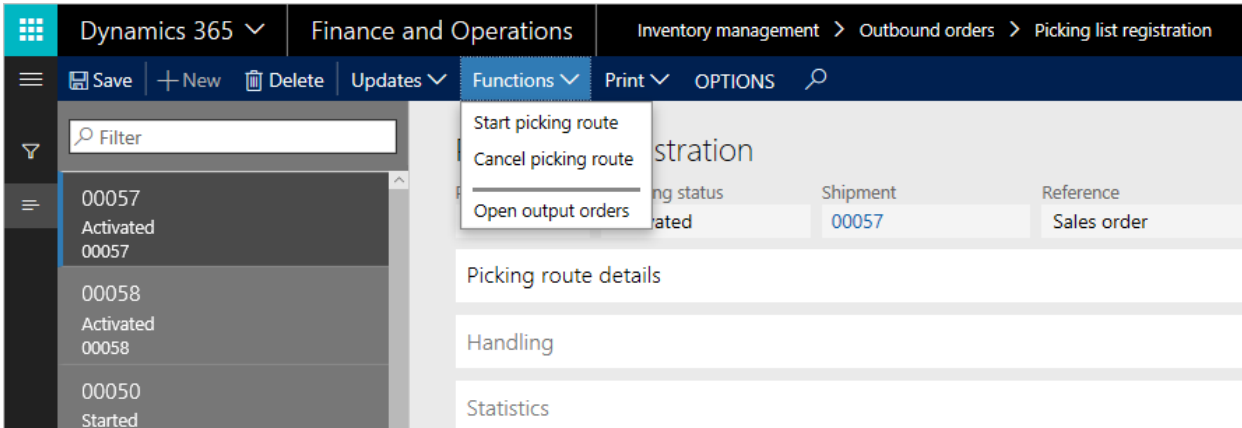

End output inventory orders

Go to **Inventory management > Setup > Inventory and warehouse management parameters**, and then, on the **General** tab, set the **End output inventory order** option.

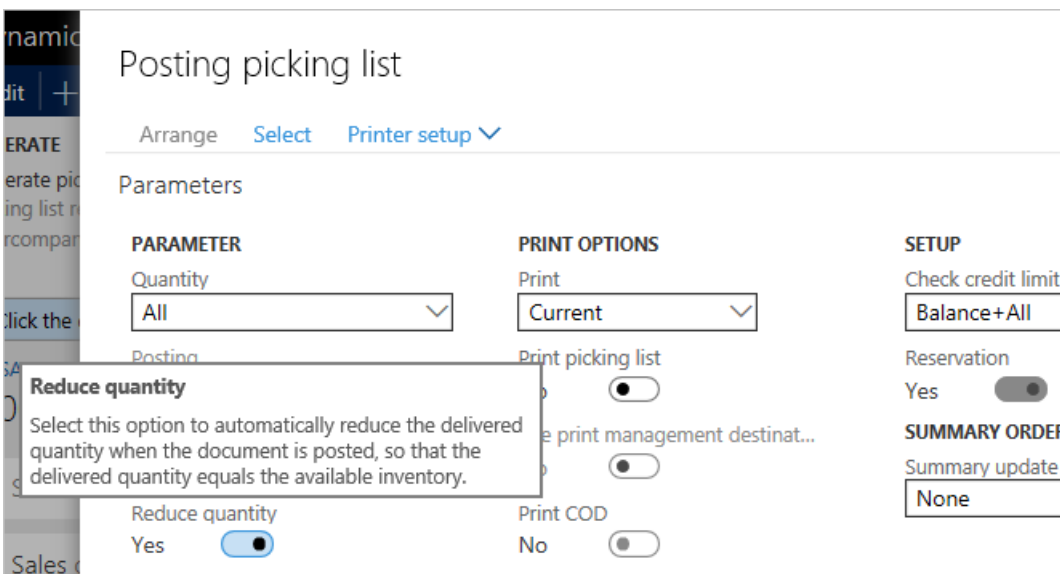

When the warehouse worker reduces the picking list quantities, then the corresponding inventory order quantities will be removed from the shipment. When the picking list is updated at a point in time, the remaining quantities get reported back to the order if the **End output inventory order** option is set to **Yes**. If the **End output inventory order** option is set to **No**, the remaining quantities are kept as an open output order quantity and must be added to a new picking list as part of the **Open output orders** functionality.

Reduce quantity

The third parameter that you can use as part of the process of generating picking lists is the **Reduce quantity** parameter. The setting of this parameter works together with the **Reservation** setting that triggers a reservation process as part of the release to the warehouse.

Example of an outbound process for a sales order

For this example, there is a sales order for two items. During picking list generation, you select the **Reduce quantity** parameter. Therefore, you release and create picking lines only for available on-hand inventory. The picking must be reported via a registration process for picking lists (**Picking route status = Activated**).

The inventory that hasn't already been reserved is reserved during picking list generation. The unavailable inventory can be either removed from the sales order or released to the warehouse for outbound processing later, when inventory is available for picking.

Picking list registration

Picking route: 00065 | Handling status: Started | Shipment: 00065 | Reference: Sales order

Picking route details

Handling

Statistics

Delivery

Customer: US-001 | Requested ship date: 9/11/2017 | Mode of transport: 10

Lines

Select	Handling status	Item number	Pick quantity
<input type="checkbox"/>	Picked	D0001	1.00
<input checked="" type="checkbox"/>	Activated	D0003	1.00

As soon as all the picking lines have been picked on the **Picking list registration** page, the associated shipment is completed. The process for sales order packing slips can then be initialized based on the picked inventory.

SHIPMENTS

Reserve inventory quantities

2/18/2021 • 5 minutes to read • [Edit Online](#)

This topic describes the different options that are available for reserving inventory.

You can automatically reserve inventory quantities for a specific sales order. This means that reserved inventory cannot be withdrawn from the warehouse for other orders unless the inventory reservation, or part of the inventory reservation, is canceled.

There are several reasons for reserving inventory:

- First ordered, first delivered, which means that customers get available items in the same order in which they place their orders.
- Shortage of items due to a long or unknown delivery time from the vendor. You might want to make sure that certain customers or orders get delivery of the first-available items.
- Certain customers and certain types of orders have first priority for delivery.
- Items with serial or batch numbers. You can mark certain items that have been or will be delivered to specific orders.
- Specially ordered items that are reserved for certain orders.
- Production orders. For example, you can mark items that are produced for and adjusted to specific orders.

Inventory can be reserved automatically when a new order line is created, or inventory can be reserved manually on the individual orders. It's also possible to reserve inventory at different stages in a production process. Only stocked products can be reserved. Services cannot be reserved, because there is no on-hand inventory. Both physical on-hand inventory and ordered, but not yet received, inventory can be reserved. If a larger quantity is reserved than what the on-hand inventory contains, a message displays that you cannot reserve such a large quantity. You can then either reserve the quantity anyway, or change the ordered quantity. The quantity can be either reserved or changed. If more items are reserved than are available, the shortage is covered the next time that items are available for delivery.

Inventory reservation policies

Inventory reservation policies are set on the **Item model groups** page, the **Inventory and warehouse management parameters** page, and the **Production parameters** page.

Policies on the Item model groups page

The **Inventory policies** section contains the following reservation policies.

Reservation policy	Description
FIFO date-controlled	If you select the FIFO date-controlled option, the inventory reservation is controlled by a sorting date according to the FIFO principle. Batches are reserved based on the earliest date of receipt of items, according to the principle of first in, first out (FIFO).

Backward from ship date	This option becomes available if you have selected the FIFO date-controlled option. If you select Backward from ship date , the inventory is reserved backward from the desired ship date according to the principle of last in, first out (LIFO). If no receipts are available before the ship date, a FIFO reservation is used.
Item sales reservation	Determines whether item reservation is manual or automatic. If a reservation is automatic, inventory is reserved when order lines are created. It's possible to make reservations at the item number level for BOMs (Automatic option), or for the individual elements of a BOM (Explosion option). The default value for Item sales reservation may be inherited from Accounts receivable parameters . On that page, the value is set in the Reservation field in the Sales default values section on the General tab.
Same batch selection	Same batch reservation lets you reserve inventory for a sales order line against a single batch of inventory. If you want to use this option, you must also set the Consolidate requirement option to Yes . There are additional settings that are required for the tracking dimension group and storage dimension group. For more information, see Reserve the same batch for a sales order .
Consolidate requirement	This option is similar to the Same batch selection option, and it consolidates inventory that's reserved for sales order lines into a single requirement.
FEFO date-controlled	This option allows you to reserve batches that are close to their expiration date or best before date. You also need to set the Pick criteria field to select either Expiration date or Best before date .

Example for FIFO date-controlled and Backward from ship date

In this example, on-hand inventory for item number A exists for three different batch numbers.

ITEM NUMBER	BATCH NUMBER	QUANTITY	DATE
A	1000	5	February 2, 2016
A	1001	3	January 1, 2016
A	1002	7	March 3, 2016

A sales order that should be automatically reserved and delivered on April 4, 2016, reserves the following batch:

- If both the **FIFO date-controlled** and **Backward from ship date** check boxes are cleared, batch 1000 is reserved because it is the batch with the lowest number.
- If the **FIFO date-controlled** check box is selected and the **Backward from ship date** check box is cleared, batch 1001 is reserved because it is the batch with the first date of receipt (FIFO).
- If both the **FIFO date-controlled** and **Backward from ship date** check boxes are selected, batch 1002 is reserved because it is the batch receipt closest to the sales order ship date.

Policies on the Inventory and warehouse management parameter page

There are two options related to reservations on the **Inventory and warehouse management parameters**

page:

- The **Reserve ordered items** option on the **General** tab lets you to reserve item receipts that are ordered against item issues in Accounts receivable, Project management and accounting, and Production control. If you clear this option, you can only reserve items that have been physically received. If a particular item has been set up to accept negative inventory, this field is not relevant.
- The **Reserve items automatically** option on the **Transport** tab determines the default setting if items are automatically reserved for transfer orders. The default setting can be overridden on individual transfer orders.

Inventory reservation policies on the Production parameters page

The value of the **Reservation** field on the **General** tab on the **Production parameters** page determines the default point in the production process at which inventory should be reserved. For example, inventory could be reserved when work is scheduled, or when work is started.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Reserve the same batch for a sales order

2/18/2021 • 2 minutes to read • [Edit Online](#)

This article explains how to set up a product to allow reservation of inventory against a single batch of inventory.

Same batch reservation lets you reserve inventory for a sales order line against a single batch of inventory. For example, a customer who orders wallpaper can request that the whole order be filled from the same batch or lot, to avoid inconsistencies among the rolls. To set up a product to use same batch reservation, the following settings must be active in the item model group, tracking dimension group, and storage dimension group that you assign to the product:

- **Item model groups** – The item model group must have the **Same batch selection** and **Consolidate requirement** fields selected in the **Reservation** field group for inventory policies.
- **Tracking dimensions groups** – The tracking dimension group must have the **Coverage plan by dimension** field selected for the batch number.
- **Storage dimensions groups** – The storage dimension group must have the **Coverage plan by dimension** field selected for **Site** and **Warehouse**.

When you reserve inventory for a product on a sales order line that is set up for same batch selection, the system tries to reserve the ordered quantity from a single inventory batch. Any specific batch attribute requirements are also considered. If the quantity can't be filled from a single batch, the **Same batch reservation conflict** page appears. This page describes the issues and also the actions that you can take to continue with the reservation. The following conditions might prevent the batch from being reserved:

- The batch disposition code has **Block reservation** for sales flagged as **Blocked**.
- The batch has expired, based on the expiration date and any applicable customer sellable days. The item can still be considered for reservation if the item model group for the item is First Expiry First Out (FEFO) date-controlled, and if the best-before date is selected as the pick criterion.
- The batch doesn't have enough shelf-life days remaining, based on the expiration date and best-before date, plus any customer sellable days.

For items associated with a storage dimension group that has **Use warehouse management processes** enabled, you can reserve specific batch numbers by using a reservation hierarchy with the batch number inventory dimension defined above the location dimension. The **Batch reservation** page for sales and transfer order lines also lets you select and reserve multiple lines based on the available batch numbers. For more information about what to do if you are using a reservation hierarchy that has the batch number dimension below the location, see [Flexible warehouse-level dimension reservation policy](#).

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Inventory close

2/18/2021 • 5 minutes to read • [Edit Online](#)

As part of the process to settle issue transactions with receipt transactions, you can also choose to have the general ledger updated to reflect the adjustments that have been made.

The inventory close process settles issue transactions to receipt transactions, based on the inventory valuation method that is selected in the item's item model group. As part of the settlement process, you can specify that the general ledger should be updated, so that it reflects the adjustments that have been made. However, until inventory close or recalculation has been run, issue transactions are posted at the calculated running average cost price.

After inventory close, you can no longer post in periods that are before the inventory closing date that you set, unless you reverse a completed inventory close process. For example, if inventory close is run for the period that ends on January 31, you can't post transactions that have a date that is earlier than January 31.

Items in inventory are assigned to one of two inventory types: item or service. Inventory close performs the same functions for both types. However, for service items, inventory close still settles issues to receipts.

How often the inventory close process is run varies by company. However, transaction volume should help determine how often you decide to run inventory close. In general, most companies run inventory close as part of their month-end close and reconciliation procedures.

Inventory recalculation and the general ledger

If adjustments to inventory and the general ledger are required during a month or other inventory period, you can run inventory recalculation instead of inventory close. Inventory recalculation makes adjustments but doesn't make settlements to inventory transactions.

During inventory recalculation, on-hand inventory is adjusted, inventory transactions are adjusted, and inventory recalculations and inventory closes are run. These tasks affect any ledger account that is linked to the original inventory transaction.

Example

When you create a purchase order from a sales order, the general ledger accounts that are used for the original sales order are updated. Even if the ledger accounts for the item group that is assigned to the item were changed after the sales order was posted, and an inventory recalculation created an adjustment amount, the adjustment amount is posted to the original ledger accounts. The adjusted amount isn't posted to the new ledger accounts that are assigned to the item.

After the update is completed, you can review the ledger voucher that is posted because of one of these tasks.

1. On the **Closing and adjustment** page, on the **Overview** tab, select the update to review.
2. Click **Details**, and then select **Voucher**.

Effects of the inventory close process on the general ledger

Several of the tasks that you can perform on the **Closing and adjustment** page cause an update to general ledger. For example, the general ledger is updated when you make inventory on-hand adjustments, make inventory transaction adjustments, run inventory recalculation, and run inventory close.

The ledger accounts that are updated because of these tasks are linked to the original inventory transaction. For

example, if a sales order is settled to a purchase order, the general ledger accounts that were used for the original sales order are adjusted. This behavior occurs even if the ledger accounts for the item group that is assigned to the item have changed since the sales order was posted. After inventory close creates a settlement amount, the settlement amount is still posted to the original ledger accounts, not to the new ledger accounts that are assigned to the item. The general ledger might also be updated if you reverse an inventory close.

NOTE

- Inventory close is a required step in the month-end closing procedure for all inventory models except moving average. You will be warned if you try to close a financial period without first performing the inventory close as of the period end date.
- Before you run the closing procedure, you can view a list of items that can't be settled during the update.
- We recommend that you run inventory close during off-peak hours, to distribute computing resources more evenly.

The inventory close log

After the inventory close process has been completed, a message in the message center might inform you that a unit cost price might be incorrect because a transaction could not be fully settled.

Before this message is shown, the system reports the item number and the affected transaction. The message informs you that the cost amount that is used for this transaction wasn't updated because of the inventory close. This message appears when a transaction of the issue type can't be settled.

During the inventory close process, the system checks each financial dimension to see whether there are more issues than receipts up to the specified closing date. This type of imbalance can occur when an inventory transaction from a purchase order isn't fully posted financially, either because the vendor invoice hasn't been received, or because bill of materials (BOM) components that are included in a production on a higher level aren't financially posted. (The sub-production isn't cost-calculated.) In this case, the subsequent close won't adjust all issues to the correct cost price, because not enough receipt information is available.

For each run of the closing procedure, the system indicates whether a log that contains the warnings is stored and can be viewed.

If you receive many warnings in the message, we recommend that you perform the following actions:

- Update receipts financially.
- Advance the closing date.
- Reevaluate the business procedures.

In some circumstances, you might not be able to do anything about the warnings. For example, if marking is used, and the marked purchase order has a financial date that is after the closing date, the closing date can't be changed.

Reversing a completed inventory close

Occasionally, you might have to reverse a completed inventory close to return settlements to the state that they had before adjustments were made. When you reverse a completed inventory close, inventory is reopened to enable posting in the period that the inventory close covers. Related changes might also be made in the general ledger. After you've finished making adjustments, you can run inventory close again for the period that you're working with.

NOTE

Only the last inventory period that was closed can be reopened. To reverse an earlier inventory close, you must reverse each subsequent inventory close one at a time, starting with the most recent close.

Running average cost price

2/18/2021 • 4 minutes to read • [Edit Online](#)

The inventory close process settles issue transactions to receipt transactions, based on the inventory valuation method that is selected in the item's item model group. However, before inventory close is run, the system calculates a running average cost price that is typically used when issue transactions are posted.

The system estimates this running average cost price for an item by using the following formula:

Estimated price = (Physical amount + Financial amount) ÷ (Physical quantity + Financial quantity)

Using the running average cost price

The following table shows when the system posts inventory transactions by using the running average cost price, and when it uses the cost price that is defined on the item master record instead.

CONDITION	THE SYSTEM USES THE ESTIMATED RUNNING AVERAGE COST PRICE	THE SYSTEM USES THE COST PRICE THAT IS DEFINED ON THE ITEM MASTER
Both the numerator* and denominator** are positive.	Yes	No
The numerator*, denominator**, or both are negative.	No	Yes
The denominator** is 0 (zero).	No	Yes

* Numerator = (Physical amount + Financial amount) ** Denominator = (Physical quantity + Financial quantity)

Note: If the **Include physical value** option isn't selected for an item, the system uses 0 (zero) for both the physical amount and the physical quantity. For information about this option, see [Include physical value](#).

Avoiding pricing amplification

On rare occasions, the system prices several issues before it has enough receipts to base the price on. This scenario can cause estimates of the running average cost price to be overly inflated. However, there are steps that you can take to avoid pricing amplification, or to reduce its impact when it does occur. **Scenario** The following transactions occur for an item that you've selected the **Include physical value** option for:

1. You financially receive a quantity of 100 at USD 100.00.
2. You financially issue a quantity of 200.
3. You physically receive a quantity of 101 at USD 202.00.

When you examine the estimated running average cost price for the item, you expect a cost price of USD 1.51. Instead, you find an estimated running average of USD 102.00, which is based on the following formula:
Estimated price = $[202 + (-100)] \div [101 + (-100)] = 102 \div 1 = 102$ This pricing amplification occurs because, when 200 items are issued financially in step 2, the system must price 100 of the items before it has any corresponding receipts. This situation causes negative inventory. The system then estimates a unit price of USD 1.00, as we might expect. However, when the corresponding 100 receipts arrive, they are at a unit price of USD 2.00 each.

Note: Although the issues create negative inventory, inventory is positive when the issue price is calculated.

Therefore, the running average cost price is used instead of the price on the item master. At this point, the system has an inventory value offset of USD 100.00. Although that offset was built up over 100 pieces, where there was a unit offset of USD 1.00 each, we now have only one piece in inventory. Therefore, the offset of USD 100.00 is allocated to this one piece. The result is the overly inflated estimated cost price.

Note: For comparison, notice that if steps 2 and 3 are reversed in the scenario, 200 items will be issued at a unit price of USD 1.51, and one piece will remain at a unit price of USD 1.51. Because this pricing amplification scenario can occur when negative inventory is involved, it's difficult to avoid in the following cases:

- You must estimate issue prices on the on-hand value and quantity.
- You must adjust the on-hand value and quantity on issues and receipts.
- Your business model allows you to send out, or price, more pieces than you have.
- You must accept any receipt value and quantity that are submitted to you.

However, if your business model allows for the following practices, they can help you avoid the negative quantities that make the pricing amplification scenario possible:

- If you select the **Include physical value** option for an item, clear the **Physical negative inventory** check box on the **Item model groups** page.
- If you do *not* select the **Include physical value** option for an item, clear the **Financial negative inventory** option on the **Item model groups** page.

Additionally, consider that the maximum offset in your physical inventory value is limited by the number of physical transactions, and the difference between physical and financial prices. Provided that all physical transactions are eventually updated financially, the physical value can't rise to extreme levels. Finally, note that the amplification effect decreases significantly when the accumulated offset is spread out over several on-hand pieces instead of just one.

Adjust on-hand inventory cost values

2/18/2021 • 2 minutes to read • [Edit Online](#)

Use the Adjustment of on-hand inventory page to adjust the cost value of the on-hand inventory quantities after an inventory close process is run.

You can use the **Adjustment of on-hand inventory** page to adjust the cost value of on-hand inventory quantities after an inventory close process is run. **Note:** To open the **Adjustment of on-hand inventory** page, on the **Closing and adjustment** page, select the record of a completed inventory close process, and then click **Adjustment > On-hand**. **Example:** You have the following transactions in February:

- February 1: An inventory financial receipt for a quantity of 2 at a cost of USD 10.00
- February 5: An inventory financial receipt for a quantity of 1 at a cost of USD 13.00
- February 19: An inventory financial issue for a quantity of 1 at a running average cost of USD 11.00

This item was set up with the first in, first out (FIFO) inventory model, and inventory close was performed as of February 28. The financial issue transaction of USD 11.00 will be settled against the financial receipt that is dated February 1, and an adjustment of USD 1.00 will be made. The following inventory receipts will then contain open inventory quantities:

- February 1: A quantity of 1 at a cost of USD 10.00
- February 5: A quantity of 1 at a cost of USD 13.00

To set the cost of these two items to USD 15.00, use the on-hand adjustment option to adjust the open on-hand quantities as of the last inventory close period. **Note:** The posting date of the on-hand adjustment transaction will be the date of the last inventory close. This date can't be modified.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Track running average cost per inventory dimension

2/18/2021 • 2 minutes to read • [Edit Online](#)

An inventory dimension group is attached to every inventory item. Therefore, the running average cost price of an item is calculated based on the selected inventory dimensions that are being tracked financially.

There are three types of inventory dimensions: product, storage, and tracking. Product dimensions include configuration, size, and color. Product dimensions are always tracked financially. Storage and tracking dimensions include site, warehouse, location, inventory status, license plate, batch number, and serial number. You can decide which storage and tracking dimensions are tracked financially.

Example 1

If the storage dimension group that is attached to the item is financially tracked by warehouse, the running average cost price is calculated per warehouse. The following purchase orders have been invoiced:

- A purchase order for a quantity of 2 at a cost price of USD 10.00 has been invoiced for warehouse GW.
- A purchase order for a quantity of 3 at a cost price of USD 12.00 has been invoiced for warehouse GW.
- A purchase order for a quantity of 5 at a cost price of USD 15.00 has been invoiced for warehouse MW.

The running average cost price for warehouse GW is USD 11.20, and the running average cost price for warehouse MW is USD 15.00. A sales order invoice is posted for warehouse GW. The value of the inventory and the cost of goods sold (before inventory close is run and without marking) is USD 11.20. Another sales order is posted for warehouse MW. The value of the inventory and the cost of goods sold (before inventory close is run and without marking) is USD 15.00.

Example 2 If the storage dimension group that is attached to the item is financially tracked by warehouse, and the tracking dimension group is financially tracked by batch number, the running average cost price is calculated for each batch.

Note: We recommend that you always view the cost price for all financial dimensions that are being tracked. The following purchase orders have been invoiced:

- A purchase order for a quantity of 2 at a cost price of USD 10.00 has been invoiced for warehouse GW and batch AAA.
- A purchase order for a quantity of 3 at a cost price of USD 12.00 has been invoiced for warehouse GW and batch AAA.
- A purchase order for a quantity of 2 at a cost price of USD 15.00 has been invoiced for warehouse GW and batch BBB.

The running average cost price for warehouse GW and batch AAA is USD 11.20, and the running average cost price for warehouse GW and batch BBB is USD 15.00.

Inventory Visibility Add-in

2/18/2021 • 13 minutes to read • [Edit Online](#)

IMPORTANT

Some or all of the functionality noted in this topic is available as part of a preview release. The content and the functionality are subject to change. For more information about preview releases, see [One version service updates FAQ](#).

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see [Power Automate Blog](#).
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see [Terminology updates](#).

This topic will be updated soon to reflect the latest terminology.

The Inventory Visibility Add-in is an independent and highly scalable microservice that enables real-time on-hand inventory tracking, thus providing a global view of inventory visibility.

All information that relates to on-hand inventory is exported to the service in near real-time through low-level SQL integration. External systems access the service through RESTful APIs to query on-hand information on given sets of dimensions, thus retrieving a list of available on-hand positions.

Inventory Visibility is a microservice built on Microsoft Dataverse, which means you can extend it by building Power Apps and applying Power BI to provide customized functionality to meet your business requirements. It is also possible to upgrade the index to do inventory queries.

Inventory Visibility provides configuration options that let it integrate with multiple third-party systems. It supports the standardized inventory dimension, customized extensibility, and standardized, configurable calculated quantities.

This topic describes how to install and configure the Inventory Visibility Add-in for Dynamics 365 Supply Chain Management, and how to use its application programming interface (API).

Install the Inventory Visibility Add-in

You need to install the Inventory Visibility Add-in using Microsoft Dynamics Lifecycle Services (LCS). LCS is a collaboration portal that provides an environment and a set of regularly updated services that help you manage the application lifecycle of your Dynamics 365 Finance and Operations apps.

For more information, see [Lifecycle Services resources](#).

Prerequisites

Before you install the Inventory Visibility Add-in, you must do the following:

- Obtain an LCS implementation project with at least one environment deployed.
- Generate the beta keys for your offering in LCS.
- Enable the beta keys for your offering for your user in LCS.
- Contact the Microsoft Inventory Visibility product team and provide an environment ID where you want to

deploy the Inventory Visibility Add-in.

If you have any questions about these prerequisites, please contact the Inventory Visibility product team.

Install the add-in

To install the Inventory Visibility Add-in, do the following:

1. Sign in to the [Lifecycle Services \(LCS\)](#) portal.
2. On the home page, select the project where your environment is deployed.
3. On the project page, select the environment where you want to install the add-in.
4. On the environment page, scroll down until you see the **Environment add-ins** section. If the section isn't visible, make sure the prerequisite beta keys have been fully processed.
5. In the **Environment add-ins** section, select **Install a new add-in**.

The screenshot displays the environment configuration page for 'ivtsrv-dev-demo-3'. At the top, there are action buttons: Deallocate, Edit, Stop, History, and Microsoft Azure settings. Below this is a table of users with columns for user name, role, and status. The 'AZURE CONNECTOR' section shows a table with one entry: 'DEVTEST (West US)' with subscription ID '7cecb429-6008-4b29-ae38-8...' and region 'West US 2'. The 'CLOUD SERVICE NAME' is 'ivtsrv-dev-demo-3-D2-9be917b01b320f89' and the 'RESOURCE GROUP' is 'ivtsrv-dev-demo-3'. At the bottom, the 'Environment add-ins' section contains a button labeled '+ Install a new add-in'.

6. Select the **Install a new add-in** link. A list of available add-ins opens.
7. Select **Inventory service** from the list. (Note, this may now be listed as **Inventory Visibility Add-in for Dynamics 365 Supply Chain Management**.)
8. Enter values for the following fields for your environment:
 - AAD application ID
 - AAD tenant ID

Setup add-in

Inventory Service

The Inventory Service add-in for Dynamics 365 Finance and Operations allows tracking of inventory for high volume, and exposing it through a REST Api

[Learn more](#)

AAD application ID [What is this?](#)

AAD tenant ID [What is this?](#)

9. Agree to the terms and condition by selecting the **Terms and conditions** check box.
10. Select **Install**. The status of the add-in will show as **Installing**. When it's done, refresh the page to see the status change to **Installed**.

Get a security service token

Get a security service token by doing the following:

1. Sign in to Azure Portal and use it to find the `clientId` and `clientSecret` for your Supply Chain Management application.
2. Fetch an Azure Active Directory token (`aadToken`) by submitting an HTTP request with the following properties:

- **URL** - `https://login.microsoftonline.com/{aadTenantId}/oauth2/token`
- **Method** - `GET`
- **Body content (form data):**

KEY	VALUE
client_id	<code>\${aadAppId}</code>
client_secret	<code>\${aadAppSecret}</code>
grant_type	<code>client_credentials</code>
resource	<code>0cdb527f-a8d1-4bf8-9436-b352c68682b2</code>

3. You should receive an `aadToken` in response, which resembles the following example.

```

{
  "token_type": "Bearer",
  "expires_in": "3599",
  "ext_expires_in": "3599",
  "expires_on": "1610466645",
  "not_before": "1610462745",
  "resource": "0cdb527f-a8d1-4bf8-9436-b352c68682b2",
  "access_token": "eyJ0eX...8WQ"
}
```

4. Formulate a JSON request that resembles the following:

```
{
  "grant_type": "client_credentials",
  "client_assertion_type": "aad_app",
  "client_assertion": "{Your_AADToken}",
  "scope": "https://inventoryservice.operations365.dynamics.com/.default",
  "context": "5dbf6cc8-255e-4de2-8a25-2101cd5649b4",
  "context_type": "finops-env"
}
```

Where:

- The `client_assertion` value must be the `aadToken` you received in the previous step.
- The `context` value must be the environment ID where you want to deploy the add-in.
- Set all of other values as shown in the example.

5. Submit an HTTP request with the following properties:

- **URL** - `https://securityservice.operations365.dynamics.com/token`
- **Method** - `POST`
- **HTTP header** - Include the API version (key is `Api-Version` and value is `1.0`)
- **Body content** - Include the JSON request that you created in the previous step.

6. You will get an `access_token` in response. This is what you need as a bearer token to call the Inventory Visibility API. Here is an example.

```
{
  "access_token": "{Returned_Token}",
  "token_type": "bearer",
  "expires_in": 1200
}
```

Uninstall the add-in

To uninstall the add-in, select **Uninstall**. Refresh LCS and the Inventory Visibility Add-in will be removed. The uninstall process will remove the add-in registration and also start a job to clean up all of the business data stored in the service.

Inventory Visibility Add-in public API

The public REST API of the of the Inventory Visibility Add-in presents several specific endpoints of integration. It supports three main interaction types:

- Posting on-hand changes to the add-in from an external system.
- Querying current on-hand quantities from an external system.
- Automatic synchronization with Supply Chain Management on-hand.

The automatic synchronization isn't part of the public API but is instead handled in the background for environments that have enabled the Inventory Visibility Add-in.

Authentication

The platform security token is used to call the Inventory Visibility Add-in, so you must generate an Azure Active Directory token using your Azure Active Directory application.

For more information about how to get the security token, see [Install the Inventory Visibility Add-in](#).

Configure the Inventory Visibility API

Before using the service, you must complete the configurations described in the following subsections. The

configuration may vary based on the details of your environment. It primarily includes four parts:

- [Partitioning](#)
- [Dimension configurations](#)
- [Indexing](#)
- [Custom measurement](#)

Partitioning

Partitioning can significantly influence the performance of the Inventory Visibility API. It's a good idea to define a scheme that allows for small groupings of data while still allowing for meaningful data queries.

The `organizationId` (`dataAreaId` in Supply Chain Management) will always be part of the partitioning, and by default Inventory Visibility is set to partition by dimensions as *Site + Location*. This means that the service must always be queried with these dimensions defined on the filters.

NOTE

Site and *Location* are two general default dimensions in Inventory Visibility. In Supply Chain Management, those dimensions are called *Site* (`InventSiteId`) and *Warehouse* (`InventLocationId`)

Dimension configurations

Inventory Visibility will provide a list of general default dimensions to enable the multiple source system integration.

The following table lists the inventory dimensions that will be the default dimension names in Inventory Visibility.

DIMENSION TYPE	DIMENSION NAME
Product	<code>ColorId</code>
Product	<code>SizeId</code>
Product	<code>StyleId</code>
Product	<code>ConfigId</code>
Tracking	<code>BatchId</code>
Tracking	<code>SerialId</code>
Location	<code>LocationId</code>
Location	<code>SiteId</code>
Inventory Status	<code>StatusId</code>
Warehouse Specific	<code>WMSLocationId</code>
Warehouse Specific	<code>WMSpalletId</code>
Warehouse Specific	<code>LicensePlateId</code>

NOTE

The dimension type listed in the previous table is for reference only. You don't need to define the dimension type in Inventory Visibility.

If a custom dimension exists and needs to flow to a default value when consumed by Inventory Visibility, you can configure the **Custom dimension** name in Inventory Visibility.

External systems access Inventory Visibility through RESTful APIs that enable on-hand information on given sets of dimensions to be queried. For the integration, Inventory Visibility enables you to configure the *external channel data source* and the source dimension to the *target dimensions* in Inventory Visibility.

The target dimensions should be one of the following:

- Default dimensions in Inventory Visibility
- Custom dimensions

The purpose of dimension configuration is to standardize the multi-system integration for the query on dimensions and the posting event with dimensions.

Indexing

Most of the time, the inventory on-hand query will not only be on the highest "total" level, but you may want to see results aggregated based on the inventory dimensions.

Inventory Visibility provides flexibility by allowing you to set up the indexes, which are based on the dimension or the combination of the dimensions.

NOTE

Currently, you can only configure indexes to a maximum of five. You need to carefully consider which dimension or dimension combination you will use before the implementation to ensure that it will meet your business needs. For example, if you want to query products as follows:

- Query the aggregated product on-hand by the *Color* and *Size* dimensions.
- In some cases, you just want to query on the product in total.

You would have two indexes defined as the following:

- ["ColorId", "SizeId"]
- []

The empty bracket will aggregate based on the product ID within the partition.

The indexing defines how you can group your results based on the `groupBy` query setting. In this case if you don't define any `groupBy` values, you'll get totals by `productId`. Otherwise if you define `groupBy` as `groupBy=ColorId&groupBy=SizeId`, you'll get multiple lines returned, based on the different color and size combinations in the system.

You can put your query criteria in the request body.

Here is a sample query on the product with color and size combination.

```

{
  "filters": {
    "OrganizationId": ["usmf"],
    "ProductId": ["MyProduct"],
    "LocationId": ["21"],
    "SiteId": ["2"],
    "ColorId": ["Red"]
  },
  "groupByValues": [
    "SizeId",
    "ColorId"
  ],
  "returnNegative": true
}

```

Custom measurement

The default measurement quantities are linked to Supply Chain Management, however you may want to have a quantity that is made up of a combination of the default measurements. To do this, you can have a configuration of custom quantities, which will be added to the output of the on-hand queries.

The functionality simply allows you to define a set of measures that will be added, and/or a set of measures that will be subtracted, in order to form the custom measurement.

For example, with the following query condition, you will configure the custom measurement quantity as

`MyCustomAvailableforReservation` to be consumed by the consumption system.

```

[
  {
    "productId": "MyProduct",
    "dimensions": {
      "colorid": "Red"
    },
    "quantities": {
      "mypos": {
        "outbound": 20.0,
        "inbound": 80.0
      },
      "fno": {
        "availphysical": 100.0,
        "orderedintotal": 50.0,
        "orderedreserved": 10.0
      },
      "exterchannel": {
        "received": 90.0,
        "scheduled": 30.0,
        "issued": 60.0,
        "reserved": 40.0
      }
    }
  }
]

```

CONSUMPTION SYSTEM	CALCULATED MEASURERS	DATA SOURCE	MODIFIER	MODIFIER CALCULATION TYPE
CustomChannel	MyCustomAvailableforRe	fno tion	availphysical	Addition
CustomChannel	MyCustomAvailableforRe	fno tion	orderedintotal	Addition

CONSUMPTION SYSTEM	CALCULATED MEASURERS	DATA SOURCE	MODIFIER	MODIFIER CALCULATION TYPE
CustomChannel	MyCustomAvailableforRe	fno tion	orderedreserved	Subtraction
CustomChannel	MyCustomAvailableforRe	mypos on	inbound	Addition
CustomChannel	MyCustomAvailableforRe	mypos on	outbound	Subtraction
CustomChannel	MyCustomAvailableforRe	exterchannel	received	Addition
CustomChannel	MyCustomAvailableforRe	exterchannel	scheduled	Addition
CustomChannel	MyCustomAvailableforRe	exterchannel	issued	Subtraction
CustomChannel	MyCustomAvailableforRe	exterchannel	reserved	Subtraction

With that, the query on the custom measurement quantity will return the following output.

```
[
  {
    "productId": "MyProduct",
    "dimensions": {
      "colorid": "Red"
    },
    "quantities": {
      "mypos": {
        "outbound": 20.0,
        "inbound": 80.0
      },
      "fno": {
        "availphysical": 100.0,
        "orderedintotal": 50.0,
        "orderedreserved": 10.0
      },
      "exterchannel": {
        "received": 90.0,
        "scheduled": 30.0,
        "issued": 60.0,
        "reserved": 40.0
      },
      "CustomChannel": {
        "MyCustomAvailableforReservation": 220.0
      }
    }
  }
]
```

The `MyCustomAvailableforReservation` output is based on the calculation setting in the custom measurements as: $100 + 50 + 80 + 90 + 30 - 10 - 20 - 60 - 40 = 220$

Posting on-hand changes

The exact URL that the event will be posted to will depend on your geographical region. It will take the form:

```
https://{serviceURL}/api/environment/{environmentId}/onhand
```

When authenticated, this URL can be used along with the HTTP `POST` method to send on-hand change events to the service.

A special header is used for communicating with Dynamics 365 services through HTTP requests, denoting the environment ID of the Supply Chain Management instance the data is linked to. For example:

```
x-ms-environment-id: 2db79622-f97a-4d64-9844-d12efed41796
```

Posting on-hand changes query example 1

This example shows a scenario where you will set up the dimension configuration in Power Apps.

Use the following query to configure the dimension mapping in Power Apps:

```
{
  "PosSizeId": "SizeId",
  "PosColorId": "ColorId",
  "PosSiteId": "SiteId",
  "PosLocationId": "LocationId"
}
```

Now you can specify the `dimensionDataSource` and use custom dimensions in your queries. The system will automatically convert custom dimensions to base dimensions.

```
{
  "id": "demo-test-00007",
  "organizationId": "usmf",
  "productId": "MyProduct",
  "quantities": {
    "pos": {
      "Outbound": 1
    }
  },
  "dimensionDataSource": "pos",
  "dimensions": {
    "PosSizeId": "Large",
    "PosColorId": "Red",
    "PosSiteId": "2",
    "PosLocationId": "21"
  }
}
```

Posting on-hand changes query example 2

This example shows a scenario where no mappings are set up for the dimension configuration in Power Apps, so the posting should also use the base dimensions. All dimensions must be base dimensions when the `dimensionDataSource` field is null, empty, or whitespace.

```
{
  "id": "demo-test-00007",
  "organizationId": "usmf",
  "productId": "MyProduct",
  "quantities": {
    "pos": {
      "Outbound": 1
    }
  },
  "dimensions": {
    "SizeId": "Large",
    "ColorId": "Red",
    "SiteId": "2",
    "LocationId": "21"
  }
}
```

The fields from the JSON query examples provided previously have the properties listed in the following table.

FIELD ID	DESCRIPTION
<code>id</code>	A unique ID for the specific change event. This ID is used to ensure that if communication with the service fails during posting, resubmitting the event would not result in the same event being counted twice in the system.
<code>organizationId</code>	The identifier of the organization linked to the event. This maps to Supply Chain Management organizations or data area IDs.
<code>productId</code>	The identifier of the product in question.
<code>quantity</code>	The quantity by which the on-hand needs to be changed. If, for instance, 10 new bagels were added to a shelf, this value would be 10. If 3 bagels were then removed from the shelf or sold, this value would be -3.
<code>dimensionDataSource</code>	The data source of the dimensions used in the posting change event and query. If you specify the data source, you can use the custom dimensions from the specified data source. With the dimension configuration, Inventory Visibility can map the custom dimensions to the general default dimensions. If the <code>dimensionDataSource</code> is not specified, you can only use the general default dimensions in your queries.
<code>dimensions</code>	A dynamic bag of key/value pairs. These will map to some of the dimensions in Supply Chain Management, but you could also add custom dimensions (like <i>Source</i>) that may denote if the event was coming from Supply Chain Management or an external system.

Querying current on-hand

The endpoint for querying the current on-hand will have a similar URL:

```
https://{serviceURL}/api/environment/{environmentId}/onhand/indexquery
```

It will be queried with the HTTP `POST` method.

Current on-hand query example 1

This example shows a scenario where you have already completed the dimension configuration in Power Apps.

Use the following query to configure the dimension mapping in Power Apps:

```
{
  "PosSizeId": "SizeId",
  "PosColorId": "ColorId",
  "PosSiteId": "SiteId",
  "PosLocationId": "LocationId"
}
```

Now you can specify the `dimensionDataSource` and use custom dimensions in your queries. The system will automatically convert custom dimensions to base dimensions. You can specify the `DimensionDataSource` in `filters` and specify custom dimensions in both `filters` and `groupByValues`. The system will automatically convert custom dimensions to base dimensions.

```

{
  "filters": {
    "OrganizationId": ["usmf"],
    "ProductId": ["MyProduct"],
    "DimensionDataSource": ["Pos"],
    "PosLocationId": ["21"],
    "PosSiteId": ["2"],
    "PosColorId": ["Red"]
  },
  "groupByValues": [
    "PosSizeId",
    "PosColorId"
  ],
  "returnNegative": true
}

```

Current on-hand query example 2

This example shows a scenario where no mappings are set up for the dimension configuration in Power Apps, so the posting should also use the base dimensions. All dimensions must be base dimensions when the `dimensionDataSource` field, under `filters` is null, empty, or whitespace.

```

{
  "filters": {
    "OrganizationId": ["usmf"],
    "ProductId": ["MyProduct"],
    "LocationId": ["21"],
    "SiteId": ["2"],
    "ColorId": ["Red"]
  },
  "groupByValues": [
    "SizeId",
    "ColorId"
  ],
  "returnNegative": true
}

```

Example return result

The queries shown in the previous examples could return a result like this.

```
[
  {
    "productId": "MyProduct",
    "dimensions": {
      "colorid": "Red"
    },
    "quantities": {
      "mypos": {
        "outbound": 20.0,
        "inbound": 80.0
      },
      "fno": {
        "availphysical": 100.0,
        "orderedintotal": 50.0,
        "orderedreserved": 10.0
      },
      "exterchannel": {
        "received": 90.0,
        "scheduled": 30.0,
        "issued": 60.0,
        "reserved": 40.0
      },
      "CustomChannel": {
        "MyCustomAvailableforReservation": 220.0
      }
    }
  }
]
```

Note that the quantities fields are structured as a dictionary of measures and their associated values.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

IoT Intelligence home page

2/18/2021 • 2 minutes to read • [Edit Online](#)

IMPORTANT

This feature is currently only available in the following countries/regions:

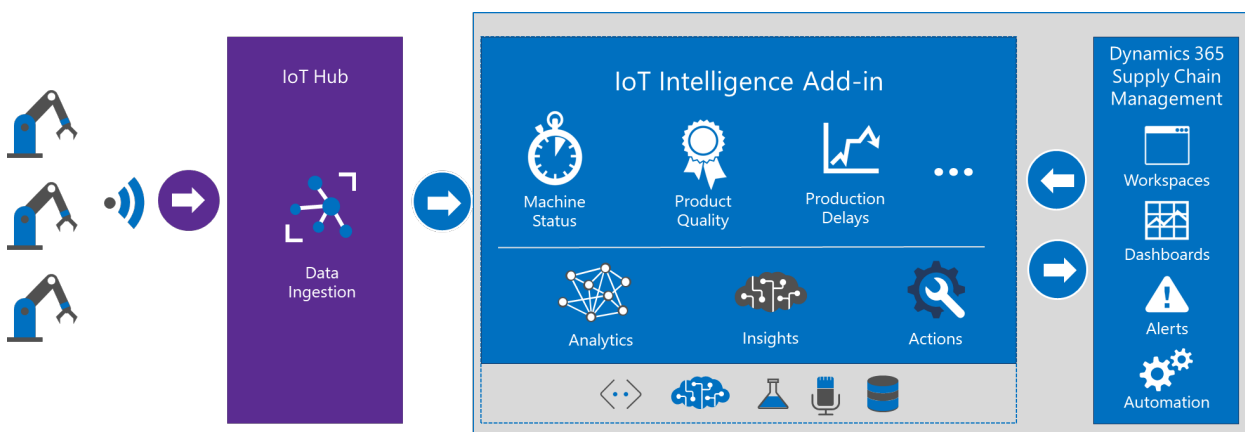

- US (United States of America)
- EU (European Union)
- AU (Australia)
- CA (Canada)
- UK (United Kingdom)

IoT Intelligence is an add-in for Microsoft Dynamics 365 Supply Chain Management. It integrates Internet of Things (IoT) signals with data in Supply Chain Management to produce actionable insights.

IoT Intelligence supports the following scenarios:

- **Production delays** – This scenario compares actual cycle time to planned cycle time. Supply Chain Management notifies you when production isn't on schedule, so that you can intervene to maximize operating efficiency and avoid order delays.
- **Equipment downtime** – This scenario compares measured uptime to user-defined parameters. Supply Chain Management notifies you when an outage threshold is exceeded, so that you can take actions such as rescheduling a production work order or creating a maintenance work order.
- **Product quality** – This scenario compares sensor readings, such as moisture and temperature, to user-defined quality metrics. Supply Chain Management notifies you when a deviation occurs, so that you can intervene to maintain quality standards and minimize waste.

The following illustration shows the interaction of Azure IoT Hub, IoT Intelligence, and Supply Chain Management.

Setup

You can set up and configure IoT Intelligence without writing any code. Here are the basic steps.

1. [Set up Azure resources](#) – Create an IoT hub, a Redis cache, and a key vault that can be accessed from Supply Chain Management.
2. [Message schema formats for IoT Hub](#) – Configure your devices to send messages to IoT Hub, and define the

JavaScript Object Notation (JSON) message format.

3. In Feature Management, enable the IoT Intelligence feature flag.
4. [Install the IoT Intelligence add-in in Microsoft Dynamics Lifecycle Services \(LCS\)](#) – Install the add-in in LCS, and configure the Azure secrets.
5. [Set up metrics](#) – Set up metrics in Supply Chain Management.
6. [Scenario setup](#) – Set up the scenarios in Supply Chain Management.

Tracking and maintenance

- [Monitor scenarios in Dynamics 365 Supply Chain Management](#)
- [Disable a scenario](#)
- [Uninstall the add-in](#)
- [Modify a running IoT Intelligence scenario](#)
- [Simulation options](#)

NOTE

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Set up Azure resources for IoT Intelligence

2/18/2021 • 4 minutes to read • [Edit Online](#)

This topic explains how to create and configure the Microsoft Azure resources that you require for IoT Intelligence.

Create Azure resources

Follow these steps to create an IoT hub, a Redis cache, and a key vault that can be accessed by Microsoft Dynamics 365 Supply Chain Management.

Verify that the Microsoft Dynamics ERP Microservices first-party app ID is in your tenant

To verify that the app ID for the Microsoft Dynamics ERP Microservices first-party app is in your tenant, follow these steps.

1. Sign in to the Azure portal at <https://portal.azure.com>.
2. Go to **Azure Active Directory**.
3. Go to **Enterprise applications**.
4. In the **Application type** field, select **Microsoft applications**.
5. In the search field, enter **Microsoft Dynamics ERP Microservices**.
6. Verify that **Microsoft Dynamics ERP Microservices** is in the list. Other applications have similar names. Therefore, make sure that you find the correct application. The app ID is **0cdb527f-a8d1-4bf8-9436-b352c68682b2**.

If the application isn't in the list, you must add it to your tenant:

- a. In the Azure portal, on the toolbar, select the button to open Azure Cloud Shell.
- b. Run the command **Install-Module AzureAD**. Enter Y to install the module.
- c. Run the command **Get-InstalledModule -Name "AzureAD"** to verify that the module is installed.
- d. Run the command **Connect-AzureAD -Confirm** to run the authentication.
- e. Run the command **New-AzureADServicePrincipal -AppId 0cdb527f-a8d1-4bf8-9436-b352c68682b2**.

You can now repeat steps 1 through 6 to verify that the app ID is in your tenant.

Create a key vault resource

To create a key vault resource, follow these steps.

1. In the Azure portal, create or go to a resource group.
2. Select **Add**.
3. On the **New** page, in the search field, enter **Key vault**. Then select **Create**.
4. On the **Create key vault** page, in the **Key vault name** field, enter a name.
5. Review the default values, and then select **Review + create**.
6. Select **Create**.

The key vault is created in the background.

Create an IoT hub resource

To create an IoT hub resource, follow these steps.

1. Create or go to a resource group.
2. Select **Add**.
3. On the **New** page, in the search field, enter **IoT Hub**. Then select **Create**.
4. In the **IoT hub name** field, enter a name.
5. Review the default values, and then select **Review + create**.
6. Select **Create**.

The IoT hub is created in the background.

NOTE

We recommend that you create only one IoT hub resource per environment.

Create a Redis cache resource

To create a Redis cache resource, follow these steps.

1. Create or go to a resource group.
2. Select **Add**.
3. On the **New** page, in the search field, enter **Azure Cache for Redis**. Then select **Create**.
4. In the **DNS name** field, enter a name.
5. Review the default values, and then select **Create**.

The Redis cache is created in the background.

NOTE

We recommend that you create only one Redis cache per environment.

All the resources have now been created.

Configure the Azure resources

Configure the IoT hub

To configure the IoT hub, follow these steps.

1. In your resources, select the IoT hub resource.
2. In the left navigation pane, select **Built-in endpoints**.
3. Under **Consumer groups**, paste the following consumer groups. These consumer groups correspond to the out-of-box scenarios.
 - microsoft.dynamics.iotintelligence-1
 - microsoft.dynamics.iotintelligence-2
 - microsoft.dynamics.iotintelligence-3

Configure the key vault

To configure the key vault, follow these steps.

1. In your resources, select the key vault resource.
2. In the left navigation pane, select **Access policies**.
3. Select **Add an access policy**.

4. On the **Add access policy** page, in the **Secret permissions** field, select **Get** and **List**.
5. Click in the **Select principal**.
6. In the **Principal** dialog box, search for and select **Microsoft Dynamics ERP Microservices**. Then select **Select**.
7. Select **Add**.
8. Select **Save**.

The app now has access to the secrets in the key vault.

Save the IoT hub connection string secret

To save the secret for the IoT hub connection string, follow these steps.

1. In your resources, select the IoT hub resource.
2. In the left navigation pane, select **Built-in endpoints**.
3. Copy the value in the **Event Hub-compatible endpoint** field.
4. Go to the key vault resource.
5. In the left navigation pane, select **Secrets**.
6. Select **Generate/Import**.
7. In the **Name** field, enter a name.
8. In the **Value** field, paste the endpoint value that you copied earlier.
9. Select **Create**.

Save the Redis cache connection string secret

To save the secret for the Redis cache connection string, follow these steps.

1. In your resources, select the Redis cache resource.
2. Select **Access keys**.
3. Copy the value in the **Primary connection string** field.
4. Go to the key vault resource.
5. In the left navigation pane, select **Secrets**.
6. Select **Generate/Import**.
7. In the **Name** field, enter a name.
8. In the **Value** field, paste the connection string that you copied earlier.
9. Select **Create**.

NOTE

Whenever you update one of the connection strings, you must also update the secret values.

You've now finished provisioning the required Azure resources. The next step is to [install the IoT Intelligence add-in in Microsoft Dynamics Lifecycle Services \(LCS\)](#).

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Schema formats for IoT Hub messages

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic explains how you should design a message schema that you can use in IoT Intelligence.

Message requirements

The following rules apply to the monitoring of messages in IoT Intelligence:

- Message schemas must be in JavaScript Object Notation (JSON) format.
- A UNIX **timestamp** property, where the value is expressed in milliseconds (ms), must be present in the Microsoft Azure IoT Hub message.
- A message is tracked only if it contains all the properties that are defined in the scenario setup. For example, if you define **id**, **timestamp**, and **value** properties, the following message is monitored.

```
{
  "id": "IoTInt.Machine1225.PartOut",
  "timestamp": 1576016821614,
  "value": True
}
```

This message isn't monitored, because the **value** property is missing.

```
{
  "id": "IoTInt.Machine1225.PartOut",
  "timestamp": 1576016821614,
}
```

- IoT Intelligence ignores properties in the message that aren't defined in the scenario configuration. For example, if you define **id**, **timestamp**, and **value** properties, IoT Intelligence will monitor all the following messages.

```
{
  "id": "IoTInt.Machine1225.PartOut",
  "timestamp": 1576016821614,
  "value": True
},
{
  "id": "IoTInt.Machine1225.PartOut",
  "timestamp": 1576016821614,
  "value": True,
  "machine" : "Machine1225",
},
{
  "id": "IoTInt.Machine1225.PartOut",
  "timestamp": 1576016821614,
  "value": True,
  "activity": "PartOut"
},
```

- IoT Intelligence silently ignores messages that don't match the scenario configuration criteria.
- You can define and use multiple types of message schemas.

- Not every type of message schema must be defined. Only schemas that will be used for the IoT Intelligence scenarios must be defined.

Id-value pair schema

An id-value pair is a common pattern for IoT Intelligence message schemas. By using an id-value pair, you ensure that your message schema is the same across all the scenarios. For example, here is a message for the **Equipment downtime** or **Production delays** scenario.

```
{
  "id": "IoTInt.Machine1225.PartOut",
  "timestamp": 1576016821614,
  "value": True
}
```

Here is a message for the **Product quality** scenario.

```
{
  "id": "IoTInt.Machine1225.Temperature",
  "timestamp": 1576016821614,
  "value": 105
}
```

Both the preceding messages contain **id** and **value** properties. The **id** values can be mapped in the **Signal Data Values** table during scenario setup. For the **Equipment downtime** scenario, you will map the **IoTInt.Machine1225.PartOut** value. For the **Product quality** scenario, you will map the **IoTInt.Machine1225.Temperature** value.

For more information, see [Azure IoT Hub Documentation](#).

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Install the IoT Intelligence add-in in LCS

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic explains how to install the IoT Intelligence add-in in Microsoft Dynamics Lifecycle Services (LCS). Note that add-ins cannot be installed on a demo/trial environment. Before you can install the add-in, you must [create the Azure resources](#).

Set up the LCS environment

1. Open LCS, and go to your Microsoft Dynamics 365 Supply Chain Management environment.
2. Scroll to the **Environment add-ins** section.
3. Select **Install a new add-in** to show the list of add-ins that have been enabled for the environment.
4. In the **Select an add-in to install** dialog box, select **IoT Intelligence**.
5. In the **Setup add-in** dialog box, provide the details of your IoT hub and Redis cache. You can find the required values in the key vault that you created in [Create Azure resources](#).
 - **Tenant ID** – In the Azure portal, go to the key vault, and then, in the left navigation pane, select **Overview**, and copy the **Directory ID** value. Paste that value in the **Setup add-in** dialog box.
 - **IoT Event Hub-compatible endpoint Key Vault URI** – Go to the key vault, and then, in the left navigation pane, select **Overview**, and copy the **DNS name** value. Paste that value in the **Setup add-in** dialog box.
 - **IoT Event Hub-compatible endpoint secret name** – Go to the key vault, and then, in the left navigation pane, select **Secrets**, and copy the name of the secret where the event hub connection string for the IoT hub is stored. Paste that value in the **Setup add-in** dialog box.
 - **Redis cache key vault URI** – Go to the key vault, and then, in the left navigation pane, select **Overview**, and copy the **DNS name** value. Paste that value in the **Setup add-in** dialog box.
 - **Redis cache endpoint secret name** – Go to the key vault, and then, in the left navigation pane, select **Secrets**, and copy the name of the secret where the connection string for the Redis cache is stored. Paste that value in the **Setup add-in** dialog box.
6. Select the check box to accept the terms and conditions.
7. Select **Install**.
8. A message box appears that states, "Add-in has been successfully triggered for installation." Select **OK**.

LCS setup is now completed. The next step is to [set up the scenarios](#).

Uninstall the add-in

1. In Supply Chain Management, [disable the scenarios](#).
2. In LCS, go to your Supply Chain Management environment details.
3. Scroll to the **Environment add-ins** section.
4. Select **Uninstall** for the IoT Intelligence add-in.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Set up metrics for IoT Intelligence

2/18/2021 • 2 minutes to read • [Edit Online](#)

Configure metrics

If you want to view the time series charts of your messages in Microsoft Dynamics 365 Supply Chain Management, you must set up the metrics by following these steps.

1. Copy the connection string for the Redis cache:
 - a. In the Azure portal, go to the Redis cache.
 - b. Go to **Settings** > **Access keys**.
 - c. Copy the value in the **Primary connection string** field.
2. In Supply Chain Management, go to **Production control** > **Setup** > **IoT Intelligence** > **Scenario parameters**.
3. On the **Scenario parameters** page, on the **Time series** tab, in the **Redis metric store connection string** field, paste the connection string that you copied earlier. This step enables the metrics from Azure IoT Hub to be visualized in Supply Chain Management. When you paste the value into the field, it's shown as *********.

NOTE

Whenever you update the Redis cache connection string, you must also update this field.

4. Go to **Production control** > **Inquiries and reports** > **IoT Intelligence** > **Metric keys**.
5. On the **Metric keys** page, select **Update**.
6. In the **Update metric keys** dialog box, notice that **Run in the background** is selected in the field. Select **OK**.

All the metric keys in the Redis cache are retrieved and added to the **Metric keys** list. Metric values won't appear until you [enable the scenarios](#).

Configure the Resource Status time series

To configure the **Resource Status** time series, follow these steps.

1. In Supply Chain Management, go to **Production control** > **Manufacturing execution** > **Resource Status**.
2. On the **Resource status** page, select **Configure**.
3. In the **Configure** dialog box, in the **Resource** list, select an item to monitor.
4. Select the **Edit** button for **Time series 1**.
5. In the **Select time series** dialog box, select a metric in the grid. (You can also use the **Update metric keys** link to update the metric keys from this dialog box.)
6. Select **OK** to return to the **Configure** dialog box.
7. Enter a display name.
8. In the **Show data from** field, select a time frame.
9. Select **OK**.

The chart is shown.

Delete a metric key

1. In Supply Chain Management, go to **Production control > Inquiries and reports > IoT Intelligence > Metric keys**.
2. On the **Metric keys** page, select the metric key to delete.
3. Select **Delete**.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Scenario setup for IoT Intelligence

2/18/2021 • 6 minutes to read • [Edit Online](#)

This topic explains how to configure scenarios for IoT Intelligence in Microsoft Dynamics 365 Supply Chain Management. Before you can set up the scenarios, you must [set up Microsoft Dynamics Lifecycle Services \(LCS\)](#).

In this topic, you will configure the **Equipment downtime** scenario so that a notification is generated in Supply Chain Management when a machine goes down. The topic also shows how to configure the **Product quality** scenario so that a notification is generated if an attribute of an item is outside a specified range, and how to configure the **Production delays** scenario so that a notification is generated if the production throughput falls below a threshold value.

Configure the Equipment downtime scenario in Supply Chain Management

The **Equipment downtime** scenario maps a **PartOut** signal to a machine alert threshold. The machine is monitored only when it's selected for the scenario and when is set to **Running** in Supply Chain Management. If the time since a **PartOut** signal was last received from the machine exceeds the alert threshold, a **Machine down** notification is triggered. If the machine is still running, a **Machine up** notification is triggered when the next **PartOut** signal is received. If a machine stays down for 30 minutes, a new **Machine down** notification is triggered.

The **Equipment downtime** scenario has the following dependencies:

- An alert can be triggered only if a production order is running on a mapped machine.
- A signal that represents a mapped machine's **PartOut** signal must be sent to the IoT hub, and a unique property name must be included.
- A UNIX **timestamp** property, where the value is expressed in milliseconds (ms), must be present in the Azure IoT Hub message.

To configure the scenario, follow these steps.

1. Sign in to Supply Chain Management.
2. Enable the IoT Intelligence feature flag. For more information, see [Feature management overview](#).
3. Configure the metrics. For more information, see [How to configure metrics](#).
4. Go to **Production control > Setup > IoT Intelligence > Scenario management**.
5. On the **Equipment downtime** tile, select **Configure** to open the configuration wizard.

The first page in the wizard is the **Equipment sensor schema definition** page. On this page, your goal is to set up the schema in Supply Chain Management so that it matches the JavaScript Object Notation (JSON) format of the IoT Hub messages. Multiple message schemas can be defined. For more information, see [Schema formats for IoT Hub messages](#). In this example, the message payload contains a batch of messages that has the following format.

```

{
  "timestamp": 1576016821614,
  "payload": [
    {
      "id": "IoTInt.Machine1225.PartOut",
      "timestamp": 1576016821614,
      "value": True
    },
    {
      "id": "IoTInt.Machine1226.PartOut",
      "timestamp": 1576016991616,
      "value": True
    }
  ]
}

```

6. Add a row to the table, and set the following values:
 - a. Set the **Schema name** field to **ID**.
 - b. Set the **Schema path** field to **/payload[*]/id**.
 - c. Set the **Description** field to **Message ID**.
7. Add another row to the table, and set the following values:
 - a. Set the **Schema name** field to **Timestamp**.
 - b. Set the **Schema path** field to **/payload[*]/timestamp**.
 - c. Set the **Description** field to **Message timestamp**.
8. Add another row to the table, and set the following values:
 - a. Set the **Schema name** field to **Value**.
 - b. Set the **Schema path** field to **/payload[*]/value**.
 - c. Set the **Description** field to **Message value**.

NOTE

You don't have to define all the properties in the message. Define only the properties that you require. In the preceding steps, you didn't create a row for **Root timestamp**. The path of **Root timestamp** would be **/timestamp**.

9. Select **Next** to go to the **Equipment sensor schema map** page.
10. In the row for **Equipment resource ID**, in the **Schema name** field, select **ID**.
11. In the row for **UTC time**, in the **Schema name** field, select **Timestamp**.
12. In the row for **Part produced signal**, in the **Schema name** field, select **Value**.
13. Select **Next** to go to the **Equipment resource ID configuration** page.
14. Follow these steps to map the values in the IoT Hub message to the Supply Chain Management resources:
 - a. In the **Signal Data Values** table, add a new row. In the **Value** field, enter **IoTInt.Machine1225.PartOut**. This value comes from the JSON **id** property in the IoT Hub message.
 - b. Select **Save**.
 - c. In the **Business Record Mapping** table, select **New**. A default value for the **Business record type** field is automatically filled in, and you don't have to change it.
 - d. In the **Business record** field, select the Supply Chain Management machine resource that the signal

value is being sent from.

- e. Select **Save**.
 - f. Repeat these steps to add a new business record mapping for **Machine1226**. You can map multiple signal data values to a single record in Supply Chain Management.
15. Use the **Selected** column to select the machines that you want to process. You don't have to define all signal values, and you don't have to select all machines.
 16. Select **Next** to go to the **Part produced signal configuration** page.
 17. In the **Signal Data Values** table, add a row, and set the **Value** field to **True**. This value comes from the JSON **value** property in the IoT Hub message. You can add as many values as you require for your scenario.
 18. Select **Save**.
 19. Select **Next** to go to the **Equipment downtime threshold** page. The machines that are listed are the machines that were previously mapped to signal values. On this page, you will define a threshold to determine whether a machine is down. For example, if you set the threshold to **10**, Supply Chain Management will generate a notification if no **PartOut** signal is received from a machine for 10 minutes.
 20. Select **Next** to go to the **Enable scenario** page. Set the option to enable the scenario.
 21. Select **Finish**.

The scenario setup is now completed. IoT Intelligence will automatically start to process the IoT Hub messages.

Configure the Product quality scenario in Supply Chain Management

The **Product quality** scenario generates a notification if an attribute of an item is outside a specified range. For example, a sensor sends the weight of each item to IoT Hub. If an item is too heavy or too light, a notification is generated in Supply Chain Management.

The **Product quality** scenario has the following dependencies:

- An alert can be triggered only if a production order is running on a mapped machine and producing a product that has a mapped batch attribute.
- A signal that represents the batch attribute must be sent to the IoT hub, and a unique property name must be included.
- A UNIX **timestamp** property, where the value is expressed in ms, must be present in the IoT Hub message.

Configure the Production delays scenario in Supply Chain Management

The **Production delays** scenario generates a notification if the production throughput falls below a threshold value. In this scenario, a **PartOut** signal is sent to IoT Hub for each item that is produced. In Supply Chain Management, the order delay is calculated based on the amount of time that the production order is scheduled to run, the number of items that should be produced, the amount of time that the job has been running, and the number of **PartOut** signals that are received. A delay notification is generated if the number of **PartOut** signals for the job falls below the threshold value.

The **Production delays** scenario has the following dependencies:

- An alert can be triggered only if a production order is running on a mapped machine.
- A signal that represents a mapped machine's **PartOut** signal must be sent to the Azure IoT hub, and a unique property name must be included.
- A UNIX **timestamp** property, where the value is expressed in ms, must be present in the IoT Hub message.

Disable a scenario

To disable a scenario, follow these steps.

1. In Supply Chain Management, go to **Production control > Setup > IoT Intelligence > Scenario management**.
2. On the tile for the scenario, select **Configure**.
3. Select **Next** to go to the last wizard page.
4. Set the option to disable the scenario.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Monitor and manage IoT Intelligence

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic explains how to monitor and manage IoT Intelligence.

Monitor scenarios in Microsoft Dynamics 365 Supply Chain Management

You can monitor IoT Intelligence processing from several places:

- **Modules > Production control > Inquiries and reports > IoT Intelligence > Notifications** – View the list of unresolved notifications.
- **Modules > Production control > Inquiries and reports > IoT Intelligence > Closed notifications** – View the list of notifications that have been resolved or dismissed.
- **Modules > Production control > Inquiries and reports > IoT Intelligence > Metric keys** – View the metric keys for the **Resource Status** times series charts.
- **Modules > Production control > Manufacturing execution > Resource status** – Track specific metrics by using the **Configure** dialog box. If a scenario detects an exception, a notification shows the details of the exception.
- **Workspaces > Production floor management > Notifications** – View the list of unresolved notifications.

Modify a running IoT Intelligence scenario

When a scenario is running, you can make these changes:

- Add new sensor schema definitions.
- Select new signal data values.
- Cancel the selection of existing signal data values.
- Add and map new signal data values.
- Update threshold values.

When a scenario is running, these changes are prohibited:

- Delete or modify any schema definitions that are currently consumed by an enabled scenario.
- Change the enabled scenario's selected schema paths.

Simulation options

You can simulate factory machine signals. For more information, see these topics:

- [Connect IoT DevKit AZ3166 to Azure IoT Hub](#)
- [Connect Raspberry Pi online simulator to Azure IoT Hub \(Node.js\)](#)
- [Device Simulation solution accelerator overview](#)

NOTE

Master planning home page

2/18/2021 • 2 minutes to read • [Edit Online](#)

At its core, Master planning allows companies to determine and balance the future need for raw materials and capacity to meet company goals. Master planning assesses the following:

- What raw materials and capacities are currently available?
- What raw materials and capacities are required to complete production? For example, what must be manufactured, purchased, transferred, or set aside as safety stock before you can complete production.

Master planning uses the information to calculate the requirements and generate planned orders.

The three main planning processes are:

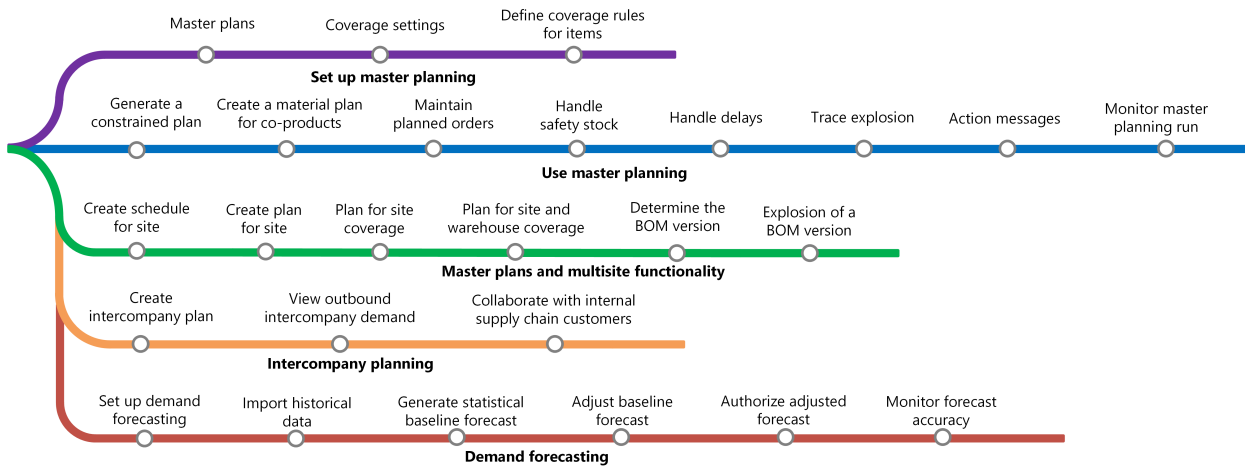

- **Master planning** - The Master plan calculates net requirements. It is based on actual current orders and enables companies to control inventory replenishment on a short-term, day-to-day basis. Another term to describe it is the *Net requirements plan*. For more information, see [Master plans overview](#).
- **Forecast planning** - The Forecast schedule calculates gross requirements. It is based on future projections (or forecasts), and enables companies to conduct long-term planning of materials and capacity. For more information, see [Demand forecasting overview](#).
- **Intercompany master planning** - The Intercompany master plan calculates net requirements across legal entities. It connects demand and supply between companies not only for short term, firm demand and supply but also for long-term, planned (that is not yet firmed) demand and supply. For more information, see [Intercompany master planning](#) (eLearning) (requires CustomerSource account).

Companies can change the output of the plan. They can run regenerative, net change, or both. Regenerative plans update all requirements, whereas, net change plans only update the plan on items with new requirements that have come in since the last scheduling run.

Master scheduling plans typically involve the short term, which can be anywhere from one week to six months. The Master planning module determines the supply (materials) and capacity (resources) needs that will meet current demand (the net requirements). In most companies this is extended to include the longest cumulative lead time among the products to be received.

Learning map

Migration to Planning Optimization for master planning

2/18/2021 • 5 minutes to read • [Edit Online](#)

The built-in master planning engine is scheduled to be made obsolete (deprecated). It's being replaced by the Planning Optimization Add-in for Microsoft Dynamics 365 Supply Chain Management. This topic provides information about the impact on new and existing deployments. It includes information about required actions.

Planning Optimization enables master planning calculations to occur outside Supply Chain Management and its Azure SQL database. The benefits that are associated with Planning Optimization include improved performance and minimized impact on the SQL database during master planning runs. Because quick planning runs can be done even during office hours, planners can immediately react to demand or parameter changes.

For more information about Planning Optimization, see [Planning Optimization overview](#).

Obsolescence of the existing master planning engine

Microsoft is in the process of making the built-in planning engine obsolete in favor of Planning Optimization. This change affects all cloud environments. On-premises installations aren't affected. In version 10.0.16 and later, you will receive an error message if you run the built-in master planning without generating planned production orders. However, the master planning run will be successfully completed despite the error message.

For more information about the obsolescence of the built-in planning engine, see the announcements in [Removed or deprecated features in Dynamics 365 Supply Chain Management](#).

Migration, messages, and exceptions

Owners of existing environments who run the built-in master planning engine without generating planned production orders will receive an email that provides details about the exception process. We recommend that you work with a partner to evaluate and plan the migration to Planning Optimization.

As has been mentioned, you will receive an error message in version 10.0.16 and later if you run the built-in master planning without generating planned production orders. This error message includes guidance about migration and instructions for requesting an exception.

New deployments

Planning Optimization should be considered the default master planning engine for all new deployments in the cloud. In general, Planning Optimization should be used for all new deployments that don't generate planned production orders during master planning. If a new deployment depends on functionality that Planning Optimization doesn't currently support, you can request an exception so that you can continue to use the built-in master planning engine.

Existing deployments

Owners of existing cloud-based deployments that depend on master planning should plan to migrate to Planning Optimization. If your implementation depends on functionality that Planning Optimization doesn't currently support, you can request an exception so that you can continue to use the built-in master planning engine.

For environments that currently use master planning processes that are being made obsolete, Microsoft will send an email to the environment admin. This email will provide information about the actions that are required to migrate or to request an exception.

The exception process

You can request an exception if you must continue to use the built-in master planning engine because your business processes depends heavily on at least one feature that isn't currently implemented in Planning Optimization. For a list of available features, see [Planning Optimization fit analysis](#).

Currently, exceptions for Planning Optimization migration are only relevant if your master planning process doesn't include production (that is, planned production orders that are generated by master planning), and you require the built-in master planning engine beyond version 10.0.15.

After the required features become available, Microsoft will provide a grace period until the exception expires. The environment admin will be informed when the required features have become available and the grace period has started.

NOTE

You can only request an exception for production environments, not for sandbox environments. If you need to disable the Planning Optimization exception error on an infrastructure as a service (IaaS) sandbox environment, run the SQL query provided in [Sandbox environments](#).

Frequently asked questions

Sandbox environments

Can I use built-in master planning on my sandbox environment? Do I need an exception?

Answer: Exceptions aren't normally relevant for sandbox environments because the Planning Optimization exception error doesn't prevent the built-in master planning engine from running successfully. However, if the error message disturbs you, you can disable it on an IaaS (not Service Fabric) sandbox environment by running the following query on your database:

```
-- Insert or update an enabled flight:
DECLARE @flightName NVARCHAR(100) = 'ReqPlanningOptimizationExceptionToggle';
IF NOT EXISTS (SELECT TOP 1 1 FROM SysFlighting WHERE flightName = @flightName)
    INSERT INTO SYSFLIGHTING(FLIGHTNAME,ENABLED, FLIGHTSERVICEID,PARTITION)
    SELECT @flightName, 1, 12719367,RECID FROM DBO.[PARTITIONS];
ELSE
    UPDATE SysFlighting SET enabled = 1, flightServiceId = 12719367 WHERE flightName = @flightName;
```

On-premises environments

My environment is on-premises. Do I need an exception?

Answer: No. An exception isn't required for on-premises environments. You can continue to use the built-in master planning. Your environment admin will be informed if any action is required.

Production scenarios

We use planned production orders, but I'm concerned about what will happen when we upgrade to version 10.0.16. Should I take any action?

Answer: You should not be concerned. You can continue to use the built-in master planning in version 10.0.16. However, we recommend that you evaluate whether migration to Planning Optimization can start with the current functionality. We also recommend that you remain informed about new functionality.

Email from Microsoft

Our environment admin received an email from Microsoft. This email states that we should migrate to Planning Optimization or request an exception. Do I need to take any action?

Answer: Yes. Your environment will be affected unless you follow the instructions in the email. You can either migrate to Planning Optimization by the date specified or request an exception by using the link in the email. This link opens a questionnaire. After you've completed and submitted this questionnaire, you will receive a reply via email. Although this process is manual, Microsoft tries to reply within a week after the questionnaire is submitted.

Error messages

I'm using version 10.0.16 or later, and I receive the following error message when I run master planning. Is master planning blocked?

You receive this error message because the built-in master planning engine was used for scenarios supported by Planning Optimization. You should migrate to Planning Optimization now, as the current built-in master planning will be deprecated. Note that this master planning run did complete successfully.

In case your migration has strong dependencies on pending features, an exception to continued usage of the built-in master planning engine can be requested.

Please complete the following questionnaire to get started and if relevant request exception from migration to Planning Optimization.

Answer: No, master planning isn't blocked. Your master planning run was successfully completed, and you can use the result in the usual way. However, to avoid receiving this error message during future master planning runs, you must either migrate to Planning Optimization immediately or request an exception by using the link in the error message.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

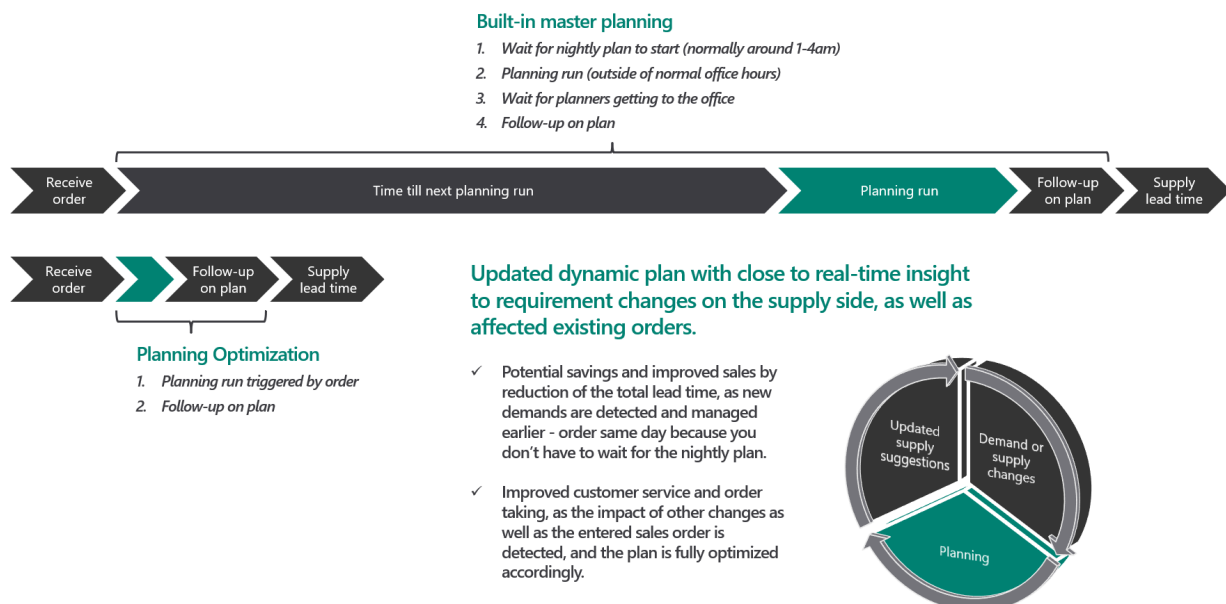

Planning Optimization overview

2/18/2021 • 2 minutes to read • [Edit Online](#)

The Planning Optimization Add-in for Microsoft Dynamics 365 Supply Chain Management enables master planning calculation to occur outside Dynamics 365 Supply Chain Management and the related SQL database. The benefits that are associated with the Planning Optimization functionality include improved performance and minimal impact on SQL database during master planning runs. Quick planning runs can be done even during office hours, so that planners can immediately react to demand or parameter changes.

To use Planning Optimization, you must install the Planning Optimization Add-in from your project in Microsoft Dynamics Lifecycle Services (LCS) and turn on the Planning Optimization functionality in Supply Chain Management. For more information, see [Get started with Planning Optimization](#).

The following illustration shows the advantage of running Planning Optimization during office hours.

Improved performance

Planning Optimization can be used in scenarios that involve long-running master plans. It's specifically designed for very fast calculations that involve very large volumes of data. Because it's built as a hyper-scalable multitenant service, multiple instances can work together simultaneously to calculate the plan. Additionally, the planning service removes the load of master planning from your system and works with a data stream that minimizes the server load.

Planning Optimization can help you achieve the following goals:

- Improve planning performance through a shorter runtime.
- Reduce the impact on other processes during the master planning run.
- Do more frequent planning runs. (You aren't limited to daily runs.)
- Be confident that future business growth won't overload the planning system.

Architecture and data flow

When the Planning Optimization Add-in is installed from LCS, a secure connection to the Planning Optimization service is established. The service is located in the same data center country or region as the related Supply

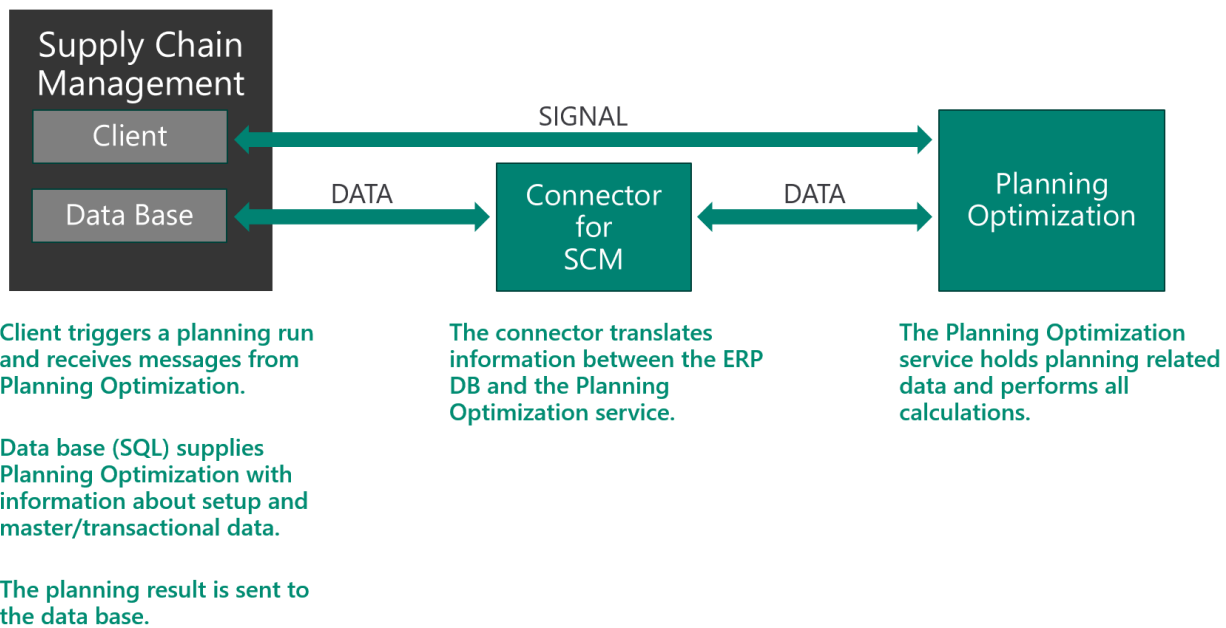

Chain Management instance. After Planning Optimization is set up, when master planning is run, master data and transactional data are sent from Supply Chain Management to the Planning Optimization service.

If the Planning Optimization Add-in is uninstalled, all related data in the Planning Optimization service is removed.

High-level data flow for regeneration runs

1. The Supply Chain Management client sends a signal to request a planning run from Planning Optimization.
2. Planning Optimization requests the required data via the integrated connector.
3. The SQL database sends the requested information about setup, master, and transactional data to Planning Optimization via the connector. The connector translates information between Supply Chain Management and the Planning Optimization service.
4. The Planning Optimization service holds planning-related data in memory and does the required calculations.
5. The planning result is sent to the Supply Chain Management database via the connector. The results include information such as planned orders and pegging information. Planning Optimization sends a signal to Supply Chain Management to indicate that the planning run has been completed. It also sends any relevant messages and warnings.

The following illustration shows the data flow.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Get started with Planning Optimization

2/18/2021 • 5 minutes to read • [Edit Online](#)

As [previously announced](#), Planning Optimization is scheduled to replace the existing built-in master planning engine.

If you currently use the built-in master planning engine, you should start planning your migration to Planning Optimization now. It is important to start the migration process right away because your operations may be impacted when deprecation is enforced. To avoid last-minute issues when deprecation is enforced, we strongly encourage you to complete the migration before December 1, 2020.

The Planning Optimization functionality doesn't currently support all the features that are available in the planning engine that is built into Supply Chain Management. Therefore, it's important that you evaluate whether the feature set that is currently available in Planning Optimization will meet your requirements. The Planning Optimization functionality isn't currently turned on by default in Dynamics Lifecycle Services (LCS), so you have the opportunity to do your evaluation before the feature is turned on.

NOTE

You need to request an exception from migration to Planning Optimization if your master planning process does not include production (master planning generated planned production orders) and you require the built-in master planning engine beyond version 10.0.15. Starting in version 10.0.16, an error will be shown in environments when running built-in master planning without generation of planned production orders. Planning Optimization should be used for all new deployments that do not generate planned production orders during master planning. Owners of existing environments running the built-in master planning engine without generation of Planned production orders, will receive a mail with details about the exception process. We recommend that you work with a partner to evaluate and plan the migration to Planning Optimization.

Before you turn on Planning Optimization, we strongly recommend that you evaluate the results of the Planning Optimization fit analysis. For more information, see [Planning Optimization fit analysis](#).

Availability

Planning Optimization is currently available in the following Azure geographies: United States, Canada, Europe, United Kingdom, Australia, and Asia Pacific. If you try to install the add-in from another geographic region, then LCS will show a message that this geographic is not supported.

Note that Planning Optimization does not support on-premises deployments of Dynamics 365 Supply Chain Management.

Licensing

If you can run master planning by using your current license, you don't have to buy an additional license to start to use Planning Optimization.

Install and enable Planning Optimization

To use Planning Optimization, you must make sure your system has all of the prerequisites in place and then enable its license key and install the Planning Optimization Add-in for Dynamics 365 Supply Chain Management.

Prerequisites

Before you install the Planning Optimization Add-in, the following prerequisites must be in place:

- You must be running Supply Chain Management on an LCS enabled high-availability environment, tier 2 or higher (not a OneBox environment), with Dynamics 365 Supply Chain Management version 10.0.7 or later. If you try to install the add-in on a OneBox environment, the installation will not complete and you will need to cancel the installation.
- Your system must be set up for Power Platform integration. For more information, see [Prerequisites for setting up add-ins](#) and [Set up add-ins](#).

Enable the Planning Optimization license

To use Planning Optimization, you must enable its configuration key. To do so:

1. Put your system into maintenance mode, as described in [Maintenance mode](#).
2. Go to **System administration > Setup > License configuration**.
3. On the **Configuration keys** tab, select the check box for **Planning Optimization**.
4. Turn off maintenance mode, as described in [Maintenance mode](#).

Install the Planning Optimization Add-in

You must install the add-in from your LCS project and then turn on the Planning Optimization functionality from the Supply Chain Management user interface.

To install the Planning Optimization Add-in:

1. Sign in to LCS, and open the desired environment.
2. Go to **Full details**.
3. Scroll down to the **Environment add-ins** FastTab.
4. Select **Install a new add-in**.
5. Select **Planning Optimization**.
6. Follow the installation guide, and agree to the terms and conditions.
7. Select **Install**.
8. On the **Environment add-ins** FastTab, you should see that Planning Optimization is installing.
9. After a few minutes, **Installing** should change to **Installed** (you may need to refresh the page). When installed, you are ready to activate Planning Optimization in Dynamics 365 Supply Chain Management.

The main purpose of installing the Planning Optimization Add-in is to connect the service and the environment. Therefore, you must install the add-in separately on each environment where you will use Planning Optimization, regardless of any code moved between the environments.

Integrate Planning Optimization with your system

To configure whether the Planning Optimization Add-in should be used for master planning, go to **Master planning > Setup > Planning Optimization parameters**.

Connection status

The connection status indicates the current status of the connection between Supply Chain Management and the Planning Optimization service. The following table shows the possible values.

CONNECTION STATUS	DESCRIPTION	CAN PLANNING OPTIMIZATION BE USED?
-------------------	-------------	------------------------------------

CONNECTION STATUS	DESCRIPTION	CAN PLANNING OPTIMIZATION BE USED?
Connected	A connection has been established between the Planning Optimization service and Supply Chain Management.	Yes
Enabling connection	A request to turn on the connection to the Planning Optimization service is currently in progress.	No
Disconnected	There is no connection to the Planning Optimization service. The connection can be turned on from LCS, as described earlier in this topic.	No
Disabling connection	A request to turn off the connection to the Planning Optimization service is currently in progress.	No
Getting status	The system is waiting for status information from the Planning Optimization service.	No

The Use Planning Optimization option

The setting of the **Use Planning Optimization** option determines which planning engine is used for master planning:

- **Yes** – Planning Optimization is used for master planning.
- **No** – The built-in Supply Chain Management planning engine is used for master planning.

NOTE

If existing planning batch jobs that were created for the built-in Supply Chain Management planning engine are triggered while the **Use Planning Optimization** option is set to **Yes**, those jobs will fail.

Integration with the setup

If the Planning Optimization is turned on, master planning is done by using the Planning Optimization Add-in. In this case, master planning results and features are affected.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Planning Optimization fit analysis

2/18/2021 • 12 minutes to read • [Edit Online](#)

You should analyze the result from the Planning Optimization fit analysis as part of the migration process. Note that the scope of Planning Optimization is not equal to the current built-in master planning functionality. We recommend that you work with your partner and read the documentation to prepare for the migration.

Planning Optimization fit analysis helps you to identify where the result might differ between the built-in master planning engine and Planning Optimization. This analysis is done based on your current setup and data.

To see the Planning Optimization fit analysis result, go to **Master planning > Setup > Planning Optimization fit analysis**, and then select **Run analysis**. If the analysis finds any inconsistencies, they are listed on the same page. (The analysis can take a few minutes to run.)

NOTE

If inconsistencies are found, you can still use Planning Optimization. The results of the fit analysis just show places where the planning service won't honor your current setup. In other words, they show places where some processes might be ignored or might not be supported.

Analysis results: Example 1

- **Feature:** Production
- **Issue:** Items with a bill of materials (BOM) level greater than zero: 56
- **Explanation:** The fit analysis found 56 items that have a BOM setup for production. Because the current version of Planning Optimization doesn't support production, Planning Optimization will generate planned purchase orders instead of planned production orders. It will also show a warning that lists the affected items.

Analysis results: Example 2

- **Feature:** Actions
- **Issue:** Coverage groups with actions calculation enabled: 6
- **Explanation:** The fit analysis found six coverage groups where action calculation is turned on. Because the current version of Planning Optimization doesn't support actions, no actions will be generated during master planning.

Overview of possible results from the fit analysis

The following table shows the various results that can be shown after a fit analysis. Number signs (#) will be replaced with a number that indicates the number of records that have the listed issue. Supported or in-preview features are available with version 10.0.9 or later (unless a higher version number is listed in the "Expected availability" column).

FEATURE	LISTED ISSUE	EXPLANATION	EXPECTED AVAILABILITY
---------	--------------	-------------	-----------------------

FEATURE	LISTED ISSUE	EXPLANATION	EXPECTED AVAILABILITY
Actions	Coverage groups with Actions calculation enabled: #	This feature is pending. Currently, actions aren't generated during master planning when Planning Optimization is enabled, regardless of this setting. The main purpose of actions is to suggest changes to existing orders. Evaluate if actions are actively applied as part of your business processes or if the delay information related to the orders is sufficient.	October 2021
Base calendars	Calendars using base calendar: #	This feature is pending. Currently, the base calendar is ignored when Planning Optimization is enabled. Evaluate if the base calendar is needed for your business processes or if direct setup in calendars is sufficient.	April 2021
Batch disposition codes	Non-nettable batch disposition masters: #	This feature is pending. Currently, batch disposition codes are ignored when Planning Optimization is enabled.	October 2021
Capable to promise (CTP)	Default order settings with delivery date control set to CTP: #	This feature is pending. Currently, CTP is ignored when Planning Optimization is enabled, regardless of this setting.	October 2021
Copy static to dynamic plan	Copy of static to dynamic plan is enabled on the master planning parameters.	Planning Optimization doesn't copy the static plan to the dynamic plan, regardless of this setting. In general, this concept is less relevant because of the speed and complete regeneration that Planning Optimization provides. If two or more plans are used, master planning should be triggered for each plan.	October 2021

FEATURE	LISTED ISSUE	EXPLANATION	EXPECTED AVAILABILITY
Firming	Coverage groups with auto firming time fence set: #	In version 10.0.7 and later, firming is supported as a separate firming batch job after master planning is completed (provided the <i>Auto-firming for Planning Optimization</i> feature has been enabled in feature management). Note that auto firming for Planning Optimization is based on the order date (start date), not the requirement date (end date). This behavior ensures that firming of planned orders occurs in due time, without having to include lead time in the firming time fence.	Supported
Firming	Item coverage records with auto firming set: #	In version 10.0.7 and later, auto firming is supported as a separate firming batch job after master planning is completed (provided the <i>Auto-firming for Planning Optimization</i> feature has been enabled in feature management). Note that auto firming for Planning Optimization is based on the order date (start date), not the requirement date (end date). This behavior ensures that firming of planned orders occurs in due time, without having to include lead time in the firming time fence.	Supported
Firming	Master plans with auto firming set: #	In version 10.0.7 and later, auto firming is supported as a separate firming batch job after master planning is completed (provided the <i>Auto-firming for Planning Optimization</i> feature has been enabled in feature management). Note that auto firming for Planning Optimization is based on the order date (start date), not the requirement date (end date). This behavior ensures that firming of planned orders occurs in due time, without having to include lead time in the firming time fence.	Supported

FEATURE	LISTED ISSUE	EXPLANATION	EXPECTED AVAILABILITY
FitAnalysisPlanningItems	Planning Items: #	This feature is pending. Currently, planning items are handled like regular items when Planning Optimization is enabled.	October 2021
Forecast	Coverage groups with "Include intercompany orders" enabled: #	This feature is pending. Currently, master planning doesn't include downstream planned demand when Planning Optimization is enabled, regardless of this setting. Note that released/firmed orders still work with the regular intercompany functionality and will cover most scenarios.	In preview
Forecast	Coverage groups with "Reduce forecast by" setting set to a value different than "Orders": #	By default, Planning Optimization uses "Reduce forecast by" for orders, regardless of this setting.	Supported
Forecast	Forecast models with sub models: #	This feature is pending. Currently, forecasts that use sub-models aren't supported when Planning Optimization is enabled. They will be ignored, regardless of this setting.	April 2021
Forecast	Master plans with "Include supply forecast" enabled: #	This feature is pending. Currently, supply forecasts aren't supported when Planning Optimization is enabled. They will be ignored, regardless of this setting.	October 2021
Freeze time fence	Coverage groups with freeze time fence set: #	The freeze time fence isn't often used, and there are currently no plans to include it for Planning Optimization. Currently, the freeze time fence setup is ignored when Planning Optimization is enabled, regardless of this setting.	N/A
Freeze time fence	Item coverage records with freeze time fence set: #	The freeze time fence isn't often used, and there are currently no plans to include it for Planning Optimization. Currently, the freeze time fence setup is ignored when Planning Optimization is enabled, regardless of this setting.	N/A

FEATURE	LISTED ISSUE	EXPLANATION	EXPECTED AVAILABILITY
Freeze time fence	Master plans with freeze time fence set: #	The freeze time fence isn't often used, and there are currently no plans to include it for Planning Optimization. Currently, the freeze time fence setup is ignored when Planning Optimization is enabled, regardless of this setting.	N/A
Intercompany	Master plans including planned downstream demand: #	This feature is pending. Currently, master planning doesn't include downstream planned demand when Planning Optimization is enabled, regardless of this setting. Note that released/firmed orders still work with the normal intercompany functionality and will cover most scenarios.	In preview
Kanban	Item coverage records with planned order type kanban: #	This feature is pending. Currently, item coverage that is set to kanban will be ignored when Planning Optimization is enabled. The kanban planned order type will create a warning during master planning, and planned purchase orders will be created to cover the related demand.	October 2021
Kanban	Items with default order type kanban: #	Currently, a default order type that is set to kanban will be ignored when Planning Optimization is enabled. The kanban default order type will create a warning during master planning, and planned purchase orders will be created to cover the related demand.	October 2021
Product lifecycle state	Product lifecycle states not active for planning: #	This is a pending feature. Currently the Product lifecycle state is ignored with Planning Optimization enabled. You can adjust the plan level product filter to avoid including products where product lifecycle state is disabled for planning.	Supported

FEATURE	LISTED ISSUE	EXPLANATION	EXPECTED AVAILABILITY
Production	BOM lines with rounding or multiple setup: #	This feature is pending. Currently, rounding and multiple setups are ignored on BOM lines when Planning Optimization is enabled, regardless of this setting.	April 2021
Production	BOM/formula lines with formula measurement: #	This feature is pending. Currently, formula measurement is ignored on BOM and formula lines when Planning Optimization is enabled, regardless of this setting.	October 2021
Production	BOM/formula lines with item substitution (plan groups): #	This feature is pending. Currently, item substitution (plan groups) is ignored on BOM and formula lines when Planning Optimization is enabled, regardless of this setting.	October 2021
Production	BOM/formula lines with negative quantity: #	This feature is pending. BOM and formula lines that have negative quantity will be included with a quantity of 0 (zero) and a warning will be issued when Planning Optimization is enabled. Update master data to avoid warnings.	October 2021
Production	BOM/formula lines with resource consumption: #	This feature is pending. Currently, BOM and formula lines that have resource consumption are ignored when Planning Optimization is enabled. When this feature is supported, the material requirement will be set to the production start date. Until this feature is supported, requirements will not be generated for materials that are marked with a resource consumption flag.	April 2021
Production	BOM/formula lines with step consumption: #	This feature is pending. Currently, step consumption is ignored on BOM and formula lines when Planning Optimization is enabled.	October 2021

FEATURE	LISTED ISSUE	EXPLANATION	EXPECTED AVAILABILITY
Production	BOMs with constant scrap or variable scrap defined: #	This feature is pending. Currently, constant scrap and variable scrap that are defined on BOMs are ignored when Planning Optimization is enabled.	October 2021
Production	BOMs with subcontracting: #	This feature is pending. Currently, the subcontracting setup on BOMs is ignored when Planning Optimization is enabled, regardless of this setting.	October 2021
Production	BOMs without a site: #	This feature is pending. Currently, BOMs without a site are ignored when Planning Optimization is enabled.	Supported
Production	Demand with specific BOM or route requirements defined: #	This feature is pending. Currently, the specific BOM or route requirements that are defined on the demand (such as a sub-BOM or sub-route on a sales order) are ignored when Planning Optimization is enabled. The standard BOM or route will be used, regardless of this setting.	October 2021
Production	Formula versions with Co/By products: #	This feature is pending. Currently, co-products and by-products that are associated with the formula version are ignored when Planning Optimization is enabled.	October 2021
Production	Formula versions with Yield: #	This feature is pending. Currently, yield that is associated with the formula version is ignored when Planning Optimization is enabled.	October 2021
Production	Plans including sequencing: #	This feature is pending. Currently, sequencing is ignored when Planning Optimization is enabled, regardless of this setting.	October 2021

FEATURE	LISTED ISSUE	EXPLANATION	EXPECTED AVAILABILITY
Production	Released production orders that are not started, where scheduled start is earlier than today: #	This feature is pending. Currently, if a production order is delayed, then master planning will assume that it will be completed today. This is relevant for released production orders where a delivery date is in the past, but it has not been completed yet.	October 2021
Production	Resources scheduled with finite capacity: #	This feature is pending. Currently, resources that are scheduled with finite capacity are ignored when Planning Optimization is enabled. Scheduling is done based on the default lead time from the product.	April 2021
Production	Routes used in planning: #	This feature is pending. Currently, routes are ignored when Planning Optimization is enabled. The default lead time from the product is used.	April 2021
Production	Sales line reservation using explosion: #	Sales line reservation that uses explosion isn't supported when Planning Optimization is enabled.	October 2021
Production	Scheduling with explosion of production orders: #	Scheduling that uses explosion of production orders isn't supported when Planning Optimization is enabled. Production orders can be scheduled individually.	October 2021
Request for quotations	Master plans with request for quotations enabled: #	This feature is pending. Currently, requests for quotation (RFQs) aren't considered as demand when Planning Optimization is enabled. They will be ignored, regardless of this setting.	October 2021
Requisitions	Master plans with requisitions enabled: #	This feature is pending. Currently, requisitions aren't considered when Planning Optimization is enabled. They will be ignored, regardless of this setting.	October 2021

FEATURE	LISTED ISSUE	EXPLANATION	EXPECTED AVAILABILITY
Safety margins	Coverage groups with safety margin: #	This feature is pending. Currently, safety margin is ignored when Planning Optimization is enabled. To compensate for this behavior, you can increase the lead time so that it includes the safety margin.	Receipt margin: Supported. Reorder margin and issue margin: April 2021
Safety margins	Master plans with safety margin: #	This feature is pending. Currently, safety margin is ignored when Planning Optimization is enabled, regardless of this setting. To compensate for this behavior, you can increase the lead time so that it includes the safety margin.	Receipt margin: Supported. Reorder margin and issue margin: April 2021
Safety stock fulfillment	Item coverage records with "Fulfill minimum" different from "Today's date + procurement time": #	Planning Optimization always uses <i>Today's date + procurement time</i> . This change is made to prepare for a simplified planning setup in the future, and to provide an actionable result. If the procurement time isn't included for safety stock, planned orders that are created for current low on-hand inventory will always be delayed because of the lead time. This behavior can cause significant noise and unwanted planned orders. The best practice is to change the setting so that <i>Today's date + procurement time</i> is used. Update master data to avoid warnings.	N/A
Sales quotations	Master plans with sales quotations enabled: #	This feature is pending. Currently, quotations aren't considered when Planning Optimization is enabled. They will be ignored, regardless of this setting.	October 2021
Shelf life	Master plans with shelf life enabled: #	This feature is pending. Currently, shelf life isn't considered when Planning Optimization is enabled, regardless of this setting.	October 2021

Apply filters to a plan

2/18/2021 • 2 minutes to read • [Edit Online](#)

When the Planning Optimization functionality is used, you can apply a filter to a plan. The **Plan filter** will always be applied during a master planning run. A **Plan filter** is useful when you want to limit a plan to a specific group of items and make sure that no other items are included as part of the resulting master planning.

If a **Plan filter** is applied, and a runtime filter is also applied during the master planning run, only the intersection of the two filters is included in the planning run.

The **Plan filter** can be accessed from **Master plans** when Planning Optimization is used.

Example scenario

A plan filter is set up that includes items A, B, and C. Master planning runs are then run for the same plan, but different runtime filters are applied:

- **Runtime filter that includes item D:** No items are planned, because there is no intersection between the plan filter and the runtime filter.
- **Runtime filter that includes item A and D:** Only item A is included in the planning run, because item D isn't part of the plan filter.
- **Runtime filter that includes item B:** Only item B is included in the planning run, and the previous planning output for item A is kept.
- **Runtime filter that includes all items (blank filter):** Items A, B, and C are included in the planning run, and the previous planning output for items A and B is overwritten.

NOTE

You should avoid setting a plan filter on the plan that is selected as **Current dynamic master plan** on the **Master planning parameters** page. Otherwise, the dynamic master plan functionality will be limited to the filtered items. For example, if the net requirements are updated for an item that isn't part of the plan filter, no result will be generated.

Master planning with demand forecasts

2/18/2021 • 15 minutes to read • [Edit Online](#)

You can use a demand forecast together with Planning Optimization to account for expected demand in your master planning. You can manually create a demand forecast, import it, or generate it by using the demand forecasting functionality in Microsoft Dynamics 365 Supply Chain Management. For more information about demand forecasting, see [Demand forecasting overview](#).

NOTE

Separate forecast planning isn't supported with Planning Optimization. Therefore, the **Current forecast plan** setting on the **Master planning parameters** page has no effect when you use Planning Optimization.

Set up a master plan to include a demand forecast

To configure a master plan so that it includes a demand forecast, follow these steps.

1. Go to **Master planning > Setup > Plans > Master plans**.
2. Select an existing plan, or create a new plan.
3. On the **General** FastTab, set the following fields:
 - **Forecast model** – Select the forecast model to apply. This model will be considered when a supply suggestion is generated for the current master plan.
 - **Include demand forecast** – Set this option to *Yes* to include the demand forecast in the current master plan. If you set it to *No*, demand forecast transactions won't be included in the master plan.
 - **Method used to reduce forecast requirements** – Select the method that should be used to reduce forecast requirements. For more information, see the [Forecast reduction keys](#) section later in this topic.
4. On the **Time fence in days** FastTab, you can set the following fields to specify the period that the demand forecast is included during:
 - **Forecast plan** – Set this option to *Yes* to override the forecast plan time fence that originates from the individual coverage groups. Set it to *No* to use the values from the individual coverage groups for the current master plan.
 - **Forecast time period** – If you set the **Forecast plan** option to *Yes*, specify the number of days (from today's date) that the demand forecast should be applied.

IMPORTANT

The **Forecast plan** setting isn't yet supported with Planning Optimization.

Set up a coverage group to include a demand forecast

To configure a coverage group so that it includes a demand forecast, follow these steps.

1. Go to **Master planning > Setup > Plans > Coverage groups**.
2. Select an existing coverage group, or create a new group.

3. On the **Other** FastTab, set the following fields:

- **Forecast plan time fence** – Enter the number of days (from today's date) that the demand forecast should be applied for. This value can be overridden by using the **Forecast plan** option on the master plan, as described in the previous section.
- **Reduction key** – Select the reduction key to apply. For more information, see the [Create and set up a forecast reduction key](#) and [Use a reduction key](#) sections later in this topic.
- **Reduce forecast by** – For master plans where the **Method used to reduce forecast requirements** field is set to *Transactions - reduction key* or *Transactions - dynamic period*, specify which transactions should reduce the forecast. Select one of the following values:
 - **All transactions** – All transactions should reduce the forecast.
 - **Orders** – Only sales orders should reduce the forecast.

NOTE

If you select *All transactions*, transactions that have both demand and supply in the same inventory dimensions are considered neutral and are ignored during the forecast reduction. For example, if the planning dimension is set to site only, not warehouse, a transfer order between site 1, warehouse 11, and site 1, warehouse 13, will be ignored and won't reduce the remaining demand forecast.

- **Include intercompany orders** – Set this option to *Yes* if intercompany orders should be included when the forecast is reduced. Otherwise, set it to *No*.
- **Include customer forecast in the demand forecast** – Specify whether a customer forecast should be included in the overall forecast. This option determines how actual demand reduces the forecasted demand. You can use it to ensure that master planning covers the supply of items that are purchased by specific customers.
 - Set this option to *Yes* to include a customer forecast in the overall forecast. In this case, actual customer demand reduces both the customer forecast and the overall forecast. Master planning generates planned orders to cover only the overall forecast quantity.
 - Set this option to *No* if you don't want to include a customer forecast in the overall forecast. In this case, actual customer demand reduces only the customer forecast. Master planning generates planned orders to cover both the overall forecast quantity and the forecast for each customer quantity.

Forecast reduction keys

This section provides information about the different methods that are used to reduce forecast requirements. It includes examples of the results of each method. It also explains how to create, set up, and use a forecast reduction key. Some methods use a forecast reduction key to reduce forecast requirements.

Methods that are used to reduce forecast requirements

When you include a forecast in a master plan, you can select how the forecast requirements are reduced when actual demand is included. Note that master planning excludes forecast requirements from the past, which means all forecast requirements before today's date.

To include a forecast in a master plan and select the method that is used to reduce forecast requirements, go to **Master planning > Setup > Plans > Master plans**. In the **Forecast model** field, select a forecast model. In the **Method used to reduce forecast requirements** field, select a method. The following options are available:

- None

- Percent – reduction key
- Transactions – reduction key (not yet supported with Planning Optimization)
- Transactions – dynamic period

The following sections provide more information about each option.

None

If you select **None**, the forecast requirements aren't reduced during master scheduling. In this case, master planning creates planned orders to supply the forecasted demand (forecast requirements). These planned orders maintain the suggested quantity, regardless of other types of demand. For example, if sales orders are placed, master planning creates additional planned orders to supply the sales orders. The quantity of the forecast requirements isn't reduced.

Percent – reduction key

If you select **Percent - reduction key**, the forecast requirements are reduced according to the percentages and periods that are defined by the reduction key. In this case, master planning creates planned orders where the quantity is calculated as forecasted quantity × reduction key in each period. If there are other types of demand, master planning also creates planned orders to supply that demand.

Example: Percent – reduction key

This example shows how a reduction key reduces demand forecast requirements according to the percentages and periods that are defined by the reduction key.

For this example, you include the following demand forecast in a master plan.

MONTH	DEMAND FORECAST
January	1,000
February	1,000
March	1,000
April	1,000

On the **Reduction keys** page, you set up the following lines.

CHANGE	UNIT	PERCENT
1	Month	100
2	Month	75
3	Month	50
4	Month	25

You assign the reduction key to the item's coverage group. Then, on the **Master plans** page, in the **Method used to reduce forecast requirements** field, you select **Percent - reduction key**.

In this case, if you run forecast scheduling on January 1, the demand forecast requirements are consumed according to the percentages that you set up on the **Reduction keys** page. The following requirement quantities are transferred to the master plan.

MONTH	PLANNED ORDER QUANTITY	CALCULATION
January	0	= 0% × 1,000
February	250	= 25% × 1,000
March	500	= 50% × 1,000
April	750	= 75% × 1,000
May through December	1,000	= 100% × 1,000

Transactions – reduction key

If you select **Transactions - reduction key**, the forecast requirements are reduced by the transactions that occur during the periods that are defined by the reduction key.

Example: Transactions – reduction key

This example shows how actual orders that occur during the periods that are defined by the reduction key reduce demand forecast requirements.

For this example, you select **Transactions - reduction key** in the **Method used to reduce forecast requirements** field on the **Master plans** page.

The following sales orders exist on January 1.

MONTH	NUMBER OF PIECES ORDERED
January	956
February	1,176
March	451
April	119

If you use the same demand forecast of 1,000 pieces per month that was used in the previous example, the following requirement quantities are transferred to the master plan.

MONTH	NUMBER OF PIECES REQUIRED
January	44
February	0
March	549
April	881
May through December	1,000

Transactions – dynamic period

If you select **Transactions - dynamic period**, the forecast requirements are reduced by the actual order transactions that occur during the dynamic period. The dynamic period covers the current forecast dates and ends at the start of the next forecast. In this case, master planning creates planned orders to supply the forecasted demand (forecast requirements). However, when actual order transactions are placed, the forecast

requirements are reduced. The actual transactions consume part of the forecasted requirements.

When this option is used, the following behavior occurs:

- Reduction keys aren't required or used.
- If the forecast is completely reduced, the forecast requirements for the current forecast become 0 (zero).
- If there is no future forecast, forecast requirements from the last forecast that was entered are reduced.
- Time fences are included in the forecast reduction calculation.
- Positive days are included in the forecast reduction calculation.
- If actual order transactions exceed the forecasted requirements, the remaining transactions aren't forwarded to the next forecast period.

Example 1: Transactions - dynamic period

Here a simple example that shows how the **Transactions - dynamic period** method works.

For this example, you include the following demand forecast in a master plan.

DATE	DEMAND FORECAST
January 1	1,000
February 1	1,000

You also create the following sales orders.

DATE	SALES ORDER QUANTITY
January 15	200
February 15	400

In this case, the following planned orders are created.

DEMAND FORECAST DATE	QUANTITY	EXPLANATION
January 1	800	Forecast requirements (= 1,000 – 200)
January 15	200	Sales orders requirements
February 1	600	Forecast requirements (= 1,000 – 400)
February 15	400	Sales orders requirements

Example 2: Transactions - dynamic period

In most cases, systems are set up so that transactions reduce demand forecast in specific forecast periods: weeks, months, and so on. These periods are defined in the reduction key. However, the time between two demand forecast lines can also *imply* a period.

For this example, you create a demand forecast for the following dates and quantities.

DATE	DEMAND FORECAST
January 1	1,000
January 5	500

DATE	DEMAND FORECAST
January 12	1,000

Notice that, in this forecast, there isn't a clear period between the forecast dates. Between the first and second dates there is a four-day span, and between the second and third dates there is a seven-day span. These spans are the dynamic periods.

You also create the following sales order lines.

DATE	SALES ORDER QUANTITY
December 15 in the previous year	500
January 3	100
January 10	200

In this case, the forecast is reduced in the following manner:

- Because the first sales order isn't in any period, it doesn't reduce any forecast.
- Because the second sales order is between January 1 and January 5, it reduces the forecast for January 1 by 100.
- Because the third sales order is between January 5 and January 12, it reduces the forecast for January 5 by 200.

Therefore, the following planned orders are created.

DEMAND FORECAST DATE	QUANTITY	EXPLANATION
December 15 in the previous year	500	Sales order requirements
January 1	900	Forecast requirements period January 1 to January 5 (= 1,000 – 100)
January 3	100	Sales order requirements
January 5	300	Forecast requirements period January 5 to January 10 (= 500 – 200)
January 12	1,000	Forecast requirements period January 12 to end

Create and set up a forecast reduction key

A forecast reduction key is used in the **Transactions - reduction key** and **Percent- reduction key** methods for reducing forecast requirements. Follow these steps to create and set up a reduction key.

1. Go to **Master planning > Setup > Coverage > Reduction keys**.
2. Select **New** to create a reduction key.
3. In the **Reduction key** field, enter a unique identifier for the forecast reduction key. Then, in the **Name** field, enter a name.
4. Define the periods and the reduction key percentage in each period:

- The **Effective date** field indicates the date when creation of the periods starts. When the **Use the effective date** option is set to **Yes**, the periods start on the effective date. When it's set to **No**, the periods start on the date when master planning is run.
- Define the periods that the forecast reduction should occur during.
- For a specific period, specify the percentages that the forecast requirements should be reduced by. You can enter positive values to decrease requirements or negative values to increase requirements.

Use a reduction key

A forecast reduction key must be assigned to the coverage group of the item. Follow these steps to assign a reduction key to an item's coverage group.

1. Go to **Master planning > Setup > Coverage > Coverage groups**.
2. On the **Other** FastTab, in the **Reduction key** field, select the reduction key to assign to the coverage group. The reduction key then applies to all items that belong to the coverage group.
3. To use a reduction key to calculate forecast reduction during master scheduling, you must define this setting in the setup of the forecast plan or the master plan. Go to one of the following locations:
 - **Master planning > Setup > Plans > Forecast plans**
 - **Master planning > Setup > Plans > Master plans**
4. On the **Forecast plans** or **Master plans** page, on the **General** FastTab, in the **Method used to reduce forecast requirements** field, select either **Percent - reduction key** or **Transactions - reduction key**.

Reduce a forecast by transactions

When you select **Transactions - reduction key** or **Transactions - dynamic period** as the method for reducing forecast requirements, you can specify which transactions reduce the forecast. On the **Coverage groups** page, on the **Other** FastTab, in the **Reduce forecast by** field, select **All transactions** if all transactions should reduce the forecast or **Orders** if only sales orders should reduce the forecast.

Forecast models and submodels

This section describes how to create forecast models and how to combine multiple forecast models by setting up submodels.

A *forecast model* names and identifies a specific forecast. After you've created the forecast model, you can add forecast lines to it. To add forecast lines for multiple items, use the **Demand forecast lines** page. To add forecast lines for a specific selected item, use the **Released products** page.

A forecast model can include forecasts from other forecast models. To achieve this result, you add other forecast models as *submodels* of a parent forecast model. You must create each relevant model before you can add it as a submodel of a parent forecast model.

The resulting structure gives you a powerful way to control forecasts, because it lets you combine (aggregate) the input from multiple individual forecasts. Therefore, from a planning point of view, it's easy to combine forecasts for simulations. For example, you might set up a simulation that is based on the combination of a regular forecast with the forecast for a spring promotion.

Submodel levels

There is no limit on the number of submodels that can be added to a parent forecast model. However, the structure can be only one level deep. In other words, a forecast model that is a submodel of another forecast model can't have its own submodels. When you add submodels to a forecast model, the system checks whether that forecast model is already a submodel of another forecast model.

If master planning encounters a submodel that has its own submodels, you receive an error message.

Submodel levels example

Forecast model A has forecast model B as a submodel. Therefore, forecast model B can't have its own submodels. If you try to add a submodel to forecast model B, you receive the following error message: "Forecast model B is a submodel for model A."

Aggregating forecasts across forecast models

Forecast lines that occur on the same day will be aggregated across their forecast model and its submodels.

Aggregation example

Forecast model A has forecast models B and C as submodels.

- Forecast model A includes a demand forecast for 2 pieces (pcs) on June 15.
- Forecast model B includes a demand forecast for 3 pcs on June 15.
- Forecast model C includes a demand forecast for 4 pcs on June 15.

The resulting demand forecast will be a single demand for 9 pcs (2 + 3 + 4) on June 15.

NOTE

Each submodel uses its own parameters, not the parameters of the parent forecast model.

Create a forecast model

To create a forecast model, follow these steps.

1. Go to **Master planning > Setup > Demand forecasting > Forecast models**.
2. On the Action Pane, select **New**.
3. Set the following fields for the new forecast model:
 - **Model** – Enter a unique identifier for the model.
 - **Name** – Enter a descriptive name for the model.
 - **Stopped** – Usually, you should set this option to *No*. Set it to *Yes* only if you want to prevent editing of all forecast lines that are assigned to the model.

NOTE

The **Include in cash flow forecasts** field and the fields on the **Project** FastTab aren't related to master planning. Therefore, you can ignore them in this context. You must consider them only when you work with forecasts for the **Project management and accounting** module.

Assign submodels to a forecast model

To assign submodels to a forecast model, follow these steps.

1. Go to **Inventory management > Setup > Forecast > Forecast models**.
2. In the list pane, select the forecast model to set up a submodel for.
3. On the **Submodel** FastTab, select **Add** to add a row to the grid.
4. In the new row, set the following fields:
 - **Submodel** – Select the forecast model to add as a submodel. This forecast model must already exist, and it must not have any submodels of its own.
 - **Name** – Enter a descriptive name for the submodel. For example, this name might indicate the submodel's relation to the parent forecast model.

Master planning with purchase trade agreements

2/18/2021 • 4 minutes to read • [Edit Online](#)

This topic describes how Planning Optimization can find the vendor and/or lead time for a planned order, based on the best price or lead time that is found among all purchase trade agreements that have been specified for a given product.

Turn on the Purchase trade agreements for Planning Optimization feature

Before you can use this feature, it must be turned on in your system. Admins can use the [Feature management](#) workspace to check the status of the feature and turn it on if it's required. There, the feature is listed in the following way:

- **Module:** *Master planning*
- **Feature name:** *Purchase trade agreements for Planning Optimization*

Prepare your system to evaluate purchase trade agreements during master planning

Follow these steps to configure your system to apply Planning Optimization that evaluates purchase trade agreements.

1. Go to **Master planning > Setup > Master planning parameters**. On the **Planned orders** tab, in the **Vendor** section, set the following values:
 - **Find trade agreement** – Set this option to **Yes** to include purchase trade agreements in master planning.
 - **Search criterion** – Select the factor that you want to prioritize for each purchase trade agreement: **Minimum lead time** or **Lowest unit price**.
2. Go to **Procurement and sourcing > Setup > Prices and discounts > Activate price/discount**, and make sure that the **Vendor** option is set to **Yes**.
3. Go to **Product information management > Setup > Dimension and variant groups > Storage dimension groups**, and select a storage dimension group that applies to products that master planning should evaluate purchase trade agreements for. Make sure that each relevant storage dimension in this group has a check mark in the **For purchase prices** column. Repeat this step for every other relevant storage dimension group.

Prepare a released product to evaluate purchase trade agreements during master planning

After your system is prepared as described in the previous section, you should follow these steps to make sure that each product that you want to use with this feature is correctly set up.

1. Go to **Product information management > Products > Released products**, and open a target product.
2. On the **Purchase** FastTab, make sure that no vendor is assigned in the **Vendor** field.
3. On the Action Pane, on the **Plan** tab, in the **Coverage** group, select **Item coverage** to open the **Item**

coverage page for the selected product. Verify the following settings:

- On the **General** tab, you can set up vendor overrides. If you want Planning Optimization to use purchase trade agreements to select a vendor, you should prevent vendor overrides by clearing the **Use specific setting** check box.
 - On the **Lead time** tab, you can set up lead-time overrides. If you want Planning Optimization to use purchase trade agreements to select lead times, you should prevent lead-time overrides. Clear the check box for each type of lead time that you want to select by using purchase trade agreements (**Purchase, Production, and/or Transfer**).
4. Close the **Item coverage** page to return to the details page for the selected product.
 5. On the Action Pane, on the **Plan** tab, in the **Forecast** group, select **Supply forecast** to open the **Supply forecast** page. Make sure that no row that is shown here has a value in the **Vendor account** column.
 6. Close the **Supply forecast** page to return to the details page for the selected product.
 7. On the Action Pane, on the **Purchase** tab, in the **Trade agreements** group, select **View trade agreements**. Make sure that all the relevant purchase trade agreements are listed. Also make sure that the **Disregard lead time** option is set to **No** for each agreement where you want Planning Optimization to use the lead time that is specified for that agreement.
 8. On the Action Pane, on the **Plan** tab, in the **Order settings** group, select **Default order settings** to open the **Default order settings** page for the selected product. On the **Purchase order** FastTab, view the value of the **Purchase lead time** field. If no item coverage lead-time override is defined, Planning Optimization will use this value when it selects trade agreements where the **Disregard lead time** option is set to **Yes**. Therefore, you should adjust this value as you require.
 9. Repeat this procedure for each relevant product.

NOTE

Currency on the purchase trade agreement line must match the currency of the selected vendor. Master planning will only include information from purchase trade agreement lines where the currency matches the currency on the vendor.

Examples of how Planning Optimization finds vendor and lead times

The following table provides examples that show how various settings for a released product and its associated purchase trade agreements affect the values that are found for the resulting planned purchase order. The **bold** values in the two rightmost columns are the values that are selected by Planning Optimization. The **bold and italic** values in the other columns are the settings that produced those resulting values for each row.

Safety margins

2/18/2021 • 8 minutes to read • [Edit Online](#)

This topic describes how safety margins can be used with the Planning Optimization Add-in for Microsoft Dynamics 365 Supply Chain Management.

Safety margins overview

The purpose of safety margins is to enable a setup that provides some buffer time beyond the normal lead time. For example, when material must be unpacked or inspected after it arrives from the vendor, you can't just add the extra time to the purchase lead time, because this approach will give the additional buffer time to the supplier. In this example, the receipt margin can be used to ensure that the supplier delivers earlier. This approach provides buffer time so that the goods can be handled internally.

There are three types of safety margins:

- **Reorder margin** – The buffer time for placing the supply order
- **Receipt margin** – The buffer time for handling incoming supply
- **Issue margin** – The buffer time for handling shipments

The following illustration shows how these safety margins apply over time.

All margins are defined in days. The default value, 0 (zero), indicates that no margin is applied. If you set up multiple margins, they all add to the total time from the supply *order date* to the demand *requirement date*. For example, a setup has no lead time, and all three margin types are set to one day. In this case, there will be three days between the supply order date and the demand requirement date, so if the order date is July 1, the requirement date would be July 4.

Receipt margin

The receipt margin is probably the most used of the three safety margins. It's applied to the *delivery date* and backward from the *requirement date*. In other words, the products should be received the specified number of receipt margin days before they are required.

The following illustration highlights the receipt margin.

The receipt margin is typically used as a buffer to ensure time for warehouse registration or other time-consuming processes that aren't captured as part of the general lead time in the system. For purchases, one

benefit is that the *delivery date* of the purchase order is moved forward accordingly. If you increase the lead time instead of using a safety margin, the vendor will still be asked to deliver at the last minute.

Notice that the receipt margin doesn't change the *requirement date* of the supply. Therefore, the receipt margin isn't directly visible when requirement dates for demand and supply are compared (for example, on the **Net requirements** page). For example, if the receipt margin is set to four days, and a purchase order line is planned for receipt on the fifteenth of the month, master planning calculates the adjusted receipt date as the nineteenth of the month.

Note that a receipt margin isn't applied when on-hand inventory is used as the supply. All on-hand inventory is assumed to be available immediately, regardless of when it was actually received.

Reorder margin

NOTE

Coming soon: This feature isn't yet supported for Planning Optimization. Until it's supported, all values that are entered for **Reorder margin added to item lead time** will be treated as 0 (zero).

The following illustration highlights the reorder margin.

The reorder margin is added before the item lead time for all planned orders during master planning. Therefore, it ensures additional time for a supply order to be placed. This margin is typically used as a buffer to ensure time for approval processes or other internal processes that are required during the creation of supply orders. The reorder margin is put between the supply *order date* and *start date*.

Issue margin

NOTE

Coming soon: This feature isn't yet supported for Planning Optimization. Until it's supported, all values that are entered for **Issue margin deducted from requirement date** will be treated as 0 (zero).

The following illustration highlights the issue margin.

The issue margin is deducted from the demand requirement date during master planning. It helps ensure that you have time to react to and ship incoming demand orders. This margin is typically used as a buffer to ensure time for shipment and related outbound warehouse processes.

Notice that when an issue margin is applied, related supply and demand requirement dates don't match. Instead, they differ by the issue margin, because the issue margin is added between the supply *requirement date* and the demand *requirement date*.

Set up safety margins

Turn on safety margins in Feature management

Before you can use this feature with Planning Optimization, it must be turned on in your system. Admins can use the [Feature management](#) workspace to check the status of the feature and turn it on if it's required. There, the feature is listed in the following way:

- **Module:** *Master planning*
- **Feature name:** *Margins for Planning Optimization*

Define safety margins

Safety margins have a flexible setup. They can be set on both the *coverage group* and the *master plan*. It's important that you understand that the margins are added on top of each other. For example, a receipt margin of two days on the coverage group and three days on the master plan will produce an effective receipt margin of five days.

The ability to set the margin on the master plan can be useful when you want to simulate longer lead times or uncertainty for a specific plan, but without affecting the daily planning.

Coverage group safety margins

To apply a safety margin to a coverage group, follow these steps.

1. Go to **Master planning > Setup > Coverage groups**.
2. In the list pane, select the desired coverage group.
3. On the **Other** FastTab, in the **Safety margins in days** section, use the following fields to set the required safety margins (in days):
 - Receipt margin added to requirement date
 - Issue margin deducted from requirement date
 - Reorder margin added to item lead time

Master plan safety margins

To apply a safety margin to a master plan, follow these steps.

1. Go to **Master planning > Setup > Plans > Master plans**.
2. In the list pane, select the desired master plan.
3. On the **Safety margins in days** FastTab, use the following fields to set the required safety margins (in days):
 - Receipt margin added to requirement date
 - Issue margin deducted from requirement date
 - Reorder margin added to item lead time

Define whether calculations are based on calendar days or work days

You can set all safety margins so that they are calculated based on either calendar days or work days.

1. Go to **Master planning > Setup > Master planning parameters**.
2. On the **General** tab, in the **Safety margins in days** section, set the **Working days** option to *Yes* to calculate margins based on working days. Set the option to *No* to calculate margins based on calendar days.

For example, a calendar is open from Monday through Friday and closed from Saturday through Sunday. If there is a receipt margin of one day, a requirement date on a Monday produces a delivery date on the previous Friday, because Saturday and Sunday aren't working days.

The calendar that is used to determine the working days depends on the setup and the supply type. It can be controlled by the calendars of the coverage group, the warehouse, and the vendor.

NOTE

If *warehouse* isn't part of the coverage dimension (in other words, planning is based only on *site*), the warehouse calendar isn't used.

The system can handle a setup where one or more calendars are defined. The following subsections describe the possible combinations that can be used to control the result.

Calendar that is used for the duration

The defined calendars control the actual total lead time in calendar days, from the supply order date to the demand requirement date. The following calendar prioritization is used:

- **Purchase lead time** – Only the coverage group calendar is considered.
- **Receipt margin** – The coverage group calendar is used, if it's defined. Otherwise, the warehouse calendar is used.
- **Issue margin** – The coverage group calendar is used, if it's defined. Otherwise, the warehouse calendar is used.
- **Order margin** – Only the coverage group calendar is considered.

Calendar that is used for the final date

The following rules are applied to determine whether the planning engine can use a given date for a given date type:

- **Purchase receipt date** – The vendor calendar is used, if it's defined. Otherwise, the coverage group calendar is used, if it's defined. If neither of those calendars is defined, the warehouse calendar is used.
- **Transfer receipt date** – The coverage group calendar is used, if it's defined. Otherwise, the warehouse calendar is used.
- **Production receipt date** – The coverage group calendar is used, if it's defined. Otherwise, the warehouse calendar is used.
- **Demand issue open day** – The warehouse calendar is used, if it's defined. Otherwise, the coverage group calendar is used.
- **Order open day** – A combination (intersection) of the coverage group calendar and the vendor calendar is used. Both calendars must be open to use the date. If only one of the calendars is defined, that calendar is used alone.

Calendar setup overview matrix

The following illustration presents a matrix that summarizes which calendars apply when safety margins are calculated. (Select the image to open a high-resolution version of it.) The following abbreviations and colors are used to indicate where each type of calendar is specified:

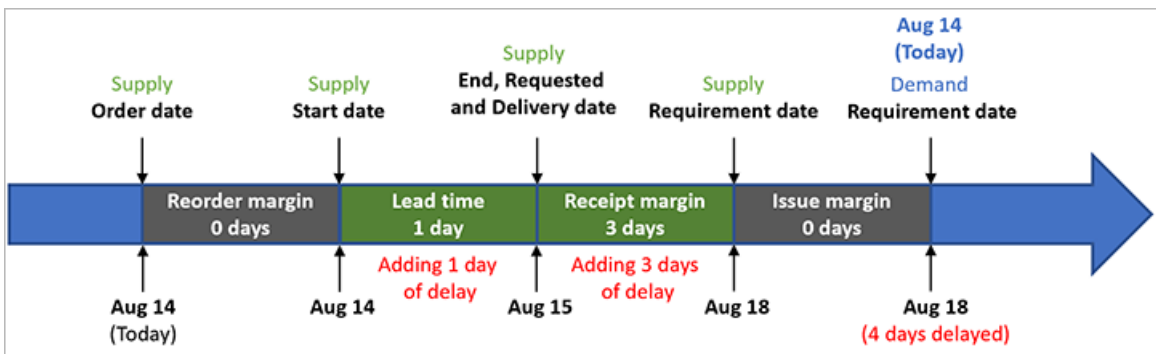

- **Coverage group (CG):** Green
- **Warehouse (WH):** Yellow
- **Vendor (V):** Blue

Calendar is specified on			Calendar used for duration Only counting open days				Calendar used for final date Is the date open or closed				
Coverage group (CG)	Warehouse (WH)	Vendor (V)	Lead time	Receipt margin	Issue margin	Order margin	Purchase requirement date	Transfer requirement date	Production requirement date	Demand requirement date	Supply Order date
Yes	Yes	Yes	CG	CG	CG	CG	V	CG	CG	WH	CG+V
No	Yes	Yes	None	WH	WH	None	V	WH	WH	WH	V
Yes	No	Yes	CG	CG	CG	CG	V	CG	CG	CG	CG+V
Yes	Yes	No	CG	CG	CG	CG	CG	CG	CG	WH	CG
Yes	No	No	CG	CG	CG	CG	CG	CG	CG	CG	CG
No	Yes	No	None	WH	WH	None	WH	WH	WH	WH	None
No	No	Yes	None	None	None	None	V	None	None	None	V
No	No	No	None	None	None	None	None	None	None	None	None

Calculating delays

All three types of safety margins are included when the system determines whether an order is delayed.

For example, an item has lead time of one day and a receipt margin of three days. A sales order for this item is set as required today. In this case, the delay is calculated as $lead\ time + receipt\ margin = four\ days$. Therefore, if today is August 14, the four days of delay produces a delivery on August 18. The following illustration shows this example.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Purchase requisitions

2/18/2021 • 3 minutes to read • [Edit Online](#)

Master planning can replenish approved purchase requisitions. Therefore, to cover purchase requisitions, users don't have to use a workflow to create purchase orders. Instead, purchase requisitions can be covered by master planning. Because of this functionality, a purchase requisition can produce a purchase order, a transfer order, or a production order, depending on the **Planned order type** value that is set for the related product.

Enable master plans to include requisitions

To include requisitions during the coverage calculation for a master plan, follow these steps.

1. Go to **Master planning > Setup > Plans > Master plans**.
2. Create or select a master plan.
3. On the **General** FastTab, set the **Include requisitions** option to *Yes*.
4. Repeat steps 2 and 3 for each additional master plan where you want to include requisitions.

Approved requisitions time fence

The *approved requisitions time fence* establishes how far back (in days) a master plan will include demand from approved replenishment requisitions. You can set an approved requisitions time fence at both the coverage group level and the master plan level.

Set the approved requisitions time fence for a coverage group

1. Go to **Master planning > Setup > Coverage > Coverage group**.
2. Create or select a coverage group.
3. On the **Other** FastTab, set the **Approved requisitions time fence (days)** field to the number of days to include in the time fence.
4. Repeat steps 2 and 3 for each additional coverage group where you want to set an approved requisitions time fence.

Set the approved requisitions time fence for individual master plans

When you set an approved requisitions time fence for an individual master plan, the setting overrides the time fence setting for any applicable coverage group.

1. Go to **Master planning > Setup > Plans > Master plans**.
2. Create or select a master plan.
3. On the **Time fences in days** FastTab, set the **Approved requisitions time fence (days)** field to the number of days to include in the time fence.
4. Repeat steps 2 and 3 for each additional master plan where you want to set an approved requisitions time fence.

IMPORTANT

Coming soon: Approved requisitions time fences aren't yet supported for Planning Optimization. Until they are supported, all values that you enter in the **Approved requisitions time fence (days)** field will be ignored.

Independent supply, regardless of coverage code

Purchase requisitions are always covered by independent planned orders, regardless of the coverage code. This behavior ensures clear traceability and workflows between purchase requisitions and replenishment orders.

Example 1

A product is set up so that it has a **Coverage code** value of *Min/max*. It has the following inventory and requisition statuses:

- Inventory on-hand quantity = 10.
- Minimum inventory quantity = 15.
- Maximum inventory quantity = 20.
- A purchase requisition for one piece exists. It has a requested date of today.

When master planning runs, two planned orders are created: one for 10 pieces to replenish inventory to the maximum quantity, and one for one piece to replenish the purchase requisition.

Example 2

A product is set up so that it has a **Coverage code** value of *Min/max*. It has the following inventory and requisition statuses:

- Inventory on-hand quantity = 17.
- Minimum inventory quantity = 15.
- Maximum inventory quantity = 20.
- A purchase requisition for one piece exists. It has a requested date of today.

When master planning runs, one planned order for one piece is created to replenish the purchase requisition.

Example 3

A product is set up so that it has a **Coverage code** value of *Period* and a period length of seven days. It has the following inventory, sales order, and requisition statuses:

- Inventory on-hand quantity = 0.
- A sales order for five pieces exists. It has an expected ship date of today plus one day.
- A purchase requisition for three pieces exists. It has a requested date of today plus three days.

When master planning runs, two planned orders are created: one for three pieces to replenish the purchase requisition and one for five pieces to replenish sales order demand.

NOTE

After a planned order that is pegged to a purchase requisition is firm, the planning engine keeps the pegging to the purchase requisition. If the firm order is later found to be missing some quantity that is required to fulfill the purchase requisition, the system will create a new planned order for the difference.

For more information about purchase requisitions, see [Purchase requisition overview](#).

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Production planning

2/18/2021 • 4 minutes to read • [Edit Online](#)

Planning Optimizations supports several production scenarios. If you're migrating from the existing, built-in master planning engine, it's important that you be aware of some changed behavior.

The following video gives a short introduction to some of the concepts discussed in this topic: [Dynamics 365 Supply Chain Management: Planning Optimization enhancements](#).

Planned production orders

When master planning creates planned orders to fulfill requirements, the order type is determined by the value of the **Planned order type** field. If the **Planned order type** field is set to *Production*, planned production orders are created. These planned production orders include information about the active bill of materials (BOM) and the route ID from the related production setup.

Requirements from BOMs

BOM information is honored during master planning. The plan output includes material supply to cover related material demand for production.

During master planning, the current, active BOM is used to determine the materials that are required for production. This step is done through all levels of the BOM structure that is related to the required production order. Material requirement is fulfilled by using available on-hand inventory, existing on-order supply, and approved planned orders. If additional material is required anywhere, a planned order is created to cover the demand.

Scheduling during firming

Planned production orders include the route ID that is required for production scheduling. However, scheduling support during the planning run for planned orders is pending. The route ID is used to schedule planned production orders during firming. Therefore, the lead time on planned production orders can differ from the lead time on related scheduled, firmed production orders that are generated from them, as described here:

- **Planned production order** – The lead time is based on the static lead time from the released product.
- **Firmed production order** – The lead time is based on scheduling that uses route information and related resource constraints.

For more information about expected feature availability, see [Planning Optimization fit analysis](#).

If you depend on production functionality that isn't yet available for Planning Optimization, you can continue to use the built-in master planning engine. No exception is required.

Delays

If the lead time for required material is longer than the period between today's date and the material requirement date, the planned order for the required material and the related production order will be delayed. For planned orders, the delay (in days) is calculated based on the lead time from the released product. The delay information is then propagated through all levels of the BOM structure. Therefore, you can follow the impact of delayed raw material all the way to the customer sales order.

Modifying planned orders

When you change information on a planned order, you receive the following message: "Note that the impact of manual changes on planned orders won't be reflected in the rest of the plan until the next master planning run."

If you want to change information on a planned order and see the impact on the related material requirements, follow these steps.

1. Update the planned order.
2. Approve the planned order.
3. Run master planning.

When you run master planning, you should not use filters if planned production orders are included. For more information, see the [Filters](#) section later in this topic.

NOTE

If the delivery date of the planned order is changed to a later date, the demand might be pegged against a new planned order. This behavior occurs when the new supply date causes a delay for the pegged demand but, according to the lead time settings, the delay can be avoided.

Explosion page

You can use the **Explosion** page to analyze the demand that is required for a specific production order or planned production order, the related coverage, and pegging information. Information on the **Explosion** page is updated during master planning. You can't update the information directly from the **Explosion** page.

Filters

For planning scenarios that include production, we recommend that you avoid filtered master planning runs. To ensure that Planning Optimization has the information that is required to calculate the correct result, you must include all products that have any relation to products in the whole BOM structure of the planned order.

Although dependent child items are automatically detected and included in master planning runs when the built-in master planning engine is used, Planning Optimization doesn't perform this action.

For example, if a single bolt from the BOM structure of product A is also used to produce product B, all products in the BOM structure of products A and B must be included in the filter. Because it can be very complex to ensure that all products are part of the filter, we recommend that you avoid filtered master planning runs when production orders are involved.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Inventory marking with Planning Optimization

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic provides information about the options that are available for marking inventory in firm orders when you use Planning Optimization.

Marking is used to link supply and demand. It resembles *pegging*, which indicates how master planning expects to cover demand. From a planning point of view, the main difference is that marking is more permanent than pegging.

Marking was introduced to support special costing scenarios for first in, first out (FIFO) and last in, first out (LIFO). However, it's now also used for some non-costing scenarios. Marking between supply and demand is optional and almost permanent. Marking can be removed manually by a user, or it can be removed by running a sales order line explosion where the **Remove marking** option is selected.

Pegging is controlled by master planning during coverage to link demand with the required supply. Pegging can be updated for each planning run to optimize the supply that is required to cover demand. When master planning updates pegging information, it respects any existing marking.

Pegging starts by including relevant marking, on-hand reservations, and on-order reservations, in the following sequence:

1. Marking between demand and supply
2. On-hand reservations
3. On-order reservations

When you firm a planned order, the **Firming** dialog box provides an **Update marking** field that you use to set marking options for the orders that are created during firming. Select one of the following values:

- **No** – No inventory marking is applied.
- **Standard** – Inventory marking is updated according to the pegging. A requirement order (demand) is marked against a fulfillment order (supply). If some quantity remains on the fulfillment order, it isn't marked, and the reference information is left blank. For example, if a sales order for 100 ea is pegged against a purchase order for 150 ea, reference information will be assigned only to the sales order.
- **Extended** – Both the requirement order (demand) and the fulfillment order (supply) are marked, regardless of any quantity that remains on the fulfillment order. For example, if a sales order for 100 ea is pegged against a purchase order for 150 ea, reference information will be assigned to both the sales order and the purchase order.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Intercompany planning

2/18/2021 • 3 minutes to read • [Edit Online](#)

For some organizations, logistics operations depend on other legal entities (companies) in the organization. These operations are handled by using intercompany sales and purchases, because each legal entity has a separate chart of accounts.

This topic describes intercompany planning and explains how to configure intercompany planning with Planning Optimization in Microsoft Dynamics 365 Supply Chain Management.

This topic uses the following important intercompany terms:

- **Upstream** – A relative reference in a firm or supply chain. It indicates movement in the direction of the raw material supplier.
- **Downstream** – A relative reference in a firm or supply chain. It indicates movement in the direction of the customer.
- **Planned intercompany demand** – Planned demand for a product in a company, based on planned demand for the product from a downstream company.

In master planning, a plan in one company can include planned intercompany demand that is related to planned orders from a plan in another company. This capability is useful, because it provides full visibility into planned orders across companies. It also ensures that all required planned supply orders are created, but without requiring that planned orders be firmed for the intercompany demand.

If you run master planning from a master plan that includes planned downstream demand, planned purchase orders from the related intercompany vendors will be included in the plan as demand.

Required setup

To use intercompany planning, you must prepare your system in the following way:

1. The relevant products must be released in all the relevant companies. For more information, see [Configure and use intercompany trade in Dynamics 365 Supply Chain Management](#) on Microsoft Learn.
2. Downstream demand must be covered by purchases from a vendor that has an intercompany relation to the upstream company and relevant default inventory dimensions (site and warehouse) on the customer. For more information, see [Configure and use intercompany trade in Dynamics 365 Supply Chain Management](#) on Microsoft Learn.
3. The master plan in the upstream company must include planned downstream demand, and the relevant company and master plan must be specified in the downstream plans.

Include planned downstream demand

Follow these steps to configure your master plan so that it includes planned downstream demand.

1. Go to **Master planning > Setup > Plans > Master plans**.
2. Select or create a master plan.
3. On the **Intercompany planning** FastTab, set the following fields:
 - **Include planned downstream demand** – Set this option to *Yes* to enable intercompany planning for the master plan.
 - **Downstream plans** – If you set the **Include planned downstream demand** option to *Yes*, use the

toolbar and grid to add the desired master plans from other companies.

Peg across companies by using multilevel pegging

In multilevel pegging, you can view pegging across companies to see the initial source of demand that is being covered by a supply.

To view multilevel pegging information, follow these steps.

1. Go to **Master planning > Master planning > Planned orders**.
2. Select or open a planned order.
3. On the Action Pane, on the **View** tab, in the **Requirements** group, select **Multilevel pegging**.

Intercompany example that involves two companies

For this example, a planned production order is created in the USMF company to cover a sales order in the DEMF company. In USMF, the direct demand is planned intercompany demand. To make this demand appear in USMF, master planning is run first in DEMF and then in USMF.

The following illustration shows how this example might appear on the **Multilevel pegging** page for the planned production order.

Intercompany example that involves three companies

For this example, a planned purchase order is created in the USMF company to cover a sales order in the FRRT company. In the DEMF and USMF companies, the direct demand is planned intercompany demand. To make this demand appear in USMF, master planning is run first in FRRT, then in DEMF, and finally in USMF.

The following illustration shows how this example might appear on the **Multilevel pegging** page for the planned production order.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Exclude products that have specific product lifecycle states

2/18/2021 • 2 minutes to read • [Edit Online](#)

Released products and released product versions include a **Product lifecycle state** field. This field lets you control, among other things, which products are included during master planning. You can add, remove, and edit lifecycle states as required by going to **Product information management > Setup > Product lifecycle state**. For each product lifecycle state, set the **Is active for planning** option to *Yes* if products that have that state should be included during master planning. When the option is set to *No*, the associated products and variants will be excluded from all master planning and all calculations at the bill of materials (BOM) level.

Released products and variants where the **Product lifecycle state** field is left blank are treated as though they have a product lifecycle state where the **Is active for planning** option is set to *Yes*. In other words, they will be included during master planning.

NOTE

To help avoid unnecessary supply suggestions, we strongly recommend that you associate all obsolete released products and variants with a product lifecycle state where the **Is active for planning** option is set to *No*. This approach is especially important when you work with product configuration variants that aren't reusable, because it will help prevent waste.

Related resources

For more information about product lifecycle states, see [Product lifecycle state overview](#).

For detailed information that includes steps for using product lifecycle states to exclude products from master planning and BOM-level calculations, see [Create a product lifecycle state to exclude products from Master planning](#).

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Coverage time fences

2/18/2021 • 5 minutes to read • [Edit Online](#)

This topic describes how to set up *coverage time fences* when you're using Planning Optimization. Planners can define the planning horizon (the coverage time fence in days), and exclude supply and demand that falls beyond that horizon. Therefore, coverage time fences help prevent "noise" that is caused by supply suggestions that you don't have to react to for months. Examples include next year's forecast and customer orders that are placed far beyond the normal lead time.

A coverage time fence is the number of days after today's date (or, more precisely, the date when you do the planning run) that supply and demand is excluded. To help avoid delays, you must ensure that the coverage time fence is longer than the total lead time. The default system value is 100 days.

You can specify a coverage time fence at each of the following levels:

- **Coverage group** – You can set a default coverage time fence for each coverage group.
- **Item coverage** – You can override the coverage time fence that is inherited from the coverage group that is assigned to an item.
- **Master plan** – You can override the coverage time fences that are inherited from the coverage group and item coverage settings.

The following sections explain how to specify a coverage group at each level.

Set a coverage time fence for a coverage group

When you specify a coverage time fence for a coverage group, the setting applies to all items (products) that belong to that group. However, you can override the setting for specific items or specific master plans.

To specify a coverage time fence for a coverage group, follow these steps.

1. Go to **Master planning > Setup > Coverage > Coverage groups**.
2. Select an existing coverage group in the list, or create a new coverage group.
3. On the **General** FastTab, set the **Coverage time fence (days)** field to the number of days that you want to use as the coverage time fence for the coverage group.

Set a coverage time fence for a specific item

Every item (product) belongs to a coverage group. If no coverage group is explicitly assigned to an item, a default coverage group applies. Every item inherits a coverage time fence from its coverage group. However, you can override this time fence for specific items as you require.

To specify a coverage time fence for a specific item, follow these steps.

1. Go to **Product information management > Products > Released products**.
2. Select a product in the grid.
3. On the Action Pane, on the **Plan** tab, in the **Coverage** group, select **Item coverage**.
4. On the **Item coverage** page, on the **Overview** tab, select or create a row for the site where you want to set a coverage time fence.
5. Select the **General** tab to open the settings for the selected site.
6. Select the **Override coverage group settings** check box.
7. Set the **Coverage time fence (days)** field to the number of days that you want to use as the coverage time

fence for the item.

Set a coverage time fence for a specific master plan

You can specify a coverage time fence at the master plan level. In this way, you define the number of days that the master planning calculation covers for a master plan. This setting overrides any coverage time settings that have been defined for each relevant item and coverage group.

To specify a coverage time fence for a specific master plan, follow these steps.

1. Go to **Master planning > Setup > Plans > Master plans**.
2. Select an existing master plan in the list, or create a new master plan.
3. On the **Time fences in days** FastTab, set the **Coverage** option to **Yes**. Then, in the field under the option, enter the number of days that you want to use as the coverage time fence for the master plan.

Considerations for coverage time fences

As you're setting up coverage time fences, consider the following points:

- Coverage time fences affect only input data for master planning. If delays occur, the resulting planned orders might have a date that is after today's date plus the coverage time fence.
- Coverage time fences are specified in calendar days. Calendars that use working days won't affect the time fence calculation. For example, a week is always considered seven days, even if weekends are set up as closed days in the working time calendar.
- Requirement transactions won't be generated for any supply and demand that falls outside the coverage time fence.
- If any approved supply and demand falls outside the coverage time fence, it won't be loaded into the engine. Therefore, it won't trigger any replenishment, and delays won't be calculated. Nevertheless, this supply and demand should not be wiped from the system.
- Variations in safety stock quantities (from minimum keys) will be ignored if they fall outside the coverage time fence.
- Intercompany demand will be ignored if the requested ship date that is calculated isn't inside the coverage time fence. Note that, for built-in master planning, intercompany demand isn't limited by the coverage time fence.
- Demand forecasts will be ignored if the budget date isn't inside the coverage time fence. Note that, for built-in master planning, demand forecasts aren't limited by the coverage time fence.
- Planning Optimization is time zone-aware. It considers the time zone at the supply and demand sites, and the time of the planning run. For example, master planning is triggered at 11 AM on October 15 from a site in Denmark (GMT+1 time zone), and a coverage time fence of ten days is used. In this case, supply and demand from a site in Seattle (GMT-8 time zone) is included until 2 AM on October 25 (= ten 24-hour days after master planning was triggered, minus the time zone difference of nine hours). Note that the built-in master planning engine considers only the date of the time fence. Therefore, the result can differ.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

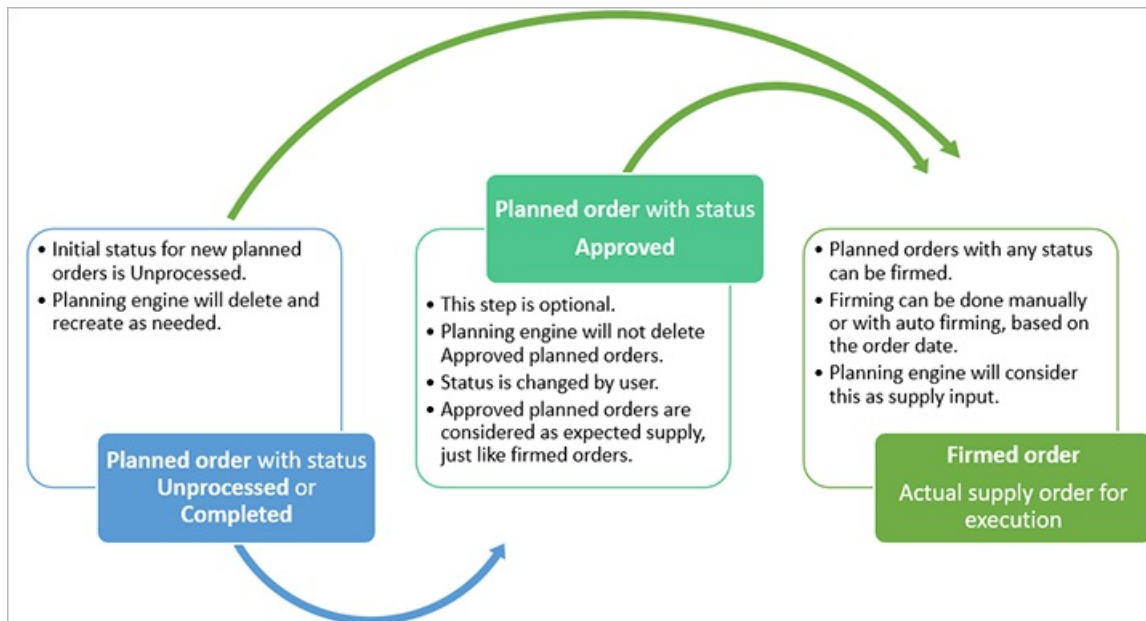

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Approve planned orders

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic provides information about how to update the status of planned orders in Planning Optimization.

Note that approval of planned orders is an optional step, on the way to create a firmed order from a planned order. It is recommended to approve modified planned orders, otherwise the edits will be ignored and overwritten by the next planning run.

The **Status** field helps you track your progress using the following values:

- **Unprocessed:** When master planning generates planned orders, the planned orders have a status of *Unprocessed*. Planned orders with this status will be deleted during the next planning run.
- **Completed:** If you decide not to firm a planned order, you can change the status to *Completed* to indicate that you completed evaluating this planned order. Note that a status of *Unprocessed* and *Completed* are treated the same by the system.
- **Approved:** If you want to keep edits or are planning to firm a planned order, change the status to *Approved*. Planned orders with *Approved* status are considered as fixed and expected supply by master planning, so they are not modified or deleted during later master planning runs. To achieve this, the planning logic copies the *Approved* planned orders from the old plan version to the new plan version during master planning. Note that *Approved* planned orders are only considered supply within the specific master plan.

You can manage planned orders from the **Master planning** workspace, the **Planned order** list, or the **Planned production orders**, **Planned purchase orders**, and **Planned transfer** lists.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

Autofirming with Planning Optimization

2/18/2021 • 3 minutes to read • [Edit Online](#)

Automatic firming lets you firm (that is, release) planned orders as part of the master planning process. When planned orders are firming, they are transformed into actual purchase orders, transfer orders, or production orders. When Planning Optimization is used, planned orders are firming during a master planning run when the order date (that is, the start date) is within the time fence for firming.

NOTE

Auto-firming of a planned purchase order can occur only if the item is associated with a vendor.

Turn on autofirming

To turn on autofirming, follow these steps.

1. In the **Feature management** workspace, on the **New** tab, select **Auto-firming for Planning Optimization** in the list. If the feature doesn't appear on the **New** tab, look on the **Not enabled** and **All** tabs.
2. Select **Enable now**. Alternatively, select **Schedule**, and then select the time when you want the feature to be turned on.

Set up the firming time fence

The firming time fence is calculated forward from the master planning run date. It's defined by the number of days that you enter. You can control the firming time fence in the following ways:

- To define the default firming time fence for a coverage group, go to **Master planning > Setup > Coverage > Coverage groups**, and select a coverage group. Then, on the **Other** FastTab, in the **Automatic firming time fence (days)** field, enter the number of days.
- To overwrite the firming time fence that is defined for the coverage group for a specific item, go to **Product information management > Released products**, then from the Action Pane select **Plan** and then select **Item coverage**. Then, on the **General** tab, select **Override time fence** and in the **Automatic firming time fence (days)** field, enter the number of days.
- To overwrite the firming time fence that is defined for the coverage group and item coverage for a specific master plan, go to **Master planning > Setup > Master plans**, and select a Master plan. Then, on the **Time fence in days** FastTab, set **Firming** to **Yes**, and enter the number of days.

If autofirming is turned on for a master planning run that uses Planning Optimization, the autofirming process is done according to the autofirming setup. If autofirming isn't turned on, or if planning is started from the **Net requirements** page, the autofirming process is skipped.

Planning Optimization vs. the built-in Supply Chain Management planning engine

Both Planning Optimization and the planning engine that is built into Microsoft Dynamics 365 Supply Chain Management can be used to autofirm planned orders. However, there are some important differences. For example, whereas Planning Optimization uses the order date (that is, the start date) to determine which planned orders to firm, the built-in Supply Chain Management planning engine uses the requirement date (that is, the

end date). Here is a summary of the differences.

Planning Optimization

- Autofirming is based on the order date (start date).
- Because the order date (start date) triggers the firming, you don't have to consider the lead time as part of the firming time fence.
- If you want to firm all orders that must start during the current week, the firming time fence must be one week.

Built-in Supply Chain Management planning engine

- Autofirming is based on the requirement date (end date).
- To help guarantee that orders are firming in due time, the firming time fence must be longer than the lead time.
- If you want to firm all orders that must start during the current week, the firming time fence must be the lead time plus one week.

Planning with negative on-hand quantities

2/18/2021 • 2 minutes to read • [Edit Online](#)

If the system shows a negative aggregate on-hand quantity, the planning engine treats the quantity as 0 (zero) to help avoid over-supply. Here is how this functionality works:

1. The planning optimization feature aggregates on-hand quantities at the lowest level of coverage dimensions. (For example, if *location* isn't a coverage dimension, planning optimization aggregates on-hand quantities at the *warehouse* level.)
2. If the aggregate on-hand quantity at the lowest level of coverage dimensions is negative, the system assumes that the on-hand quantity is really 0 (zero).

IMPORTANT

The planning system can be only as precise as the input data. If the input data is inaccurate, negative on-hand records will indicate that the inventory information in Microsoft Dynamics 365 Supply Chain Management is out of sync with the real world. Therefore, the planning result will be flawed. To get a precise planning result, you should minimize the number of records that show a negative on-hand quantity.

Example 1

Warehouse 13 is configured in the following manner:

- **Coverage code:** Min./Max.
- **Minimum:** 15 pieces (pcs.)
- **Maximum:** 25 pcs.

The lowest level of coverage dimensions is *warehouse*, and the following on-hand quantities are recorded at the *location* level:

- **Site 1, warehouse 13, location 1:** 20 pcs.
- **Site 1 warehouse 13, location 2:** -8 pcs.

Therefore, the aggregate on-hand quantity for warehouse 13 is 12 pcs. (= 20 pcs. - 8 pcs.).

In this case, the planning engine uses an aggregate on-hand quantity of 12 pcs. for warehouse 13.

The result is a planned order of 13 pcs. (= 25 pcs. - 12 pcs.) to refill warehouse 13 from 12 pcs. to 25 pcs.

Example 2

Warehouse 13 is configured in the following manner:

- **Coverage code:** Min./Max.
- **Minimum:** 15 pcs.
- **Maximum:** 25 pcs.

The lowest level of coverage dimensions is *warehouse*, and the following on-hand quantities are recorded at the *location* level:

- **Site 1, warehouse 13, location 1:** 4 pcs.
- **Site 1 warehouse 13, location 2:** -8 pcs.

Therefore, the aggregate on-hand quantity for warehouse 13 is -4 pcs. ($= 4$ pcs. $- 8$ pcs.). In other words, it's less than 0 (zero).

In this case, the planning engine assumes that the on-hand quantity for warehouse 13 is 0 pcs. instead of -4 pcs.

The result is a planned order of 25 pcs. ($= 25$ pcs. $- 0$ pcs.) to refill warehouse 13 from 0 pcs. to 25 pcs.

View plan history and planning logs

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic explains how to view the history of planning jobs that are triggered by the Planning Optimization functionality in Microsoft Dynamics 365 Supply Chain Management.

To view the history for a plan, open the plan by going to **Master planning > Setup > Plans > Master plans** and selecting **History**. The history lists all the jobs for the selected plan. The list includes completed and active jobs.

In addition to seeing the start time and status of jobs, you can view the log for a specific job. The log includes additional information and warnings. Not all jobs have a log. To view the log for a job, select **Log**.

Cancel a planning job

2/18/2021 • 2 minutes to read • [Edit Online](#)

In Microsoft Dynamics 365 Supply Chain Management, you can cancel an active planning job that uses the Planning optimization functionality. When you select **Cancel** in the dialog box when a Planning optimization job is triggered directly from the user interface (not in the background), this will not cancel the Planning optimization job. Even if you receive a warning such as "Operation canceled", you will still need to use the following steps to cancel a planning job with Planning optimization.

To cancel an active planning job, follow these steps.

NOTE

Only active jobs can be canceled.

1. Go to **Master planning > Setup > Plans**.
2. Select an appropriate plan for the planning run.
3. Select **History**.
4. Select the planning job to cancel.
5. Select **Cancel**.

The job status will be **Canceling** until the Planning Optimization service confirms that the job has been canceled. The status will then be changed to **Canceled**.

NOTE

To see status changes, you must refresh the page by selecting the **Refresh** button.

Troubleshoot Planning Optimization

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic describes how to fix common issues that you might encounter while working with Planning Optimization.

Installation of the Planning Optimization add-in doesn't complete

Planning Optimization requires a Lifecycle Services (LCS) enabled, high-availability environment, tier 2 or higher (not a OneBox environment), with Dynamics 365 Supply Chain Management version 10.0.7 or later. If you try to install the add-in on a OneBox environment, the installation won't complete.

Fix: Cancel the installation and use a high-availability environment, tier 2 or higher (not a OneBox environment).

Planning of batch jobs fails when Planning Optimization is enabled

When you enable Planning Optimization, the built-in master planning engine is automatically disabled. Master planning batch jobs that were created for the built-in Supply Chain Management planning engine will fail if they are triggered while Planning Optimization is enabled. You may receive an error message such as *This operation triggered master planning that isn't supported when Planning Optimization is enabled*.

Fix: Cancel all master planning batch jobs that were created for the built-in Supply Chain Management planning engine.

Planning Optimization results are different from earlier results

Planning Optimization differs from the built-in master planning design in some areas. This can also be caused by pending features.

Fix: Run Planning Optimization fit analysis and then analyze the results while referring to the related documentation to understand the impact. For more information, see [Planning Optimization fit analysis](#).

Can't enable Planning Optimization

The **Connection status** must be **Connected** before you can set **Use Planning Optimization** to **Yes**. For more information, see [Get started with Planning Optimization](#).

Fix: Make sure that the Planning Optimization add-in was installed successfully.

Error message is shown during CTP

If you try to run capable to promise (CTP) from a sales order when Planning Optimization is enabled, you will receive the following error message: *This operation triggered master planning that isn't supported when the Planning Optimization is enabled*.

This is related to a pending feature that is planned as part of the support for production orders.

Fix: Avoid CTP calculations when Planning Optimization is enabled until CTP support is available.

Planning Optimization extensibility

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic describes the extensibility scenarios that are related to master planning and supported in Planning Optimization. These capabilities are available starting in Microsoft Dynamics 365 Supply Chain Management version 10.0.13.

Custom processing when master planning is completed

In the most common extensibility scenario in Planning Optimization, custom processing is done after the plan has been updated. For example, you might add a column to the planned orders table (`ReqPO`), or you might want to derive some statistical information from the generated plan. The main extensibility point that enables these scenarios is the `jobCompletedSuccessfully` method in the `MpsMasterPlanningEvents` class.

```
public static void jobCompletedSuccessfully(MpsMasterPlanningJobCompletedSuccessfullyEventArgs _args)
```

Here is an example of an extension that sets a custom `CstmOrderPriority` field on the planned order.

```
[ExtensionOf(classStr(MpsMasterPlanningEvents))]
public static final class MpsMasterPlanningEvents_Cstm_Extension
{
    public static void jobCompletedSuccessfully(MpsMasterPlanningJobCompletedSuccessfullyEventArgs _args)
    {
        ttsbegin;

        var affectedPlannedOrdersQuery =
        _args.parmPostProcessingQueryBuilder().buildAffectedPlannedOrdersQuery();
        var affectedPlannedOrdersQueryRun = new QueryRun(affectedPlannedOrdersQuery);

        while (affectedPlannedOrdersQueryRun.next())
        {
            ReqPO reqPO = affectedPlannedOrdersQueryRun.get(tableNum(ReqPO));
            reqPO.selectForUpdate(true);
            reqPO.CstmOrderPriority = reqPO.RegDate - systemDateGet() < 7 ? CstmPlannedOrderPriority::Urgent
: CstmPlannedOrderPriority::Regular;
            reqPO.doUpdate();
        }

        ttscommit;

        next jobCompletedSuccessfully(_args);
    }
}
```

When you add custom logic, consider the following constraints and best practices:

- The `jobCompletedSuccessfully` method is called outside the transaction scope. Therefore, the plan is already visible to the user when the custom logic starts to run. If your customization sets additional fields on planned orders, it's important that you let users know that the values of those fields will eventually be consistent (in other words, they might be out of date immediately after a planning job is completed).
- Another master planning job can start when the `jobCompletedSuccessfully` method is called. The new job might affect the full plan or part of the plan. The new job might update or delete the same planned orders or requirement transactions that were created or updated as part of the planning job that was handled in

`jobCompletedSuccessfully` . Update conflict exceptions must be handled when this event is extended.

- Avoid using single transaction scope when you extend this method. A single master planning run can produce millions of requirement transactions and hundreds of thousands of planned orders. If all these transactions and planned orders are processed in the scope of a single transaction, many SQL locks will occur and block other planning processes. Additionally, if the transaction is held for a long time, "ghost records" will be created in the SQL database. Ghost records will negatively affect every process in the system.

NOTE

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Master plans overview

2/18/2021 • 2 minutes to read • [Edit Online](#)

Use various master plans to support your company's daily working operations, simulate different planning strategies that you want to monitor, and implement a company policy, such as a policy about internal performance or customer satisfaction.

You can configure master plans on the **Master plans** page.

There are two types of plans:

- **Static plan** – The master planning calculation uses the current data to generate a net requirements plan. This plan remains unchanged until the next time that you run master planning or manually change the plan. This is an operating plan that various company personnel, such as a purchaser or production planner, can use to base their decisions on and perform their daily activities.
- **Dynamic plan** – This plan starts with the same net requirements plan that was generated by master planning. However, you can update the dynamic plan every time that the master data changes. This could be when you create a new sales order, for example. This enables you to monitor the changing order network and item availability without disturbing the static plan that others are using for their work processes.

A company may choose to work with just a dynamic plan or it may use both static and dynamic plans. In addition, you can configure any master plan to reflect a particular strategy or address an issue. Examples are as follows:

- Set higher inventory levels to guarantee against stockouts.
- Set longer safety margins to protect against unreliable vendors.

You can also set up the starting dynamic plan so that it is updated with the new requirements plan every time that you run master planning. You can specify these settings on the **Master planning parameters** page.

Set up master planning

2/18/2021 • 16 minutes to read • [Edit Online](#)

This topic describes various important strategies and parameters that are used to set up master planning. It includes an overview of the types of plans that are used by master planning and explains which plan strategy you should use, depending on your business requirements. It also describes the main parameters that affect the plan and explains how those parameters influence the planned orders that are suggested.

Types of master plans

Master planning has two types of plans: static and dynamic. Each type is designed for a different use. For the best performance, we recommend that you use the appropriate plan for your scenario.

Static plan

The static plan remains unchanged, regardless of any changes in the supply and demand, until the next time that master planning is run.

The static plan is used to approve and firm the orders that are suggested. It's an operating plan that various company personnel (such as a purchaser or production planner) can base their decisions on and use to perform their daily tasks and activities.

The static plan also supports regeneration. A totally new optimized plan is calculated every time that master planning is run, and existing orders that haven't been approved are deleted.

Dynamic plan

The dynamic plan usually starts as a copy of the static plan, but it can be updated every time that master data changes. For example, if the data changes, a new sales order is created.

The dynamic plan is used for ad-hoc planning. It lets the company monitor the changing order network and item availability without disturbing the static plan that other people are using for their work processes. It's especially used for capable to promise (CTP). The dynamic plan is the default plan when net requirements are opened from order pages (such as sales order, purchase order, or production order pages).

The dynamic plan uses net change. Therefore, it helps guarantee a faster running time.

Strategies for using master plans

You can use either one plan or two plans in master planning. The strategy that you use depends on your business requirements.

One-plan strategy

For the one-plan strategy, you use the same master plan for the static plan and the dynamic plan. This strategy is used for make-to-stock scenarios, where you don't usually have to simulate a plan that fulfills an order.

The one-plan strategy is typically used in retail and distribution industries, or where sales delivery dates are confirmed based on service level agreements (SLAs) or lead times. For the plan, delivery date control can be used without CTP.

If you must do a simulation, the plan can be run again for the items that require the simulation. The planned orders that order simulations produce are usually firmed.

Two-plan strategy

For the two-plan strategy, you use a static plan and a different dynamic plan. The two-plan strategy is typically used for configure-to-order and make-to-order scenarios, where you must do sales order simulations and calculate exact delivery dates for sales orders, but the calculations must not affect everyday operations. These simulations are always done in the dynamic plan. The two-plan strategy is useful in the automotive and original equipment manufacturer (OEM) industries, for example.

For the two-plan strategy, delivery date control CTP can be used. When CTP is used, it automatically triggers the run in the dynamic plan.

Setting up the plans

You can create plans on the **Master plans** page (**Master planning > Setup > Plans > Master plans**).

You can specify which plans will be used for the static plan and the dynamic plan by setting the **Current static master plan** and **Current dynamic master plan** fields on the **Master planning parameters** page (**Master planning > Setup > Master planning parameters**). To use a one-plan strategy, select the same plan in the **Current static master plan** and **Current dynamic master plan** fields.

Types of planning methods

Three calculation methods can be used to run master planning: regeneration and net change. Each method produces a different plan when it's run.

You specify the planning method in the **Master planning run** dialog box. To open this dialog box, go to **Master planning > Master planning > Run > Master planning**, or select **Run** in the **Master planning** workspace.

Regeneration

The regeneration planning method deletes existing planned orders, unless they are firmed. It generates new planned orders, based on all the requirements. Regeneration is the only planning method that is available for static plans.

- Changes in supply are considered. These changes include changes in the forecast.
- This method respects the **Period** coverage code.
- This method supports product substitution functionality (PI).

Net change

The net change planning method generates planned orders to cover the requirements that have been created or changed since the last master planning run. Changes in supply aren't considered when this method is run. The system doesn't consider any new supplies, and previously created planned orders aren't deleted if they are no longer required. The net change planning method runs faster than the regeneration method. It's available only for dynamic plans.

- Action dates and futures are updated for all requirements.
- This method doesn't respect the **Period** coverage code.
- This method doesn't fulfill the forecast, even if it's selected on the plan.
- This method doesn't support product substitution functionality (PI).

Net change minimized

The net change minimized planning method generates planned orders to cover only the requirements that have been created or changed since the last master planning scheduling run. For this method, unlike the net change method, action dates and future dates are updated only for new or changed requirements. This planning method is available only for dynamic plans.

Types of scheduling methods

For each plan, on the **General** FastTab of the **Master plans** page (**Master planning > Setup > Plans > Master plans**), you must select the scheduling method that is used for production orders. You can schedule production at the operation level and the job level.

Operations scheduling

You can use operations scheduling to provide a general estimate of the production process over time. Operations scheduling doesn't explode the operations for the production route into jobs. For more information about operations scheduling, see [Operations scheduling](#).

Job scheduling

Job scheduling is a more detailed scheduling method, where each operation is divided into its individual tasks or jobs. Job scheduling includes information about capacity. It's typically used to schedule individual jobs on the shop floor for an immediate or short-term time frame. For more information about job scheduling, see [Job scheduling](#).

Time fences in days

For each plan, you can select how far in the future the various requirements and other considerations must be calculated by master planning. The period is known as a *time fence*. For the best performance in master planning, we recommend that you adjust the various time fences to meet your business requirements. For each plan, you can find the time fences on the **Time fences in days** FastTab of the **Master plans** page (**Master planning > Setup > Plans > Master plans**).

NOTE

The time fences indicate how far in the future the various requirements and other considerations are calculated by master planning. The time fences selected in this page will override the time fences defined in the coverage group. This means setting a time fence option to yes and defining the days will override the time fence defined in the coverage group. When setting to No, the time fence will be defined in the coverage group. Finally, if you don't want or need to use an option (for example you do not want to use action messages), set it to **Yes**, and then set the time fence to **0** (zero) days.

Coverage

The coverage time fence represents the scheduling period, or how far out the demand should be included. In other words, it indicates your planning horizon.

By setting the **Coverage** option to **Yes**, you can override the coverage time fence that is defined for the item during master scheduling. In this case, enter the number of days that the master scheduling calculation should cover requirements. The coverage time fence is calculated forward from the current date. Requirements that occur before the current date are always processed.

NOTE

For the best performance in master planning, we recommend that you adjust the coverage time fence to your planning horizon.

Freeze

The freeze time fence represents the period when existing planned orders aren't changed when a new master schedule is run. The planned orders are frozen, and no new planned orders will be suggested.

By setting the **Freeze** option to **Yes**, you can override the freeze time fence that is defined for the item during master scheduling. In this case, enter the number of days that planning activity should be frozen. Remember that, during this period, no new planned orders are generated, and existing planned orders can't be changed.

Firming

The firming time fence indicates the time horizon in which planned orders are automatically converted to production and purchase orders. This process is also known as *automatic firming of planned orders*.

By setting the **Firming** option to **Yes**, you can override the firming time fence that is defined for the item during master scheduling. In this case, enter the number of days that planned purchase orders and planned production orders should be automatically firming. The firming time fence is calculated forward from the master scheduling date. Automatic firming of a planned purchase order can occur only if the item is associated with a vendor.

Forecast plan

The forecast plan time fence indicates how far in the future master planning creates planned orders for items that have forecasted demand.

By setting the **Forecast plan** option to **Yes**, you can override the forecast plan time fence that is defined for the item during master scheduling. In this case, enter the number of days that the sales forecast from the forecast plan should be included in master planning.

Capacity

The capacity time fence indicates how far in the future the system considers the maximum capacity of your resources when it schedules orders. In other words, the plan schedules the production orders by using the production route for the items, and it considers the production route's resources and the maximum capacity of each resource.

By setting the **Capacity** option to **Yes**, you can override the capacity time fence that is defined for the item during master scheduling. In this case, enter the number of days that capacity should be planned for planned production orders. Master scheduling uses the active production route for the item and schedules backward from the requirement date. If the requirement date for a planned production order is outside the capacity time fence, the lead time is determined by the delivery time of the item. The capacity time fence is calculated forward from the current date.

Action message

Action messages suggest changes that can be made to the existing supply order to help optimize the supply plan. For example, they might recommend that you advance or postpone orders, or that you increase or decrease the order quantities.

By setting the **Action message** option to **Yes**, you can override the action message time fence that is defined for the item during master scheduling. In this case, enter the number of days that master scheduling should generate action messages for requirements. The action message time fence is calculated forward from the current date.

For more information about action messages, see [Action messages](#).

NOTE

The calculation of action messages causes a longer running time for master planning. If action messages aren't regularly analyzed and applied (daily, weekly, and so on), consider turning off the calculation during the master planning run. To turn off the calculation, on the **Master plans** page, set the **Action message** time fence to **0** (zero) for the master plan that you're running. Also make sure that the **Action message** setting is turned off for all the coverage groups.

Calculated delays

You can specify how far in the future possible delays in planned orders are detected and reported. In this way, you can schedule possible (delayed) delivery dates.

If a planned order can't be fulfilled for the requested date, it's planned for the earliest fulfillment date for a transaction, based on lead times, and material and capacity availability.

Approved requisitions time fence

You can set up master planning to create planned orders for requisition demand. Set the **Include requisitions** option to **Yes** on the **General** FastTab of the **Master plans** page. Then, when the purpose of an approved requisition is replenishment, master planning automatically creates a corresponding planned order to fulfill it. The replenishment method is determined by the supply policies that have been set up for the items in your organization. After the replenishment requisition is created and approved, no additional user action is required.

By setting the **Approved requisitions time fence** option to **Yes** on the **Time fences in days** FastTab, you can override the approved requisitions time fence that is defined for the item during master scheduling. In this case, enter the number of days in the past that demand from approved requisitions that have the replenishment purpose should be included in master scheduling. For example, you can specify that only unfulfilled, past-due demand from approved requisitions that were created in the last 10 days should be considered and planned for.

Sequencing

Sequencing enables planned orders to be arranged based on sequencing attributes that are associated with the finished product. It's often used to prepare production orders for packaging. For example, it can be used to pack boxes in a specific sequence, based on color and size.

By setting the **Sequencing** option to **Yes**, you can specify how far in the future the operations or jobs should be sequenced. Keep in mind that the longer the time fence is, the longer it will take for master planning to run.

Calculated delays

Delay options help guarantee that the orders have feasible planned dates. The following options are available on the **Calculated delays** FastTab of the **Master plans** page:

- **Ensure that the planned orders are not created prior to master planning run date** – Set this option to **Yes** to help guarantee that orders can't be scheduled for dates in the past.
- **Add the calculated delay to the requirement date (under Planned purchase orders)** – Set this option to **Yes** to add the calculated delay to the requirements.
- **Add the calculated delay to the requirement date (under Planned production orders)** – Set this option to **Yes** to add the calculated delay to the requirements.
- **Add the calculated delay to the requirement date (under Planned transfer)** – Set this option to **Yes** to add the calculated delay to the requirements.
- **Add the calculated delay to the requirement date (under Planned kanban)** – Set this option to **Yes** to add the calculated delay to the requirements.

When you set the **Add the calculated delay to the requirement date** options to **Yes** to add the delays to the requirements, the system considers the capacity of the resources and creates feasible planned orders. Recalculation of the planned order dates increases the running time for master planning. Therefore, if you don't need to use the delays, set the options to **No**.

Positive and negative days

Positive and negative days affect how master planning suggests planned orders and actions. Positive and negative days are set on the item coverage group of the item. You can define the various coverage groups and set their parameters on the **Coverage groups** page (**Master planning > Setup > Coverage > Coverage groups**).

Positive days

Positive days indicate how far in the future master planning considers the current inventory or receipts to fulfill a future demand. For example, if the positive days are set to **100**, the current inventory can be used to fulfill demand in the next 100 days. If there is an order 150 days from the current date, master planning will create a planned order to satisfy that demand, even though the on-hand inventory for the item can satisfy the order. For fast-moving items that have a short lead time, you might not want to use the on-hand inventory for an order that is far in the future. In this fast-moving case, the current on-hand inventory will be gone quickly, and more

orders could be placed in the future to fulfill a future demand on time, which would be possible due to the short lead time of the item.

The positive days also affect the action messages. For example, the system might recommend that you increase a planned purchase order so that it includes a demand that is within the number of positive days in the future. If the positive days are set to **100**, and if there is demand for an item in 30 days from the current date, the system will create a planned order to satisfy that demand. If there is demand for the same item in 90 days from the current date, the system will recommend that you increase the quantity of the order in 30 days from the current date, so that the order also covers the demand in 90 days. However, if there is demand for the item in 150 days from the current date, the system won't recommend that you increase the quantity of the order that was already planned. Instead, a new planned order will be created.

As a rule, the positive days are set to a number that is between the longest lead time of the items and the coverage time fence. We recommend that you assign items that are regularly procured or produced to a coverage group where the positive days equal the item's lead time.

Negative days

Negative days indicate how late item receipts will be allowed. They represent the number of days that you're willing to wait before you order new replenishment when you have negative inventory or don't have enough inventory. Negative days answer the question, Should we create a new purchase order for the item, or should we use an existing purchase, even though we know that the item will be late?

For example, you have a sales order for an item 15 days from the current date. You also have a purchase order for the same item. This purchase order will be received in 20 days from the current date. Do you want the system to create a purchase order for that sales order, or do you want to use the existing order, even though you can't fulfill the sales order on time? If the negative days are set to less than 5 to indicate the item can be delayed a maximum of five days, the system creates a new planned purchase order to satisfy the sales order. If the negative days are set to greater than 5, the system uses the existing order for the item.

The negative days also affect the performance of master planning. If the negative days are set to a high number, lots of action messages will be generated.

We recommend that you set the negative days to a number that is less than the lead time of the item.

Dynamic negative days

Dynamic negative days consider the item's lead time and the negative days that you specified. The system will create a new planned purchase order, based on the negative days time fence that is calculated by using the following formula:

Lead time + Negative days + Current date – Requirement date

The system uses only the planned supply orders that are within this time fence, and it creates a new planned order outside it. The advantage of dynamic negative days is that it will include the individual product lead time, to reuse existing orders and avoid creating new planned orders that will end up with a later day, due to delays caused by lead time.

For more information, see [Negative days and dynamic negative days](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Master planning setup wizard

2/18/2021 • 10 minutes to read • [Edit Online](#)

This topic provides a guide for the **Master planning setup wizard**. It explains how parameter suggestions are calculated and also provides examples that show how different companies set up master planning, based on their business needs.

The [Master planning setup wizard in Dynamics 365 Supply Chain Management](#) video (shown above) is included in the [Finance and Operations playlist](#) available on YouTube.

Specific requirements of your company

The first page of the wizard asks about the specific requirements of your company. Your answers to these questions don't have to be exact, but you should be able to provide a rough approximation of the number of items and planned orders that there will be for the legal entity. Your answers are used to configure parameters that apply to your legal entity, not just to the master plan that you selected. The following sections describe the parameters that are calculated and the formulas that are used.

Number of threads

- **If you manufacture any of the items:** Number of threads = Number of planned orders ÷ 1,000
- **If you don't manufacture any of the items:** Number of threads = Number of items ÷ 1,000

If the number of threads that is calculated exceeds 75 percent of the available number of threads, it's capped at 75 percent of the number of threads that is available for each customer. (The number of available threads will be determined for each customer.)

For more information, see [Number of threads](#).

Bundle size

The bundle size will be set to 1. This value is often the best value, because it helps improve the performance of master planning.

For more information, see [Number of tasks in helper task bundle](#).

Firming bundle size

- **If you manufacture any of the items:** The firming bundle size will be set to the larger of these two values: 10 and the bundle calculation
- **If you don't manufacture any of the items:** The firming bundle size will be set to the larger of these two values: 50 and the bundle calculation

Bundle calculation = (Number of planned orders × (Firming time fence ÷ Coverage time fence) ÷ Number of threads) ÷ 10

Cache size

The cache size will be set to **Maximum**. This value is often the best value, because it helps improve the performance of master planning.

For more information, see [Allocate time to jobs in a job bundle](#).

Manufacturing setup

If you manufacture items, a **Manufacturing setup** page will appear later in the wizard.

Scope of the current plan

On the **Scope of the current plan** page of the wizard, you answer questions that are related to how far in the future various requirements will be considered and calculated in master planning. Each question asks whether you want to use a feature and how you want to configure it.

For example, for the forecast plan feature, the wizard asks, "Do you want to use a forecast plan in master planning so that planned orders will be suggested to fulfill the forecasted demand?"

The following options are available:

- **No** – Master planning won't suggest planned orders to fulfill a forecast. On the **Time fences** tab of the **Master plans** page (**Master planning > Setup > Plans > Master plans**), the wizard will set the **Forecast plan (time fence)** option to **Yes** and set the number of days to **0** (zero). This setup will override the time fence that is specified in the coverage group. Because the number of days is set to **0** (zero), the feature won't be used.
- **Yes, as defined in this master plan** – A field becomes available, where you can enter the number of days that master planning will suggest planned orders to fulfill the forecasted demand. The wizard will set the **Forecast plan (time fence)** option to **Yes** and set the number of days to the number of days that is entered in the **Forecast plan** field on the **Time fences** tab of the **Master plans** page. This setup will override the values that are set in the coverage groups.
- **Yes, as defined in the coverage** – The wizard will set the **Forecast plan (time fence)** option to **No**. The time fences that are specified in the coverage group will be used to specify how long you will plan for the forecast.

The remaining questions on this page and their answers follow the same schema:

- **No** – The **Forecast plan (time fence)** option will be set to **Yes**, and the number of days will be set to **0** (zero).
- **Yes, as defined in this master plan** – The **Forecast plan (time fence)** option will be set to **Yes**. The number of days that you enter will be used and will override the values that are set in the coverage groups.
- **Yes, as defined in the coverage group** – The **Forecast plan (time fence)** option will be set to **No**.

For more information, see [Job scheduling](#).

Scheduling options

The **Scheduling options** page appears only if you answered **Yes** to the "Do you manufacture any of the items planned?" question on the first page of the wizard.

Your answer to the first question on this page ("Do you need to schedule operations divided into individual jobs?") determines the scheduling method on the **General** tab of the **Master plans** page.

- **Yes** – Job scheduling will be used.
- **No** – Operations scheduling will be used.

For more information, see [Operations scheduling](#) and [Job scheduling](#).

Updates of demand and supply

The questions on the **Updates of demand and supply** page are related to firming, action messages, and delays.

The master planning setup will be updated based on your answers, according to the same schema that is described in the previous section:

- **No** – The **Time fence** option on the **Master plans** page will be set to **Yes**, and the number of days will be set to **0** (zero).
- **Yes, as defined in this master plan** – The **Time fence** option will be set to **Yes**. The number of days that you enter will be used and will override the values that are set in the coverage groups.
- **Yes, as defined in the coverage group** – the **Time fence** option will be set to **No**.

For calculated delays, your answers to the questions in the wizard will update the corresponding parameters on the **Calculated delays** tab of the **Master plans** page.

Summary of your changes

The last page of the wizard shows the changes that are recommended based on your responses. It shows both the value in your setup (**Current setup**) and the value that the wizard recommends (**New configuration**).

You can also modify the parameters in the new configuration. The parameters are separated into parameters that apply to your legal entity and parameters that apply only to the master plan that you selected. To view all the setup parameters that can be changed by using the wizard, select **Show all parameters** at the bottom of the page. You can then change the parameters.

Finally, when you select **Finish**, the new configuration is applied. If you select **Cancel**, none of the changes are applied.

Examples

This section describes the setup of two fictional companies to show how the setup can change according to the needs of each business.

Example 1: Contoso Manufacturer

Contoso Manufacturer is a manufacturing company that produces speakers. It purchases the various raw materials and components that are used for the final speakers from various suppliers. Here are some of the characteristics of its supply and manufacturing:

- The final items that the company manufactures have a bill of materials (BOM) structure.
- All final items and components are planned by master planning. Manual planning isn't done.
- A route of operations is defined for the production of each final item.
- The manufacturing plant produces the final items. It has a defined number of milling and drilling machines that are used to process the components. The various components must be processed by these machines.
- There are many suppliers. The average lead time for items is one week. A group of items from the same supplier will have a lead time of seven weeks.

In the wizard, the following values are entered for Contoso Manufacturer:

- **Coverage:**
 - **Question:** "Do you want to specify the number of days of your planning horizon?"
 - **Answer:** "Yes, as defined in the coverage groups."

Because the lead time for items is very different, Contoso doesn't have to plan all the items for the same period in the future. Coverage groups for the items are created. Items that have a similar lead time are assigned to the same coverage group. The planning horizon for each coverage group (that is, the coverage time fence) is approximately the lead time plus a margin of one week. Master planning then makes sure that the items are planned in advance, based on their lead time.

Therefore, two coverage groups will be created for this example. One coverage group will have a coverage time fence of two weeks, and the other will have a coverage time fence of eight weeks.

If **Yes, as defined in this master plan** is selected as the answer, the number of days that is entered should exceed the longest lead time of all the items. However, because many items don't have to be planned so far in advance, many planned orders will be calculated but never used. Therefore, the master planning runtime will increase.

- **Scheduling:**

- **Question:** "Do you need to schedule operations divided into individual jobs?"
- **Answer:** "Yes."

Contoso Manufacturing must plan and schedule the individual jobs that will be performed on the shop floor. Therefore, it will use job scheduling.

- **Capacity:**

- **Question:** "Do you want to schedule using the capacity of resources?"
- **Answer:** "Yes, as defined in this master plan." **10 days** is entered.

The number of milling and drilling machines is limited. Production planning must take this limitation into account and arrange the jobs in time according to the capacity of the resources. In other words, the jobs that are scheduled will be replanned based on the limitations of the resources. Planning will use the lead time in addition to the period that is defined. (Planned production orders can overlap.) Because the production lead time for the items is seven days, the capacity of the resources for master planning will be considered during 10 days.

- **Sequencing:**

- **Question:** "Do you want to sequence planned orders using the product's sequence values?"
- **Answer:** "Yes, as defined in the coverage groups."

A route is defined for the production of each final item. Therefore, master planning will schedule the orders in time according to the defined routes.

- **Explosion:**

- **Question:** "Do you want to plan orders for all the elements in a Bill of Materials (plan for the parent and all children items)?"
- **Answer:** "Yes, as defined in the coverage groups."

All the items that are used for the production must be planned. Because the items have very different lead times, master planning will have better performance when it uses the coverage groups. Again, a margin of one week can be entered, and explosion can be done for the same time as the coverage.

Example 2: Contoso Retailer

Contoso Retailer is a distribution company in the fashion industry. It uses master planning to calculate when purchase orders should be placed, based on its forecasted sales. Here are some of its characteristics:

- Contoso Retailer uses a demand forecast to predict sales. Purchase orders will be planned according to the forecast.
- Stores use requisitions for replenishment.
- The lead time from the main warehouse to each store is approximately two weeks for all items.

In the wizard, the following values are entered for Contoso Retailer:

- **Forecast demand:**

- **Question:** "Do you want to use a forecast plan in master planning so that planned orders will be suggested to fulfill the forecasted demand?"
- **Answer:** "Yes, as defined in this master plan."

Contoso has included a demand forecast to predict its sales. Therefore, master planning must

recommend planned orders to fulfill the forecast.

- **Firming:**

- **Question:** "Do you want master planning to automatically firm planned orders into order documents, for example production or purchase orders?"
- **Answer:** "Yes, as defined in this master plan." **1 day** is entered.

Because Contoso Retailer will create purchase orders directly from the planned purchase orders, it's useful if the planned purchase orders are automatically firmed. Because the company runs master planning every day, a firming time fence of one day will automatically firm all the orders that are required for the next day.

- **Approved requisitions:**

- **Question:** "Do you want to include demand from approved requisitions to replenish retail stores?"
- **Answer:** "Yes, as defined in this master plan." **1 day** is entered.

Contoso uses the approved requisitions from its stores to create planned purchase orders to replenish those stores. Because master planning is run every day, the requisitions from the last day will be included in the planning.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Coverage settings

2/18/2021 • 3 minutes to read • [Edit Online](#)

Master scheduling uses coverage settings to calculate item requirements.

You can specify coverage settings in several ways:

- Specify coverage settings for a coverage group.

You can create a coverage group that contains settings for all products that are linked to the coverage group. To create a coverage group, go to **Master planning > Setup > Coverage > Coverage groups**. You can link a coverage group to a product. If the link is specific to a site, warehouse, or product dimension, use the **Coverage group** field on the **Item coverage** page. If the link is generic, regardless of the product dimensions, use the **Coverage group** field on the **Plan** FastTab of the **Product details** page. By default, if you don't link a coverage group to a product, master planning uses the general coverage group that is specified on the **Master planning parameters** page.

- Specify coverage settings for a product.

You can create coverage settings for a specific product. Go to **Product information management > Products > Released products**. Select the product, and then, on the Action Pane, on the **Plan** tab, in the **Coverage** group, select **Item coverage** to open the **Item coverage** page. If the product is already linked to a coverage group, you can override the coverage group settings by using the **Override** field. The coverage settings on the **Item coverage** page take precedence over the settings on the **Coverage group** page.

- Specify coverage settings for a product by using a wizard.

The wizard guides you step by step through the process of setting up the primary item coverage parameters. On the **Item coverage** page, on the Action Pane, select **Wizard** to open the **Item Coverage Wizard**.

- Specify coverage settings for a dimension group.

Go to **Product information management > Products > Released products**. On the **Released product details** page, on the **General** FastTab, in the **Administration** section, select the link in the **Storage dimension group** field. On the **Storage dimension groups** page, select the **Coverage plan by dimension** check box to create the coverage settings for a dimension in the storage dimension group. The **Coverage plan by dimension** field must be selected for all product dimensions, such as configuration, color, size, and style.

Coverage codes

Master planning can be configured to use different replenishment methods. The replenishment methods or lot-sizing methods are the techniques used by the system to determine the batch size for purchased or produced items.

Each replenishment method is assigned one of the following coverage codes:

- **Manual** - The lot-sizing method where the system does not suggest purchased, transfer, or production orders for the item. The planner for the item will be in charge of creating the required orders for the replenishment of the item.
- **Per requirement** - The lot-sizing method in which the system creates a planned purchase, transfer, or

production order per requirement for the item. This is generally used for expensive items with intermittent demand.

- **Per period** - The lot-sizing method that combines all the demand for a period into one order for the item. The order will be planned for the first day of the period and its quantity will fulfill the net requirements during the established period. The period starts with the first demand of the item and covers the defined length in time. The next period will start with the next requirements of the item.
- **Min/Max** - The lot-sizing method that contains the replenishment of inventory up to a certain level when the predicted on-hand is below a threshold. The replenishment quantity will be the difference between the maximum level and the predicted on-hand level.

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Define coverage rules for items

2/18/2021 • 3 minutes to read • [Edit Online](#)

The demo data company used to create this procedure is USMF. This procedure shows how to create coverage rules and override coverage settings for a specific item. It also shows how to specify default inventory settings.

Create a coverage group

1. Go to **Navigation pane > Modules > Master planning > Setup > Coverage groups**.
2. Click **New**.
3. In the **Coverage group** field, type a value.
4. In the **Name** field, type a value.
5. In the **Calendar** field, type a value. Choose the calendar that master planning uses to create replenishment suggestions for items in this group.
6. In the **Coverage code** field, select an option. Select 'Requirement' for this procedure.
7. In the **Coverage time fence (days)** field, enter '90'. For items in this group, master planning will create replenishment suggestions for up to 90 days in the future.
8. In the **Negative days** field, enter '1'.
9. In the **Positive days** field, enter '1'.
10. Expand or collapse the **Other** section.
11. Under the **Safety margins in days** section, in the **Receipt margin added to requirement date** field, enter '1'. For example, if the receipt margin is set to 1 day, and a purchase order line is scheduled for receipt on May 15, master planning calculates the adjusted receipt date as May 16.
12. In the **Issue margin deducted from requirement date** field, enter '1'. For example, if the safety margin is set to 1 day, and a sales order line is scheduled for delivery on May 15, master scheduling calculates the adjusted delivery date as May 14.
13. In the **Reorder margin added to item lead time** field, enter '1'.
14. Click **Save**.

Create a new product

1. Go to **Navigation pane > Modules > Product information management > Products > Released products**.
2. Click **New**.
3. In the **Product number** field, type a value.
4. In the **Product name** field, type a value.
5. In the **Item model group** field, click the drop-down button to open the lookup.
6. In the list, find and select the desired record.
7. In the list, click the link in the selected row.
8. In the **Item group** field, click the drop-down button to open the lookup.
9. In the list, find and select the desired record.
10. In the list, click the link in the selected row.
11. In the **Storage dimension group** field, click the drop-down button to open the lookup.
12. In the list, find and select the desired record.
13. In the list, click the link in the selected row.
14. In the **Tracking dimension group** field, click the drop-down button to open the lookup.

15. In the list, find and select the desired record.
16. In the list, click the link in the selected row.
17. Click **OK**.

Setup default order settings

1. On the **Action Pane**, click **Plan**.
2. Under **Order settings**, click **Default order settings**.
3. Under **Purchase order**, in the **Default site** field, type the site used as default when purchase orders are created.
4. In the **Default warehouse** field, type the site where the item is stored.
5. Expand or collapse the **Inventory** section.
6. In the **Multiple** field, type '10'.
7. In the **Min. order quantity** field, type '10'.
8. In the **Max. order quantity** field, type '100'.
9. In the **Standard order quantity**, type '10'.
10. In the **Purchase lead time** field, enter a number.
11. Select or clear the **Working days** check box.
12. Click **Save**.
13. In the **Default order type** field select 'Purchase order'.
14. Click **Save**.
15. Close the page. Close the Default order settings page.

Add an item to a coverage group

1. Expand or collapse the **Plan** section.
2. In the **Coverage group** field, click the drop-down button to open the lookup.
3. In the list, find the **Coverage group** you have created.
4. In the list, click the link in the selected row.

Create item coverage rules

1. On the **Action Pane**, click **Plan**.
2. Under **Coverage**, click **Item coverage**.
3. Click **New**.
4. Click the **General** tab.
5. Check the box on the header of **Override coverage group** settings.
6. In the **Coverage time fence (days)** field, enter '60'. Although items in coverage group Requirements are planned 90 days ahead, this item will be planned 60 days ahead.
7. In the **Negative days** field, enter '2'.
8. In the **Positive days** field, enter '2'.
9. Click the **Lead time** tab.
10. Check the box on the header of **Purchase**.
11. In the **Purchase time** field, enter '5'.
12. Click **Save**.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Generate a constrained plan

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic explains how to create a plan that takes into account both material and capacity constraints. The plan ensures that manufacturing doesn't start before materials are available and resources are not overbooked.

The demo data company used to create this procedure is USMF. This procedure is intended for the production planner.

Set up a constrained plan

1. In the home page, select the **Master planning** workspace.
2. Select **Master plans** in the list of links on the far right side of the workspace.
3. In the list, find and select the desired record. Example: **StaticPlan**
4. Select **Yes** in the **Finite capacity** field.
5. In the **Finite capacity time fence** field, enter .
6. Expand the **Time fences in days** section.
7. Select **Yes** in the **Capacity** field.
8. In the **Capacity scheduling time fence (days)** field, enter a number. Example:
9. Select **Yes** in the **Calculated delays** field.
10. In the **Calculate delays time fence (days)** field, enter a number. Example:
11. Expand the **Calculated delays** section.
12. Select **Yes** in all **Add the calculated delay to the requirement date** fields.
13. Close the page.

Create a constrained plan

1. Select **Run**.
2. In the **Master plan** field, enter or select the plan for which you have set up constraints.
3. Select **OK**.
4. Select **Planned orders**.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey](#).

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Create a material plan for co products

2/18/2021 • 2 minutes to read • [Edit Online](#)

The production planner plans the material requirements for items that are formula co-products. The demo data company used to create this procedure is USP2.

Create requirement for a co-product

1. Go to Default dashboard.
2. Click Sales order processing and inquiry.
3. Click New.
4. Click Sales order.
5. In the Customer account field, type a value.
 - Example: US-001
6. Click OK.
7. In the Item number field, type a value.
 - Example: P6003
8. In the Quantity field, enter a number.
 - Example: 50000
9. Click Save.

Create a material plan for co-products

1. Close the page.
2. Close the page.
3. Click Master planning.
4. In the Plan field, click the drop-down button to open the lookup.
5. In the list, click the link in the selected row.
 - Example: MasterPlan
6. Click Run.
7. Expand or collapse the Records to include section.
8. Click Filter.
9. In the list, select the row for Field = Item number.
10. In the Criteria field, type a value.
 - Example: P6003
11. Click OK.
12. Click OK.
13. Click Planned orders.
14. Use the Quick Filter to find records. For example, filter on the Item number field with a value of 'P6000'.
 - Filter by the formula item that has as co-product of the item that you created a sales order for.
15. In the list, mark the selected row.
 - Select any of the rows returned by the filter.
16. In the list, click the link in the selected row.
17. Expand or collapse the Pegging section.
18. In the list, click the link in the selected row.

- The planned order is pegged to the sales order for the co-product.

19. Close the page.

Create requirement for a co-product

1. Go to Default dashboard.
2. Click Sales order processing and inquiry.
3. Click New.
4. Click Sales order.
5. In the Customer account field, type a value.
 - Example: US-001
6. Click OK.
7. In the Item number field, type a value.
 - Example: P6003
8. In the Quantity field, enter a number.
 - Example: 50000
9. Click Save.

Create a material plan for co-products

1. In the Plan field, click the drop-down button to open the lookup.
2. In the list, click the link in the selected row.
 - Example: MasterPlan
3. Click Run.
4. Expand or collapse the Records to include section.
5. Click Filter.
6. In the list, select the row for Field = Item number.
7. In the Criteria field, type a value.
 - Example: P6003
8. Click OK.
9. Click OK.
10. Click Planned orders.
11. Use the Quick Filter to find records. For example, filter on the Item number field with a value of 'P6000'.
 - Filter by the formula item that has as co-product of the item that you created a sales order for.
12. In the list, mark the selected row.
 - Select any of the rows returned by the filter.
13. In the list, click the link in the selected row.
14. Expand or collapse the Pegging section.
15. In the list, click the link in the selected row.
 - The planned order is pegged to the sales order for the co-product.
16. Close the page.
17. Click Master planning.
18. Go to Master planning > Setup > Master planning parameters.
19. Select No in the Disable all planning processes field.
20. Close the page.

NOTE

Can you tell us about your documentation language preferences? [Take a short survey.](#)

The survey will take about seven minutes. No personal data is collected ([privacy statement](#)).

Maintain planned orders

2/18/2021 • 2 minutes to read • [Edit Online](#)

This topic provides information about how to manage planned orders. It describes how you can update the status of planned orders, firm them, and filter for planned orders that have the same status as a selected planned order.

You can manage planned orders from the **Master planning** workspace, the **Planned order** list, or the **Planned production orders**, **Planned purchase orders**, and **Planned transfer** lists.

Planned order status

You can use the **Status** field to help track your progress. The following values are used:

- When master planning generates planned orders, the planned orders have a status of **Unprocessed**.
- If you decide not to firm a planned order, you can give it a status of **Completed**.
- If you want to firm a planned order, you can change the status to **Approved**. Planned orders with **Approved** status are respected by master planning, so they are not modified or deleted during a later master planning run. To achieve this, the planning logic copies the **Approved** planned orders from the old plan version to the new plan version during master planning.

Firming planned orders

By firming planned orders, real orders are created. These are also known as *released* or *open orders*. When a planned order is firming, it's moved to the orders section of the relevant module.

You can select two firming options from the **Planned orders** page:

- **Firm** – This will firm one or multiple selected planned orders.
- **Firm all** – This will firm all planned orders in the filter. Using **Firm all** you don't have to select the planned order, all planned orders within the filter will be firming. This option can be useful if you are firming a high number of planned orders.

NOTE

You can track a planned order that was firming from **Firming history** under **Planned orders form > View > Firming history**.

Parallelize firming

If you are planning to firm many orders at the same time, parallelizing the run can improve the run time or performance. This option is available when firming multiple planned orders with either **Firm** or **Firm all**. The following parameters are available:

- **Parallelize firming** – If **Yes**, the firming process will be parallelized with the number of threads defined in **Number of threads**.
- **Number of threads** – Controls the number of threads used to parallelize the firming process. The parameter is only shown when **Parallelize firming** is set to **Yes**.

NOTE

The option for **Parallelize firming** is only shown when you have more than one planned order selected for firming.

Safety stock fulfillment for items

2/18/2021 • 9 minutes to read • [Edit Online](#)

Safety stock indicates an additional quantity of an item held in the inventory in order to reduce the risk that the item will be out of stock. Safety stock is used as a buffer stock in case sales orders come in and the supplier is unable to deliver the additional items to meet the customer's requested ship date. When safety stock is used to fulfill a sales order, the safety stock will be reduced. You can use Master planning to automatically bring the inventory back to the safety level.

Set up safety stock levels for items

Safety stock is set up as part of item coverage on the **Item coverage** page under **Released products > Plan > Coverage**.

In the **Minimum** field, enter the safety stock level that you want to maintain for the item. The value is expressed in inventory units. If you leave the field blank, the default value is zero. This field is available when you select **Period, Requirement, or Min/Max** in the **Coverage code** list. The stock level limit applies to the available inventory, which means that reservations and markings may trigger safety stock replenishment before the physical quantity goes below the specified minimum level.

NOTE

You must define all other planned coverage dimensions before you can define the **Minimum** field. This prevents an invalid record from being used during master planning. This situation can occur if, for example, a dimension group is extended with an additional planned coverage dimension for which the minimum and maximum inventory quantities are not yet defined.

You can use minimum keys to handle seasonal fluctuations in demand. For example, you can decrease the minimum inventory level for an item in the off-season, and then gradually increase the level during the other months. You create a minimum key by going to **Master planning > Setup > Coverage > Minimum/maximum keys**. You specify the minimum key to adjust the safety stock level by seasonality in the **Minimum key** field on the **Item coverage** page.

Example: Minimum key

If you want to set up a minimum key that accounts for increased seasonal demand during the spring and summer months, go to **Master planning > Setup > Coverage > Minimum/maximum keys** and follow these steps.

1. Create 12 lines and assign a number from 1 to 12 to the lines in the **Change** field.
2. In the **Unit** field, select **Months**.
3. In the **Factor** field, enter the values that are described in the following table.

LINE	ENTER THIS VALUE	RESULT
1-3	1	Minimum inventory is based on the setting for January through March on the Item coverage page.

LINE	ENTER THIS VALUE	RESULT
4-5	2	Minimum inventory is multiplied by a factor of 2 for April through May.
6-8	2.5	Minimum inventory is multiplied by a factor of 2.5 for June through August.
9-12	1	Minimum inventory reverts to the setting for September through December on the Item coverage page.

If the coverage code is **Min/Max**, you can also specify the **Maximum** inventory quantity that you want to maintain for the item. The value is also expressed in inventory units. If the projected available inventory falls below the minimum quantity, master planning generates a planned order to fulfill all open requirements and brings the available inventory up to the specified maximum quantity. Just like you set up **Minimum**, you must define all other planned coverage dimensions before you can define the **Maximum** field.

Example: Min/Max coverage code

The minimum quantity is 10, and the maximum quantity is 15. Current on-hand inventory is 4. This gives a minimum quantity requirement of 6. However, because the maximum quantity is 15, master planning generates a planned order for 11 items.

For items that follow seasonal demands, you may need to maintain different maximum levels. To do that, you need to define **Maximum keys** by going to **Master planning > Setup > Coverage > Minimum/maximum keys**. Fill in the **Maximum key** field on the **Item coverage** page. You can view the information about the safety stock levels, defined via minimum keys on the **Min/Max** tab, on the **Item coverage** page. You need to make sure that, for a certain period, the minimum and the maximum values are kept in sync.

Safety stock fulfillment

The **Fulfill minimum** parameter allows you to select the date or the period during which the inventory level must meet the quantity that you specified in the **Minimum** field. This field is available when you select **Period**, **Requirement**, or **Min/Max** in the **Coverage code** list.

If **Minimum keys** are used, select the **Minimum periods** check box to fulfill the minimum inventory level for all the periods that are set up in the minimum key. If you clear the check box, the minimum inventory is fulfilled for the current period only.

The following scenario shows how this parameter works and what are the differences between its values.

NOTE

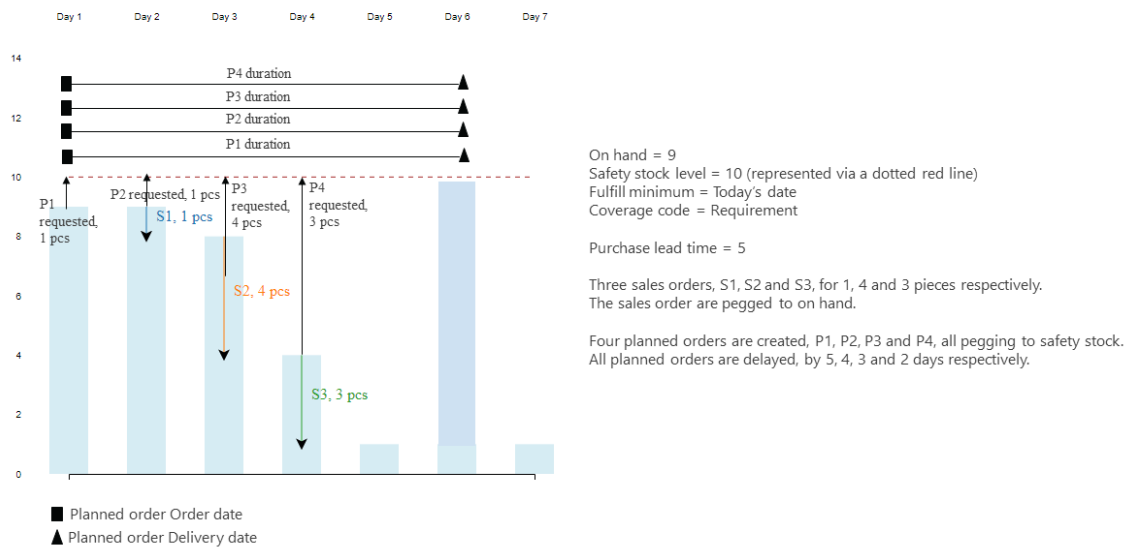

For all the illustrations in this topic, the x-axis represents inventory, the y-axis represents days, the bars represent the inventory level, the arrows represent transactions, such as sales order lines, purchase order lines, or planned orders.

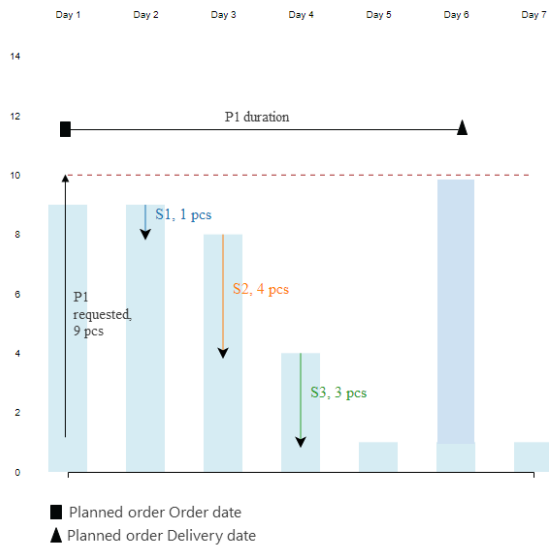

The Fulfill minimum parameter can have the following values:

Today's date

The specified minimum quantity is met on the date when master planning is run. The system tries to fulfill the safety stock limit as soon as possible, even though it can be unrealistic due to the lead time.

Planned order P1 is created for today's date to bring the available inventory above the safety stock level on this date. The sales order lines S1 to S3 continue to lower the inventory level. Planned orders P2 to P4 are generated by master planning so that the inventory level is brought back to the safety limit after each sales order requirement. When the **Requirement** coverage code is used, multiple planned orders are created. It is always a good idea to use either **Period** or **Min/Max** coverage for items and materials in frequent demand, to bundle the replenishment. The following illustration shows an example for coverage code **Period**.

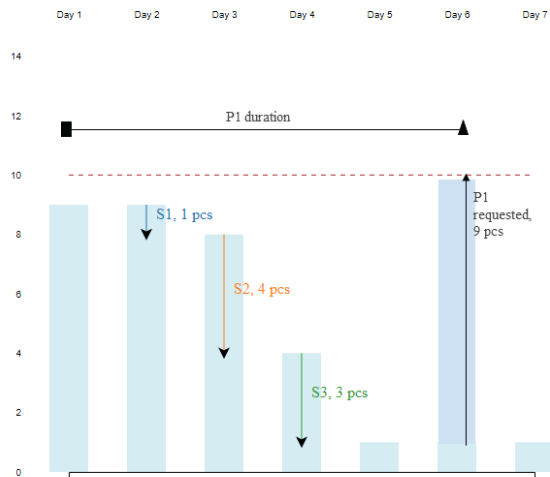

The following illustration shows an example for coverage code **Min/Max**.

Today's date + procurement time

The specified minimum quantity is met on the date when master planning is run, plus the purchase or production lead time. This time includes any safety margins. If the item carries a trade agreement, and the **Find trade agreements** check box is selected on the **Master planning parameters** page, the delivery lead time from the trade agreement is not considered. Lead times are taken from the item's coverage settings or from the item. This fulfillment mode will create plans with less delays and fewer planned orders regardless of the coverage group set up on the item. The following illustration shows the outcome of the plan if the coverage code is **Requirement or Period**.

On hand = 9
 Safety stock level = 10 (represented via a dotted red line)
 Fulfill minimum = Today's date + procurement lead time
 Coverage code = Requirement or Period (Period = 5)

Purchase lead time = 5

Three sales orders, S1, S2 and S3, for 1, 4 and 3 pieces respectively.
 The sales order are pegged to on hand.

One planned order is created, requested on Day 6 (Day 1 + Procurement lead time).
 The planned order is pegged to safety stock and needs to replenish 9 pieces.
 The planned order is not delayed.

The following illustration shows the outcome of the plan if the coverage code is **Min/Max**.

On hand = 9
 Safety stock level = 10 (represented via a dotted red line)
 Fulfill minimum = Today's date + procurement lead time
 Coverage code = Min/Max.
 Maximum = 15

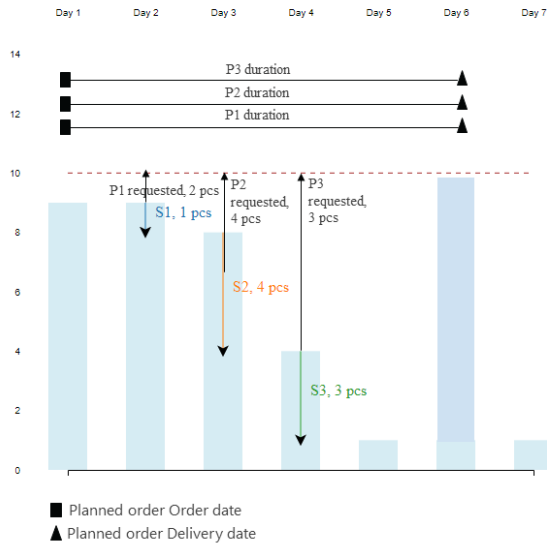

Purchase lead time = 5

Three sales orders, S1, S2 and S3, for 1, 4 and 3 pieces respectively.
 The sales order are pegged to on hand.

One planned order is created, requested on Day 6 (Day 1 + Procurement lead time).
 The planned order is pegged to safety stock and needs to replenish 14 pieces, to get to the maximum quantity.
 The planned order is not delayed.

First issue

The specified minimum quantity is met on the date when the available inventory goes below the minimum level, as shown in the following illustration. Even if the available inventory is below the minimum level on the date when master planning is run, **First issue** will not attempt to cover it until the next requirement comes in. The following illustration shows an example for coverage code **Requirement**.

On hand = 9
 Safety stock level = 10 (represented via a dotted red line)
 Fulfill minimum = First issue
 Coverage code = Requirement

Purchase lead time = 5

Three sales orders, S1, S2 and S3, for 2, 4 and 3 pieces respectively.
 The sales order are pegged to on hand.

Three planned orders are created, P1, P2, P3, all pegging to safety stock.
 The safety stock limit is replenished only on the date of the first issue.
 All planned orders are delayed, by 4, 3 and 2 days respectively.

The following illustration shows an example for coverage code **Period**.

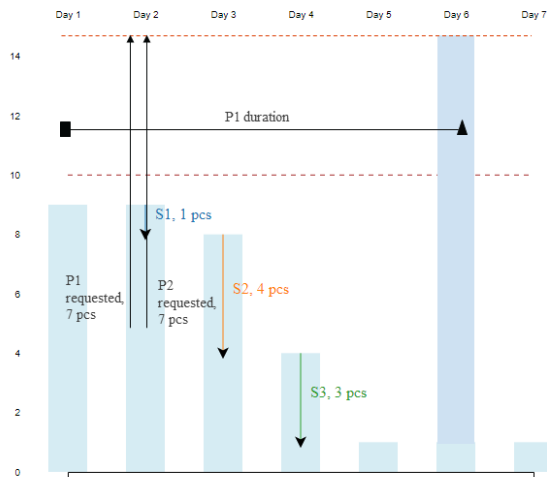

On hand = 9
 Safety stock level = 10 (represented via a dotted red line)
 Fulfill minimum = Today's date
 Coverage code = Period
 Period = Purchase lead time = 5

Three sales orders, S1, S2 and S3, for 1, 4 and 3 pieces respectively.
 The sales order are pegged to on hand.

One planned order is created, P1, covering 4 safety stock requirements of 1, 1, 3
 and 4 pieces respectively.
 The planned order is delayed for 4 days, due to the purchase lead time.

The following illustration shows an example for coverage code **Min/Max**.

On hand = 9
 Safety stock level = 10 (represented via a dotted red line)
 Fulfill minimum = First issue
 Coverage code = Min./Max.
 Maximum = 15

Purchase lead time = 5

Three sales orders, S1, S2 and S3, for 1, 4 and 3 pieces respectively.
 The sales order are pegged to on hand.

Two planned orders, P1 and P2, are created, to fulfill the safety stock limit requirement.
 P1 covers a quantity of 7 pieces and is requested on the date of the first issue, to cover the reduction in inventory due to sales order S1 and the fact that we are already 1 piece under the safety limit.
 P2 covers a quantity of 7, because there are other issues (S2 and S3) that will bring the quantity under the minimum.
 Both planned orders are delayed, due to the lead time.

On the date when master planning is run, if the available inventory is already under the safety stock limit, **Today's date** and **Today's date + procurement time** will trigger the replenishment immediately. **First issue** will wait until there is another issue transaction, such as sales order and BOM line requirement, for the item, and then it will trigger the replenishment on the date of this transaction. On the date when master planning is run, if the available inventory is not under the safety stock limit, **Today's date** and **First issue** will provide exactly the same result, as shown in the illustration below.

Coverage code = Requirement
 Safety stock = 10
 On hand = 11
 Fulfill minimum = First issue

Purchase lead time = 5

Given three sales orders, S1, S2 and S3, master planning will create two planned orders, P1 and P2, as follows:

P1
 Quantity = 4
 Requested date = Day 3
 Order date = Day 1
 Delivery date = Day 1 + purchase lead time
 Pegging to safety stock requirement, coverage quantity 4
 Delay date = Day 1 + purchase lead time
 Delay = 3 days
 Requirement date = Delay date (per plan setup)

P2
 Quantity = 3
 Requested date = Day 4
 Order date = Day 1
 Delivery date = Day 1 + purchase lead time
 Pegging to safety stock requirement, coverage quantity 3
 Delay date = Day 1 + purchase lead time
 Delay = 2 days
 Requirement date = Delay date (per plan setup)

On the date when master planning is run, if the available inventory is not under the safety stock limit, **Today's date + procurement time** will provide the following result, because it postpones the fulfillment until the end of the procurement lead time.

Coverage code = Requirement
 Safety stock = 10
 On hand = 11
 Fulfill minimum = Today's date + procurement time

Purchase lead time = 5

Given three sales orders, S1, S2 and S3, master planning will create one planned order, P2, as follows:

P2
 Quantity = 7
 Requested date = Day 1 + purchase lead time
 Order date = Day 1
 Delivery date = Day 1 + purchase lead time
 Pegging to safety stock, covered quantity = 7
 There are no delays
 The sales orders are all pegged to on hand.

Coverage time fence

The specified minimum quantity is met during the period that is specified in the **Coverage time fence** field. This option is useful when master planning does not allow available inventory to be used for real orders, such as sales or transfers, in the attempt to maintain the safety level. However, in a future release, this mode of replenishment will no longer be needed, and this option will be deprecated.

Plan safety stock replenishment for First Expired, First Out (FEFO) items

At any point in time, the inventory receipt with the latest expiry date will be used for safety stock to allow real demand, such as sale lines or BOM lines, to be fulfilled in the FEFO (First Expired, First Out) order. To show how this works, consider the following scenario.

On hand = 180, split in two batches B1 (100 pieces), B2 (80 pieces)
 Safety limit = 160

Two sales orders, S1 and S2, for 300 and 150 pieces respectively.

When planning is run, it will cover the first sales order from the existing on-hand inventory and an additional purchase order, for the remaining quantity.

Overview								
Warehouse	Site	CW minimum	Minimum	CW maximum	Maximum	Coverage group	Planned order type	
11	1		160.00		0.00	Req	Purchase order	

Overview								
Reference	Number	Item number	Requirement date	Expiration date	Requirement ...	Requirement ...	Accumulated	
On-hand		_Batch		11/13/2017	100.00		100.00	
On-hand		_Batch		11/14/2017	80.00		180.00	
Planned purchase orders	004461	_Batch	11/10/2017	11/16/2017	120.00		300.00

Number	Reference	Item number	Requirement ...	Requirement ...	Requirement ...	Covered quan...
	Safety stock	_Batch	11/13/2017	-150.00		-150.00

A planned order is created to cover safety stock.

All the batches are expire accordingly, and planned orders are created to refill the safety stock after it has expired.

How master planning handles the safety stock constraint

Safety stock is tracked in the system as a requirement type, just like sales lines or BOM requirements. You can see the safety stock requirement line on the **Net requirements** page if you remove the default filter on the **Requirement type** column.

Fulfilling the safety stock requirement transaction is deprioritized if the system determines that this causes delays in the fulfillment of real demand, such as sales lines, BOM lines, transfer requirements, or demand forecast lines. Otherwise, making sure that the available inventory is above the safety stock quantity has the same priority as any other demand types. This ensures no delays for real transactions and helps to prevent over-replenishment and early-replenishment of safety stock.

During the coverage phase of master planning, safety stock replenishment is no longer deprioritized. On-hand inventory can be used before any other demand types. During the delay calculation, new logic will be added to

go over the delayed sales lines, BOM line requirements, and all the other demand types, to determine whether they could be delivered on time, provided that the safety stock is used. If the system identifies that it can minimize delays by using safety stock, then the sales lines or BOM lines will replace their initial coverage with the safety stock, and the system will trigger the replenishment for the safety stock instead.

If the plan or the item is not set up for delayed calculation, then the safety stock constraint will have the same priority as any other demand types. This means there is a reserve of on-hand and other available inventory before other demand types.
